Summary and Conclusions: The glycoPEGylation technology platform described here is used to produce lipegfilgrastim, a novel, biologically active G-CSF with greater structural homogeneity and comparable pharmacologic properties to conventionally PEGylated G-CSFs, thus enabling a safe and effective once-per-cycle fixed dosing regimen.

P1025

SAFETY AND TOLERABILITY OF LIPEGFILGRASTIM IN BREAST CANCER PATIENTS RECEIVING CHEMOTHERAPY: AN INTEGRATED ANALYSIS OF PHASE II AND III STUDIES

O Gladkov[1,*], R Elsaesser[2], A Buchner[2], P Bias[2], U Mueller[2]
[1]Chelyabinsk Regional Clinical Oncology Center, Chelyabinsk, Russian Federation, [2]Teva ratiopharm, Ulm, Germany

Background: Myelosuppresive chemotherapy (CTx) frequently causes neutropenia, leading to an increased risk of infections and delays in subsequent chemotherapy treatments. Covalent attachment of polyethylene glycol (PEG) has been shown to prolong the half-life of therapeutic proteins, allowing for less frequent dosing, improved patient compliance, and potentially lower production costs. However, traditional PEGylation methods rely on chemical conjugation through amino acid reactive groups, which may reduce protein activity and result in non-uniform chemical, pharmaceutical, and tolerability profiles. Lipegfilgrastim is a highly homogenous once-per-cycle, fixed-dose glycoPEGylated granulocyte-colony stimulating factor (G-CSF) created with a highly site-specific glycoPEGylation technology for site-directed PEGylation, which is under review for the prevention of neutropenia in cancer patients receiving CTx. Non-inferiority of lipegfilgrastim *versus* pegfilgrastim (Neulasta®) was previously demonstrated in a Phase III trial conducted in CTx-naïve breast cancer patients.[1]
Aims: To report the safety and tolerability findings from an integrated analysis of two Phase II/III studies of lipegfilgrastim *versus* pegfilgrastim in CTx-naïve breast cancer patients.
Methods: All patients who received full-dose CTx (doxorubicin 60 mg/m^2+docetaxel 75 mg/m^2) and either a single 6 mg subcutaneous injection of lipegfilgrastim or pegfilgrastim were included in this analysis. The incidence and severity of treatment-emergent adverse events (TEAEs) and those the investigator deemed related to study drug (TEADRs) over all four cycles were compared.
Results: TEAEs were experienced by 94.7% of patients in the lipegfilgrastim group (N=151) and 89% of patients in the pegfilgrastim group (N=155). The most common TEAEs were consistent with the effects of CTx and the underlying disease and were not necessarily due to G-CSF study medication. Frequencies of TEAEs were comparable between treatment groups. As expected, there was a time-dependent trend across cycles within each treatment group; *i.e.* the frequencies of TEADRs decreased with each subsequent CTx cycle. Severe TEADRs were reported in one lipegfilgrastim patient and two pegfilgrastim patients. There were no deaths as a result of study drug treatment in either group. TEADRs were consistent with the underlying medical condition and administration of CTx. Type, incidence, and severity of TEADRs are provided in the Table 1.

Table 1. Type, incidence, and severity of TEADRs.

Adverse event category, n (%)	Lipegfilgrastim 6 mg (N=151)	Pegfilgrastim 6 mg (N=155)
Any TEAE	143 (94.7)	138 (89.0)
TEADR	46 (30.5)	49 (31.6)
Serious TEADR	2 (1.3)	1 (0.6)
Severe TEADR	1 (0.7)	2 (1.3)
Death due to TEADR	0 (0.0)	0 (0.0)
Most frequent TEADRs*		
Bone pain	19 (12.6)	19 (12.3)
Myalgia	8 (5.3)	6 (3.9)
Erythema	6 (4.0)	3 (1.9)
Arthralgia	4 (2.6)	2 (1.3)
Nausea	5 (3.3)	8 (5.2)

*Preferred term ≥3% in any cohort

Summary and Conclusions: Lipegfilgrastim has a favorable safety profile consistent with the G-CSF class of molecules and is an acceptable alternative to pegfilgrastim for the prevention of neutropenia in cancer patients receiving chemotherapy.

P1026

CARDIAC INVOLVEMENT IN TYPE 3 EGYPTIAN GAUCHER DISEASE PATIENTS: A REPORT OF 7 CASES AND A NEWLY REPORTED ANOMALY

M Abdelwahab[1,*], H Hamza[2], W Attia[2], A Beshlawy[1], K Eid[1]
[1]Pediatric Hematology, [2]Pediatrics, Cairo University Pediatric Hospital, Cairo, Egypt

Background: Gaucher disease(GD) is due to deficiency of B- glucocerebrosidase leading to depodtion of lipid laden macrophages(Gaucher cells) typically in the liver, spleen, bone marrow, lymp nodes, lungs, brain and very rarely the heart usually associated with D409H/D409H mutation.Cardiac involvement includes constrictive pericarditis, pericardial calcification, infiltration of the myocarduim leading to cardiomyopathy and calcification of the mitral, aortic valves and aortic root.
Aims: To report cardiac findings in 7 Egyptian type 3 GD
Methods: Four D409H/D409H patients, a 20 year old male with typical phenotype of D409H/D409H and 2 L444P/L444P children with cardiomeagly on x-ray were assessed for cardiac anomalies.The D409H/D409H patients did Multislice CT angiography, CT brain and ophthalmologic assessment.
Results: The 3 female D409H/D409H siblings(19.17.11 years old showed mitral regurge(MR); aortic regurge(AR), aortic root calcificationand ectatic proximal coronaries; thickened aortic valve, increased echogenicity of aortic root and MR respectively. They also had increased reflectivity of cornea, apraxia and hydrocephalic changes,The 15 year old female with cardiac symptoms showed MR, MS, AR and calcification of the aorta extending to the coronaries as well as apraxia and hydrocepahlic changes.The fifth patient had severe valvular affection, corneal opacities, apraxia and died postopeartively.The 2 L444P/L444P children had dilated cardiomyopathy and coarctation that showed improvement.
Summary and Conclusions: This is the first report of coronary ectasia in GD.Cardiac affection in GD can invlove other mutations than D409H/D409H which should be screened routinely to pickup anomalies early.

P1027

A FEASIBILITY STUDY OF HOME MONITORING OF BLOOD NEUTROPHIL COUNTS IN PATIENTS WITH CHRONIC NEUTROPENIA

D Dale[1,*], M Kelley[1], V Makaryan[1], E Rodger[1], A Bolyard[1], B Otto[1]
[1]Medicine, UNIVERSITY OF WASHINGTON, Seattle, United States

Background: Currently patients with chronic neutropenia and other hematological disorders must go to a doctor's office, medical laboratory or hospital for monitoring of their hematological status. For some chronic diseases, *e.g.*, cyclic and congenital neutropenia, an accurate diagnosis depends on obtaining a series of daily or every-other-day counts over several weeks, but many patients find it difficult to comply with the number of laboratory visits that are required. It would be far more convenient if their blood cell counts could be monitored at home. Home monitoring may prove to be useful for monitoring blood counts for patients at risk of developing febrile neutropenia, for reducing number of costly visits to medical laboratories and for reducing patients' exposure to new pathogens outside the home environment.
Aims: To determine if patients can learn to use a small home monitoring device to measure their own blood cell counts on a daily basis and to compare the accuracy of patient testing *versus* testing by a skilled laboratory technician.
Methods: Ten patients with cyclic and idiopathic neutropenia currently enrolled in the Severe Chronic Neutropenia International Registry (SCNIR) will be enrolled. Initially the patients will make three visits to the laboratory to learn to collect blood using sterile finger puncture techniques and to use the counting device (XBC, Philips, Eindhoven, NL). At each visit the patient and the technician perform counts using the XBC device and the technician makes a control count using a venous blood sample and a reference electronic counter (BC, Beckman Coulter, Miami, FL). After the third laboratory visit, the patient takes the XBC device home to monitor his/her own counts on a daily basis for 28 days. Patients return to the laboratory each week of the study period for follow-up in-laboratory counts by the patient and technician.
Results: Initially we tested three normal donors, six tests on each of three XBCs and 4 repeat tests of each sample on BC and observed no significant differences (two-way ANOVA).
We have enrolled four patients, three patients were receiving granulocyte colony stimulating factor (G-CSF) and one was being treated with prednisone. The patients and technicians both performed finger sticks and both have performed tests with XBC. The technician has performed counts on venous blood using the BC device as the reference control. Teaching and learning proceeded smoothly and easily. Comparison of counts performed in the laboratory with the XBC device *vs* the BC counter are shown in Table 1. There were no significant differences in results for the two instruments (two-way ANOVA or Students t-test). Other comparisons were: patients *vs.* technician in lab with XBC and patients using XBC in lab or at home. There were no significant differences.
For the two patients who have completed the 28 day study, compliance rates for daily counts for were: 75% and 86%, the lower percentage for the first patient due to running out of testing cassettes. Error rates requiring repeat counts were 26% and 17% and both patients regularly repeated the finger-stick sampling and counting on the second try. Patients 3 and 4 have quickly learned counting techniques, are maintaining their records and will soon complete the study. The discomfort of the finger sticks has not limited the study. The six additional patients will be studied in the spring 2013.

Table 1. Comparison of blood neutrophil count for four patients using test (XBC) *vs* reference (CB) instrument.

	Patient 1 (n=5 tests)		Patient 2 (n=5 tests)		Patient 3 (n=5 tests)		Patient 4 (n=2 tests)	
Instrument	XBC	BC	XBC	BC	XBC	BC	XBC	BC
Mean ANC ($x10^9$ /L)	11.0	10.2	1.8	2.1	1.9	1.7	1.4	1.6
SEM	2.9	1.4	0.2	0.2	0.5	0.4	0.05	0.25

Summary and Conclusions: Based on this initial experience, we believe that the XBC counter is reliable and accurate for measurement of WBC and ANC. We find that patients can quickly learn to use this device to monitor their blood leukocyte and differential counts at home. We believe that home monitoring is a promising strategy for diagnostic testing and evaluation of treatment responses in patients with neutropenia.

P1028

GRANULOCYTE FUNCTION IS NOT IMPAIRED BY ARGININE DEFICIENCY

K Kapp[1], S Prüfer[2], A Habermeier[3], C Luckner-Minden[4], J Bomalaski[5], P Kropf[6], I Müller[7], E Closs[3], M Radsak[4], M Munder[4,*]
[1]Institute of Immunology, University of Heidelberg, Heidelberg, [2]Institute of Immunology, [3]Department of Pharmacology, [4]Third Department of Medicine (Hematology, Oncology, and Pneumology), University Medical Center of the Johannes Gutenberg University, Mainz, Germany, [5]Polaris Pharmaceuticals Inc., San Diego, United States, [6]Department of Immunology and Infection, London School of Hygiene and Tropical Medicine, [7]Department of Medicine, Section of Immunology, Imperial College, London, United Kingdom

Background: Arginine deficiency is often encountered in cancer patients and has all the characteristics of a double-edged sword: on the one hand, it is induced by arginase expressing myeloid cells (neutrophil granulocytes or myeloid-derived suppressor cells) in the context of cancer-related inflammation. The ensuing arginase-mediated arginine deficiency may profoundly suppress the adaptive immune response by inhibiting T cell proliferation and cytokine synthesis. On the other hand, arginine depletion might have anti-tumoral potential, especially against tumors that are unable to resynthesize their own arginine from the precursor amino acid citrulline via argininosuccinate synthase. Pharmacological arginine depletion via pegylated arginine deiminase (ADI-PEG20) is already in clinical phase 1-3 human cancer trials.
Aims: Given the profound suppressive effect of arginine deficiency on adaptive immunity, we now studied the function of granulocytes in the context of arginine depletion.
Methods: Human primary granulocytes were purified from healthy donors and important granulocyte effector functions were measured in cell culture medium in the presence or in the absence of arginine. Arginine deficiency itself was induced either by using arginine-free preformulated medium or by subjecting normal cell culture medium or whole blood to sonicates of human granulocytes with a defined arginase activity, leading to the enzymatic depletion of arginine. The following granulocyte functions were measured *in vitro*: viability (PI/annexin V), expression of various cell membrane marker proteins, activation-induced shedding of CD62L (flow cytometry), phagocytosis (FITC-coupled *E. coli*: Phagotest®), microbicidal activity (XTT viability of *C. albicans*), generation of reactive oxygen species (cytochrome C reduction and oxydation of dihydrorhodamine 123: Phagoburst®), chemotaxis (human serum-induced migration in Boyden chamber), activation-induced synthesis of IL-8 (ELISA) and various other gene products (Real Time PCR). Granulocyte function was also analysed *in vivo* in a murine model of *Aspergillus fumigatus* pneumonia and arginine depletion *in vivo* was induced by injection of ADI-PEG20.
Results: Arginine deficiency had no influence on human granulocyte viability, expression of activation markers and constitutive cell membrane proteins, shedding of CD62L, phagocytosis, generation of reactive oxygen species, fungicidal activity, chemotaxis and induced synthesis of IL-8 or any other gene products on mRNA level. Also, profound pharmacological arginine depletion *in vivo* via ADI-PEG20 did not inhibit murine granulocyte functions: successful granulocyte-dependent clearance of *Aspergillus fumigatus* and survival of mice were not impaired.
Summary and Conclusions: Granulocyte-based innate immune function is not inhibited by arginine deficiency. This novel finding adds to a better understanding of immunity during cancer inflammation-associated arginine depletion and is also important for the development of therapeutic arginine depletion as antimetabolic tumor therapy. Our results are also consistent with the lack of co-existent infections in humans treated with ADI-PEG20.

P1029

LANGERHANS CELL HISTEOCYTOSIS (LCH) IN EGYPTIAN CHILDREN. A SINGLE CENTER EXPERIENCE.

M Sedky[1,*], H Sayed[1], E Moussa[1]
[1]Pediatric hematology Oncology, Children Cancer Hospital, Cairo, Egypt

Background: Langerhans cell histiocytosis (LCH) is a rare immune multisystem disease that behaves from spontaneous regression to rapid progression and death or repeated reactivations especially upon end of treatment. Localized monostotic disease (skin, bone or lymph node) have a good prognosis without treatment. In contrast, multiple, especially high risk organs (liver, spleen, hemopoietic system) have a poor outcome and may need chemo reinforcement.
Aims: To evaluate children cancer hospital Egypt experience in pediatric Langerhans cell Histeocytosis
Methods: In the period between 12/7/2007 and 9/12/2011, 80 LCH patients were treated at Children Cancer Hospital (CCHE) according to the LCH III protocol. M/F: 43 (46%)/37 (54%) with a mean age of 4 $^{2/12}$ years (3 months–13 $^{3/12}$y). Patients were divided into 4 groups: I monostotic lesion n=14 (17.5%), II multisystem with no risk organs RO- n=29 (36%), III multisystem with risk organs RO+: n=19 (24%) and IV unisystem multifocal lesions +/- special sites: n=18 (22.5%). Group I did not receive systemic treatment. Vinblastine (VBL) and Prednisone (PRED) were given as one +/- 2nd induction in Group II and IV, and were associated to methotrexate(MTX)in group III. Maintenance included 6 m to 1 year VBL, PRED for group IV and II respectively. Group III had a 1 year VBL, PRED, MTX and 6 mercaptopurine (6MP).
Results: *Survival* After a minimum 1 year and up to 5.5 year follow up, 70 patients are better (87.5%) in No Active Disease (NAD) or Active Disease Regressive (ADR), 3 patients are intermediate(4%) in Active Disease Stable (ADS), 3 patients are worse (4%)in Active Disease Progressive (ADP), 3 patients (4%) died (all in RO+): disease progression n=2 and viral pneumonia n=1. The Kaplan Meier 5 year

Overall Survival (OS) is (96.3%), the 5 y Event Free Survival (EFS) is (54.7%): Group I (93%), Group II (52%), Group III (47%), Group IV (83%) p0.013. The EFS is worse if age <2 years old (38%) *vs* (71%) (2-10 y), *vs* 90% (>10 y) p0.001. EFS is worse in patients received a 2nd induction (48,7%) *vs* (80.5%) p0.009. *Response*The 6 week evaluation from diagnosis revealed (75%) better. This percentage rose to 89% at W12 with or without induction(s). *Progression /Reactivation* Reactivation occurred n=25 (38%), while progression post induction n=3 (4.5%). The probability of reactivation or progression is 47%. Reactivation is less in prolonged maintenance as 37 patients non reactivated with a mean 10 m maintenance duration *vs* 25 reactivated with a 8 m treatment duration p0.043.

Summary and Conclusions: In Egyptian LCH children, response to induction is satisfactory. Although a greater incidence of reactivation, survival remains the rule. Low age and slow responder carry a worse prognosis. With RO+ methotrexate, 6MP reinforcement, EFS is nearly equivalent to RO-. However mortality are exclusively RO+.

P1030

PEGFILGRASTIM AS PROPHYLAXIS OF FEBRILE NEUTROPENIA DURING CHEMOTHERAPY OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA

C Cerchione[1,*], N Pugliese[1], L Marano[1], G Cerciello[1], S Avilia[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Patients receiving cancer chemotherapy are at an increased risk of neutropenia, leading to an increased risk of infections and delays in subsequent chemotherapy treatments. Recombinant granulocyte colony stimulating factors (G-CSFs) have been developed to stimulate proliferation and differentiation of neutrophils in patients receiving chemotherapy. Pegfilgrastim is a pegylated long-acting recombinant form of G-CSF that extends the half-life and allows for once-per-cycle dosing, requiring less frequent dosing than non-pegylated G-CSF. Multiple Myeloma (MM) in advanced phases of disease may be managed by regimens combining agents not frequently employed in early phases of treatment (*e.g.* Anthracyclines, Alkylating agents, etc), but myelotoxicity is the main expected side effect.In this context, G-CSFs are often necessary to counteract the risks of febrile neutropenia: their use is bound to a frequent evaluation of neutrophil counts that may not be easy for patients in home-care. Avoiding severe neutropenia by prophylactic pegfilgrastim seems particularly useful in these cases.

Aims: The objective of this study was to compare the efficacy and safety of pegfilgrastim in patients affected by Multiple Myeloma in advanced phase of disease. In order to determine whether a single subcutaneous injection of pegfilgrastim is as effective as daily injections of standard filgrastim, in terms of haematological toxicity, febrile neutropenic episodes, antibiotic usage and hospedalization duration.

Methods: We have enrolled in our study 18 patients (10 male and 8 female) with a median age of 62 years (range 54-82) affected by multiple myeloma, all relapsed and refractory to a median of 6 lines of therapy (range 4-8), all previously exposed to Bortezomib, Lenalidomide, Melphalan and all relapsed after auBMT, treated with different chemotherapy regimens combining Bortezomib, Lenalidomide, Bendamustine, Melphalan, Doxorubicine.

Results: Since first course, received in our out-patient department, patients performed blood counts twice weekly and received, from day 8 to day 19, prophylactic oral chinolonic antibiotics and anti-fungal drugs. Filgrastim (5 µgr/kg/day for 3 days) was given if neutrophils count was <1500×10^9 cells/L. Median number of filgrastim administrations was 4.5, r. 3-6; nadir neutropenia was registered after a median of 11 days (r. 8-14); median of nadir neutrophil count was 1.27×10^9 cells/L (range 0.4–1.8×10^9 cells/L), with maximum duration of 10 days. After the first course of chemotherapy, patients received prophylactic pegfilgrastim (6 mg), injected subcutaneously with a single administration on day 2 after last dose of chemotherapy, independently from the neutrophil count at that time. Primary endpoint was the duration of neutropenia (neutrophil count <1.5×10^9 cells/L), which was never longer than 10 days. Median nadir neutrophil count, registered 11 days after the end of the therapy (median, r. 9-15) was 1.576 (range 0.63-2.25×10^9 cells/L); two patients (11%) needed a second administration of pegfilgrastim one week after the first (day +9,+10 and +11, respectively) and also a supplement of 3 administrations of filgrastim. During pegfilgrastim, neutropenia lasted less than 10 days. Pegfilgrastim was well tolerated in all patients: main side effects in our patients were fever and bone pain, (3/18 patients,16%)

Summary and Conclusions: In conclusions, in patients affected by MM exposed to myelosuppressive agents in advanced phases of myeloma disease, pegfilgrastim seems to reduce the incidence of neutropenia and may increase the possibility to maintain the scheduled time of treatment.

P1031

CHRONIC BENIGN NEUTROPENIA IN ADULTS: LABORATORY AND CLINICAL PARAMETERS OF A 6-YEAR FOLLOW-UP

B Fattizzo[1,*], T Radice[1], F Guidotti[1], A Zaninoni[1], A Ciani[2], A Cortelezzi[2], W Barcellini[1]
[1]U.O. Ematologia e Centro Trapianti di Midollo, [2]U.O. Ematologia e Centro Trapianti di Midollo, Università degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Milano, Italy

Background: Chronic benign neutropenia (CBN) is a rare hematological condition, characterized by an absolute neutrophil counts (ANCs) lower than 1800/µl in white and 1500/µl in black people for more than 3 months. This condition can be congenital or acquired, idiopathic or secondary and may be characterized by the presence of anti-neutrophils antibodies. While congenital and acquired forms of infancy and childhood are largely studied, with particular attention to the infective diathesis, less is known about adult neutropenia.

Aims: To evaluate clinical and laboratory features of chronic benign neutropenia in adult patients, focusing on ANCs variations, on the positivity for anti-neutrophil auto-antibodies and on the incidence of infectious episodes.

Methods: Complete blood counts and physical examination were performed every 3-4 months in the first 2 years, then at least once a year. Anti-neutrophil antibodies were determined by direct and indirect granulocyte immunofluorescence test (GIFT method). Infectious episodes were defined according to Common Terminology Criteria for Adverse Events (Version 4.0 http://evs.nci. nih.gov).

Results: 47 patients (17 males and 30 females, median age 55 years, range 25-86 years) were followed up for a median time of 47 months (range 6-240 months). As Figure 1 shows, mean ANCs at enrolment and over time displayed a great variability, both inter and intra-subject (>500/µl in 74% and >1000/µl in 25% of patients). Considering the severity of neutropenia, we observed 23 patients (49%) with neutrophils lower than 1000/µl in at least one observation (median number of 470/µl neutrophils, range 100-969/µl). Finally, the mean ANCs observed during the follow up was significantly lower in males than in females (610/µl, range 100-1380/µl *versus* 1070/µl, range 100-1750/µl, respectively; P=0,02). Anti-neutrophil antibodies were detected in 18/45 patients (40%), and mean ANCs were significantly lower in positive *versus* negative cases (P=0,021 for 6 and 12 months time). Bone marrow evaluation showed features of dismyelopoiesis in 14 cases (56%), hypocellularity in 3 (12%) and normal morphology in 8 (32%). Flow cytometry demonstrated increased Natural Killer cells in 13 patients (28%), Cytogenetic was normal 22 cases (88%), while in 3 male patients karyotype was 45, X0 (7, 6 and 3 metaphases respectively). Finally, monocyte counts were higher than 600/µl in 8 patients (17%), and 5 of them (62%) showed an NK marrow infiltrate (P=0,015). Mild splenomegaly was present in 10 patients (21%) with a mean maximal diameter of11,4 cm by ultrasonography. These cases displayed lower ANCs compared with cases without splenomegaly (835/µl, 140-1400, *versus* 1380/µl, 200-3239, at 3 months; P=0,03). During the study 11 patients (23%) had an infection needing oral antibiotic or antiviral therapy (7 upper respiratory tract infections, 3 Herpes Zoster Virus infections and 1 urinary tract infection); no relationship was found between the occurrence of infections and the patient's mean ANCs value, the nadir of ANCs, and the presence of anti-neutrophil antibodies.

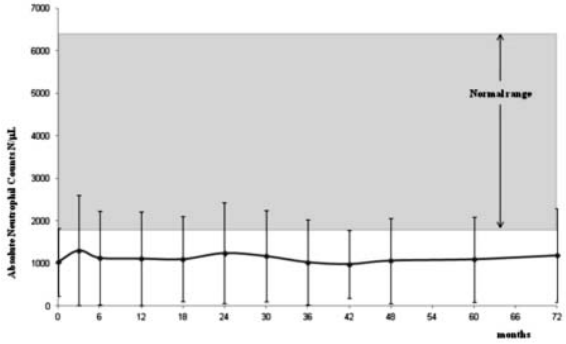

Figure 1. Mean ANCs values during follow up (mean±SD).

Summary and Conclusions: In spite of the alarm that produces in the general practitioner, CBN in adults is a benign disease, often incidentally diagnosed, with an infectious rate comparable to that of general population and frequent spontaneous ANCs variations. Bone marrow evaluation shows abnormal findings in a half of patients, without reaching the criteria for clonal hematological diseases, but suggesting that this condition deserves clinical follow up.

P1032

NEUTROPHIL RESPIRATORY BURST ACTIVITY COULD SERVE AS A PROGNOSTIC MARKER IN SEPSIS PATIENTS, AND NEUTROPHIL CD10 AND CD16 EXPRESSIONS MIGHT BE BIOMARKERS FOR SEPSIS SEVERITY

M Bae[1,*], S Park[2], E Cho[1], C Park[1], S Park[1], Y Cho[1], S Jang[1], H Chi[1], S Hong[2]
[1]Laboratory Medicine, [2]Internal Medicine, Asan Medical Center, Seoul, Korea, Republic of Korea

Background: Respiratory burst activity (RBA) is important for the killing of

microorganisms; however, it may be also detrimental to the body due to tissue damage. The role of neutrophils in septic shock has not been well investigated. Recently, changes were reported in the neutrophil surface antigens CD64 (high affinity receptor for IgG), CD10 (neutral endopeptidase), and CD16 (low affinity Fc receptor) during sepsis and DIC.
Aims: The aim of this study was to evaluate RBA and surface antigen expressions of neutrophils in septoc patients to determine their clinical significance.
Methods: EDTA peripheral blood was drawn from 105 healthy controls and consecutive 71 patients (52 males and 19 females; median age, 67 years; range, 29–92 years) with severe sepsis (16 patients) and septic shock (55 patients) from January 2011 to October 2012. Using flow cytometry, RBA was measured in nonstimulated and PMA-stimulated states by the change of nonfluorescent DCF-DA to green fluorescent DCF with the production of hydrogen peroxide. The surface expression of CD64, CD10, and CD16 on neutrophils were measured by the binding of fluorescence-conjugated anti-CD64, anti-CD10, or anti-CD16 antibodies.
Results: Compared with control neutrophils, patients' neutrophils with sepsis showed increased levels with non-stimulated RBA and CD64 expression, and decreased values in CD10 and CD16 expression (P<0.001 for all biomarkers). Expressions of CD10 and CD16 were lower in patients with septic shock than patients with severe sepsis (P=0.031, 0.002, respectively). When the patients were subdivided into 2 groups according to the mortality within 28-days, PMA stimulated RBA of the patient's neutrophils was higher in survivor group (P=0.002). CD64 expression was also elevated in survivor group, but there was no statistical significance (P=0.071).
Summary and Conclusions: During sepsis, neutrophils are highly activated, and the increased neutrophil RBA by PMA stimulation is associated with better prognosis. Neutrophil RBA could serve as a prognostic marker in patients with sepsis, and CD10 and CD16 expressions of neutrophils might be biomarkers for sepsis severity.

P1033

THE ULTRASOUND EXAMINATION OF SPLEEN CAN STRONGLY RAISE THE SUSPICION OF THE GAUCHER DISEASE.
P Pulluqi[1,*], K Pilika[2], A Ivanaj[1], A Perolla[1], T Dedej[3], T Caja[1], A Rucaj[3], P Xhumari[1]
[1]Hematology, [2]surgery, [3]Laboratory, UHC "Mother Theresa" Tirana, Albania, Tirana, Albania
Background: The Gaucher disease (GD) is a lipid storage disease inherited as an autosomal recessive trait. It results from an inherited deficiency of acid β- glucosidase leading to accumulation of glucosilceramide in tissue macrophages, causing hematologic, visceral organs, and skeletal abnormalities.
Aims: To provide clinical and laboratorical data from GD patients and to try to find any special features that raise suspicions of diagnosis prior to the bone marrow examination, or enzyme estimation.
Methods: 1996-2012 We analyzed the observational data from 11 GD patients diagnosed for the first time in our clinic and we tried to find any correlation betweem them and GD diagnosis before BM examination.
Results: Mean age was 30.7 years (16-65). 81% (9/11) of patients were diagnosed before age 35. Only one was 65 years old. Three patients were from the same family, two brothers and one sister. Ratio M/F 54% (6/5). At diagnosis, anemia, HB<11gr/dl, was present in 72% (8/11), thrombocytopenia PL<100000/μL in 63% (7/11), and leucopenia WBC<4000/μL in 54% (6/11). Albuminuria was reported in 63% (7/11) of the patients. Bone marrow examination revealed the presence of Gaucher cells in all cases. Hemoglobin electrophoresis was normal in all cases except2, in which minor thalassemia was observed. Hepatomegaly was reported in all patients. Bone pain was reported in 45% (5/11) of patients.Splenomegaly was reported in all patients at 100% (11/11). Spleen size varied from 5-20 cm under the costal arch. In 63% of pts. the spleen was larger than 10 cm under costal arch. The most surprising thing was the strong correlation between spleen size and the view of the ultrasound examination (USE) of the spleen. The USE of the spleens showed hypoechodens areas in 63% (7/11) of the pts. Hypoechodens areas are prescribed by some "brave" examiners as areas that suggest spleen lymphomas or spleen malignancy, but these were not associated with signs and symptoms of malignancies such as temperature, sweats, weigh loose, etc. These Hypoechodens areas are observed in all cases (7/7) with splenomegaly>10 cm under costal arch.
Summary and Conclusions: Splenomegaly was among the most common signs of GD patients. The hypoechodens areas reported in USE of the spleen, mainly in the large spleen, which are not associated with signs and symptoms of malignancy, may strongly generate suspicions and lead to the GD diagnosis.

P1034

LANGERHANS CELL HISTIOCYTOSIS: ONE CENTER EXPERIENCE BETWEEN 1990-2012
T Celkan[1,*], G Tuysuz[1], N Ozdemir[1], H Apak[1]
[1]Pediatric Hematology-Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Langerhanscell histiocytosis(LCH) isa disease seen in children especially.
Aims: Diagnosis andfollow-upof Langerhanscell histiocytosis(LCH)patientsat our center were evaluated in this study
Methods: Retrospectively the files of the LCH patients who were treated at our center were analyzed
Results: During the 23 year of follow up, 80 patients (56 boys and 24 girls) were diagnosed with LCH. The complains of the patients were; local swelling (n:36, 45%), bone pain (n: 24, 30%), skin eruption (n:16, 20%), discharge from the ear (n:6, 8%), polydipsia (n:6, 8%), fewer (n:3, 4%), cough-respiratory distress (n:3, 4%) jaundice (n:2, 2%), abdominal distention (n:2, 2%), tooth loose (n:2, 2%) and diarrhea (n:1, 1%). One of the patients were diagnosed with an X-Ray taken after trauma. The patients were evaluated at 4 different groups; One system one organ involvement (n:28), one system multifocal involvement (n: 15), multisystem low risk (n:21), multisystem high risk (n: 16). The mostly involved area was bone; (one system one organ involvement n:22, one system multifocal involvement n:14, multisystem low risk n:14). Mostly involved organ at multisystem risk group were; liver (n:14), skin (n:17), bone (n:6), bone marrow (n: 6), spleen (n: 5), lungs (n:5), lymph node (n:3), soft tissue (n:1) and intestine (n:1). Ten of the 80 patients were transferred to other centers after diagnosis. The remaining 70 patients were treated at our center. Fourteen patients with one system one organ involvement and 4 patients with one system multifocal involvement were treated with curretage-excision of the tumour. Only one of these patients had a local relapse and treated succesfully with re-excision of the tumour. Three patients received systemic chemotherapy (prednisolone and etoposide) after curretage because lesion could not be removed completely. No relapse occured at any of these patients. Five of the patients with one bone involvement received radiotherapy to the involved side; and 3 of these patients relapsed and all had gone into remission with treatment (1 patient recieved systemic chemotherapy an 2 had excision of the lesion). Remission was achieved at patients with soft tissue involvement with local intralesionel steroid thereapy (n:4.) One of the patients had regression of the tumour spontaneously. The chemothereapy protocole was LCH-I before 1996, LCH-II between 1997 and 2002 and LCH-III after 2002. Twenty seven of the patients with systemic involvement received prednisolone+vinblastine, 13 received prednisolone+vinblastine+etoposide and 3 patients received prednisolone+vinblastine+methotraxate. Respectively 7, 4 and 1 of these patients had reccurence. Fifty four of 70 patients achieved remission after treatment and did not have any relapse. Twelve of patients had (17%) had relapse. Six of these patients had 2, 4 of these patients had 3 and 2 of these patients had 4 times of relapses. One of these patients died after the second relapse. The rest 11 patients are in remission. Four patients with multi system involvement died during treatment due to progression of the disease. These patients were not in remission and died with an avarage of two months after the diagnosis.
Summary and Conclusions: Langerhans cell histiocytosis is a disease that involves multiples organs. Systemic or local treatment has a good response but 20-25% of patients might have relapses.

P1035

A NEW TYPE OF CHEDIAK-HIGASHI SYNDROME? CASE REPORT OF A BLACK HAIRED GIRL WITHOUT OCULOCUTANEUS ALBINISM PRESENTED WITH EARLY ONSET HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS
H Hatipoglu[1,*], M Elevli[1], M Civilibal[1], N Duru[1], S Ehl[2], O Akgun[1], T Celkan[3]
[1]Pediatrics, Haseki Education and Research Hospital, Istanbul, Turkey, [2]Centre of Chronic Immunodeficiency, Univercity of Freiburg, Freiburg, Germany, [3]Pediatric Hematology-Oncology, Cerrahpasa Medical Faculty Univercity of Istanbul, Istanbul, Turkey

Background: Chediak-Higashi Syndrome(CHS) is a rare, autosomal recessive disorder characterized by variable degrees of oculocutaneus albinism, severe immune deficiency, lymphoproliferative syndrome and intracytoplasmic giant granules in leukocytes. Giant granules may be present in Imphocytes, monocytes and melanocytes.
Aims: In this article, we report a case of CHS with neither oculocutaneus albinism nor silvery hair presented with early onset hemophagocytic lymphohistiocytosis(HLH).
Methods: Case report
A five months old girl presented with high fever. She had splenomegaly, pancytopenia, hipertrigliceridemia and high ferritin levels. Hemophagocytosis was observed on bone marrow aspiration smear. She was diagnosed with HLH. HLH-2004 treatment protocol including dexametasone and etoposide was administrated. Any known perforin gene defect was not determined. On both bone marrow aspiration and peripheral blood smears intracytoplasmic giant granules on lymphocytes were observed. She had neither oculocutaneus albinism nor silvery hair but analysis of the hair shaft with ligth microscope was consistent with CHS (photograph). Thus she was diagnosed with CHS.
Results: CHS is usually known as a disease characterized by oculocutaneus albinism and silvery hair but our patient does not have oculocutaneus albinism and she is black haired. Patients with CHS may have a variable clinical presentation due to a different mutations in the lysosomal trafficking regulator gene (LYST), other genetic factors and an exposure to other different pathogens. Nonsense and frameshift mutations of the LYST gene are asssosiated with severe early-onset

childhood CHS and characterized by fatal infections and HLH. Whereas missense mutations of the same gene are assosiated with milder, late-onset CHS with slowly progressive neurological impairment or an adolescent form with infections but no HLH. Also there is a correlation between the absence of cytotoxic T lymphocyte citotoxicity and risk of developing HLH. Probably there may be a mutation of the LYST gene that is assosiated with normal phenotype and the specific findings of the CHS on peripheral blood smear, bone marrow aspiration smear and light microscopic image of the hair shaft but however causes to an early-onset HLH. In our case there was no specific treatment for CHS. Intraveneus antibiotherapy and in accordance with HLH 2004 treatment protocol dexamethasone and etoposide were used and the patient has been positively responsive to chemotherapy. Stem cell transplantation has been planned (Figure 1).

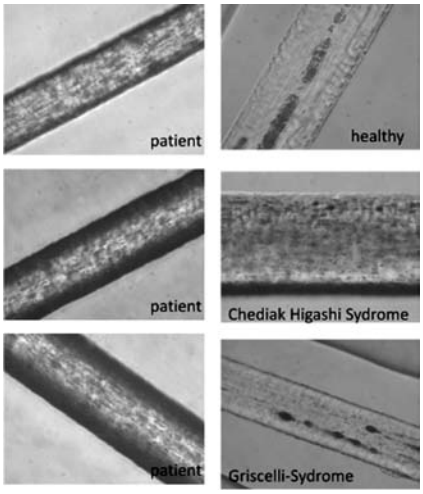

Figure 1.

Summary and Conclusions: Our case is suggestive of that it is not necessary to find oculocutaneus albinism and silvery hair in all patients to diagnose CHS. Peripheral blood smear and light microscopic image of the hair shaft findings may be sufficient to diagnose in some cases. And it is more cost effective than genetical analysis even for prenatal diagnosis.

P1036

CHEMOTHERAPY-ASSOCIATED TREATMENT BURDEN IN BREAST CANCER PATIENTS RECEIVING LIPEGFILGRASTIM OR PEGFILGRASTIM: SECONDARY EFFICACY DATA FROM A PHASE III STUDY

O Gladkov[1,*], A Buchner[2], P Bias [2], U Mueller[2], R Elsaesser[2]
[1]Chelyabinsk Regional Clinical Oncology Center, Chelyabinsk, Russian Federation, [2]Teva ratiopharm, Ulm, Germany

Background: Myelosuppressive chemotherapy (CTx) frequently causes neutropenia, leading to an increased risk of infections and delays in subsequent CTx treatments. PEGylation of the granulocyte-colony stimulating factor (G-CSF) molecule extends its half-life in the body, requiring less frequent dosing than traditional non-PEGylated G-CSFs, potentially making treatment less expensive while enhancing patient compliance and safety. Lipegfilgrastim is a long-acting, once-per-cycle glycoPEGylated G-CSF in development for the prevention of neutropenia in cancer patients receiving CTx. Noninferiority of lipegfilgrastim *versus* pegfilgrastim (Neulasta®)was demonstrated in a Phase III trial conducted in CTx-naïve breast cancer patients.[1]

Aims: To present secondary data on the incidence of hospitalization and density and intensity of CTx in lipegfilgrastim- and pegfilgrastim-treated patients.

Methods: Patients with high-risk Stage II, III, or IV breast cancer were randomized to a single 6 mg subcutaneous injection of lipegfilgrastim (n=101) or pegfilgrastim (n=101) on Day 2 of each CTx cycle. Full-dose CTx (doxorubicin 60 mg/m^2+docetaxel 75 mg/m^2) was started on Day 1 of each cycle (day 22 of the previous cycle) for up to four consecutive cycles. The primary endpoint was duration of severe neutropenia. Secondary endpoints included days in the hospital or intensive care unit (ICU) and incidence of treatment with intravenous antibiotics because of febrile neutropenia (FN) or related infections; actual *versus* scheduled cumulative CTx dose per patient; reduced, omitted, or delayed CTx doses; and duration of CTx delays.

Results: Key secondary endpoints are listed in the Table 1. In the intent-to-treat population, two pegfilgrastim-treated patients and one lipegfilgrastim-treated patient were hospitalized in Cycle 1 because of FN or associated infection. The two pegfilgrastim-treated patients were hospitalized for FN for 5 and 6 days, respectively, and the lipegfilgrastim-treated patient spent 1 day in the ICU for FN and a fungal infection. All hospitalized patients received antibiotics; the lipegfilgrastim-treated patient also received antipyretics. An additional pegfilgrastim-treated patient received antibiotics but was not hospitalized. The frequency and duration of CTx dose delays were low and comparable between groups; <40% of patients had CTx dose delays. The majority of patients received CTx as scheduled, with the mean percent of planned doxorubicin and docetaxel doses reaching over 98% in all cycles. Thirty-four patients in the lipegfilgrastim group and 41 patients in the pegfilgrastim group received delayed CTx in Cycles 2−4. There were no dose omissions or reductions in the lipegfilgrastim group and eight in the pegfilgrastim group in Cycles 2−4.

Table 1. Key secondary endpoints.

	Pegfilgrastim 6 mg				Lipegfilgrastim 6 mg			
Cycle	**1**	**2**	**3**	**4**	**1**	**2**	**3**	**4**
n	101	100	98	98	100	99	98	95
Hospitalized, n (%)	2 (2.0)	0 (0.0)	0 (0.0)	0 (0.0)	1 (1.0)	0 (0.0)	0 (0.0)	0 (0.0)
CTx delay, n (%)	N/A	15 (15.0)	17 (17.3)	9 (9.2)	N/A	16 (16.2)	14 (14.3)	4 (4.2)
CTx dose reduced/ omitted, n (%)	N/A	4 (4.0)	2 (2.0)	2 (2.0)	N/A	0 (0.0)	0 (0.0)	0 (0.0)
Actual CTx dose applied, (% of planned dose)	Mean	Mean	Mean	Mean	Mean	Mean	Mean	Mean
• Doxorubicin	99.3	98.2	98.3	98.4	99.1*	98.7	98.8	98.9
• Docetaxel	99.2	98.2	98.3	98.3	99.3*	98.9	98.9	98.9

*N=101

Summary and Conclusions: The burden of treatment associated with myelosuppressive CTx was similar in breast cancer patients treated with lipegfilgrastim or pegfilgrastim, with no clinically relevant differences in density and intensity of CTx.

P1037

USE OF ROMIPLOSTIM IN PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (CITP) DURING PERI-OPERATIVE PERIOD

R Ramakrishna[1,*], W Alexander[1], K Sarathy[1]
[1]Southern Haematology and Cancer Research Institute, Wollongong, Australia

Background: Conventional treatments for managing cITP in the peri-operative period include corticosteroids or IVIG and immunosuppressive therapies. Each of these therapies has its own drawbacks.[1-3]Romiplostim, a thrombopoiesis stimulating peptibody is currently indicated for use weekly for long-term management of patients with prolonged very low platelet counts (<20/nL) or low platelet counts with bleeding (20-30/nL). Cessation of therapy after periods >10 weeks can be associated with marked, unremitting rebound thrombocytopenia[4]. Its use in the peri-operative period is not well established. Patients who are refractory to steroids and IVIG can be a challenge to manage peri-operatively. Safety data on use of thrombopoietin agonists is limited with little or no published data exists on short-term use, such as during the peri-operative period.
Aims: The aim of this cohort study was to evaluate the safety and effectiveness of Romiplostim in managing the bleeding risk of cITP patients peri-operatively.
Methods: Patients with cITP requiring surgery who had proven refractory to IVIG and steroids were trialled on Romiplostim to determine its effectiveness at managing their bleeding risk peri-operatively. Patients were given up to three doses starting 2 weeks prior to their surgery with a starting dose of 3µg/kg. Platelet counts were monitored and subsequent doses were adjusted as necessary.
Results: Thirteen surgical procedures were performed after using this protocol and none of the patients treated with this protocol experienced any bleeding complications peri-operatively (Table 1). One patient experienced mild headaches associated with Romiplostim usage which resolved once therapy was ceased. One patient experienced mild rebound thrombocytopenia which resolved to baseline spontaneously after 4 weeks. One patient had a delayed response to treatment. One patient achieved sub-optimal response but no surgical complications. Possible platelet dysfunction did not appear to contribute to any bleeding complications.

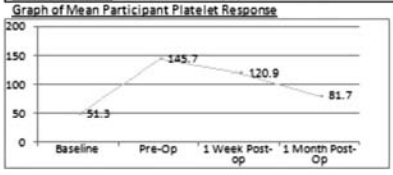
Table 1.

Summary of Results

Demographics	Type of Surgery	Baseline Plts	Pre-Op Plts	1 Week Post-Op Plts	1 Month Post-Op Plts	Platelet Function	Complications
Female/ 63 years old	Mitral valve replacement	65	139	174	146	Abnormal	Nil
Male/ 65 years old	Mitral valve replacement	35	100	70	40	Abnormal	Nil
Male/ 52 years old	Liver biopsy	32	114	80	45	Abnormal	Headache
Male/ 56 years old	Thyroidectomy	35	145	164	97	Abnormal	Nil
Male/ 52 years old	Aortic valve replacement	68	215	128	166	Abnormal	Nil
Female/ 46 years old	Mucosectomy	39	122	139	86	Normal	Nil
Male 69 years old	Coronary artery bypass graft	51	104	52	57	N/A	Nil
Male/ 56 years old	Cystoscopy and prostate enucleation	75	207	200	114	Abnormal	Nil
Male/ 45 years old	Thyroidectomy and neck dissection	64	420	42	62	Normal	Rebound thrombocytopenia
Male/ 75 years old	Spinal surgery	62	104	247	73	Abnormal	Nil
Female/ 59 years old	Colonoscopy/ gastroscopy	54	50	134	51	N/A	Had a delayed response to therapy.
Female/ 58 years old	Liver Biopsy	47	104	102	89	N/A	Nil
Male/ 64 years old	Colon Polypectomy	39	70	40	36	Abnormal	Platelet count only 70 pre-op, surgeon happy to go ahead.

Abbreviations used: Plts = platelet count (nL)

Graph of Mean Participant Platelet Response



Summary and Conclusions: Romiplostim so far appears to be effective in managing bleeding risk in the peri-operative period. It eliminates the need for platelet transfusions or immunoglobulin infusions, saving this resource. In addition, it is relatively convenient for patients when compared to intravenous therapies, in terms of time required, invasiveness and incidence and severity of adverse events. The platelet response is maintained beyond one month in some cases, and rebound thrombocytopenia does not appear to be a concern in our experience. Our data supports use of Romiplostim as a safe and effective therapy for management of bleeding risk for patients with cITP, during the peri-operative period.

CIRCULATING FOLLICULAR HELPER T CELLS IN CHILDREN WITH IMMUNE THROMBOCYTOPENIC PURPURA

E Parodi[1,*], M Lanza[1], E Ricotti[2], F Ferro[2], D Montin[3], M Giraudo[4], U Ramenghi[1]
[1]Pediatric Department, Universirty of Torino, Hematology Unit, Pediatric Department, [2]Lab of Hematology, Regina Margherita Children Hospital, [3]Department of Immunology, [4]Department of Mathematics, University of Torino, Torino, Italy

Background: Immune Thrombocytopenic Purpura (ITP) is an autoimmune disorder characterised by low platelet count and mucocutaneous bleeding. Immunological tolerance among T cells is of paramount importance for the control of autoimmune antibody specificities. Recent studies examined the T-cell repertoire in patients with ITP and found differences compared with healthy individuals, lending further credence to T cells being at the heart of the pathogenesis of the disease. T follicular helper cells (TFH) are the effector T helper that regulates the steP-wise development of antigen-specific B cell immunity *in vivo*. It is likely that TFH cells provide inappropriate helper signals to self-reactive B cells in cases of antibody-mediated autoimmune diseases. Recent studies raised the possibility that dysregulated TFH cell activity may contribute to SLE in humans.
Aims: The aim of the study is to analyze the TFH cells in children with ITP.
Methods: Thirty-one pediatric ITP patients, 15 males and 16 females, with a median age of 5 years (range 1-15), were enrolled in the study. In13, TFH analysis was performed at diagnosis, prior to any drug treatment (acute ITP). Eighteen patients were enrolled in the chronic phase of the disease (ITP lasting for more than 12 months); at the time of sample collection, patients were at least one month off-treatment. Twelve healthy children were enrolled as control group.T cells were analyzed by flow cytometry from peripheral blood mononuclear cells (MNC). Immunofluorescence was performed using the following monoclonal antibodies (Becton Dikinson): FITC anti-CD45RO, PE anti-CXCR5, Per-CP anti-CD3, APC anti- CD4. Cells were analyzed by using aBD FACS Canto II equipment and were gated for lymphocytes on the basis of their forward scatter and side scatter profile. A minimum of10,000 events of the MNC fraction was collected. Statystical analysis was performed with the Wilcoxon's rank sum test and the t-student test. Spearman's rank correlation test was used for correlation analysis.
Results: The median percentage of circulating TFH cells resulted significantly lower in acute ITP patients than in chronic ITP patients (4,23*versus*8,60; P=0.0001) and in acute ITP patients than in controls (4,23*versus*7,79; P=0.0004). No significant correlations were detected between TFH cells and platelet count, between TFH cells and gender, and between TFH cells and anamnestic data (family history for autoimmune disease, recent history for infection or vaccination).
Summary and Conclusions: Our results suggest that dysregulated TFH may have a prognostic value in ITP.

P1039

A MULTICENTER OBSERVATIONAL STUDY FOR EARLY DIAGNOSIS OF GAUCHER DISEASE IN PATIENTS WITH SPLENOMEGALY AND/OR THROMBOCYTOPENIA

I Motta[1,*], M Stroppiano[2], W Barcellini[1], E Poggiali[1], A Dragani[3], G Gaidano[4], F Merli[5], M Cappellini[1]
[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, [2]Istituto Gaslini, Genova, [3]Ospedale Civile Spirito Santo, Pescara, [4]Ospedale Maggiore Della Carita', Novara, [5]AO S. Maria Nuova, Reggio Emilia, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disorder resulting from deficiency of beta-glucosidase and the accumulation of glucocerebroside in the reticuloendothelial cells. Prevalence of GD is elevated in Ashkenazi Jewish population (1/450-1/1000), and rare in the non-Ashkenazi (1/40000-1/60000). GD is a multisystemic disease; cytopenias and splenomegaly are frequently the presenting symptoms leading to hematological evaluation. Data from the Gaucher Registry 2008 show that splenomegaly and thrombocytopenia are present at diagnosis in more than 5000 patients (respectively 86% and 60%). Because of the non-specific presenting symptoms, diagnostic delays are frequent, leading to severe complications including hematological malignancies.Enzyme replacement therapy is available and-

effective in reversing or preventing many manifestations, including hepatosplenomegaly, marrow infiltration, cytopenias and osteopenia (Weinreb 2002). A global survey among 406 Hematology-Oncology specialists demonstrated that only 20% consider GD in the differential diagnosis of cytopenia, hepatosplenomegaly, and bone pain (Mistry 2007). It is clear that a different approach based on a specific diagnostic algorithm is necessary to avoid underdiagnosis (Mistry PK 2010).

Aims: The aim of this multicenter observational study is to evaluate the prevalence of GD in a selected population presenting to hematological clinic with at least one of the two including criteria: 1) splenomegaly, 2) thrombocytopenia associated to at least one of the following symptoms: anemia (Hb<11 g/dl for women, and Hb<12 g/dl for men), MGUS, policlonal gammopathy in patient younger than 30 yo, splenectomy or history of bone pain. Exclusion criteria include: a) splenomegaly due to portal hypertension in cirrhosis, b) hematological malignancy, c) hemoglobinopathies or other hemolitic anemias.

Methods: Thirty five Italian Hematologic Centers participate in this study. According to a preliminary survey, 18% of all hematologic first evaluations are positive for splenomegaly and/or thrombocytopenia, among them 11% did not received an appropriate diagnosis. According to these data 762 patients are expected to be tested every year (mean of 1100 first evaluations/year for each center). Patients fulfilling including criteria who have given their informed consent are recruited into the study and tested for beta-glucosidase enzyme activity on Dried Blood Spot (DBS). All the analysis are centralized and performed by the Laboratory of diagnosis of Metabolic Diseases Ospedale Gaslini, Genova. Results can show normal, decrease or borderline beta-glucosidase activity. In the last case, DBS must be repeated to confirm the result. Beta-glucosidase deficiency and GD diagnosismust be subsequently confirmed dosing the enzyme activity in the leukocytes from fresh blood and by DNA analysis. The expected duration of the study was 24 months, starting from September 2010, subsequently extended up to the enrollment of 500 patients (recruitment still active at present).

Results: Starting from September 2010 153 patients (45 female, 108 male) have been enrolled. All the patients are non-Ashkenazi, among them 61% had splenomegaly, 4% thrombocytopenia and 35% both of them. Six patients have been diagnosed with GD.

Summary and Conclusions: Our results are clinically relevant, showing that the use of a simple diagnostic algorithm helps identify patients presenting to hematologists with a early diagnosis of GD, leading to an appropriate and prompt therapy to prevent the development of complications.

P1040

A RETROSPECTIVE ANALYSIS OF EPSILON-AMINO-CAPROIC ACID THERAPY IN HYPOPROLIFERATIVE THROMBCYTOPENIA

S Jain[1,*], T Gernsheimer[1], S Slichter[2]
[1]Medical Edication, [2]Research, Puget Sound Blood Center, Seatle, United States

Background: We performed a retrospective analysis of epsilon-amino-caproic acid (EACA) use in patients with hypoproliferative thrombocytopenia from January 2006 to July 2012. 221 patients, 18 years or older, received EACA on 260 separate occasions. EACA use increased from 13 courses in 2006 to 57 during Jan-July 2012. Of the 160 patients reviewed to date, 101 were treated with at least two doses of EACA and were included in this analysis. Data were collected on indications for EACA therapy (to treat bleeding *vs.* prophylaxis), WHO bleeding grade before and during therapy, platelets and red blood cells transfused for 3 days prior to and up to the first 7 days after starting therapy, and thrombotic events for 2 weeks after beginning therapy. We used a modification of the WHO bleeding scale to identify patients with grade 2a bleeding, defined as WHO grade 2 excluding skin bleeding.

Aims: To review the efficacy of EACA therapy for prevention and treatment of bleeding in hypoproliferative thrombocytopenia.

Results: Of the 101 patients evaluated, 92 were treated with chemotherapy for hematologic malignancy, and of those 32 were post stem cell transplant. The other 9 patients had aplastic anemia, immune thrombocytopenia or drug induced marrow aplasia. All 101 patients received EACA in hospital; 12 were also treated as outpatients. Twenty-two patients were treated with 3 to 8 grams of EACA prophylactically [14 (63%) were platelet refractory], and none developed bleeding. Seventy-nine patients were treated with 2 to 24 grams of EACA daily for treatment of bleeding [43 (54%) were platelet refractory]. Among the 79 bleeding patients, the highest grade of bleeding was grade 1 in 12 patients (15%), 2a in 29 (37%), grade 3 in 26 (33%) and grade 4 in 12 (15%). Bleeding improved in 58 (74%) patients, was unchanged in 14 (18%), and worsened in 7 (8%). Improvement in bleeding grade was seen in 7 of the 12 patients with grade 1 bleeding, 24 of 29 patients with grade 2a bleeding, 21 of 26 patients with grade 3 bleeding, and 6 of the 12 patients with grade 4 bleeding. The average platelet and red blood cell transfusion rate decreased substantially while on EACA therapy (Table 1).

None of the patients treated with EACA prophylactically had a thrombotic event. Of the bleeding patients, 4 patients developed thrombotic events: 1 patient had an incidental sub-segmental pulmonary embolus identified on a CT chest exam; 1 patient developed atrial fibrillation 3 days after stopping EACA and had an upper extremity central line related deep venous thrombosis and a sub-segmental pulmonary embolism; 1 patient developed a central line associated internal jugular vein thrombus; and 1 patient had hypoxia secondary to circulatory overload and an incidental finding of a sub-segmental pulmonary embolus. None of the 101 treated patients developed sinusoidal obstructive syndrome (veno-occlusive disease). The overall incidence of thrombotic events in all patients treated with EACA was 4/101 patients (3.9%), not unlike the incidence previously reported in similar patients not treated with EACA.

Table 1. Transfusion frequency before and after EACA treatment.

	Before EACA Treatment*		During EACA Treatment**	
All Patients (n=101)	*Red Blood Cells*	*Platelets*	*Red Blood Cells*	*Platelets*
Units per patient /day	0.87	1.16	0.51 (-37%)	0.95 (-22%)
	Before EACA Treatment*		During EACA Treatment**	
Bleeding Patients (n=78)	*Red Blood Cells*	*Platelets*	*Red Blood Cells*	*Platelets*
Units per patient/day	0.98	1.24	0.56 (-43%)	1.04 (-21%)
	Before EACA Treatment*		During EACA Treatment**	
Clinically significant Bleeding * (n=67)**	*Red Blood Cells*	*Platelets*	*Red Blood Cells*	*Platelets*
Units per patient/day	1.09	1.31	0.60 (-49%)	1.12 (-19%)

*Three days of observations before EACA treatment
**Seven days of observations after EACA treatment
***Bleeding grade 2a or greater

Summary and Conclusions: Our data support the hypothesis that EACA therapy decreases bleeding and reduces transfusion requirements in patients with hypoproliferative thrombocytopenia.

P1041

THE USE OF MYCOPHENOLATE MOFETIL IN THE TREATMENT OF CHRONIC REFRACTORY IMMUNE THROMBOCYTOPENIA PURPURA

A Taylor[1,*], L Neave[2], S McGuckin[1], I Terrinoni[2], J Westwood[1], N Cooper[2], M Scully[1]
[1]Haematology, University College London Hospital, [2]Haematology, Hammersmith Hospital, Imperial College, London, United Kingdom

Background: Immune thrombocytopenia purpura (ITP) is an autoimmune disorder frequently encountered in clinical practice. It is characterized by an isolated thrombocytopenia without an obvious precipitant.

There is a general consensus that first-line treatment includes steroids and/or immunoglobulin. Second-line treatment options are more variable and less evidence-based. Failure to sustain a response to standard first line therapies (steroids and IVIg) frequently presents a clinical challenge. Thrombopoietin agonists are not yet universally available, and so more commonly available drugs may be useful interim measures.

Aims: We present 25 chronic or refractory ITP patients treated with mycophenolate mofetil (MMF), in order to investigate whether this is a useful treatment modality in this difficult disease.

Methods: Retrospective data was collected and a total of 25 patients were identified as having been treated with MMF. We collected demographic information, co-morbidities, previous treatment strategies, when MMF was commenced, type and time to response, duration of response, dose of MMF required to maintain a response, intercurrent therapies (eg steroids), side effects and the current status of all patients.

Results: The 25 patients were aged 20 to 93 years old (median 45 years), 14 men and 11 women. Previous treatment strategies included IVIg (n=20), steroids (n=20), rituximab (n=10), splenectomy (n=2), azathioprine (n=4), anti-D (n=4) and eltrombopag (n=1). Comorbidites were varied and included hepatitis C, HIV, diabetes, systemic lupus erythematosus, liver cirrhosis and schizophrenia. These influenced treatment options and outcome. 12 of 25 patients (48%, 5 men and 7 women), responded to MMF, defined as a platelet count of $>30\times10^9$/L and absence of bleeding, most on an initial dose of 1gram BD. Responders were aged 19 to 85 years (median 43 years). 4 patients showed a sustained complete response (platelets $>100\times10^9$/L); 2 men and 2 women aged between 21 and 67 years of age. Time to response was on average 2 to 5 weeks. and sustained at a median dose of 500mg BD MMF.

7 responders had a sustained platelet count of 50-100 × 10^9/L; 3 men and 4 women aged 19 to 85 years. Time to response was 4 weeks, and sustained at 500mg BD (range 2–52 months). There was 1 partial responder, with a sustained platelet count of 30- 50 × 10^9/L on 500mg BD MMF and no bleeding, in a 43-year-old woman whom had failed to respond to multiple therapies including TPO agonists. No significant side effects were documented. The 13 non-responders (5 men and 8 women) included 2 patients who discontinued MMF before any response was seen, due to gastrointestinal and dermatological side effects. Age range was 30 to 93 years. 4 patients were HIV or hepatitis C (HCV) positive. 4 of the non-MMF responders subsequently responded to a TPO agonist.

Summary and Conclusions: From our case series, we conclude that MMF is a useful steroid-sparing immunosuppressant in resistant, non-viral induced ITP. There were response rates in 48% of cases and 20% achieved a complete response. There was an acceptable side effect profile in patients who previously had refractory immune thrombocytopenia.

P1042

SELF-ADMINISTRATION OF ROMIPLOSTIM BY PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA DOES NOT ADVERSELY IMPACT EFFICACY OR SAFETY COMPARED WITH ADMINISTRATION BY A HEALTHCARE PROVIDER

D Selleslag[1,*], R Bird[2], I Altomare[3], A Giagounidis[4], A Janssens[5], I Pabinger[6], V Pullarkat[7], H Wei[8], G Kreuzbauer[9]
[1]A-Z Sint-Jan, Brugge-Oostende, Belgium, [2]Princess Alexandra Hospital, Woolloongabba, Australia, [3]Duke University Medical Center, Durham, United States, [4]St Johannes Hospital, Duisburg, Germany, [5]University Hospitals, Leuven, Belgium, [6]Div of Haematology and Haemostaseology, Dept of Medicine I, Medical University, Vienna, Austria, [7]Keck School of Medicine, University of Southern California, Los Angeles, [8]Amgen Inc., Thousand Oaks, United States, [9]Amgen (Europe) GmbH, Zug, Switzerland

Background: Romiplostim is a subcutaneously administered thrombopoietin-receptor agonist that significantly increases and maintains platelet counts in patients with chronic immune thrombocytopenia (ITP). Romiplostim was initially approved in the EU and US for administration by a healthcare provider; however, self-administration has recently been approved by the European Medicines Agency.

Aims: To evaluate the impact of self-administration on efficacy, safety, and maintenance of therapy in adult patients who received romiplostim by self-administration in the home setting (SA group) compared with those who received romiplostim by a healthcare provider in a clinical setting (HCP group).

Methods: Outcomes were retrospectively compared between SA and HCP groups using data from 2 phase III randomized controlled trials and 1 open-label trial of romiplostim in adult patients with ITP in which self-administration was allowed. Patients achieving a stable romiplostim dose for ≥3 consecutive weeks could begin SA. The start of SA was used as the first week of analysis for the SA group. The HCP group included patients who had all romiplostim doses administered by a HCP and who stayed in the study for at least8,6, and 12 weeks (representing the first weeks of analysis in studies1,2, and3, respectively, and the median time of initiation of SA). Evaluations of efficacy, safety, and maintenance of therapy were conducted for 12-week treatment intervals. Endpoints for this analysis included maintenance of self-administration, platelet counts, and percentage of weeks with a platelet response. Duration-adjusted rates of adverse events (AEs), serious adverse events (SAEs), and treatment-related AEs, were also summarized.

Results: There were 563 patients in the SA groups and 241 patients in the HCP groups (Table 1). Baseline characteristics (eg, age and prior/concurrent ITP therapy in study 1; lower baseline platelet count, history of splenectomy, and concurrent ITP therapy in study 2; and history of splenectomy in study 3) suggested more severe disease in the HCP groups than in the SA groups. Greater proportions of patients in the SA groups achieved the target platelet range, and patients in the SA groups maintained platelet counts within the target range for a greater proportion of the treatment period than patients in the HCP groups (75.1–88.3% of weeks for the SA groups *vs* 46.9–76.3% of weeks for the HCP groups; Table 1). The rate of discontinuation of romiplostim was 2- to 4-fold lower in the SA groups than the HCP groups, with AEs and requirement for alternative therapy being common reasons for discontinuation. Rates of duration-adjusted AEs, SAEs, and treatment-related AEs were lower in the SA groups than the HCP groups.

Summary and Conclusions: In adult patients with ITP receiving romiplostim, self-administration did not reduce efficacy or compromise safety profiles as compared with healthcare provider administration. Indeed, compared with administration by a healthcare provider, a greater percentage of patients who self-administered romiplostim maintained target platelet counts and for longer time periods, and had lower rates of discontinuation. Duration-adjusted AEs were generally lower in the SA group than in the HCP group. However, patients were not randomized to SA/HCP groups, and the imbalance of the baseline characteristics may have confounded the results. Nonetheless, these results suggest that self-administration of romiplostim is a feasible option for certain patients with ITP.

P1043

DURATION OF BLEEDING SYMPTOMS >14 DAYS BEFORE DIAGNOSIS IS A STRONG PREDICTOR FOR DEVELOPMENT OF CHRONICITY IN CHILDHOOD PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

A Papagianni[1,*], M Economou[1], A Tragiannidis[2], E Karatza[1], F Athanassiadou - Piperopoulou[2], N Vavatsi - Christaki[3], M Athanassiou - Metaxa[1], F Papachristou[1], N Gompakis[1]
[1]"HIPPOKRATEION" GENERAL HOSPITAL THESSALONIKIS, 1ST PEDIATRIC UNIVERSITY CLINIC, [2]AXEPA GENERAL HOSPITAL, THESSALONIKI, 2nd PEDIATRIC UNIVERSITY CLINIC, [3]BIOCHEMISTRY LABORATORY, ARISTOTLE UNIVERSITY OF THESSALONIKI, Thessaloniki, Greece

Background: Immune thrombocytopenia is the commonest cause of bleeding diathesis in children. Most of the patients run a mild course with complete remission usually within three months from diagnosis. It still remains challenging though to predict which children will develop chronic thrombocytopenia.

Aims: The aim of the present study is to identify clinical and/or laboratory findings at presentation predicting a chronic course for childhood immune thrombocytopenia (ITP).

Methods: This study included 53 patients diagnosed with immune thrombocytopenia, 17 of which were known patients with chronic ITP and 36/53 were prospectively recruited between March 2008 and August 2010 and were followed up for at least 12 months post recruitment for study purposes. Data such as age, duration of bleeding symptoms before suspicion of ill health, bleeding stage according to Provan *et al.*, 2010 and platelet count at diagnosis were collected in all patients either prospectively or retrospectively in chronic patients (using medical notes and patient/parent interviews). Age at diagnosis, age >10yrs at diagnosis, platelet count of >10000/μL at diagnosis, bleeding stage 3+4 at diagnosis and duration of symptoms >14 days at diagnosis were associated with the course of the disease, using student's t–test, Mann–Whitney U test and Fisher's exact test accordingly.

Results: The cohort consisted of 26 boys and 27 girls with a mean age of 5.95±3.88 years (range: 0.375–14.83 years).Thirty–two out of 53 patients ran an acute/persistent course (duration <12 months) and 21 followed a chronic course of the disease. The percentage of children with duration of bleeding symptoms >14 days before suspicion of the disease was significantly higher between the children who developed chronic ITP (75% *vs* 3% in the group with acute/persistent course). None of the other parameters studied proved to be statistically significant.

Summary and Conclusions: Insidious onset of disease defined as duration of symptoms >14 days before diagnosis of childhood primary immune thrombocytopenia is a strong predictor for development of chronic ITP. This information is important for management approach and parent/patient consultations.

P1044

PLATELET ACTIVATION MARKERS IN PATIENTS WITH INCREASED CARDIOVASCULAR RISK

E Gavriilaki[1,*], E Gkaliagkousi[1], E Yiannaki[2], D Markala[2], N Papadopoulos[1], A Triantafyllou[1], P Anyfanti[1], K Petidis[1], S Vakalopoulou[1], V Garypidou[1], M Doumas[1], S Douma[1]
[1]2nd Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, [2]Department of Hematology, Theagenion Cancer Center, Thessaloniki, Greece

Background: Platelet activation is considered a significant factor contributing to the increased incidence of arterial thrombotic complications observed in patients with increased cardiovascular risk, such as patients with essential

hypertension. Although a variety of platelet activation markers have been proposed, their usefulness in the clinical setting has been questioned.
Aims: The aim of this study was to estimate the degree of platelet activation at rest and after acute high-intensity exercise in a group of naïve, never treated patients with essential hypertension (UH) as compared to normotensive (NT) individuals, using the most reliable flow cytometric markers of platelet activation (circulating monocyte-platelet aggregates or MPA and platelet P-selectin). Secondly, we investigated whether antihypertensive treatment reduces exercise-induced platelet activation in essential hypertension.
Methods: We studied 15 NT and 30 UH individuals, 17 of which were followed-up after a 3-month period of monotherapy with antagonists of the renin-angiotensin system (RAS). All subjects underwent a treadmill exercise test. Circulating monocyte- MPA levels and platelet P-selectin were measured using flow cytometry at baseline, at maximal exercise and at10, 30 and 90 minutes later.
Results: Maximal platelet activation was observed at 10 minutes post-peak exercise in both groups. In UH, MPA levels remained increased at 30 minutes post-peak exercise, despite BP fall to baseline levels. MPA levels were significantly higher in UH than NT at maximal exercise, and at 10 and 30 minutes of recovery. P-selectin expression also increased during exercise in both groups, with no significant differences between UH and NT. Post-treatment MPA levels increased significantly only at 10 minutes into recovery. Post-treatment MPA and P-selectin values at each time point were similar to those of NT individuals.
Summary and Conclusions: Circulating MPA levels represent a sensitive and reproducible marker of platelet activation in the clinical setting, potentially useful in the evaluation and management of patients with increased cardiovascular risk. Platelet activation in response to acute high-intensity exercise is exaggerated and prolonged in UH compared to NT individuals. RAS blockade with adequate BP control greatly improves exercise-induced platelet activation in essential hypertension. Further studies are needed to clarify whether this phenomenon depends purely on BP lowering or benefits also from the pleiotropic effects of RAS antagonists.

P1045

FC GAMMA RECEPTOR POLYMORPHISMS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

M Pavkovic[1,*], R Angelkovic[1], S Terzieva-Trpkovska[1], T Sotirova[1], G Amzai[1], O Karanfilski[1], L Cevreska[1], M Spiroski[2], A Stojanovic[1]
[1]University Clinic for Hematology, [2]Institute for Immunobiology and human genetics, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic of Korea

Background: Immune thrombocytopenia (ITP) is an autoimmune blood disease with unknown etiology. Both genetic and environmental factors are thought to play role in the development of the disease. The aim of our study was to investigate a possible role of two polymorphisms in the Fc gamma receptor 2A and 3A (FCGR2A and FCGR3A) in the development of primary ITP.FCGR2A is polymorphic and has two alleles, FCGR2A-H131 and FCGR2A-R131. This polymorphic variation of FCGR2A is due to a single base substitution at nucleotide adenine for guanine in position 494. The allele FCGR2A-H131 has a higher affinity for human IgG2, comparing to FCGR2A-R131. The gene for FCGR3A has also two polymorphic variant alleles: 158 valine (V158) and phenylalanine (F158) due to single base substitution of timidine to guanine at nucleotide 559. This polymorphism influences ligand binding. FCGR3A-158V allele variant has higher affinity for Fc fragment of IgG1 and IgG3 than 158F variant. These Fc gamma receptor polymorphisms may influence antibody-mediated phagocytosis and antigen presentation activity.
Aims: The aim of our study was to investigate a possible role of FCGR2A and FCGR3A polymorphisms in the development of primary immune thrombocytopenia.
Methods: We have analyzed 125 unrelated adult patients with ITP (35 men and 90 women), with median age of 47(range 14-83) and 120 healthy matched controls. The median follow up of the patients was 44 months (12-384). All 125 patients were initially treated with corticosteroids, 38 were splenectomized. Forty two (34%) patients had refractory or unresponsive form of disease, according to the definition of the International Working group for ITP. Refractory ITP was present in 14 (11%) of patients. Twenty eight (22%) patients had "unresponsive to one or more treatments" form of ITP. Genotyping was performed by using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) methods. The distribution of genotypes and allele frequencies were compared between patients and controls using a chi-squared test or Fisher's exact test.
Results: Our results have shown significantly higher frequency of high affinity FCGR3A-158V allele in patients with ITP comparing with control subjects (47.2% *versus* 37.5%; P=0.037). We did not found significant differences in the genotype distribution or allele frequencies for FCGR2A-131H/R between patients with ITP and controls, P=0.652 and P=0.478. In the group of patients with unresponsive and responsive ITP we found significantly different genotype distribution and allele frequencies for FCGR3A, P=0.036 and P=0.008 respectively. There was no significant difference in genotype and allele frequencies for FCGR2A between these two groups of patients. We did not found significant differences in genotype and allele frequencies for both gene polymorphisms between splenectomized and unsplenectomized ITP patients.Our results confirmed that, the combination of high affinity FCGR2A-131H and FCGR3A-158V allele was more common in patients with ITP than in control subjects (55% *versus* 40%; P=0.024).
Summary and Conclusions: Results of this study, suggest possible role of FCGR3A polymorphism in the etiology, development and clinical outcome of immune thrombocytopenia, but further larger prospective studies are necessary to confirm these results.

P1046

THROMBOCYTOPENIA PREDICT MORTALITY IN CRITICALLY ILL PATIENTS

V Haksöyler [1], E Karakoç[2], F Başlamışlı[3], E Gürkan[3,*]
[1]Internal Medicine, [2]Intensive Care Unit, [3]Dept of Hematology, Çukurova University Medical School, Adana, Turkey

Background: Thrombocytopenia is a common laboratory abnormality seen in ICU patients. There are retrospective studies suggesting that thrombocytopenia in medical ICU patients is associated with adverse outcomes like prolonged hospital stay and decreased survival.
Aims: In this prospective study we investigated the prognostic significance of thrombocytopenia in critically ill patients.
Methods: We have included a cohort of 548 consecutive patients admitted to Çukurova University Medical School Hospital Intensive Care Unit which is a tertiary referral center in southern region of Turkey for a population of approximately two million people, between July 2011 and August 2012. Of these, 165 (30.1%) patients met the inclusion criteria. Patients were stratified according to the degree of thrombocytopenia and APACHE II score. Primary cause necessitating hospitalization of the patient, comorbidities and exposure to drugs were also recorded. APACHE II score was used in order to measure the severity of the disease in ICU patients. Higher scores correspond to a more severe disease and a higher risk of death in general with this scoring system.
Results: Among 165 patients, 104 (63%) were male and the median age was 57.2 yrs. While 143 (81.2%) of the patients had thrombocytopenia on admission, 31 (18.8%) of the patients developed thrombocytopenia during their ICU stay. Sepsis and DIC (Disseminated intravascular coagulation) were the most common causes for thrombocytopenia in medical ICU patients. Totally 115 (69.7%) of the 165 thrombocytopenic patients and 173 (45.1%) of the 383 non-thrombocytopenic patients were deceased while on ICU stay (P=0.02). Mortality rate was significantly higher in thrombocytopenic patients with lower counts and a similar APACHE II scores (P=0.002). Thrombocytopenia was also a poor prognostic factor for thrombocytopenic patients who developed thrombocytopenia after admission compared to patients with existing thrombocytopenia on admission (P=0.001).
Summary and Conclusions: In conclusion, sepsis and DIC were the most frequent causes for thrombocytopenia in medical ICU patients. Thrombocytopenia seem to be an independent risk factor for survival in critically ill ICU patients.

P1047

IDIOPATHIC THROMBOCYTOPENIC PURPURA IN CHILDREN: A 20-YEAR NATURAL COURSE AT A SINGLE INSTITUTION

H Yoon[1,*], C Kim[1], Y Choi[1]
[1]Department of Pediatrics, Kyung Hee University Medical Center, Seoul, Korea, Republic of Korea

Background: Idiopathic thrombocytopenic purpura is an hematologic disorder with a variable clinical course. However, there is paucity of data on long term probability of remission in chronic idiopathic thrombocytopenic purpura.
Aims: This study reviewed the clinical manifestation and response to therapy in patients with ITP, in order to identify natural course of chronic ITP.
Methods: The study included all patients diagnosed as ITP between January 1992 and December 2011.
Results: Two hundred sixty four patients were identified (48% male, 52% female). Median age at diagnosis was 4.8 years (range: 1 month-17 years). The mean platelet count was12,000/uL (range:3,000-135,000/uL). There are no seasonal variation of presentation. Twenty-six patients (10%) improved without any specific treatment. Intravenous immunoglobulin (IVIG) were used as a first-line treatment in 114 patients and showed a total response of 70% compared to 78% for steroids treated 14 patients. 10 children received anti-D immunoglobulin (Response rate 60%). Chronic ITP was noted in 41 patients (15.5%). Chronic patients presented at an older age (6.6 *vs* 3.9 years, $P<0.05$) and with higher platelet count (22,000/Ul *vs*7,000/uL, $P<0.05$) at diagnosis. In 80% of them, remission was observed between 13 month and 6 year 2 month. The probabilities of remission for chronic ITP were 22%, 44% and 51% at 1 year, 2 year and 3 year respectively. Splenectomy was performed in four patients with chronic disease. Threre are no severe bleeding such as intracranial hemorrhage.
Summary and Conclusions: ITP patients have a benign course in the majotiry of cases. The predicted spontaneous remission rate with chronic ITP was 22% and 80% at 1 year years, respectively.

P1048

ABSOLUTE LYMPHOCYTE COUNT AND RISK OF SHORT-TERM INFECTION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

M Hu[1,*], C Liu[1]
[1]Hematology and Oncology, Taipei Veteran General Hospital, Taipei City, Taiwan

Background: Patients with ITP may have increased risk of infection for that steroid and other immunosuppressive agents have been the mainstay treatment for ITP.
Aims: This study aimed to characterize risk of infection events within 6 months after diagnosis of ITP and its impact on short-term outcome of these patients.
Methods: We retrospectively evaluated 239 patients (107 men, 132 women; median age: 61 yr) diagnosed between Jan1, 1997 to Aug 31, 2011. Every patient received at least steroid treatment according to platelet count or bleeding symptoms after diagnosis. Patients who were found to have malignancies, systemic autoimmune diseases, lymphoproliferative disorders or other secondary thrombocytopenia within 3 months after ITP diagnosis was excluded.
Results: 62 patients (25.9%) had a total of 73 infection events within 6 months after ITP diagnosis and treatment, including 10 patients had 2 events and 1 patient had 3 events. Among these infection events, 32 (43.9%) was pneumonia, 13 (17.8%) was UTI, 9 (12.3%) was herpes zoster, 8 (10.9%) was cellulitis, and 11 (15.1%) were other infections, including oral candidiasis, cholangitis, fungemia, bacteremia, intra-abdominal abscess, facial abscess, osteomyelitis, and pseudomembranous colitis Using univariate analysis, ALC $<1\times10^9$/l (P=0.008, OR 2.263), old age (age>65) (P=0.004, OR 2.416), and at least one comorbidity (P=0.050, OR 1.794) were identified as a risk factor for infection within the 6 months after ITP diagnosis. Multivariate analysis revealed that low ALC was the most significant risk factor (P=0.039, 95% CI 1.033 to 3.599, OR 1.928) associated with short term infection in patients with ITP. A total of 11 patients died during follow-up after ITP diagnosis, among whom 10 patients died of infectious disease and the remaining 1 died of bleeding complication. 9 patients died within 1 year after ITP diagnosis. Kaplan-Meier survival curve showed that patient had infection within the first 6 months after ITP treatment had poorer one-year survival than those without infection (P=0.001) (Figure 1).

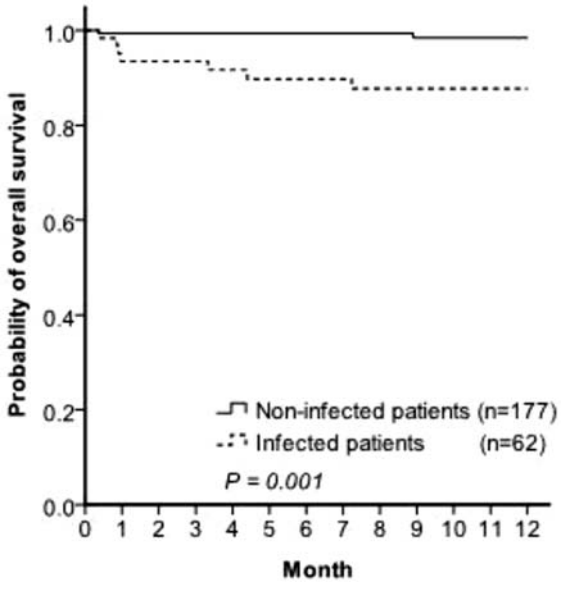

Figure 1.

Summary and Conclusions: In conclusion, ITP patients with infection occurring within 6 months post diagnosis had inferior one-year survival, and a low ALC may be associated with increased risk of infection within the 6 months of diagnosis. Apart from attention to bleeding risks, individualized management with cautious monitoring and surveillance for infection complications was also needed for better outcome.

P1049

THE IMMATURE PLATELET FRACTION IS SENSITIVE TO THE PLATELET SIZE AND A USEFUL PARAMETER FOR SCREENING FOR MACROTHROMBOCYTOPENIA

K Miyazaki[1,*], Y Koike[2], Y Yatomi[3], M Higashihara[4]
[1]Department of Hematology, Kitasato University School of Medicine, Sagamihara, [2]Department of Internal Medicine, Tokyo Hitachi Hospital, [3]Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, [4]Department of Clinical Laboratory Medicine, Kitasato University School of Medicine, Sagamihara, Japan

Background: The immature platelet fraction (IPF) is a useful parameter indicating thrombopoietic activity to differentiate the causes of thrombocytopenia. We previously reported that the percentage of IPF (%IPF) is negatively correlated to the platelet count among ITP patients, and not among myelodysplastic syndrome (MDS) patients. We also noticed that some MDS patients exhibited extremely high%IPF values, which were dissociated from the percentages of reticulated platelets (%RP) measured by flow cytometry. Such discrepancies were also observed in hereditary macrothrombocytopenias, which are sometimes difficult to be distinguished from ITP, because ITP also exhibits increased number of reticulated platelets in a slightly larger size. Once misdiagnosed, a hereditary macrothrombocytopenia patient might be subjected to an invasive treatment such as splenectomy. In order to avoid such mistreatments, a clear marker to differentiate macrothrombocytopenia is desperately needed.
Aims: To elucidate the mechanisms of the aberrant increase of IPF among macrothrombocytpenic patients, and search for a useful parameter to distinguish macrothrombocytopenia from ITP
Methods: The IPF values and other platelet indices of various hereditary macrothrombocytopenia were determined using Sysmex XE-2100 automatic hematology analyser in the blood samples. Platelet count and other parameters of platelet, such as MPV, PDW and P-LCR were measured simultaneously. Phosphorylation of myosin light chain was also examined to estimate activation status. Sixteen individuals from twelve families of hereditary macrothrombocytopenia were enroled in this study. We also monitored the IPF during EDTA-induced aggregation, platelet agglutination by macroglobulinemia and cold-storage. The morphological changes of platelets were also examined on the blood film.
Results: The IPF values were about 5 times higher in MYH9 disorders (%IPF 48.0±1.8) and about 1.5 times higher in other macrothrombocytopenias (%IPF 17.0±2.2) than immune thrombocytopenic patients with similar platelet counts (%IPF 9.3±0.4). These results suggested that the platelet size affect the IPF value. However it still remains the possibility that some factors other than the size might make an influence on the IPF. No one knows whether large platelets are functionally identical to normal platelets except for the size. In order to exclude the possibility, we next examined the changes of IPF values during EDTA aggregation, agglutination by macroglobulinemia and cold-storage. The IPF was significantly increased under these conditions in a time dependent manner along with forming platelet clumps. Durnig cold-storage, each platelet increased in size with fewer granules probably due to degranulation, and a couple of platelets stuck to each other to form a few tiny clumps. The IPF was strongly influenced by a few tiny platelet aggregates rather than other platelet indices, such as mean platelet volume (MPV), platelet-large cell ratio (P-LCR) and platelet distribution width (PDW).
Summary and Conclusions: IPF is susceptible to the platelet size, and could be a useful parameter for screening of macrothrombocytopenia from ITP.

P1050

THE INCIDENCE OF THROMBOCYTOPENIA AMONG OLDER PRIMARY MDS PATIENTS: A SEER-MEDICARE ANALYSIS

D Bennett[1,*], S Shantakumar[2], M Kobayashi[2], N Wang[2], C Snider[3]
[1]WWEpidemiology, Research and Development, GlaxoSmithKline, Collegeville, [2]WWEpidemiology, Research and Development, [3]Formerly with WWEpidemiology, Research and Development, GlaxoSmithKline, Research Triangle Park, United States

Background: Myelodysplastic syndromes (MDS) represent a heterogeneous group of hematological malignancies, affecting predominantly the elderly. Although MDS have been studied recently, the epidemiology of MDS is still not fully characterized, especially the occurrence of thrombocytopenia among MDS patients.
Aims: To estimate the incidence of thrombocytopenia among older MDS patients, we used the linked Surveillance, Epidemiology, and End Result and Medicare (SEER-Medicare) database.
Methods: The SEER-Medicare database consists of the SEER cancer registries, the authoritative source of cancer epidemiology information in the U.S. linked with Medicare claims data in people aged 65+ years. SEER data represent a diversity of geographic areas across the U.S. and thus population-based reflecting 'real world' practice. We included MDS patients 65+ years who were newly diagnosed between January1, 2001 and December 31, 2002, and who were enrolled in Part A and Part B Medicare coverage. MDS was defined using ICD-O 3 codes where the primary site was bone marrow (C42.1), histology code (9980, 9982—9986, 9989, 9945), and behavior code was malignant neoplasm (3). All MDS diagnoses were histologically confirmed. Subtypes of MDS were classified according to two classification systems: FAB and WHO. Thrombocytopenia was defined using ICD-9 codes (287.3, 287.4, 287.5). Descriptive statistics were calculated and Cochran-Armitage trend test was used to test for trend.
Results: During the two years,2,734 patients with primary diagnosis of MDS were identified. Fifty four percent were males and 46% females. The majority of patients were Caucasians (88%) and 47% were 80+ years. The overall frequency of thrombocytopenia among the primary MDS patients was 53% (n=1,449). With increasing age groups, the incidence decreased: 65-69 years (59.5%), 70-74 years (58.9%), 75-79 years (53.5%), 80-84 years (50.8%), 85+ (46.4%). This trend was statistically significant (P<0.001). The incidence of

thrombocytopenia was statistically significantly higher among males (55.5%) *vs* females (50.1%) (P<0.01). Among1,382 FAB MDS subtypes, thrombocytopenia was more common among patients diagnosed with RAEB type (216 of 323; 66.9%), RAEB-T (26 of 39; 66.7%), CMML (182 of 288; 63.2%), followed by RA (191 of 441; 43.3%) and RARS (96 of 291; 33.0%). Of2,407 patients with WHO MDS subtypes, the greatest proportion with thrombocytopenia were observed among those with RAEB subtype (216 of 323; 66.9%), MDS-U (677 of1,234; 54.9%), RCMD (38 of 72; 52.8%), followed by 5Q (23 of 46; 50.0%), RA (191 of 441; 43.3%), and RARS (96 of 291; 33.0%).

Summary and Conclusions: Overall, thrombocytopenia is a very frequent symptom that occurs among patients with MDS. The study brings new data on incidence of thrombocytopenia among older patients with MDS in the U.S., which will help in the development of new therapies to manage the disease. Moreover, the high incidence data gathered in this study are similar with that observed in other studies of thrombocytopenia in MDS patients and confirms that thrombocytopenia continues to be a frequent clinical problem in older patients with MDS.

P1051

MEAN PLATELET VOLUME AND LABORATORY MARKERS FOR CARDIAC DISEASE: A LINK BETWEEN PLATELET SIZE AND HS-CRP

S Cho[1,*], Hee Joo Lee[1], W Lee[1], H Yoon[2], T Park[1]
[1]Department of Laboratory Medicine, [2]Department of Hematology-Oncology, School of Medicine, Kyung Hee University, Seoul, Korea, Republic of Korea

Background: Mean platelet volume (MPV) is a parameter generated by fully-automated blood count analyzers as part of a routine complete blood count (CBC). It is also a useful platelet function index that can show platelet activation and its production rate in bone marrow. Other than just hematologic diseases, MPV has been studied in various disease groups such as cardiovascular and rheumatic diseases as well. Recently we have also studied this platelet index, MPV in various conditions (Platelets. 2013;24(1):75-6., Platelets. 2012;23(8):648-9., Platelets. 2013;24(2):164-5., Thromb Res. 2012 Sep;130(3):557-8.).

Aims: In this study, we investigated MPV in Korean patients who have cardiovascular diseases to analyze the association between this platelet index and various laboratory markers for cardiac diseases such as hs-CRP, TnI and apolipoprotein.

Methods: This study included1,059 retrospective results with increased hs-CRP level above the upper reference limit (>3.9 mg/L) for the patients group, at Kyung Hee Medical Center, a tertiary teaching hospital, between January 2011 and April 2012. For the control group, 143 subjects for medical check-ups were enrolled from the same hospital. Individuals with a history of high blood pressure and diabetes were excluded from the control group. Blood sampling was performed through venepuncture and MPV was measured using EDTA-containing tubes in Advia 2120 (Siemens Healthcare Diagnostics, Tarrytown, NY, USA) within 2 hours. hs-CRP was measured in BN™ II analyzer(Siemens Healthcare Diagnostics, Marburg, Germany) with CardioPhase® High Sensitivity C-Reactive Protein (Siemens Healthcare Diagnostics, Marburg, Germany) and TnI was estimated by Access II (Beckman Coulter Inc., Fullerton, CA, USA) with AccuTnI reagent (Beckman Coulter Inc., Fullerton, CA, USA). Independent t-test and Pearson's correlation analysis were done to evaluate the diagnostic performance and to examine the relationship between variables. Statistical analyses were performed with MedCalc v11.6 (MedCalc Software, Mariakerke, Belgium) and Excel 2007 (Microsoft corporation, Redmond, WA). *P* values <0.05 were considered statistically significant.

Results: In the patients group, the mean age was 57.84 (median 63.0, range 0-90 yr) and the male to female ratio was 542:517. The mean of serum hs-CRP was 15.88 mg/L. Mean MPV levels did not show a significant difference between the patients and the control group, which were 8.06 fl in the patients group and 7.96 fl in the control group, respectively (*P*<0.001). Moreover, MPV showed a positive correlation with hs-CRP in the patients group (correlation coefficient *r*=0.07656, *P*=0.0127). Out of 269 patients with the TnI test results, this positive correlation grew stronger for 79 patients whose TnI increased more than 0.04 (correlation coefficient *r*=0.444, *P*=0.0001). However, there was no significant correlation between MPV and pro-BNP. Finally, there was a strong negative correlation between MPV and HDL (*r*=-0.1511, *P*<0.0001).

Summary and Conclusions: This study showed a positive correlation between MPV and hs-CRP in the patients group with increased hs-CRP levels. MPV has been regarded as an hematologic index for platelet reactivity and hs-CRP has been known to a sensitive biochemical maker for the presence of vascular lesions. The meaningful relationship in these two markers reconfirms the close link between endothelial damage and platelet activation. It also sheds new light on the interesting connection between hematologic and biochemical maker in the field of vascular pathology. Further study should be conducted to understand underlying mechanisms on the relationship of MPV and hs-CRP.

P1052

OVERVIEW OF RUSSIAN PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) REGISTRY

V.I. Razumovskiy, Saratov, [11]Research Institute of Hematology, Moscow, [12]Leningrad Region Clinical Hospital, St Petersburg, [13]Perm Regional Hospital, Perm, [14]Clinical Hospital №1, Orenburg, [15] State Medical University, Rostov on Don, [16] Regional Clinical Hospital, Krasnoyarsk, [17]Regional Oncology Dispensary N1, Volgograd, [18] Regional Clinical Hospital, Perm, [19]Research Institute of Hematology and Blood Transfusion, St Petersburg, [20]Regional Clinical Hospital, Surgut, [21]Mordovia Republic Clinical Hospital №1, Saransk, [22]Regional Hospital, Tula, [23]Tatarstan Republic Clinical Hospital, Kazan, Russian Federation

Background: Clinical presentation of ITP is variable from no symptoms to serious bleeding manifestations. There are very few precise data about course features of ITP and treatment methods of patients with ITP in Russia.

Aims: We aim to evaluate disease characteristics and treatment practices of ITP in Russia.

Methods: Clinical and laboratory data of 415 patients (363 adults and 52 children) were extracted from ongoing multicentre prospective observational cohort study (Russian ITP registry). Using web based data transfer investigators from major Russian haematological centres registered all patients with ITP visited him/her as out-patients or admitted to hospital and fulfilling inclusion/exclusion criteria. Inclusion criteria: primary diagnosis of ITP, signed informed consent. Exclusion criteria: secondary ITP. Primary objectives: to describe the features of clinical course, outcomes and current treatment options for ITP patients in Russia. The results of first planned interim analysis are presented below. Descriptive statistics was used.

Results: At the moment of the first interim analysis mean follow up period was6,9±2,6 months (0,3-12,6) for adults and5,47±2,7 (1,3-9,64) for children. Newly diagnosed, persistent and chronic ITP were reported in 34,6%,11,5% and 51,9% of children and in16,8%, 19,8% and 63,4% of adults. Mean lowest platelet count (min, max) was 22,1 (1-72) × 10^9/L in children and 22,2 (0-119) × 10^9/L in adults. Bleeding history was reported in 98,1% of children and 92,6% of adults, WHO grade 3-4 bleeding at the onset was observed in5,8% of children and14,9% of adults. History of intracranial hemorrhage, GI bleedings and haematuria were observed in1,5%, 0%, 0% of children and in 0,6%,4,7%,2,8% of adults. Splenectomy was performed in 63 (17,4%) adults patients with complete response in 39,7% of these pts, objective response in 19%, no response in3,2%, loss of response in 36,5%. Refractory ITP (resistance to medical therapy in splenectomized patients) developed in15,9% of adults. Patients receiving ≥2nd line of therapy were reported in 23,3% of children and 27,7% of adult population. Treatment with rituximab and TPO-R agonists were reported in1,9% and11,5% of adults. Resistance to ≥2nd line of therapy was observed in1,9% of children and in12,9% of adults.

Summary and Conclusions: The interim analysis of the first in Russia prospective ITP Registry has shown a variable clinical course of the disease. Serious bleeding complications were rare, 36,5% of patients lost response on splenectomy, 1/3 of patients developed a resistance to medical therapy and received a multi drug treatment. The study is ongoing and further data are essential for planning of future trials including targeted therapy with TPO-R agonists and for developing new treatment approaches for ITP patients in Russia.

This investigator-sponsored study was supported by a grant from Amgen Russia.

P1053

DIFFERENTIAL DIAGNOSIS OF THROMBOTIC MICROANGIOPATHY: DATA FROM PADOVA TTP CASE SERIES

G De Marinis[1,*], A Lombardi[1], F Fabris[1]
[1]Department of Medicine, University of Padova, Padova, Italy

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare but fatal disease. Differential diagnosis is often difficult, due to similarity in presentation features with others thrombotic microangiopathies (TMA), including hemolytic uremic syndrome (HUS).

Aims: To investigate differences in clinical and laboratory features (including ADAMTS13 activity and IgG anti-ADAMTS13 levels) between TTP, HUS and other TMA in our case series.

Methods: Patients admitted to our court with a first clinical diagnosis of acute TMA were included. Clinical and laboratory data were retrospectively analyzed. TTP and HUS diagnosis were clinically made as reported in the literature. All patients not fitting these criteria were included in the other TMA group. ADAMTS13 activity and IgG anti-ADAMTS13 were assessed using commercially available FRETS-VWF73 and ELISA assays respectively. Severe protease activity deficiency was considered as ≤10%, as reported in the literature; however two subgroups were made (protease activity ≤5% and 6-10%) to compare different threshold of the assay. IgG anti-ADAMTS13 was considered present for title ≥17 U/mL, according to the manufacturers instructions. Chi-square test and Anova analysis were used for groups comparison.
Results: 119 patients between June 2005 and November 2012 were collected (M/F=44/85; mean age 44±17, range 3-82): 88 were TTP, 9 HUS and 22 other TMA patients. Half of the TTP patients showed an associated condition, namely autoimmune disease (25%), infectious disease (15%, including 1 patient with HIV infection), cancer (3%), drugs (3%), pregnancy (2%) and obesity (9%). Patients clinical characteristics are shown in Table 1. TTP patients more often presented with neurological signs as compared with HUS and other TMA patients (p 0.006). Acute renal failure was always present in HUS patients, while observed in 28% of TTP and 50% of other TMA patients (P<0.001). Bleeding prevalence was significantly different between groups too (p 0.014). Mean platelet count at diagnosis was lower in TTP as compared with HUS and other TMA patients (P<0.001). Mean levels of creatinine at diagnosis was higher in HUS respect to TTP and other TMA patients (P<0.001). ADAMTS13 activity assay and the presence of IgG anti-ADAMTS13 were tested in 106 patients; these parameters showed a significant difference between the three groups (P<0.001); in fact none of TTP patients had normal values of ADAMTS13 activity, while none of HUS or other TMA patients had severely reduced levels of the protease at diagnosis. Comparison of ADAMTS13 activity between HUS and other TMA groups didn't show any difference. Most of TTP patients were positive when tested for the presence of IgG anti-ADAMTS13, while most of patients in the two other groups were negative.

Table 1. Clinical and laboratory features of patients with acute TMA (Padova case series, June 2005-November 2012).

	TTP (88 pts)	HUS (9 pts)	Other TMA (22 pts)	P value
Fever	36 (41%)	5 (56%)	10 (45%)	n.s.
Neurological impairment	57 (65%)	3 (33%)	7 (32%)	0.006
Acute renal failure	25 (28%)	9 (100%)	11 (50%)	< 0.001
Bleeding	68 (77%)	3 (33%)	15 (68%)	0.014
		53 ± 36	48 ± 28	< 0.001
Plts (G/L, mean ± SD)	18 ± 17	94 ± 21	83 ± 16	n.s.
Hb (g/L, mean ± SD)	87 ± 21	2320 ±	2141 ±	n.s.
LDH (U/L, mean ± SD)	1721 ± 1151	1555	2684	< 0.001
Creatinine (umol/L, mean ± SD)	101 ± 63	448 ± 363	157 ± 155	
ADAMTS13 activity (%)				
- ≤ 5%	68 (77%)	0	0	
- 6-10%	5 (6%)	0	0	< 0.001
- 11-64%	3 (3%)	4 (44%)	14 (64%)	
- ≥ 65%	0	4 (44%)	8 (36%)	
-Untested	12 (14%)	1 (12%)	0	
Anti-ADAMTS13 IgG (%)				
- negative	6 (7%)	6 (66%)	20 (91%)	< 0.001
- positive	70 (79%)	2 (22%)	2 (9%)	
- Untested	12 (14%)	1 (12%)	0	

TTP, thrombotic thrombocytopenic purpura; HUS, hemolytic uremic syndrome; TMA, thrombotic microangiopathy; pts, patients; plts, platelets; Hb, hemoglobin; LDH, lactic dehydrogenase; n.s., not significant.

Summary and Conclusions: Clinical features at presentation can guide differential diagnosis when TMA is present; in particular a low level of platelet count and predominant neurological impairment orient toward a diagnosis of TTP, while the presence of acute renal failure with high levels of creatinine can be more specific for HUS diagnosis. Very low levels of ADAMTS13 activity are specific for TTP diagnosis. As a consequence, when protease activity is >10% at presentation, the diagnosis of TTP can be reasonably excluded. There seems to be no difference when choosing a threshold of 5 or 10% activity to define a severe reduction for FRETS-VWF73 assay. ADAMTS13 activity, however, seems not useful for the distinction between HUS and other TMA.

P1055

EXTREME THROMBOCYTOSIS (>1000×10^9 /L) IN 336 PATIENTS- REPORT OF A FOUR-YEAR EXPERIENCE

E Papadakis[1], K Skarmoutsou-Tsimirika[1,*], D Theocharidou[2], K Loukidis[3], K Tsepanis[2], V Papadopoulos[1], V Papageorgiou[1], E Gatsa[1], A Banti[1], I Korantzis[1], A Kioumi[1]
[1]Hemostasis Unit-Hematology Department, [2]Microbiology Laboratory, Papageorgiou Hospital, Thessaloniki, Greece, [3]Hematology Clinic, Offenbach General Hospital, Offenbach, Germany

Background: Extreme thrombocytosis (EXT), defined as a platelet count >1,000×10^9/L, is quite rare, as only 2–5.8% of patients demonstrate this degree of thrombocytosis.
Aims: There are limited data on the etiology and frequency of EXT, we aim to explore retrospectively the causes and complications of 336 serial cases of EXT.
Methods: During 2006- 2010, we evaluated 793525 complete blood counts of 188914 patients. Among those, 336 patients (0.18%), with a median age of 45 years (0.1-100), were identified with EXT. Medical records of all 336 patients were examined concerning the etiology of thrombocytosis, peak of platelet count and complications such as bleeding tendency or thrombosis.
Results: Exploring the etiology of EXT, 294 cases (87.5%) had reactive EXT and 42 patients (12.5%) had clonal thrombocytosis, due to MPNs. The RT group included post surgical and orthopedic conditions and oncologic malignancies, that were the most common causes of RT (23.13% and 22.11%, respectively). Infection (10.20%) was also a frequent RT cause, accounting mainly younger age groups. Among MPNs, Essential Thrombocytosis was the predominant cause of EXT (85.72%), followed by Polycythemia Vera (9.52%) and Myelofibrosis (4.76%). Concerning age distribution of EXT, MPN EXT appears by the 3rd decade, and shows increasing rates at older age groups, achieving its' highest percentage (23.53%) at patients older than 70 years. As a result, there was statistically significant difference between the median age of RT and MPN patients, P=0.044. Focusing on children of the first decade of life, 65.17% of EXT cases, were attributed to infection, with respiratory infection being high on the list of causes. Children younger than 8 years old account the majority of patients (70%) with infection induced EXT. Mean PLT Max of MPN patients (1396.36×10^9/L) was significantly higher (P=0.017) than Mean PLT Max of RT patients (1186.01×10^9\L). Exploring admission PLT count of the patients we found out that Mean PLT count at the time of admission of the MPN group (1088.29×10^9\L) was significantly higher (P<0.005) compared to RT group (642.28×10^9/L). Moreover, 75.17% patients of the RT group had PLT count <1000×10^9/L by the time they were admitted at the hospital. However, significantly lower number of patients (30.95%) at the MPN had PLT count <1000×10^9/L (P<0.001). EXT complications, thrombosis or bleeding, were observed at 4.76%. The incidence of EXT complications was statistically significantly higher among MPN patients- 30.95%>than among RT patients- 1.02% (P<0.005). At the MPN group both thrombosis (23.81%) and bleeding (7.14%) were present. Although Mean PLT Max of patients who suffered bleeding (2625.67×10^9/L) was much higher than thrombosis patients (1596.10×10^9/L), it didn't reach significance levels, P=0.069.
Summary and Conclusions: Based on our study and previously published data, bleeding or thrombotic complications at RT EXT are quite infrequent, so RT EXT could remain untreated, and followed up. However, there are cases that the underlying condition requires PLT anti- aggregation agents, such as Kawasaki syndrome.

Bleeding and thrombosis

P1056

ANTIPLASMIN, BUT NOT AMILORIDE, PREVENTS SYNOVITIS AND CARTILAGE DESTRUCTION FOLLOWING HEMARTHROSIS IN HEMOPHILIC MICE

L Nieuwenhuizen[1,2,*], G Roosendaal[1], K Coeleveld[2], D Biesma[1], F Lafeber[2], R Schutgens[1]
[1]Hematology & Van Creveldkliniek, [2]Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Blood-induced joint damage in hemophilia is characterized by synovitis and cartilage destruction. Recently, we demonstrated that a joint bleeding in hemophilic mice results in alterations in the fibrinolytic system with an increase in synovial cells expressing urokinase-type plasminogen activator (uPA), an increase in synovial levels of uPA and plasmin, and in plasmin-mediated cartilage destruction.
Aims: In this study, we evaluate the alterations in synovitis and cartilage destruction following the induction of a joint bleeding in hemophilic mice treated with placebo, amiloride (a specific inhibitor of uPA), or antiplasmin.
Methods: The right knees of hemophilic mice were punctured to induce hemarthrosis. Subsequently, mice were randomized between daily oral treatment with amiloride or control, while other mice were randomized between weekly intra-articular treatment of the right knee joint with amiloride, antiplasmin, or control. After five weeks of treatment, the mice were sacrificed, knee joints were isolated, sectioned for histology, and stained with hematoxylin-eosin (synovitis) or safranin O (cartilage destruction). Hemophilic synovitis and cartilage destruction were determined by two blinded observers according to Valentino (score 0-10) and Glasson (score 0-6). An increase in Valentino and Glasson score represents an increase in hemophilic synovitis and cartilage destruction, respectively. Treatment with amiloride or antiplasmin was compared with control. Categorical data were analyzed by loglinear analysis and Pearson Chi-Square.
Results: No significant alterations in synovitis and cartilage destruction were found when comparing the oral amiloride group with the oral control group, and when comparing the intra-articular amiloride group with the intra-articular control group. In contrast, intra-articular treatment with antiplasmin resulted in a statistical significant (P<0.01) reduction in synovitis, as assessed by the Valentino score, when comparing the intra-articular control group to the intra-articular antiplasmin group: 1 (0% *vs.* 11.1%), 2 (4.2% *vs.* 11.1%), 3 (16.7% *vs.* 61.1%), 4 (29.2% *vs.* 5.6%), 5 (20.8% *vs.* 11.1%), 6 (8.3% *vs.* 7.7%), 7 (8.3% *vs.* 0%), and 8 (12.5% *vs.* 0%). In addition, treatment with intra-articular antiplasmin resulted in a statistically significant (P<0.01) reduction in cartilage destruction, as assessed by the Glasson score, when comparing the intra-articular control group to the intra-articular antiplasmin group: 2 (8.3% *vs.* 10%), 3 (12.5% *vs.* 50%), 4 (33.3% *vs.* 30%), 5 (33.3% *vs.* 10%), and 6 (16.7% *vs.* 0%).
Summary and Conclusions: Intra-articular treatment with antiplasmin following the induction of a joint bleeding prevented synovitis and cartilage destruction in hemophilic mice. Oral and intra-articular treatment with amiloride failed to attenuate synovitis and cartilage destruction. Given that complete prevention of joint bleeds in hemophilia is not feasible at the moment despite the prophylactic use of factor replacement, the data presented herein offer promise for the use of antiplasmin as a new therapeutic intervention.

P1057

A VERY RARE SIMULTANEOUS PRESENCE OF A RING CHROMOSOME 13 AND A SPLICING SITE MUTATION ON FACTOR X GENE

M Menegatti[1,*], D Balestra[2], B Fabbrizi[3], R Asselta[4], M Pinotti[2], F Peyvandi[1]
[1]A. Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan and Luigi Villa Foundation, MILAN, [2]Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, [3]Department of Paediatric Oncohematology, Ospedali Riuniti, Ancona, [4]Department of Medical Biotechnology and Translational Medicine, University of Milan, MILAN, Italy

Background: Factor X (FX) coagulation disorder is a rare autosomal recessive disease with an incidence of 1 in10^6 in the general population. Patients affected with the severe form of this defect tend to be the most seriously affected among those with rare bleeding disorders. The bleeding tendency may appear at any age, although the more severely affected patients present early in life with umbilical-stump or central nervous system (CNS) bleeding. The *F10* gene is located on chromosome 13q34 and spans 27 kb; to date, more than 100 mutations were reported to cause FX deficiency and most of them (80%) are missense mutations located at the catalytic domain.
Aims: Molecular characterization of a two-years-old boy with severe FX deficiency (FX:C <2%) associated with severe clinical symptoms such as spontaneous CNS subdural haemorrhages.
Methods: Direct sequencing analysis of the *F10* gene by ABI PRISM 310 Genetic Analyzer (Applied Biosystems, Milan, Italy); analysis of 7 highly polymorphic short tandem repeats (STRs) selected from the Genethon human linkage map (ABI PRISM Linkage Mapping Set MD10) to verify the presence of parental alleles; investigation of aberrant splicing mechanisms by expression of FX minigenes in mammalian cells; FISH on metaphase chromosomes using Vysiss LSI probe for 13q34 and Vysis TelVysion probe for 13q (Abbott Molecular, Hoofddorp, The Netherlands).
Results: The proband resulted to be homozygous for the c.370+2T>C mutation occurring at the conserved GT dinucleotide of the donor splice site (5'ss) of intron 4. This genetic change is predicted to significantly reduce the splicing efficiency from a score of 39 to undetectable. Expression studies with minigenes constructs indicated that the mutation c.370+2T>C abolishes the canonical 5'ss and activates a cryptic 5'ss in intron 4 (position +55), leading to the insertion of an intronic sequence with a premature stop codon, therefore preventing synthesis of a functional protein. However, while the proband's father confirmed to be heterozygous for the same mutation, the mother was wild type. The presence of a gross deletion on the second allele of the proband or an uniparental disomy (UPD) were then hypothesized. Six out of 7 analyzed STRs indicated that the proband had both paternal and maternal alleles; the remaining STR (D13S1265) indicated the possibility of a reduction to homozygosity in the proband due to a partial UPD or of a partial deletion of chromosome 13q34. A further cytogenetic analysis on 80 cells showed 46 chromosomes including a small ring chromosome 13 with breakpoints at p13 and q34. The karyotype was 46, *XY*, r(13)(p11q34). The karyotypes of both parents were normal and confirm the absence of subtelomere 13q and 13q34 region.
Summary and Conclusions: The molecular characterization in this family identified a very rare simultaneous presence of a ring chromosome 13 causing the loss of the entire FX gene associated with a splicing site mutation resulting in an aberrant splicing event. These abnormalities led to a severe case of FX deficiency who required regular prophylaxis.

P1058

MOLECULAR DIAGNOSTIC IN 47 UNRELATED FAMILIES WITH HAEMOPHILIA A IN ARAGON (SPAIN)

S Catalina[1,*], X Arias[1], B De Rueda[2], L Costilla[2], J Lucia[1,2], D Rubio[2]
[1]IACS, [2]Hematology Department, Miguel Servet University Hospital, Zaragoza, Spain

Background: Haemophilia A (HA) is an X-linked bleeding disorder caused by deficiency or absence of coagulation factor VIII which is required for blood coagulation. HA is one of the most common coagulation disorders with an incidence of 1 in5,000 males worldwide. Haemophilia severity is defined by depending on the activity level of coagulation F8 (FVIII:C) in plasma. The disease is defined as severe (<1%), moderate (1%>5%) and mild (>5%><40%). F8 is located at Xq28, spans 186kb and comprises 26 exons. The cDNA is approximately 9kb in size and encodes a mature protein of 2332 amino acids.
Aims: In this study we analyze the type and distribution of molecular events in HA families referred to our center, located in Aragon (middle-west region of Spain).
Methods: DNA samples were extracted from peripheral blood leucocytes from 47 unrelated families (65 patients) with HA. Initially, intron 22 and intron 1 inversions were detected in patients with severe HA using a long range PCR. The mutations in patients with mild/moderate and non-inversion severe patients were identified by PCR and DNA sequencing. A presumed mutation was validated on a second independent PCR product.
Results: HA causative mutation was identified in 63 patients from 46 families. We were not able to identify it in one family (2%). HA phenotype of the studied families was 49% mild, 4% moderate and 47% severe. In 14 families we detected Intron 22 and intron 1 inversions (28% and 2% of the total mutations, respectively). Besides the recurrent gene inversion, 30 different F8 mutations were detected (see attached Table 1). Severe non-inversion mutations were associated with 5 mutations predicted to cause a truncated protein, 3 nonsense (7%) and 2 frameshift (4%). Severe phenotype was related also to 1 missense, 1 splicing (2%) and 1 deletion in-frame (2%). We detected 25 families with missense mutations (53%). All moderate and mild cases with a causative mutation identifiedwere missense.Recurrent missense mutation p.K2136E was found in three unrelated families. Five novel missense mutations were found, representing 11% of the mutations in the entire group. Four of them were associated with mild phenotype: p.D82E; p.K123N; p.D569E (c.1764C>G) and p.I1852S. By contrast, the mutation p.W208C was related to severe phenotype. Among reported mutations p.R531H is well known by the discrepancy between FVIII:C results in one-stage and two-stage which has clinical importance in mild HA. In our study not only found this discrepancy in both methods, but also we identified a different behavior with distinct APTT reagents. F8 inhibitors were not found in this study except one in three patients from the family with p.R593C mutation. It has been shown to have an increased risk of developing F8 inhibitory antibody in mild HA. However, it seems to others non genetic factors could have an important role. F8 mutations in this study were located along all the FVIII domains. A2, A3 and A1 held the major mutations with 27%, 21% and 18% of the total non-inversion mutations. B domain contained the least number of mutations (3%).

Table 1.

13	2103G>A	M682I	24	6686T>C	L2210P
14	2149C>T	R698W	25	6857A>G	A2267G

Summary and Conclusions: The results from this study suggest that we were able to identify the causative mutation in 98% of the studied families what shows that our protocol is a useful tool to find F8 gene defects. The characterization of these mutations is important to avoid misdiagnosis in some cases of mild haemophilia, to prevent the development of inhibitors in mutations with high risk and to determine the carrier status in female relatives with prenatal diagnosis if necessary.

P1059

IMPAIRED PROPLATELET FORMATION IN A NOVEL GLANZMANN VARIANT MACROTHROMBOCYTOPENIA

K Miyazaki[1,*], S Kunishima[2], H Kashiwagi[3], Y Tomiyama[4], M Higashihara[5]
[1]Department of Hematology, Kitasato University School of Medicine, Sagamihara, [2]Department of Advanced Diagnosis, Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, [3]Department of Hematology and Oncology, Graduate School of Medicine, Osaka University, [4]Department of Blood Transfusion, Osaka University Hospital, Osaka, [5]Kitasato University School of Medicine, Sagamihara, Japan

Background: Glanzmann thrombasthenia (GT) is an autosomal recessive bleeding disorder caused by a defect in the expression or the function of integrin αIIbβ3. Although the majority of patients with mutations in *ITGA2B* and *ITGB3* have a normal platelet size and count, it has been recently demonstrated that variant-type GT patients with a mutaion in the cytoplasmic domain residues αIIbArg995 and β3Asp723, which form a salt bridge, manifest moderate thrombocytopenia and large platelets, and the mutated integrins were shown to be partially activated.
Aims: The aims of this study is to characterize a novel missense mutation (S175P) in αIIb associated with a Glanzmann variant macrothrombocytopenia.
Methods: We investigated the genetic relevance of large platelets among the patient's family members. Protein expression of integrin αIIbβ3 was determined with flowcytometry, and megakaryocytopoiesis and proplatelet formation in this congenital macrothrombocytopenia was studied using peripheral blood CD34+cells.
Results: The case is a 39yo Japanese female with a novel congenital macrothrombocytopenia associated with compound heterozygous mutations (p.S175P and p.Y238X; c.523T>C and c.713_714 insA) of the *ITA2B* gene. The surface expression of platelet αIIbβ3 was decreased. The mean fluorescence intensities of αIIb, β3 and αIIbβ3 in flow cytometric analyses complex were decreased to 36.4%, 52.8% and 15.7% compared to the control respectively. Spontaneous PAC-1 binding to the resting platelets wasn't observed. Both mRNA and protein from Y238X mutant were not detected. Her father has a heterozygous mutation of S175P, her mother and sons have a heterozygous Y238X, and neither of them manifested giant platelets, even though αIIbβ3 expression was impaired in their platelets. Megakaryocytes derived from CD34+ cells of the patient's peripheral blood extended a reduced number of proplatelets and the tips were significantly decreased in number and larger in size compared with control.
Summary and Conclusions: The mutation S175P is located in β-propeller domain of the αIIb and impaired the normal function. The mechanisms of producing giant platelets could be different from αIIb R995W, who manifests constitutive sub-maximal activation. These data may provide new insight on the role of the αIIbβ3 in giant platelet formation.

P1060

MUTATION ANALYSIS IN TURKISH RARE BLOOD DISORDERS

D Torun[1,*], N Akar[2]
[1]Pediatric Molecular Genetics, Ankara University, Faculty of Medicine, [2]TOBB-ETU Economy and Technical University Hospital, Pediatrics Department, Ankara, Turkey

Background: Rare bleeding disorders (RBDs) are autosomal recessive diseases including the inherited deficiencies of coagulation factors such as fibrinogen, factor (F) II, FV, FV+FVIII, FVII, FX, FXI, FXIII, and multiple deficiency of vitamin K-dependent factors, with clinical manifestations ranging from mild to severe. The molecular diagnosis of RBDs is based on the mutation search in the genes encoding the corresponding coagulation factors.
Aims: In our study, we performed mutation analysis of ERGIC, MCFD2, MYH9, GpIIB, GpIIIA, FGB genes in order to analyse Combined FV-FVIII Deficiency, Macrothrombocytopenia, Glanzmann Thrombasthenia and Afibrinogenemia patients of Turkish origin respectively.
Methods: DNA was isolated from by proteinase K and phenol/chloroform extraction. All of the exons of the genes screened. Exons were amplified by polymerase chain reaction (PCR). Patient sample was sequenced, using a DNA sequencer (Beckman Coulter DNA Sequencer,USA)
Results: Direct PCR analysis and sequencing revealed novel mutations at these genes. In our study, we detected two novel mutations, a novel polymorphism at ERGIC-53 gene; four novel missense mutations at MYH9 gene; five novel mutations at GpIIB gene and a novel mutation at FGB gene.
Summary and Conclusions: All of these novel mutations were not defined Human Gene Mutation Database (HGMD) and not reported previously. (Table 1).

P1061

CONGENITAL FXI DEFICIENCY: EVALUATION OF BLEEDING PHENOTYPE AND CORRELATION WITH FXI ACTIVITY (FXI:ACT).

C Santoro[1,*], R Mauro[1], E Baldacci[1], C Mercanti[1], R Abbruzzese[1], F Barone[1], R Bochicchio[1], L Parlanti[1], R Foà[1], M Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology, Sapienza University, Rome, Italy

Background: Bleeding phenotype in FXI deficiency is variable and generally related to surgery/trauma. Moreover, there is a poor correlation between bleeding and baseline FXI:Act.
Aims: To retrospectively describe the hemorrhagic phenotype of our FXI deficient population and to relate the phenotype with FXI:Act.
Methods: Since 1973, we have been following 94 FXI deficient patients from 65 different families: 43 F, 51 M; diagnosis median age: 28.7 years (0.9-83.9); median follow-up: 0.9 years (0.1-36.2); median FXI:Act of all patients: 38% (range 0.5-69%; normal values: 70-140); FXI:Act ≤1% in 5 patients, >1≤5% in12, >5≤10 in3, >10≤20 in6, >20≤70 in 68. Excessive bleeding is reported as described in the medical records.
Results: Fifty six patients experienced bleeding episodes not surgery-related: ecchimoses in 27, hematomas in2, epistaxes in 23, gastrointestinal hemorrhages in14, meno-methrorrhagia in2, hematuria in4, post-traumatic intracranial hemorrhage in1, gum bleeding in1, pulmonary bleeding in 1. Prior to diagnosis, 64 patients underwent 133 surgeries (93 major, 40 minor). Prophylactic treatment was administered in 3/133 procedures: tranexamic acid (TA) in1,

fresh frozen plasma (FFP) in 2. Twenty eight/133 (21%) post-surgery hemorrhages were reported in 19 patients; in 12/28 cases, transfusional therapy (FFP and/or red blood cells units) was needed. Median FXI:Act of bleeding patients was 28% (0.5-53%). Twenty nine spontaneous deliveries (SD) and 8 cesarian sections (CS) were performed without prophylaxis: 4 post-partum hemorrhages occurred (patients FXI:Act:2,6, 27, 52.3%, respectively). In 3 cases, transfusional therapy was necessary. Forty nine patients underwent dental surgeries without prophylaxis: 17 experienced (bleeders median FXI:Act: 11% [1-57%]). In one case, FFP was necessary to stop the bleeding. After diagnosis, 23 patients underwent 34 surgeries (14 major, 20 minor). Prophylactic treatment was administered in 23/34 procedures: TA in7, FFP in2, desmopressin in4, FFP+TA in8, desmopressin+TA in 2. The only bleeding reported (1/23, 4%) was after an emergency appendectomy performed under TA administration in a patient whose FXI:Act was 2.8%. In 2/11 surgeries performed without prophylaxis, an excessive bleeding was reported but transfusional therapy was not necessary; FXI:Act was 29% for both bleeding patients. Four SD and 5 CS were performed with prophylaxis: FFP in4, TA in2, desmopressin in 3. No post-partum hemorrhages occurred. Sixteen patients underwent 20 dental surgeries; prophylactic treatment was administered in 15/20 procedures without any bleeding complications: TA in6, FFP+TA in4, FFP in4, desmopressin+TA in 1. During two dental procedures performed without prophylaxis, patients bled excessively; their FXI:Act was 6% and 45%, respectively.

Summary and Conclusions: We confirm the broad variability in bleeding phenotype in FXI deficient patients, not related to the baseline FXI:Act levels. Moreover, we highlight that a good management of prophylaxis treatment dramatically reduces the percentage of bleedings in case of surgery (21% *vs* 4%), deliveries and dental procedures. Because of the low correlation between FXI:Act and the phenotype, we underline the need of laboratory-based prognostic factors for a better management of these patients.

P1062

HOW DO WE ENCOUNTER RARE FACTOR DEFICIENCIES IN CHILDREN? SINGLE CENTER RESULTS

Zafer Salcioglu[1,*], Deniz Tugcu[1], Arzu Akcay[1], Hulya Sen[1], Gonul Aydogan[1], Ferhan Akici[1], Muge Gokce[1], Nuray Ayaz[1], Rengin Siraneci[1]
[1]Pediatric Hematology Oncology, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey

Background: Rare factor deficiencies are autosomal recessively inherited coagulation factor deficiencies encountered at a frequency of between one in 500 thousand and one in 2 million.

Aims: 192 rare factor deficiency cases followed and treated at our clinic between 1990 and 2012 were retrospectively evaluated in our study.

Methods: We retrieved from patient records and from the records contained in the dataprocessing environment introduced in 2005.

Results: One hundred and thirty of the cases were boys and 62 were girls. The age range was between two week-24 years and the ages at the admission of 192 patients were between 2 weeks-16 years. The rate of familial consanguinity was 49.4%. From the 192 cases, 10 suffered from Fibrinogen, one from Factor II, 6 from Factor V, 2 from FV+FVIII, 142 from Factor VII, 15 from Factor X, 14 from Factor XI, and 2 from Factor XIII deficiencies. FVII deficiencies had the largest share in our patient group with a rate of 74%. The F:C levels of patients were <5% in 48 patients, between 5 and 30% in 40 patients, and between 30 and 50% in 104 patients. Eighty eight of our patients were asymptomatic (45.8%) and 104 were symptomatic (54.2%). Asymptomatic patients were diagnosed by family histories (39.8%), preoperative laboratory studies (54.6%) and operational bleeding (5.6%). Sixty eight of our symptomatic patients have grade II (65.4%) and 36 have grade III bleeding symptoms (34.6%). The ages at the admission of symptomatic patients were between 2 weeks-16 years (mean: 1.12±0.8 year). Forty two of symptomatic cases were diagnosed before the age of one (40.4%). When all patients were taken into consideration, first bleeding regions were skin bleedings 32.7%, epistaxis 27.8%, Central Nervous System (CNS) bleedings 15.4%, oral cavity bleedings 10.4%, haematomas 5.7%, haemarthrosis 2.8%, hematuria 1.9%, Gastrointestinal System (GIS) bleedings 1.9%, respectively. The bleeding prevalence rates of our cases are listed as epistaxis 62.5%, skin bleedings 53%, oral cavity bleedings 28.8%, haematoma 18.3%, CNS bleedings 17.3%, haemarthrosis 14.4%, GIS bleedings 3.8%, menorrhagia 2.9%, haematuria 1.9%, bleedings due to operations 1.9%, ileopsoas bleedings 1.9%. CNS bleedings (47.3%) take the first place among the serious bleedings of our cases, followed by haemarthrosis (40%), Gastrointestinal System (GIS) bleedings (9.1%) and ileopsoas bleedings(3.6%). Prophylaxy was applied to 8 patients (five patients with FVII and one each with Fibrinogen, FV, and FX deficiency).

Summary and Conclusions: The characteristics, clinical manifestations, bleeding attacks, and treatments in our rare factor deficiency cases as well as prophylactic approaches are discussed in our article.

P1063

CLINICAL AVAILABILITY OF REPORTING PROTHROMBIN TIME AS INTERNATIONAL NORMALIZED RATIO FOR PATIENTS WITH CHRONIC LIVER DISEASE

H Kim[1,*], J Lee[1]
[1]Laboratory Medicine, Chung-Ang University College of Medicine, Seoul, Korea, Republic of Korea

Background: The international normalized ratio (INR), which standardizes prothrombin time (PT) during oral anticoagulation, has been extended to standardize PT in liver diseases and is included in prognostic models such as the Model for End-stage Liver Disease (MELD). However, PT prolongation mechanisms in liver diseases differ from those in oral anticoagulation, and thromboplastin sensitivities to these 2 mechanisms differ.

Aims: We aimed to establish liver patient-specific international sensitivity index (ISI_{liver}) and INR (INR_{liver}) values with thromboplastins and to evaluate the effect of their use in chronic liver disease patients.

Methods: Sixty cirrhosis patients were selected and their PTs measured with 5 thromboplastins. Twenty healthy subjects were involved to assign the mean normal PT (MNPT) and ISI. Each thromboplastin was also assigned an ISI_{liver} by substituting plasma from vitamin K antagonist patients with that from cirrhosis patients in the calibration. INR, INR_{liver}, MELD, and $MELD_{liver}$ values for individual patients were calculated using the ISI and the ISI_{liver}, respectively.

Results: The INR obtained with the 5 thromboplastins were significantly different (P=0.049). Conversely, the INR_{liver} were not. The mean INR differences between the thromboplastins were significantly larger than that of INR_{liver} (P=0.000). The mean values were 0.12 and 0.06, respectively. The mean INR CV between the 5 thromboplastins were significantly larger than that of INR_{liver} (P=0.000). The mean values were 5.4% and 3%, respectively. Though there was no significant difference in MELD scores obtained with the 5 thromboplastins (P=0.871) or $MELD_{liver}$ (P=0.100), the mean MELD differences between the 5 thromboplastins were significantly larger than that of $MELD_{liver}$ (P=0.000). The mean values were 0.80 and 0.45, respectively.

Summary and Conclusions: Alternative thromboplastin calibration using plasma from cirrhosis patients instead of vitamin K antagonist patients is feasible and may resolve the variability of INR measurement. However, further studies are needed to clarify the clinical impact.

P1064

THE HAEMOCARE PROTOCOL–A COMPOSITE METHOD TO MEASURE THE DISEASE BURDEN FROM HAEMOPHILIA IN DEVELOPING COUNTRIES

N Gupta[1,*], M Belhani[2], A Benbouzid[3], M Andaloussi[4], K Maani[5], J Mahlangu[6,7], Y Wali[8], A Saad[9], S Fegoun[10]
[1]Maulana Azad Medical College & Associated Lok Nayak and GB Pant Hospitals, New Delhi, India, [2]Department of Haematology, University Hospital of Beni Messous, [3]Department of Orthopaedics, University Medical Centre of Ben Aknoun, Algiers, Algeria, [4]Department of Paediatric Orthopaedics and Traumatology, Ibn Rochd Hospital, [5]Department of Paediatrics, Haematology and Oncology, Children's Hospital of Casablanca, Casablanca, Morocco, [6]Haemophilia Comprehensive Care Centre, Charlotte Maxeke Johannesburg Hospital, [7]Department of Molecular Medicine and Haematology, National Health Laboratory Services and University of Witwatersrand, Johannesburg, South Africa, [8]Department of Child Health, Sultan Qaboos University, Muscat, Oman, [9]Novo Nordisk A/S, Dubai, United Arab Emirates, [10]Novo Nordisk Health Care AG, Zurich, Switzerland

Background: Burden of disease has immense impact on the suffering of individuals, the family, society and the nation. Measuring disease burden, so vital for policy planning and interaction for improving outcomes, is a complex issue ranging from estimation of macro-level 'global burden of diseases' to micro-level assessments of a given disease in a given society/region within a given healthcare environment. No single measure of disease burden is applicable to all diseases or to all countries. The issue is even more complex and amorphous for rare diseases such as haemophilia, an X-linked recessive bleeding disorder.

Aims: To develop a protocol for studying the disease burden from haemophilia in developing countries.

Methods: Based on the cross-sectional HAEMOCARE study of haemophilia in five developing countries–Algeria, India, Morocco, Oman and South Africa–we propose a composite methodology for assessing disease burden from haemophilia in developing countries. This methodology captures study parameters relating to the three different aspects of disease burden–epidemiology of musculoskeletal morbidity, quality of life and economic costs–in 282 male patients with previously confirmed severe haemophilia (A or B) alone. Participants were aged ≥6 years and receiving on-demand treatment with anti-haemophilia factors (AHF). Patients were stratified by presence or absence of inhibitors, and were free of hepatitis C or HIV infection.

Results: Clinical morbidity parameters included the standard Haemophilia Joint Health score (HJHS) and Pettersson score. Secondary assessments related to different aspects of haemophilia management, including bleeding

episodes, requirement for AHF, use of adjunctive treatments, and access to specialist care. Quality of life was assessed using the standard EQ-5D-3L questionnaire to study index scores for mobility, self-care, usual activities, pain/discomfort and anxiety/depression. In addition to the direct cost of AHF treatment, indirect costs were studied in terms of transportation costs/distances, and schooldays missed or workdays lost. All economic costs were computed across time in this cross-sectional study. Overlapping costs from other healthcare facilities were not computed separately. Some opportunity costs could be deduced indirectly from the protocol. From these practical yet comprehensive parameters, a composite measure with possible index score may be generated by assigning weights in accordance with the demographic, ethnic, sociocultural, and healthcare environment as applicable to our developing countries. Though epidemiological prevalence of haemophilia was not studied, the percentage of the expected cases diagnosed in a given country (a predictable occurrence) may be accounted for in a realistic assessment at any given timepoint. Preliminary results have shown musculoskeletal problems in 84% of the study population.
Summary and Conclusions: Based on our HAEMOCARE study, a methodology and protocol for a composite assessment of disease burden from haemophilia in developing countries is proposed, in which different weights may be assigned to the study parameters to produce meaningful index scores for local use. Such composite measures and index scores may be valuable tools for making uniform comparisons and for assessment of future/intervention benefits in developing regions of the world.

P1065

DIAGNOSIS AND MANAGEMENT OF ACQUIRED HEMOPHILIA A (AHA) PATIENTS: EXPERIENCE OF A SINGLE CENTER.

C Mercanti[1], C Santoro[1,*], E Baldacci[1], R Abbruzzese[1], F Barone[1], R Bochicchio[1], R Mauro[1], L Parlanti[1], R Foà[1], M Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology, Sapienza University, Rome, Italy

Background: AHA is a rare bleeding disorder with an incidence of 1.5/million/year. Mortality rate is high (9-22%), if the diagnosis is delayed and treatment is not promptly implemented.
Aims: A retrospective evaluation of AHA affected patients diagnosed and followed at our Institution. Patients characteristics, bleeding symptoms and treatment, eradication therapy and response, occurrence of possibly related diseases have been considered.
Methods: Between 1984 and 2012, 34 patients (M, 14; F, 20) were diagnosed with AHA. Diagnosis median age: 70.2 years (25-89); median time from the first bleeding symptoms and diagnosis: 48.5 days (4-264); median follow-up (FU): 19.7 months (2.6-215.4).
Results: At diagnosis, bleeding symptoms were present in 33/34 patients (97%) (28 muscle hematomas, 3 hematuria, 2 post-partum hemorrhages, 1 GI bleeding, 1 hemoperitoneum, 1 hemarthrosis, 2 post-surgerybleedings); the median inhibitor titer was 9.6 BU/mL (2.5-138) and the median FVIII:C level 2% (0.01-21); in 16 patients, the FVIII:C level was <1%. Clinical conditions capable of triggering the inhibitor appearance were present in 17 patients (50%): a previous delivery in9, autoimmune diseases in4, cancer in 4. First-line eradication therapy was prescribed in all patients: prednisone (PDN) (median dose 1 mg/kg day, range 0.5-2) for 4 weeks in 23 (68%), dexamethasone (DXM) (median dose 24 mg/day, range 24-40) for 4-day courses in 7 (20%), azathioprine (AZA) 100 mg/day for 3 months in 2 (6%), cyclophosphamide (CTX) (0.5 and 1.5 mg/kg/day) plus PDN (standard doses) for 2 months in 2 (6%). Thirty-one patients are evaluable for response, 27 treated with PDN/DXM, 4 with other immune suppressive drugs. An inhibitor eradication (undetectable inhibitor, normal FVIII:C levels, absence of bleedings) was obtained in 24/31 patients (77%) (22/27 [81%] on PDN/DXM, 2/4 [50%] on other immune suppressants). Second-line therapy was administered to 4/7 non-responder patients: CTX+PDN in2, DXM in1, PDN in 1. Inhibitor eradication was obtained in 1. Third-line therapy was performed in 2/3 second-line non-responders: 1 CTX+PDN, 1 AZA+PDN. No responses were observed. One of these 2 patients was then treated with Rituximab, which allowed to obtain a persistent inhibitor eradication. Three patients relapsed after first-line treatment (3/24, 12.5%). At the last control, 23 patients have maintained a persistent inhibitor eradication at a median FU of 25.9 months (2.6-150.9). Bypassing agents (rFVIIa or FEIBA) were used in 21 patients with a high efficacy to control bleeding symptoms: FEIBA in11, rFVIIa in7, either FEIBA or rFVIIa in 3. A severe bleeder, non-responsive to eradication therapy, is on FEIBA prophylaxis 3 times weekly with a good control of hemorrhagic events. During the FU, occurrence of diseases possibly related to the inhibitor presence (cancer) was recorded in 2/17 idiopathic cases (11.7%); 5/34 deaths, not bleeding-related, were recorded. No relapses were observed in two post-partum inhibitor affected patients who underwent 3 deliveries after a period of 2, 3.6 and 7.3 years, respectively, after inhibitor eradication.
Summary and Conclusions: We confirm that the prevalence of idiopathic AHA is about 50% of cases. We observed a high response rate after steroid administration (81%). Bypassing agents were efficacious in all treated patients. The relapse rate was relatively low (12.5%). A good and prompt management of AHA reduces the bleeding-related mortality risk.

P1066

ACQUIRED VON WILLEBRAND SYNDROME AND MONOCLONAL GAMMOPATHY: CLINICAL CHARACTERIZATION AND RECOVERY TO INFUSION OF VWF-CONTAINING CONCENTRATES

C Ambaglio[1], M Russo[2], N Montani[2], M Sazio[2], G Gamba[2,*]
[1]Clinica Medica III, Fondazione IRCCS Policlinico San Matteo, [2]Università degli Studi di Pavia, Pavia, Italy

Background: Acquired von Willebrand syndrome (AVWS) is a rare bleeding disorder caused by structural or functional defects of von Willebrand factor. It has been described as secondary to autoimmune, hematologic, malignant or cardiovascular disorders. Diagnosis is generally underestimated because of the presence of moderate bleeding tendency in diseases that may be associated with drug related impaired haemostasis. The suspicion of AVWS is supported by the detection of both lone low plasma levels of vWF:RCo alone and in association with low vWF:Ag and FVIII:C levels, in absence familial or personal bleeding history and with previously normal clotting screening tests. Diagnosis is supported by impairment in recovery of infused plasma derived concentrates rich in vWF/FVIII. This study reports the recovery in five patients with monoclonal gammopathy and low levels of vWF/FVIII.
Aims: The evaluation of recovery after infusion of vWF-containing concentrates and its role to support the diagnosis of acquired coagulopathy.
Methods: Activated partial thromboplastin time (aPTT) and vWF:RCo, vWF:Ag and FVIII:C levels have been detected before the infusion of plasma derived vWF-containing concentrates (30 U/Kg bw) and after 30, 60, 120, 180 minutes, 6 and 24 hours.
Results: Five patients were evaluated from 2006 to 2012. All patients presented prolonged aPTT, low levels of vWF:Ag and vWF:RCo and no family history of bleeding disorders. Four out to five patients had not prior personal history of bleeding. Patient 1. 69 years old man, affected by Waldenstrom Macroglobulinemia (WM, IgMk). He suffered from acute severe epistaxis. After infusion of concentrates he had temporary uncomplete recovery of vWF:RCo. Patient 2. 73 years old man, with biclonal gammopathy (IgGk and IgMk); he presented melena due to acute intestinal microhemorrhages. After the infusion of concentrates he presented a temporary good recovery of vWF:RCo. Patient 3. 75 years old man, with monoclonal gammopathy of undetermined significance (MGUS, IgGk). He had an acute severe mucocutaneous hemorrhage after minor surgery and epistaxis. There was not significative recovery of vWF:RCO after infusion of concentrates. Patient 4. 40 years old woman, with MGUS (IgGk). She presented acute menorrhagia and severe anemia, needing for blood transfusions. The infusion tests showed only mild and temporary increase without any normalization of the parameters. Patient 5. 65 years old woman, with WM (IgMk) and frequent epistaxis, menorrhagia before menopause and mucocutaneous bleeding tendency. She had complete and sustained recovery, with normalization of vWF/FVIII levels over 6 hours after infusion of concentrates. In this case personal history and results of the infusion test may be consistent with a coincidental presence of congenital von Willebrand disease and the lymphoproliferative disorder.
Summary and Conclusions: To distinguish AVWS and von Willebrand disease (vWD) important features are the late onset of bleeding and a negative family history for hemorrhagic disorders but it's also known that mild vWD can be asymptomatic for decades and lack of a significative family history may be due to its low penetrance. Monoclonal gammopathy can coexist with congenital vWD. Studying the recovery to vWF-containing concentrates may be helpful to differentiate AVWS from vWD.

Thrombosis and vascular biology 2

VENOUS THROMBOEMBOLISM (VTE) PROPHYLAXIS IN HOSPITALIZED OBSTETRIC PATIENTS: A MULTICENTRE CROSS-SECTIONAL STUDY

Maeve P Crowley[1,*], Caroline Noone[1], John R Higgins[2], Susan O'Shea[1]
[1]Haematology, Cork University Hospital, [2]Obstetrics, Cork University Maternity Hospital, Cork, Ireland

Background: VTE complicates 1 - 2/1000 pregnancies, and the risk increases with age, mode of delivery, and presence of co-morbidities. It continues to be one of the leading causes of maternal death. Prophylaxis with low molecular weight heparin (LMWH) is safe. Despite having a population of only 4.5 million, Ireland has 20 maternity hospitals. Given this large number, it is difficult to standardize practice with international best practice.
Aims: To assess the prevalence of VTE risk in pregnant women in the hospital setting and to determine the proportion of at-risk patients who receive effective prophylaxis.
Methods: The study period was September 2011 to November 2012. All patients admitted to the participating hospitals on the day of investigation were assessed for risk of VTE on the basis of hospital chart review. Risk was assessed in accordance with the 2009 Royal College of Obstetricians and Gynaecologist Guidelines. Patients undergoing procedures or on the labour ward at the time of review were excluded. Ethical approval was obtained from the ethics committees governing all centres.
Results: 540 pregnancies were reviewed across 16 centres. The average age of was 31+/- 5.65yrs (Range 16-47), with 21.87% (117/535) aged over 35. 22% (118/535) had a parity of 3 or more. The average weight was 71.51kg (Range 42-134kg, SD 14.482kg). Data on BMI was available for 77% - 34% were overweight and 21% were obese. 1% (6/420) had a BMI>40. 31% (168/540) were antenatal and 69% (372/540) were postnatal. 63% (105) of antenatal patients were low risk (<2 risk factors), 35% (59) were intermediate risk (2 or more risk factors, prophylaxis should be considered) and 2% (4) were high risk. All the high risk patients were on prophylaxis at an appropriate dose. 4% (6) of the low risk patients were on prophylaxis unnecessarily. Only 7% (4/59) of the intermediate risk patients were on prophylaxis (3/4 were on too low a dose) Among postnatal patients, 41% (153) were low risk (<2 risk factors), 58% (217) were intermediate risk (2 or more risk factors, require prophylaxis) and <1% (2) were high risk. 80% (296) were appropriately risk stratified and put on LMWH if necessary. 59% (219) of patients should have been on LMWH but only 42% (157) were (92% Tinzaparin and 8% Enoxoparin). This included 8 patients who were on LMWH unnecessarily. 38% (59/157) were on too low a dose.
Summary and Conclusions: VTE prophylaxis is an important issue in obstetrics given its prominent role in maternal morbidity and mortality and the increasing prevalence of risk factors such as obesity and increasing maternal age. It is clear that while there is good awareness of the risk in the postnatal period, there is less emphasis on risk assessment in antenatal patients where prophylaxis is rarely used. Those on prophylaxis are also likely to be on too low a dose. Given the number of maternity hospitals in Ireland, there is a role for a national guideline to standardize care for all pregnant women.

P1068

INVESTIGATION TO IMPROVE DETECTION OF LUPUS ANTICOAGULANT IN A LOCAL POPULATION EXPERIENCING RECURRENT MISCARRIAGE AND INTRAUTERINE DEATH

A McMahon[1,*], C Holt[1], D Keeffe[2]
[1]Haematology Laboratory, [2]Haematology, HSE, Limerick, Ireland

Background: It is widely reported that antiphospholipid syndrome (APS) is detectable in approximately 15% of women with recurrent miscarriage in the absence of any other abnormalities. The detection rate in our laboratory is much lower, at 1-2%. All screening is carried out according to international guidelines published by the Scientific Standards Committee of the International Society for Thrombosis and Haemostasis which caused us to question why the detection rate is so low. As lupus anticoagulant (LA) detection is the most complicated part of the APS screening process, with numerous tests and interpretation methods available, this became the focus of our investigation.
Aims: To investigate the use of alternative interpretation methods for dilute Russell's viper venom (dRVVt)-based screening tests, to investigate the use of integrated screening and confirmatory testing methods and to determine the usefulness of factor assays in LA screening, with the ultimate aim of improving detection of LA in our laboratory.
Methods: Factor assays for VIII, IX, XI and XII were carried out at serial dilutions- 1:10, 1:20, 1:40 and 1:80 on 50 patients. The results were than analysed for a pattern of inhibitory activity, *i.e.* presence of LA; and compared to the PTT-LA results from the routine LA screen. dRVVt and dRVV Confirm assays were carried out on 80 samples and interpreted using 3 different methods, namely the dRVVt/Confirm ratio, the normalised ratio and the calculation for the percentage correction of clotting time. The use of the dRVVt and Confirm together as an integrated test was also compared to the dRVVt alone as a screening test. All results were compared using Chi-Square analysis where a $P<0.05$ was considered statistically significant.
Results: Factor assays were found to be of no additional benefit to the LA screening process, as was the percentage correction of clotting time calculation for interpretation of the dRVVt and Confirm tests; both methods were shown to increase equivocal results. Integrated testing using the normalised ratio as the interpretation method of choice showed an improvement in sensitivity detecting three new weak-titre LAs. A more significant development occurred on further analysis of the data when it was noted that 15% of patients showed increased factor VIII activity, indicative of an acute phase, which one would expect to witness in pregnancy; the mean dRVVt was also lower for this study population than for the general population. This study population, though no longer pregnant appear to share characteristics with pregnant women in relation to their coagulation assays. If this is the case then these patients should not be compared to reference ranges derived from the general population but to reference ranges relevant to their own specific population. To investigate this discovery further new study population reference ranges were generated. Comparing our results to the new reference ranges produced one weak positive from the three previously detected. More significantly, the dRVVt for this sample was actually prolonged using the new reference range, therefore this LA would be detected without the use of integrated testing.
Summary and Conclusions: This study has shown for the first time that population-specific reference ranges increase the sensitivity of LA screening assays and may provide a more specific alternative to integrated testing, as illustrated by the dRVVt results.

P1069

PRACTICAL EXPERIENCE OF THROMBOPROPHYLAXIS AFTER LOWER LIMB REPLACEMENT–RIVAROXABAN VERSUS ENOXAPARIN

J Won[1,*], H Park[1], J Yun[2], K Kim[1], H Kim[3], S Kim[2], S Lee[3], H Kim[2], S Bae[3], C Kim[2], N Lee[1], K Lee[3], S Park[2], Dae2, Y Kim[1], N Ham[1]
[1]Soonchunhyang University Hospital, Seoul, [2]Soonchunhyang University Hospital, Bucheon, [3]Soonchunhyang University Hospital, Cheonan, Korea, Republic of Korea

Background: Since October 2010, rivaroxaban has been approved by Korean government to be covered by national health insurance reimbursement system as thromboprophylaxis after total hip arthroplasty and total knee arthroplasty. However, there is no available data on outcomes of rivaroxaban as thromboprophylaxis in Korea.
Aims: We performed a retrospective study to compare the efficacy and safety of venous thromboembolism prophylaxis with enoxaparin or rivaroxaban in 195 consecutive patients undergoing major orthopaedic surgery at our center.
Methods: This study retrospectively reviewed the medical records of the 195 patients who underwent a total hip replacement arthroplasty or total knee replacement arthroplasty and received thromboprophoylaxis with enoxaparin or rivaroxaban at Soonchunhyang University Hospital between March 2009 and May 2012. Each patient's medical records included information on age, sex, comorbidities (active malignant disease, renal insufficiency), treatment details (type of surgery, type of anesthesia, duration of surgery,), duration of prophylaxis, efficacy (death, pulmonary embolism, deep vein thrombosis), safety (major bleeding, cerebrovascular accident), cause of drug interruption.
Results: Of 195 patients, 129 patients received thromboprophylaxis with enoxaparin (group 1; our hospital standard since March 2009), 66 received rivaroxaban (group 2; our hospital standard since February 2011). Symptomatic venous thromboembolism was found in 0.7% of patients in the group 1 (1/129 patients) compared to 1.5% of group 2 (1/66 patients; P=0.627). No significant differences in the rates of symptomatic VTE were found. However, patients with received rivaroxaban had significantly more rates of major bleeding (0 in group 1 *vs* 3% (2/66 patients) in group 2; P=0.047). Although group 1 patients were planed receiving thromboprophylaxis with rivaroxaban from day one post operatively, mean time from the end of surgery to first rivaroxaban intatake was 4.2 days.
Summary and Conclusions: Despite lower compliance in rivaroxaban group, venous thromboembolism prophylaxis with rivaroxaban is not inferior to prophylaxis with enoxaparin with regard to the prevention of symptomatic venous thromboembolisms. But, more bleeding complications and wound problems revealed in rivaroxaban group. Further studies and experiences are needed to assess the efficacy and safety of rivaroxaban in clinical practice.

P1070

THROMBOSIS IN CHILDHOOD ACUTE LEUKEMIA

H Şahin[1], Y Yaman[2,*], G Özek[2], Ö Cartı[2], B Güneş[2], E Albudak[2], B Demirağ[2], A Yıldırım[3], Y Oymak[4], F Özkınay[5], U Karaarslan[1], C Vergin[1]
[1]Dr.Behçet Uz Children Hospital, izmir, Turkey, [2]Pediatric hematology, Dr.Behçet Uz Children Hospital, izmir, [3]Pediatric hematology, Diyarbakır Chil-

drens Hospital, Diyarbakır, [4]Pediatric hematology, Harran University Medical Faculty, Şanlıurfa, [5]Medical Genetics, Egean University Medical Faculty, izmir, Turkey

Background: Thromboembolism can occur during acute leukemia, especially acute lymphoblastic leukemia (ALL) treated with L-asparaginase and steroids and acute promyelocytic leukemia (AML M3). The presence of central venous lines, usage of Escherichia coli asparaginase, sepsis and hereditary thrombophilic abnormalities are risk factors for thrombosis in children.
Aims: To evaluate the risk of thrombosis in children with ALL and AML.
Methods: One hundred and ninety-seven consecutive patients with acute leukemia were recruited for this study from April 2005 to October 2010 retrospectively. Ages of patients at time of diagnosis, symptomatic thromboembolic events, type of leukemia, chemotherapy protocol, time of thromboembolic events during chemotherapy, site of thromboembolic events, hereditary and acquired risk factors for thromboembolic events had been examined from the patients' records retrospectively.
Results: One hundred seventy-five patients with ALL, 10 patients with AML M3 and 12 patients with non-M3 AML were detected. All were in treatment according BFM protocols; ALL BFM 95 and AML BFM 2004 protocols for ALL and AML patients, respectively. Sixteen patients of the 197 patients had tromboembolic events (8,1%). Fourteen of sixteen were patients with ALL, one with AML M3, one with non-M3 AML. Thromboembolic events were more common in follow-up of patients with high risk ALL (23,8%) than patients with standart and intermediate risk. A half (50%) of thromboembolic events were seen in patients who were under treatment for standart and intermediate risk ALL during the induction phase and reinduction phase of treatment. Site of thrombus were iliac vein, catheter tip, finger tip, arteria dorsalis pedis, spleen, femoral vein, renal and central nervous system. The use of central vein increased risk of tromboembolic events to 20,3%. Hereditary thrombophilic factors were positive in nine of patients with thrombosis. Factor V Leiden heterozygosity, MTHFR heterozygosity, prothrombin 20210 heterozygosity, Factor V Leiden heterozygosity+MTHFR heterozygosity were found in3,4,1,1 of these patients respectively. None of these patients were elevated activated protein C resistance and homocystein level of these patients were not evaluated. Three of the 16 patients died due to sepsis during thromboembolic events.
Summary and Conclusions: The incidence of thromboembolic event in patients with leukemia is not negligible. Guidelines for leukemia specific risk factors, thrombosis prevention and treatment strategies in acute leukemia patients are required.

P1071

PROTHROMBIN TIME AND ANTIPHOSPHOLIPID ANTIBODIES: THE NUMBER OF POSITIVE TESTS PREDICTS PROTHROMBIN TIME PROLONGATION

Marta Pereira[1,*], Gilberto Marques[2], Margarida Lourenço[2], Rosário Cunha[2], Fernando Rodrigues[2], Graça Ribeiro[2]
[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospitals, Coimbra, Portugal

Background: The presence of antiphospholipid antibodies (aPLA) - lupus-like anticoagulant (LAC), anti-Beta2-glycoprotein I (B2G) or anti-cardiolipin (aCL) - is one of the necessary criteria for the diagnosis of antiphospholipid syndrome (APS), a prothrombotic state. LAC prolongs the activated partial thromboplastin time (aPTT), *in vitro*; in contrast, in the majority of patients, LAC does not prolong the prothrombin time (PT) - this finding is clinically relevant, underlying the rationale of using PT (through the INR) to monitor anticoagulation in patients with APS, in whom PT results are assumed to reflect the effect of warfarin, and not an interference of the underlying disease. Nevertheless, some authors have noted a prolonged PT in a selection of patients with LAC; in these patients, it can be postulated that there is a risk of undertreatment with warfarin, with PT prolongation being in part due to an *in vitro* artifact, and not solely to the effect of treatment. The identification of patients with a prolonged PT ab initio will help optimize patient management and reduce the risk of undertreatment. The characterization of the subset of patients in whom aPLA associate with a prolonged PT is the first step towards this goal.
Aims: To determine whether the nature or the number of positive aPLA are determinants of PT prolongation.
Methods: We reviewed all lab requests from 01-01-2000 to 12-31-2012, selecting patients with simultaneous diagnostic PT, aPTT, LAC, G2B and aCL determinations (IgM and IgG considered together). Patients were grouped according to the type (LAC, B2G and aCL) and number of positive results; the mean PT and aPTT (normalized to control) were compared across the groups.
Results: Inclusion criteria were fulfilled by 1669 results. The difference between PT and control was 1.3±3.3s when all tests were negative, and increased to 2.1±3.9s, 3.4±6.3s and 4.4±7.3s when one, two or all three tests were positive (P<0.001). When only one test was positive, the difference was 1.6±4.3s with B2G, 1.7±2.7 with aCL and 2.6±4.2 with LAC (P=NS); when two tests were positive, the difference was 2.7±6.0 for B2G and LAC, 3.5±6.4 for B2G and aCL, and 3.5±6.6 for LAC and aCL (P=NS). The ratio of aPTT to control was 1.0±0.2 when all three tests were negative, increasing to 1.3±0.5, 1.4±0.6 and 2.4±1.3 when one, two or all three tests were positive (P<0.001). When only one test was positive, the ratio was 1.0±0.2 with B2G, 1.1±0.3 with aCL (P=NS) and 1.5±0.6 with LAC (P<0.001); when two tests were positive, 1.2±0.4 for B2G and aCL, 1.6±0.6 for aCL and LAC, and 2.0±0.7 for B2G and LAC (P<0.001).
Summary and Conclusions: Considering the three APS-associated tests (B2G, aCL and LAC), we found a significant increase in PT and aPTT with an increase in the number of positive tests. For aPTT, not just the number, but also the type of test that was positive influenced the ratio: single positivity for B2G or aCL was comparable to negativity for all tests, but positivity for LAC had the strongest impact on aPTT; two-positive-test combinations including LAC were also associated with higher aPTT ratios than the B2G-aCL combination. These findings are in accordance with the known mechanism of LAC interference on lab testing. On the other hand, for PT, we found that only the number of positive tests was significant, with no differences between test combinations; positivity for LAC did not impact on PT results. These results can contribute to our understanding of PT-prolongation in LAC-positive patients: our data suggests that increased PT, in these patients, could be due to simultaneous positivity for B2G and/or aCL. We propose that in patients with positivity for two or, especially, all three of the aPLA, special care should be taken to identify an ab initio increased PT, and INR results obtained during anticoagulation should be interpreted in its light.

P1072

ULTRASTRUCTURAL ANALYSES OF THE NOVEL CHIMERIC HEMOSTATIC AGENT GENERATED VIA NANOTECHNOLOGY, ABS NANOHEMOSTAT, AT THE RENAL TISSUE LEVEL

E Huri[1], I Haznedaroglu[2,*], M Hayran[3], M Ergun[3], A Firat[3], Y Beyazit[4], R Mammadov[5], M Guler[5], M Dadali[1], H Goker[2]
[1]Ankara Training and Research Hospital, Urology, [2]Hematology, [3]Anatomy, Hacettepe University Medical School, [4]Gastroenterology, YIH hospital, [5]Nanotechnology, UNAM, Ankara, Turkey

Background: Biomaterials used as tissue engineering scaffolds have specific physical properties and might form fibrous networks similar to collagenous extracellular matrix. They also can be programmed to carry chemical and physical cues to provide bioactivity for cell-materials interactions. In the search for more improved bioactive materials for tissue engineering purposes, peptide amphiphile (PA) molecules are good candidates to bring scaffold properties and bioactivity together.
Aims: We have generated a chimeric hemostatic agent, ABS Nanohemostat, via combining self-assembling peptide amphiphile (PA) molecules with the traditional ABS (Ankaferd Hemostat). The synthesis of the specific self-assembling peptide molecules capable of being a part of the combined ABS Nanohemostat compound and the assembly of the peptide nanofibers and ABS to generate the ABS Nanohemostat have already been published (Int J Biomaterials 2013, ID 949460, http://dx.doi.org/10.1155/2013/949460). The aim of this study is to assess renal tissue effects of the ABS Nanohemostat formed by the combination of self-assembling PA molecules and ABS.
Methods: Peptides were constructed on Rink Amide MBHA resin. Amino acid couplings were done with 2 equivalents of Fmoc protected amino acid, 1.95 equivalents HBTU and 3 equivalents of N,N-diisopropylethylamine (DIEA) for 2 hours. The PA was synthesized by Fmoc Solid Phase Peptide Synthesis (SPPS) method. It is composed of a lauryl (C12) group, hydrophobic region of the PA, and a peptide sequence. VVAG peptide sequence is used as β-sheet-inducer that causes nanofiber formation, while the lysine (K) residue is protonated at physiological pH and increase solvation of PA molecule in aqueous solution at pH 7. Renal artery and vein was revealed by hilar vascular dissection in 24 Wistar rats weighing 200 to 300 g. Subsequently renal artery and vein were clamped with Rommel vascular clamp. The lower third of the left kidney was resected in guillotine fashion with a single stroke of an amputating knife. Scanning Electron Microscopy (SEM) experiments were performed with FEI Nova NanoSEM 230, using the ETD detector at low vacuum mode with 30 keV beam energy to assess renal tissue alterations.
Results: SEM analyses revealed that significant erythroid aggregation are present inside the capillary bed of the renal tissue. However, neither the signs of necrosis nor any other sign of a tissue damage are not evident in the surrounding renal tissue supplied by those microcapillary vasculature. Furthermore, the appearance of the nucleus, cytoplasm of the vascular endothelial cells and their organelles are completely normal.
Summary and Conclusions: In previous investigations, histopathological examination of the damaged vascular structures revealed ABS-induced red blood cell aggregates supporting the hypothesis that ABS-induced formation of the protein network with vital erythroid aggregation covers the entire physiological hemostatic process (Critical Reviews in Oncology/Hematology 83 (2012) 21–34). We have observed the same structures in the kidney tissue in the present study via SEM analyses. In the current study, ABS Nanohemostat has lead to a more pronounced erythroid aggregation at the renal tissue level in comparison to the traditional ABS (Ankaferd hemostat).

P1073

MORTALITY OF PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND RELATION TO COAGULATION AND INFLAMMATORY BIOMARKERS

S Elmoamly[1,*], M Mattar[1], S Amin[2], M Yacoub[1]
[1]Internal Medicine & Hematology department, Faculty of Medicine, Cairo University, Cairo, [2]Clinical pathology department, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Patients with hematological malignancies often have a hypercoagulable state due to the production of substances with procoagulant activity. Also the role of inflammatory cells and pathways in the pathogenesis of cancer has become well established. Venous thromboembolism and inflammatory events are considered imortant causes of mortality in cancer patients. The impacts of vascular and inflammatory markers on the prognosis of hematological malignancies are still to be studied.
Aims: to study whether vascular and inflammatory biomarkers (as well as clinical variables) can be used as predictors of mortality in patients with hematological malignancies.
Methods: This study is a prospective observational cohort study; it was conducted on a group of 86 patients with malignant haematological conditions. They have been followed up for an average period of 314.45 days with an endpoint of mortality. **Exclusion criteria included** Overt bacterial or viral infection within the last 2 weeks, Venous or arterial thromboembolism within the last 3 months, Continuous anticoagulation with vitamin K antagonists or low molecular weight heparin (LMWH). Hypercoagulability and inflammation were assessed at the initiation of the study by measuring the circulating levels of the following parameters: Markers of coagulation and fibrinolysis activation (D-dimer, Fibrinogen, Thrombin, plasminogen activator inhibitor 1 [PAI-1]); Markers of endothelium and platelet activation (von Willebrand Factor [vWF], soluble P-selectin); and Markers of inflammation (Tumor necrosis factor alpha [TNF-α], Interleukin-6 [IL-6]).
Results: In our study, the mean age was 48.8 years. Our study included 38 (44.19%) female patients and 48 (55.81%) male patients. Out of 86 patients, 23 (26.74%) were diagnosed to have Lymphoproliferative disorders, 26 (30.23%) were diagnosed to have Myeloproliferative neoplasms, 19 (22.09%) were diagnosed to have AML (or MDS progressed to AML), 9 (10.47%) were diagnosed to have ALL, 9 (10.47%) were diagnosed to have Paraproteinaemias. Thirty two (37.21%) patients died during follow up. Twenty four (75%) patients died within 6 months after diagnosis. Eighteen patients (56.25%) died of disease progression, 7 patients (21.88%) died of infection, 4 patients (12.5%) died suddenly with suspected pulmonary embolism, 1 patient (3.13%) died of each of heart failure, bleeding, liver cell failure. There were statistically significant associations between mortality and ECOG performance status (P value: 0.001), duration of hospital stay (P value: 0.006), platelet count (P value: 0.033), transfused blood units (P value: 0.002), transfused platelet units (P value: 0.04), PTT (P value: 0.014), serum albumin (P value: 0.004), total bilirubin (P value: 0.007) Antithrombin (P value: 0.016), soluble P-selectin (P value 0.038), vWF (P value: 0.009), IL-6 (P value: 0.042). For prediction of mortality, ROC Curve of Albumin level showed that a level of 3.35 g/dl showed the highest likelihood ratio (LR) of 2.04 with sensitivity of 60% and specificity of 72.5%. For prediction of mortality, ROC Curve of total bilirubin level showed that a level of 0.58 mg/dl showed the highest likelihood ratio (LR) of 1.67 with sensitivity of 65.6% and specificity of 60.8%. ROC Curve of Antithrombin level showed that a level of 16.25 mg/dl showed the highest likelihood ratio (LR) of 1.8 with sensitivity of 61.3% and specificity of 66%. ROC Curve of soluble P-selectin level showed that a level of 28.28 ng/mL showed the highest likelihood ratio (LR) of 1.8 with sensitivity of 61.3% and specificity of 66%. ROC Curve of vWF level for showed that a level of 2.525mU/mL showed the highest likelihood ratio (LR) of 1.9 with sensitivity of 61.3% and specificity of 68%. ROC Curve of IL-6 level showed that a level of 3.35pg/mL showed the highest likelihood ratio (LR) of 1.62 with sensitivity of 61.3% and specificity of 62.3% (Figure 1).

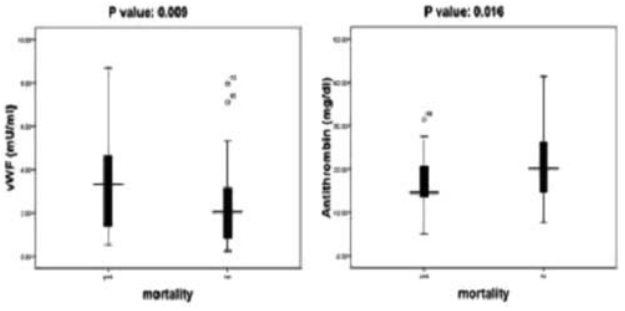

Figure 1. Relation between coagulation and inflammatory biomarkers and mortality in hematological malignancy.

Summary and Conclusions: our study concluded that initial levels of Albumin below 3.35g/dl, Total bilirubin above 0.58 mg/dl, Antithrombin below 16.25 mg/dl, soluble P-selectin below 28.28 ng/mL, vWF above 2.525mU/mL and IL-6 above of 3.35pg/mL are associated with poor outcome with increased mortality. these biomarkers can be included in a larger pridective model for mortality in patients with hematological malignancies

P1074

EPCR SER219GLY POLYMORPHISM AND SUSCEPTIBILITY TO VENOUS THROMBOEMBOLISM IN THE POPULATION OF NORTH-WESTERN RUSSIA

S Kapustin[1,*], A Demyanenko[2], V Kobilyanskaya[1], J Sidorova[1], T Morozova[1], A Polyakova[1], P Chechulov[2], N Saltykova[1], V Kargin[1], V Soroka[2], V Shmeleva[1], L Papayan[1]
[1]Russian Research Institute of Haematology and Transfusiology, [2]Emergency Research Institute, Saint-Petersburg, Russian Federation

Background: Venous thromboembolism (VT) is a multifactorial disorder. The genetic basis of predisposition to VT is not fully understood. Endothelial protein C receptor (EPCR) plays an important role in protein C anticoagulant pathway. An amino acid change Ser219Gly is associated with increased plasma levels of soluble EPCR and can affect thrombin degradation rate by activated protein C. The data on the role of EPCR Ser219Gly substitution in susceptibility to VT are still scarce.
Aims: To assess the role of EPCR Ser219Gly polymorphism in susceptibility to VT in the population of the North-Western region of Russian Federation.
Methods: We examined 300 patients with VT (147 men and 153 women, mean age 39.9±12.4 years) and 172 age- and sex-matched healthy controls (HC). In 200 patients, the first episode of VT was diagnosed at young age (before 45 years of old). All individuals originated from the North-Western region of Russia and gave informed consent for participation in the study. Allelic variants of the EPCR gene corresponding to Ser219Gly polymorphism were discriminated by PCR-RFLP method. The differences in genotype distributions between the groups were estimated by Fisher`s exact test. Odds ratios (OR) with their 95% confidence intervals (CI) as well as P-values were calculated by using GraphPad Prism software, version 4.0.
Results: The EPCR Gly219 variant was more frequently detected in the VT group (25.7% *vs.* 18.6% in controls, OR=1.5, 95% CI: 0.9-2.4, P=0.09). Notably, both hetero- and homozygosity for the EPCR Gly219 were more prevalent in patients than in HC, although not statistically significant (24.0% *vs.* 18.0%, and 1.7% *vs.* 0.6%, respectively). In the group of patients under 45 years of old, the frequency of individuals positive for the EPCR Gly219 variant was 2-times higher than in those with late-onset VT (31.0% *vs.* 15.0%, respectively, OR=2.5, 95% CI: 1.4-4.8, P=0.003). When comparing to HC, we found an increased risk of early-onset VT development in persons having EPCR Gly219 (OR=2.0, 95% CI: 1.2-3.2, P=0.008). Moreover, this variant of EPCR was present in 52 (33.5%) out of 155 young patients without factor V (G1691A) and factor II (G20120A) gene mutations (OR=2.2, 95% CI: 1.3-3.7, P=0.002, compared to control group).
Summary and Conclusions: Our data suggest that the EPCR Gly219 variant could independently increase the risk of VT development at young age in the population of North-Western Russia.

P1075

POLYMORPHISM OF VASCULAR TONE REGULATING GENES AND THE RISK OF VENOUS THROMBOEMBOLISM IN INDIVIDUALS WITH INHERITED THROMBOPHILIA

A Polyakova[1,*], V Shmeleva[1], V Soldatenkov[1], N Saltikova[1], V Kargin[1], M Blinov[1], S Kapustin[1]
[1]Russian Research Institute of Hematology and Blood Transfusion, Saint-Petersburg, Russian Federation

Background: Venous thromboembolism (VT) is one of the most actual multifactorial diseases in the world. Genetic predisposition plays a significant role in pathogenesis of VT. Mutations in the factor II (FII G20210A) and factor V (G1691A, FV Leiden) genes are the most frequent inherited risk factors for VT and could be detected in about 9% and 20% of VT cases, respectively, in the population of North-Western Russia. Endothelial dysfunction is an important mechanism underlying thrombosis, and it frequently occurs as a result of imbalance between vasoconstriction and -dilatation processes. Variations in the genes coding for components of the renin-angiotensin system (RAS) and endothelial NO-synthase (eNOS) can lead to changes in their structure and/or functional activity and modulate the risk of VT.
Aims: To investigate the role of angiotensinogen (AGT), angiotensin II receptor type 1 (AGTR1), angiotensin-converting enzyme (ACE) and eNOS genes polymorphism in the development of VT at young age in individuals with inherited thrombophilia.
Methods: Retrospective study involved 181 patients with early-onset VT (mean group age 34,0±8,6 years) and 156 sex- and age-matched healthy controls (HC). All individuals originated from the North-Western region of Russia and gave informed consent for participation in the study. Variations in the FII

(G20210A), FV (G1691A, Leiden), ACE (Ins/Del), AGT (T704C, Met235Thr), AGTR1 (A1166C) and eNOS (T−786C) genes were discriminated by PCR-RFLP method. The differences in genotype distributions between groups were estimated by Fisher`s exact test.
Results: The distributions of alleles and genotypes of the vascular tone regulating genes in patients without known inherited risk factors, as well as in those having FII G20210A mutation were not significantly different from HC. At the same time, the positive association between the FV G1691A and eNOS −786CC genotypes was observed in the VT group (OR=3,2; 95% CI:1,3-7,5; P=0,01). Homozygosity for the eNOS −786C allele was more frequently seen among carriers of FV Leiden mutation than in patients with normal FII and FV genotypes (29,7% *vs.*13,1%, respectively, P=0,024). The "unfavorable" variants of the RAS genes were also over-represented in patients with FV Leiden. In particular, the simultaneous presence of the ACE Del/Del and AGT 704CC genotypes was almost 5-times more frequently seen in these individuals than in patients with normal FV and FII genotypes (15,2% *vs.*3,1%, respectively, P=0,018) Interestingly, neither the eNOS −786CC variant nor the "ACE Del/Del-AGT 704CC" combination was detected in VT patients having FII G20210A mutation and normal FV genotype.
Summary and Conclusions: We suggest that polymorphism of the vascular tone regulating genes can affect the imbalance between vasoconstriction and vasodilatation processes and play a provocative role in the development of early-onset VT among patients with FV Leiden variant.

P1076

PROPHYLAXIS FOR VENOUS THROMBOEMBOLISM IN PATIENTS TREATED FOR ACUTE LYMPHOBLASTIC LEUKEMIA–A SYSTEMATIC REVIEW

M Lauw[1,2,*], L Hubers[2], S Barco[2], C Van Ommen[3], B Hutten[4], B Biemond[1], S Middeldorp[2]
[1]Dept. of Hematology, [2]Dept. of Vascular Medicine, Academic Medical Center, [3]Department of Pediatric Hematology, Emma's Childrens Hospital/Academic Medical Center, [4]Department of Clinical Epidemiology & Biostatistics, Academic Medical Center, Amsterdam, Netherlands

Background: Venous thromboembolism (VTE) occurs frequently in patients with acute lymphoblastic leukemia (ALL). Reported incidences vary between 2 and 36%. Occurrence is often associated with treatment components, particularly L-asparaginase. Efficacy and optimal approach of VTE prevention during ALL treatment are unclear.
Aims: To investigate the efficacy and safety of systemic thromboprophylaxis, using blood-derived products, *i.e.* fresh frozen plasma, cryoprecipitate or antithrombin concentrate, or anticoagulant agents, *i.e.* (low-molecular-weight) heparin, fondaparinux or oral anticoagulants (vitamin K antagonists), on VTE incidence in pediatric and adult patients treated for primary ALL with L-asparaginase therapy. Also, impact of thromboprophylaxis on overall survival and treatment outcomes of ALL were investigated.
Methods: We systematically searched The Cochrane Central Register of Controlled Trials (CENTRAL, *The Cochrane Library*, Issue 7 2012), MEDLINE (January 1966 to August 2012; accessed via Pubmed) and EMBASE (January 1980 to August 2012; accessed via OVID). We handsearched conference proceedings and checked references of included studies. All randomized controlled trials (RCTs) that assessed the efficacy and safety of systemic thromboprophylaxis in patients treated for primary ALL with L-asparaginase therapy were eligible. Interventions included any dose of the above mentioned blood-derived products or anticoagulants, in comparison with no intervention or placebo, or a comparison of two different interventions. Three authors independently assessed eligible articles and systematically extracted the data from selected articles. Discrepancies were resolved by discussion or with the opinion of a fourth author. Risk of bias, quality of evidence, potential heterogeneity and reporting biases were explored.
Results: Of 304 identified citations, 44 articles were selected for full-text evaluation. Cross-referencing of articles yielded another 20 articles. Finally, one RCT enrolling 109 patients fulfilled our inclusion criteria and was analyzed for our review. This study assessed a randomization between antithrombin concentrate infusions (once weekly for 4 weeks) and no intervention in children treated for primary ALL. Outcomes were symptomatic and asymptomatic thrombosis (by radiographic screening following completion of the induction phase), and bleeding events. 7 of 25 analyzed children with antithrombin had thrombosis (28.0%) *versus* 22 of 60 patients without antithrombin (36.7%; OR 0.67; 95% CI 0.3-2.3, P=0.43). One major bleeding event (1.7%) occurred in the non-antithrombin arm, *versus* no major but two minor bleeds in the antithrombin arm. Impact of thromboprophylaxis on survival or ALL treatment outcomes was not assessed.
Summary and Conclusions: Only one RCT in children with ALL was identified, with a high risk of bias due to an open-label design and incomplete outcome data as a result of a per protocol analysis. In this study, no statistically significant effect of antithrombin infusions was seen on the outcomes of interest. However, the sample size was small with a skewed randomization ratio, and may have missed a clinically important effect. No RCTs were found addressing other blood-derived products or anticoagulants. Therefore, the efficacy and safety of thromboprophylaxis to prevent VTE during ALL treatment remain unclear. The use of thromboprophylaxis during ALL treatment, in particular during L-asparaginase therapy, needs to be assessed in randomized controlled trials.

P1077

THROMBOPHILIAS INCIDENCE IN PATIENTS WITH FETAL LOSS IN LAST TRIMESTER AND EVALUATION OF THE EFFECTIVENESS OF TREATMENT

L Martínez[1,*], R Herrero[1], R Martínez[1], I de Torres[2], B Sierra[1], C Cornacchia[1], J Hernández[1], A Mateo[1], S Castillo[1], RSantamaria[3], J Martín[1]
[1]Hematology, [2]Clinical Analysis, [3]Gynecology, General Hospital of Segovia, Segovia, Spain

Background: Up to 5% of women of reproductive age, have >2 fetal losses, one of the most common causes of female infertility. Several studies identify thrombophilia as a major cause of these events.
Aims: We set as our primary objective to analyze the incidence of thrombophilia in a population of women who had pregnancies with fetal deaths (defined as a gestational age>20 weeks). Secondly, we evaluate both the presence of hereditary thrombophilia(HT), as the existence of acquired variations, to estimate the influence of both hypercoagulable states over the course of pregnancy. Finally correlate the use of low molecular weight heparin(LMWH) with gestational viability in these patients.
Methods: Retrospective January1999/December2011 taking as its starting point the existing number of stillbirths during this period in the Gynecology Service of the Hospital of Segovia. Mothers who were evaluated after the event came to the Hematology Service to perform hypercoagulability´s study. Collect the incidence of HT, acquired or absence of these alterations in coagulation studies. In parallel we analyzed the characteristics of obstetric patients for the presence of abortions, bleeding events during birth and number of live births. Finally the women were assessed in held LMWH prophylaxis and treatment, collecting potential medication side effects and the success of this therapy.
Results: During the study period, we collected a total of 97 patients with at least one pregnancy, in which the result was a dead fetus, performing hypercoagulability in 50 patients (51,5%). The average age of women at the time of the event was 33 years (range: 20-42). 38% of these patients (n=19) had suffered a previous abortion, distributed by episodes: 1 abortion (n=13;68%), 2 abortions (n=4;21%), 3 abortions (n=1;5%) and 5 (n=1;5%). Stresses that 36% (n=18) of women in the study had at least one living child prior to the event, not objectified in neither case malformations in children born. Regarding coagulation studies, 64% (n=32) were diagnosed with various syndromes of hypercoagulability (SH). The percentage distribution of final diagnoses are shown in Table 1. Since one of the most common diagnoses in the population was the mutation at the gene level of homocysteine(C-677-T), we performed a subanalysis in which we evaluated the mean serum levels of homocysteine in patients with a homozygous mutation *vs.* heterozygous, no statistically significant differences (8,61*vs.*7,96;P>0.5). 78% patients (n=25) diagnosed with SH, were treated with LMWH and folic acid as needed. In all cases we chose Bemiparin for easy administration (once daily).Close monitoring was performed during pregnancy and postpartum by measuring anti-Xa and platelet count to detect possible side effects. The mean platelet count at baseline was 270,000/mm³(range:135-402), and monitoring functions at3, 6 and 9 months (mean: 252, 243 and 207 respectively) demonstrated the absence of thrombocytopenia. Of all patients with SH 78%(n=25) had a pregnancy after the event, when assessed by subgroups was observed that 92%(n=23) of patients treated getting a viable fetus compared to 28%(n=2) of the untreated group.

Table 1.

DIAGNOSTIC	CASE NUMBER	% TOTAL
MUTATION HOMOCYSTEINE HOMOZYGOUS	13	41%
MUTATION HOMOCYSTEINE HETEROZYGOUS	3	10%
FACTOR V LEIDEN MUTATION	2	6%
ANTIPHOSPHOLIPID SYNDROME	2	6%
PLASMINOGEN DEFICIT	1	3%
MIXED PATTERNS	11	34%
—	N=32	100%

Summary and Conclusions: The incidence of fetal deaths in our population is similar to that reported in the literature. The most common types are the inherent SH and combined. Hypercoagulability studies identify patients with high-risk pregnancies, candidates for the implementation of therapeutic strategies. The use of LMWH in these patients achieved pregnancy with good fetal viability, with success rates similar to those reported.

P1078

IS THERE AN ASSOCIATION BETWEEN ABO BLOOD GROUP AND MICROANGIOPATHIC HEMOLYTIC ANEMIA?

Z Mozaheb[1,*]
[1]hematology, mashhad university of medical science, mashhad, Iran, Islamic Republic of Korea

Background: Bachground: Several studies have reported the relationship between ABO blood groups and thrombosis and hemorrhagic disorders, most of them showing that non-O blood groups have a high risk for thrombosis and O blood groups have a high risk for hemorrhage. However, there are no studies about the relationship between the microangiopathic hemolytic anemia (MAHA) and the ABO blood groups.
Aims: Due to the different risks for hemorrhage and thrombosis in relation to ABO blood groups in different studies, in this study we evaluate the relationship between ABO blood groups and MAHA.
Methods: A prospective case-control study was conducted in the ICU centers of the Hasheminejhad and the Imam Reza Hospital of the Mashhad University of Medical Science in Mashhad, Iran between May 2011-Desember 2012. Patients admitted to the ICU with different etiology showed symptoms and signs of microangiopathic hemolytic anemia. There were 80 patients (age: 20-70 years) and 100 controls in this study. Controls were selected at random from a laboratory.
Results: In this study, we show that there is a significant difference in all blood groups between patients with microangipatic hemolytic anemia and the control group (P. value=0.009), with a significant difference between O and non-O blood groups (P. value=0.023).
Summary and Conclusions: previous studies confirm the historical linkage between some vascular disorders and non-O blood group status. In this study we show the significant relationship between microangiopathic hemolytic anemia and non-O blood groups; therefore, we recommended non-O blood group consider as a risk factor for this group of disease.

P1079

THE NOVEL NOX INHIBITOR 2-ACETYLPHENOTHIAZINE IMPAIRS COLLAGEN-DEPENDENT THROMBUS FORMATION IN A GPVI-DEPENDENT MANNER

D Vara[1,*], M Campanella[2], G Pula[1]
[1]Pharmacy and Pharmacology, University of Bath, Bath Spa, [2]Department of Veterinary Basic Sciences, Royal Veterinary College, London, United Kingdom

Background: Besides classical agonist-induced signal transduction pathways, platelet activation is also regulated by reactive oxygen species (ROS). In particular, superoxide ions from exogenous and endogenous sources increase collagen-dependent aggregation and thrombus formation. NADPH oxidases (NOXs) play a critical role in the generation of superoxide ions in platelets and contribute to platelet activation, although their mechanism of action remains largely unknown. Therefore, NADPH inhibitors may represent novel potential candidates for the development of anti-platelet agents.
Aims: In this project, we studied the effect of the novel NOX inhibitor 2-acetylphenotiazine (2-APT) on human platelet functional responses and intracellular signalling pathways.
Methods: The generation of superoxide ions was assessed by single cell imaging on adhering platelets using dihydroethidium (DHE), while cumulative ROS generation was detected with 5-(and-6)-carboxy-2',7'-dichlorodihydrofluorescein diacetate (CM-H2-DCFDA). Whole blood thrombus formation, washed platelet aggregation, integrin αIIbβ3 inside-out signalling, Syk phosphorylation, and protein kinase C (PKC) activation were analysed to understand the functional consequences of NOX inhibition by 2-APT in platelets.
Results: Superoxide ion generation stimulated by platelet adhesion on collagen and fibrinogen was significantly inhibited by 2-APT in concentration-dependent manner within the submicromolar range, whereas this pharmacological agent did not affect cumulative ROS generation. 2-APT impaired washed platelet aggregation in response to collagen but not thrombin and abolished whole blood thrombus formation stimulated by collagen but not fibrinogen. The activation of integrin αIIbβ3 and protein kinase C in response to the GPVI-specific agonist collagen-related peptide (CRP) was significantly reduced, whereas the same responses to thrombin were not significantly affected by 2-APT. Finally, Syk activation in response to collagen but not thrombin was inhibited by 2-APT, which suggests a stimulatory role for NOX-generated superoxide ions in the early events of the signalling cascade of GPVI.
Summary and Conclusions: Taken together, our results suggest that 2-APT attenuates GPVI-specific signalling and is a novel inhibitor of collagen-induced platelet activation. Therefore, 2-APT can represent a novel candidate for the development of anti-thrombotic drugs and NOXs are promising new targets for anti-thrombotic drug discovery.

Quality of life

COMPARISON OF PATIENTS' AND PHYSICIANS' PERCEPTIONS OF PATIENTS' BASELINE HEALTH-RELATED QUALITY OF LIFE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

I Broek[1,*], P Murphy[2], M Petrucci[3], C Kyriakou[4,5], M Welslau[6], P Bacon[7], P Lewis[8], H Gilet[9], B Arnould[9], ABottomley[10], X Leleu[11]
[1]AZ Nikolaas, Sint-Niklaas, Belgium, [2]Beaumont Hospital, Dublin, Ireland, [3]Department of Cellular Biotechnology and Hematology, Division of Hematology, Sapienza University of Rome, Rome, Italy, [4]Northwick Park Hospital, London, [5]Royal Free hospital, London, United Kingdom, [6]Studienzentrum Hämatologie, Aschaffenburg, Germany, [7]Celgene International Sarl, Boudry, Switzerland, [8]Celgene GmbH, Munich, Germany, [9]MAPI Consultancy, Lyon, France, [10]European Organisation for Research and Treatment of Cancer, Brussels, Belgium, [11]CHRU-Hôpital Huriez, Lille, France

Background: The use of novel therapeutic agents has significantly improved both progression-free survival and overall survival over recent years in multiple myeloma (MM) patients. With increasing extension of patients' life expectancy, elements related to health-related quality of life (HRQoL) gain in importance. One aspect not considered so far in the literature on HRQoL in MM is the level of concordance between patient- and physician- reported outcomes.
Aims: To compare MM patients' assessment and physicians' judgment of perceived patients' HRQoL.
Methods: A multicenter, observational study was conducted in 31 sites in Italy, Germany, France, UK, Ireland and Belgium in relapsed/refractory multiple myeloma (RRMM) patients starting 2nd or 3rd line treatment. Patients were asked to complete three EORTC questionnaires: 1) Quality-of-Life Core Questionnaire (QLQ-C30), including 15 domains (*Global Health Status/QOL, Physical Functioning, Role Functioning, Emotional Functioning, Cognitive Functioning, Social Functioning, Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea* and *Financial Difficulties*); 2) The EORTC QLQ-Multiple Myeloma (QLQ-MY20), including four domains (*Disease Symptoms, Side-Effects of Treatment, Body Image* and *Future Perspective*); and 3) The EORTC QLQ-Chemotherapy-Induced Peripheral Neuropathy (QLQ-CIPN20), including three domains (*Sensory scale, Motor scale* and *Autonomic scale*). All EORTC questionnaires were adjusted according to robust international standards to be completed by physicians. Paired t-tests and Intra-Class Correlation Coefficients (ICC) were calculated to compare patient- and physician-reported scores at baseline. Discordant scores were defined as those with an ICC<0.40.

Table 1. Results of analyses of comparison of patients' and physicians' perceptions of patients' HRQoL at baseline.

EORTC questionnaires	Domains	Mean score (patient – physician)	p-value*	ICC
QLQ-C30	Global Health Status/QOL	-0.2	0.9247	0.5016
	Physical Functioning	-0.5	0.7508	0.7713
	Role Functioning	-1.3	0.5627	0.6257
	Emotional Functioning	1.4	0.5161	0.4304
	Cognitive Functioning	-1.9	0.3547	0.4006
	Social Functioning	6.3	0.0153	0.4503
	Fatigue	0.8	0.6967	0.5100
	Nausea and Vomiting	2.2	0.1027	0.3430
	Pain	2.0	0.3699	0.6277
	Dyspnea	5.1	0.0257	0.3465
	Insomnia	6.5	0.0297	0.3548
	Appetite loss	5.3	0.0148	0.4590
	Constipation	12.7	**<.0001**	0.3735
	Diarrhea	6.3	**<.0001**	0.2482
	Financial Difficulties	2.7	0.2019	0.3585
QLQ-MY20	Disease Symptoms	3.6	0.0451	0.4773
	Side Effects of Treatment	9.7	**<.0001**	0.2769
	Body Image	-0.0	1.000	0.2574
	Future Perspective	4.1	0.0773	0.4754
QLQ-CIPN20	Sensory scale	5.3	**0.0002**	0.4760
	Motor scale	5.3	**<.0001**	0.4975
	Motor scale: using the pedals	-4.1	0.1291	0.3395
	Autonomic scale	6.5	**<.0001**	0.3753
	Autonomic scale: getting or maintain an erection	14.1	0.0232	0.3853

*From paired t-test;
In grey, ICC <0.40 considered as discordant scores

Results: As of Dec 2012, 155 patients (mean age=69; 52.0% male) were enrolled in the study and included in this interim analysis, with an average time since diagnosis of 3 years. At baseline, 14.2% of patients were ECOG ≥2 in terms of their performance status. A total of 87.7% of patients started 2nd line treatment and 12.3% of patients started 3rd line treatment. The majority of EORTC questionnaires were completed at baseline by physicians (n=152; 98.1%) and patients (n=151; 97.4%). The mean difference between patient- and physician-reported scores was highly statistically significant (P-value <.001) for *Constipation, Diarrhea, Autonomic scale, Motor scale, Sensory scale* and *Side-Effects of Treatment* (Table 1) and mostly also showed a low ICC (<0.40, showing high discordance). Additionally, low ICC (high discordance) was observed in the following scores: *Nausea and Vomiting, Dyspnea, Insomnia, Financial Difficulties, Body Image, "Motor scale: using the pedals"* and *"Autonomic scale: getting or maintaining an erection"*. In comparison, for *Global Health Status/QoL* and all five functioning scales, the mean differences between patients' and physicians' scores were not statistically significant and showed a high ICC (>0.40), reflecting lower discordance.
Summary and Conclusions: The level of concordance between patients' and physicians' ratings of functioning domains and QoL was high. However, when rating symptom and side effect domains, physicians underestimated the burden of MM disease and possible effects of prior treatment as compared to the individual patient's experience. A greater awareness especially of an MM patient's symptom level may help to better target improvements in symptom-related QoL.

P1081

PROFILING PATIENTS WITH HIGH-RISK MYELODYSPLASTIC SYNDROMES WHO PREFER TO RECEIVE SURVIVAL PROGNOSTIC INFORMATION. FINAL RESULTS FROM A LARGE INTERNATIONAL PROSPECTIVE COHORT OBSERVATIONAL STUDY

Background: Physicians often face challenges in prognostic discussions with their patients at the time of diagnosis. This might be critical in patients with high-risk myelodysplastic syndromes (MDS), given the often poor prognoses of these patients.
Aims: The main objective was to investigate preferences for prognostic information on survival at the time of diagnosis and to identify clinical and socio-demographic factors associated with this preference. Also, we explored whether preference for information was associated with functional status and symptom burden so as reported by patients themselves.
Methods: This was an international prospective cohort observational study.

Newly diagnosed IPSS intermediate-2 and high risk patients were consecutively enrolled in 37 centers from nine countries in Europe, Asia and the USA. Patients were invited to participate during one of the first consultations, after confirmed diagnosis of MDS. Physicians completed a survey including a question on whether patients explicitly requested information on life expectancy (yes *vs.* no). Patients also completed the European Organization for Research and treatment of Cancer, Quality of Life Questionnaire-Core30 (EORTC QLQ-C30). The EORTC QLQ-C30 is a psychometrically robust quality of life (QoL) cancer measure assessing both symptoms and functional aspects. The following baseline socio-demographic and clinical variables were investigated for their association with desire for prognostic information: age, gender, education, living arrangements, ECOG performance status (0 *vs.* ≥1), IPSS risk category (int.2 *vs.* high-risk), comorbidity (0 *vs.* ≥1) and hemoglobin level. Univariate and multivariate logistic regression analyses were performed to investigate possible predictors for request of information, amongst socio-demographic and clinical variables (α=.05). Also, we explored possible associations between desire for information and EORTC QLQ-C30 scales by Chi-square and Wilcoxon-Mann-Whitney test as appropriate.

Results: Overall, 280 patients (37% female and 63% male) were enrolled between November 2008 and August 2012. Mean age of patients was 70 years (range: 32-89). Seventy-four percent were diagnosed with IPSS intermediate-2 while 26% with high-risk IPSS. Sixty-one percent of patients explicitly requested information about expected survival to their physicians and 39% did not. In univariate logistic regression analysis, with request for prognostic information (yes *vs.* no) as dependent variable, a younger age (P=.002) and having no comorbidity (P<.001) were the only variables significantly associated with desire for prognostic information. These two factors were also confirmed in multivariate logistic regression analysis. Mean age of patients requesting information was 68 (range 32-88 years) while mean age of patients who did not requested information was 73 (range 47-88 years). When we explored desire for prognostic information by patients' self reported functional status and symptom burden, we found that those who wished to receive information where generally doing better. This was mainly evident for fatigue (P=.007), physical functioning (P=.009) and role functioning (P<.001) so as measured by the EORTC QLQ-C30.

Summary and Conclusions: This data might be of help to physicians in clinical practice by suggesting that younger patients and those who are generally in better health conditions are more likely to be interested in receiving prognostic information on survival.

P1082

CROSS-CULTURAL DEVELOPMENT OF AN EORTC QUESTIONNAIRE FOR ASSESSING QUALITY OF LIFE IN CHRONIC MYELOID LEUKEMIA PATIENTS: THE EORTC QLQ-CML24

F Efficace[1,*], G Rosti[2], M Breccia[3], S Saussele[4], G Abel[5], G Caocci[6], F Guilhot[7], A Naeem[8], F Cottone[1], S Oerlemans[9], F Castagnetti[2], F Bombaci[10], G Sharf[11], L Noens[12], S Pallua[13], F Mandelli[1], M Baccarani[2]

[1]Italian Group for Adult Hematologic Diseases (GIMEMA), Data Center and Health Outcomes Research Unit, Rome, [2]University of Bologna, S. Orsola-Malpighi Hospital, Department of Hematology-Oncology, Bologna, [3]University of Rome "Sapienza", Azienda Policlinico Umberto I, Rome, Italy, [4]Universität Heidelberg, Medizinische Fakultät Mannheim, Mannheim, Germany, [5]Division of Population Sciences, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States, [6]University of Cagliari, Department of Internistic Medical Sciences, Cagliari, Italy, [7]University Hospital of Poitiers, Inserm CIC 0802, Poitiers, France, [8]Baghdad Teaching Hospital, Department of Hematology, Baghdad, Iraq, [9]Comprehensive Cancer Centre South, Eindhoven, Netherlands, [10]Gruppo AIL Pazienti LMC (Italian member of CML Advocates Network), Turin, Italy, [11]CML Advocates Network, Tel-Aviv, Israel, [12]Ghent University Hospital, Department of Hematology, Ghent, Belgium, [13]Innsbruck Medical University, Department for Psychiatry and Psychotherapy, Innsbruck, Austria

Background: Quality of Life (QoL) is now an important treatment otucome for chronic myeloid leukemia (CML) patients. However, there is lack of internationally validated QoL measures for this population.

Aims: To present final results of the cross cultural development of an European Organization for Research and Treatment of Cancer (EORTC)-QoL questionnaire for patients with CML (*i.e.* EORTC QLQ-CML24).

Methods: The process followed a predefined and systematic stepwise iterative process as defined by the EORTC guidelines for Questionnaire development. The CML Advocates Network was involved providing logistic and administrative support and in key steps of the development process and participated in the Investigators' meetings. The process was divided into 3 phases: 1) generation of relevant QoL issues, 2) operationalization of the QoL issues into a set of items, 3) pre-testing the questionnaire for relevance and acceptability. Descriptive statistics and psychometric analyses were performed. Internal consistency was assessed using Cronbach's alpha coefficient. The construct validity was also examined by correlation with the core questionnaire (EORTC QLQ-C30) using Pearson's product moment correlation coefficients. Clinical validity was assessed with known-group comparisons to assess the extent to which questionnaire scores were able to discriminate between subgroups of patients known to differ in terms of clinical status (*i.e.*, Karnofsky performance status and complete cytogenetic response –CCyR- to therapy). Group differences were assessed for significance using the Wilcoxon rank sum test.

Results: A preliminary list of 74 issues was identified from the literature and was the basis to conduct semi-structured interviews with 137 patients recruited in seven hospitals from five countries. Forty-three percent of patients were in treatment with first line imatinib and 46% were in second line treatment with second generation Tyrosine Kinase Inhibitors (TKI). A preliminary version of the questionnaire with 30 items was then tested in a larger international sample. The provisional questionnaire was tested on 312 patients at 14 centres in 10 countries (including Europe, Asia and the USA) by also conducting cognitive debriefing interviews. The resulting questionnaire consisted of 24 items assessing the following aspects: *symptom burden, impact on daily life, impact on worry/mood, body image problems and satisfaction with care an information and satisfaction with social life.* Cronbach's alpha coefficients were 0.83, 0.74, 0.73 and 0.83, for symptom burden, impact on worry/mood, impact on daily life, and satisfaction with care and information scales, respectively. Clinical validity was confirmed as comparisons between responders and non-responders (*i.e.*, reaching at least a CCyR) showed statistically significant better QoL outcomes (P<0.01) for patients responding to therapy on four out of six scales. Construct validity analyses confirmed that all scales of the QLQ-CML24 correlated in the expected directions with scales of the EORTC QLQ-C30. To illustrate, the symptom burden and impact on daily life scales from the module and the fatigue scale from the core questionnaire were highly correlated (0.64 and 0.65, respectively).

Summary and Conclusions: The use of our questionnaire could help better inform physicians of a true intolerance to a given therapy by providing the unique patient's perception of the burden of treatment over time. Also, its implementation in comparative effectiveness studies will provide invaluable information to help guide clinical decision-making.

P1083

QUALITY OF LIFE AND RETURN TO NORMAL LIVING PATTERNS TWENTY YEARS AFTER TRANSPLANTATION FOR THALASSEMIA

G Caocci[1,2,*], F Efficace[3], A Vacca[2], E Piras[2], M Sanna[1], G Spanu[1], R Littera[4], G Lucarelli[5], G Nasa[1,2]

[1]Hematology Unit, Department of Medical Sciences "Mario Aresu", University of Cagliari, [2]Bone Marrow Transplant Center, R. Binaghi Hospital - ASL8, Cagliari, [3]Health Outcome Research Unit, Italian Group for Adult Hematologic Diseases (GIMEMA) Data Center, Rome, [4]Regional Transplant Center, R. Binaghi - ASL8, Cagliari, [5]IME Foundation, Mediterranean Institute of Hematology, University of Tor Vergata, Rome, Italy

Background: More than 30 years have passed since the first successful hematopoietic stem cell transplantation (HSCT) was performed for thalassemia. Since that time, HSCT has become a widely used therapeutical approach for the treatment of this disorder.

Aims: For the first time, we investigated health related quality of life (HRQoL) and return to normal living patterns in a large cohort of thalassemia patients who underwent HSCT more than 20 years ago.

Methods: Socio-demographic and clinical data were collected from surviving Sardinian ex-thalassemic patients transplanted in the 1980s and 90s in the Centers of Pesaro and Cagliari. Patients were sent Short Form 36 (SF-36) and Functional Assessment of Cancer Therapy–Bone Marrow Transplant (FACT-BMT) health survey questionnaires. HRQoL outcomes were compared to those of matched peers from the Italian SF-36 normative database. Separate comparisons were performed to account for age at HSCT (≤15 and >15 years) and the presence or absence of graft-*versus*-host disease (GVHD).

Results: One hundred and nine out of 130 thalassemia-free surviving patients responded to the survey (83.8%; median age 34 years, range 21-48). Median age at HSCT was 12 years (range 1-36) with a median follow up of 22.8 years (range 11.7- 30.3). Acute and chronic GVHD were registered in 35.8% and 18.3% of the patients, respectively. About 75% reported at least one disorder at the time of the survey, with a higher incidence for liver, metabolic or endocrine alterations. Two patients underwent solid organ transplantation (kidney, liver) and 4 reported a secondary malignancy. Seven pregnancies were reported by 6 of the 44 female patients (13.6%); 16 pregnancies regarded 11 partners of the 65 male patients (16.9%). Mean scores as well as adjusted mean differences for SF-36 scores only showed clinically meaningful differences between patients and controls for the General Health scale (-8.9; 95% CI, -15.0 to -2.7, P=0.005); no differences were observed for the 4 physical and 5 mental domains of SF-36. Comparisons of patients, with or without acute/chronic GVHD, to the respective population norms showed significantly worse scores for GVHD patients (Figure 1). The HRQoL profile of patients without GVHD was similar to that of the control population with even better scores for Mental Health and Mental Component Summary (5.3; 95% CI, 1.6 to 9; P=0.003). Worse and clinically significant scores for general health (-12.8; 95% CI, -23.1 to -2.6; P=0.015) were also observed in the group of patients transplanted above 15 years (adults). Most patients (74.4%) had either resumed or completed their studies after HSCT, with results comparable to the healthy population. Surprisingly, employment status was considerably higher

among ex-thalassemia patients (77.1%) in comparison with a healthy Sardinian control population aged 20-45 years (59.9%).

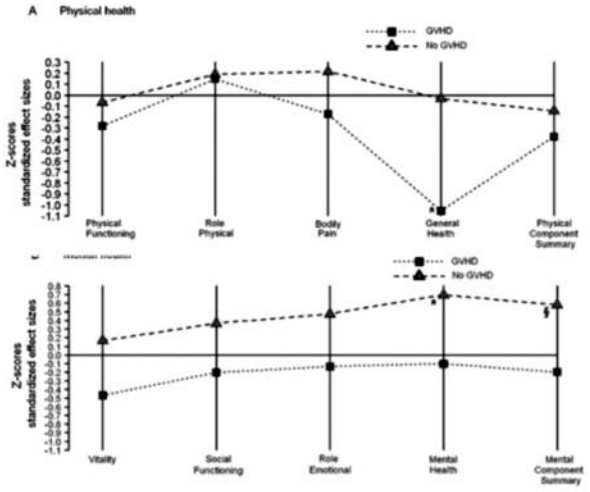

Figure 1.

Summary and Conclusions: Our data provide robust evidence that in the long term ex-thalassemia patients achieve good HRQoL after HSCT with return to normal life style. Nonetheless, GVHD remains an impairing factor and so, whenever possible, HSCT should be performed in pediatric age.

P1084

HOW ACCURATE ARE PHYSICIANS IN ESTIMATING SYMPTOM SEVERITY AND HEALTH STATUS OF THEIR CHRONIC MYELOID LEUKEMIA PATIENTS?

F Efficace[1,*], G Rosti[2], F Cottone[1], M Vignetti[1], F Mandelli[1], M Baccarani[2]
[1]Italian Group for Adult Hematologic Diseases (GIMEMA), Data Center and Health Outcomes Research Unit, Rome, [2]University of Bologna, S. Orsola-Malpighi Hospital, Department of Hematology-Oncology, Bologna, Italy

Background: Several studies conducted in patients with solid tumors have shown that patients more frequently report worse symptom severity than physicians. On this ground, we hypothesized this would hold true in the chronic myeloid leukemia (CML) clinical setting.
Aims: The main objective of this study was to compare the reporting of health status and symptom severity, for a set of core symptoms related to first line imatinib therapy, between patients and their treating physicians. A secondary objective was to investigate whether either physician or patient-reported symptoms best reflected patient's overall health status.
Methods: Analysis was performed on 422 CML patients consecutively enrolled in a large survivorship project. All respective paired physicians (N=29) completed a paired questionnaire and the following analyses are thus based on 422 patient-physician paired questionnaires. The questionnaire administered to patients and physicians consisted of a nine core symptoms checklist developed for patients treated with imatinib. In addition, to these symptoms a question on health status from the well validated Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36) was also included. Severity of the following symptoms was investigated: abdominal discomfort, diarrhea, edema, fatigue headache, muscle cramps, musculoskeletal pain, nausea and skin problems. Severity was rated on a four-Likert scale (*i.e.*, not at all, a little, quite a bit and very much). The self-rated question on health status was formulated as follow: "in general you would say your health is" with the following response options: excellent, very good, good, fair, poor. To avoid any risk of convergence in symptom ratings, the study was designed to avoid that patients and their treating physicians knew of each other's answer.
Results: Agreement on symptom ratings ranged between 34% to 66% respectively for muscular cramps and nausea. For all symptoms, patients graded higher severity more often than their physicians. The top three symptoms most frequently underestimated by physicians were respectively fatigue (51%), muscular cramps (48%) and musculoskeletal pain (42%). The majority of discrepancies were within one point, however, for edema, skin problems, musculoskeletal pain, muscular cramps and fatigue, differences of 2 points were also noted in at least 10% of evaluations. Agreement on overall health status rating was observed in 26% of pairs. However, health status was overestimated by physicians in 66% of paired evaluations. When physicians underestimated symptom severity, this was most frequently evident in the lower scales intensities. In the majority of cases, physicians rated the symptom as not being present while patients rated the same symptom as of mild intensity (*i.e.*, a little). Investigation on whether either patient-reported or physician-reported symptoms better reflected overall health status, revealed that patient reports had higher levels of concordance compared to physician reports. Fatigue was the most correlated symptom with overall health status for both patients and physicians. However, the level of concordance was higher for patient reports (Kendall=0.43; 95% C.I.=0.354 to 0.500), compared to physician reports (Kendall=0.26; 95% C.I.=0.186 to 0.348).
Summary and Conclusions: Physicians often underestimate symptom severity and overestimate health status of their patients. This miss-mach might have major implications in clinical management. Physicians' failure to note the presence of mild symptoms, for example, could lead them to underestimate the risk that their patients do not fully adhere to treatment schedule to minimize burden of side effects.

P1085

PATTERNS OF FATIGUE IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA: A MULTICENTER OBSERVATIONAL STUDY

Eugenio Hospital, Rome, [13]Department of Oncology, Hematology and Respiratory Diseases, Section of Hematology, University of Modena and Reggio Emilia, Azienda Ospedaliero-Universitaria Policlinico, Modena, [14]Hematology Unit, "Di Venere" Hospital, Bari, [15]Bone Marrow Transplant Center, R. Binaghi Hospital, Cagliari, [16]Division of Hematology, University of Messina, Messina, [17]Unit of Transfusion and Hematology, Treviglio Hospital, Treviglio, [18]University of Rome "Sapienza", Department of Cellular Biotechnologies and Hematology, Rome, Italy

Background: Health-related quality of life (HRQoL) and fatigue are major concerns for patients with primary immune thrombocytopenia (pITP) due to the symptoms associated with the disease and its treatment. However, while these are critical issues, there is paucity of evidence-based data in this area.
Aims: The main objective of this study was to identify specific patterns of fatigue in pITP patients by disease phase (i.,e, chronic, persistent and newly diagnosed). A secondary objective was to investigate socio-demographic and clinical factors that could be associated with fatigue severity in this pITP population overall.
Methods: Data were gathered through an ongoing multicenter cross-sectional observational study. The Multidimensional Fatigue Inventory (MFI) was used to assess patient-self reported fatigue. This is a psychometrically robust measure consisting of 20-items. This questionnaire covers the following five dimensions (i.e, scales): General Fatigue (GF), Physical Fatigue (PF), Mental Fatigue (MF), Reduced Motivation (RM) and Reduced Activity (RA). Each scale includes four items with five-point Likert scales. GF was regarded as the primary outcome of our analysis as this was designed to encompass both physical and psychological aspects of fatigue. PF concerns physical sensations related to fatigue. MF pertains to cognitive functioning, including difficulty concentrating. RA refers to the influence of physical and psychological factors on the level of activity. RM relates to lack of motivation for starting any activity. Scores on each subscale range from 4 to 20, with higher scores indicating greater fatigue. Socio-demographic, clinical variables examined for their association with fatigue were: age, gender, education level, comorbidity, time since diagnosis, as well as hemoglobin and platelets counts at diagnosis. Descriptive statistics and univariate and multivariate linear regression analyses were used.
Results: To date 342 pITP patients are enrolled in this study and current analysis is based on 257 patients with full data available for analysis. Of these, there were 67%, 16% and 17%, respectively diagnosed with chronic, persistent and newly diagnosed pITP. At study participation, mean age of patients was *52 years* (*64% female and 36% male*). At least one comorbidity was present in *53%* of patients. The median time from initial diagnosis to study entry was *0.6, 8 and 64 months*, respectively for newly diagnosed, persistent and chronic patients. The three groups were well balanced (*i.e.*, no statistically significant differences) for the following variables: age, gender, education level and comorbidity. Newly diagnosed pITP patients reported lower fatigue severity compared to persistent and chronic patients. This finding was consistent across all scales

of the MFI (see Figure 1), however this was statistically significant only for GF (P=0.014). Further investigation revealed that this difference in fatigue levels between pITP groups was independent of time since diagnosis. In multivariate analysis, investigating factors independently associated with GF, gender was the only statistically significant factor. Female patients reported greater levels of fatigue (P=0.009).

Fatigue dimensions	Values	Newly diagnosed	Persistent	Chronic	Total	P
General Fatigue	Mean (SD)	10.20 (4.16)	12.38 (4.67)	12.20 (4.35)	11.88 (4.42)	0.014
	median	11	12	12.5	12	
	n	45	40	172	257	
Physical Fatigue	Mean (SD)	9.80 (4.16)	11.33 (5.03)	10.73 (4.30)	10.66 (4.40)	0.307
	median	9	11.5	11	11	
	n	45	40	172	257	
Reduced Activity	Mean (SD)	9.22 (3.60)	10.03 (4.67)	9.74 (4.05)	9.70 (4.07)	0.694
	median	9	10	10	10	
	n	45	40	172	257	
Reduced Motivation	Mean (SD)	8.11 (3.16)	9.48 (4.22)	8.80 (3.59)	8.78 (3.63)	0.267
	median	7	9	8.5	8	
	n	45	40	172	257	
Mental Fatigue	Mean (SD)	8.44 (3.37)	10.05 (4.84)	9.59 (4.27)	9.46 (4.24)	0.251
	median	8	9.5	9	9	
	n	45	40	172	257	

Legend: the higher the score the higher fatigue severity (score range between 4 to 20); SD. Standard deviation.

Figure 1. Fatigue severity by pITP groups.

Summary and Conclusions: Fatigue severity is higher in patients with persistent and chronic pITP patients compared to that reported by newly diagnosed patients. Also, female patients are at greater risk of experiencing higher fatigue levels. Current results begs for more research and can potentially help guide the development of tailor-based supportive care interventions.

P1086

PAIN AND EMOTIONAL DISTRESS IN HEMATOLOGIC PATIENTS THROUGHOUT ALL PHASES OF DISEASE: RESULTS FROM A MULTIDISCIPLINARY RESEARCH TEAM IN MODENA UNIVERSITY HOSPITAL

P Alfieri[1,*], E Bandieri[2], A Berti[1], C Bulgarelli[1], F Rizzello[1], V Favale[1], F Forghieri[1], L Galli[1], M Morselli[1], L Potenza[1], R Zanin[1], F Artioli[2], F Narni[1], M Luppi[1]

[1]UO-C e Cattedra di Ematologia, Azienda Ospedaliero-Universitaria Policlinico di Modena, [2]Unità di Cure Palliative, UO Medicina Oncologica, Ospedali di Carpi e Mirandola, Azienda Sanitaria Locale di Modena, Modena, Italy

Background: According to some outdated reports, physical pain has been considered for many years a rare feature in the majority of blood malignancies, especially in acute leukemias, with the exception of advanced and terminal phases of disease. Unlike myeloma and lymphoma, there are few published data regarding the frequency of pain in patients with leukemia. Based on the modern concept of total cancer pain and on the importance of patient-reported outcomes, routine symptom assessment for hematologic patients should include, together with pain, even emotional distress, expressed in terms of anxiety and depression.
Aims: In order to investigate prevalence and clinical relevance of pain and emotional distress in patients with acute myeloid (AML) and lymphoid (ALL) leukemia referred to our center, a multidisciplinary team consisting of nurses, physicians and psychologists has adopted two validated tools in the daily clinical practice: NRS (Numeral Rating Scale) and HADS (Hospital Anxiety and Depression Scale). ESAS (Edmonton Symptom Assessment System) has been compared with HADS with the aim to evaluate its diagnostic accuracy.
Methods: NRS, HADS and ESAS scales were administered to newly diagnosed AML and ALL patients at diagnosis (T0), during the neutropenic phase (T15) and at discharge (T30), throughout hospital admissions and different phases of treatment. According to NRS scale pain intensity was classified as absent (0), mild (1-3), moderate (4-6) or severe (7-10). HADS is 14-item scale given by 7 questions related to anxiety and 7 to depression, determining a score from 0 to 21. ESAS is a multiple-item visual analogue scale from 0 to 10. Anxiety and depression were considered positive with HADS 8 and ESAS 2 or more. Sensitivity and specificity tests were also performed. Results were mainly focused on induction phase, bone marrow transplation (BMT) and home care.
Results: From June 2007 to December 2011 137 patients with AML and ALL were enrolled in the study (AML=109, ALL=28, M=85, F=52, median age=60). Another cohort of 31 patients referred to the home care program and affected by several blood disorders (NHL=8, MM=6, AML=5, MF=3, ITP=2, MDS=2, AA=1, ALL=1, CLL=1, CML=1, ET=1) was evaluated in parallel (M=18, F=13, median age=79) on monthly basis. 842 questionnaires were collected in the AML-ALL group. At diagnosis pain was reported in 46.2% of cases (mild=30.3%, moderate-severe=15.9%). The highest prevalence and intensity of pain was observed in post-BMT neutropenic phase associated to mucositis (overall pain=61.5%, severe=30.8%). At diagnosis anxiety scores were positive in 33.6% for HADS and 51.1% for ESAS, while depression was present in 22.4% and 42.4% of cases, respectively. A higher prevalence of anxiety and depression was documented at T15 both in induction and post-BMT phases. Considering all HADS questionnaires anxiety and depression were positive in 26.7% and 25.2% of cases, respectively (10% with HADS from 11 upward, accounting for more severe symptoms), while an ESAS score of 2 or more was reported in 36.5% (anxiety) and 31.9% (depression) of cases. In the home care group pain was reported in 78 of all 157 questionnaires (overall pain=49.7%, mild=26.1%, moderate-severe=23.6%). Anxiety and depression were positive in 31.2% and 45.2% of HADS and in 45.9% and 49% of ESAS questionnaires, respectively. Overall test accuracy of ESAS (score of 2 or more) was 77.5% for anxiety and 76.4% for depression.
Summary and Conclusions: Pain, anxiety and depression are common symptoms in a significant proportion of acute leukemia patients, impacting quality of life, clinical decisions and outcomes. Compared with HADS, ESAS showed adequate diagnostic accuracy in screening for anxiety and depression, and could be an excellent candidate for large-scale and routine assessment of physical pain, emotional distress and other symptoms, at diagnosis and during the active phase of disease. Some issues remain open, such as the identification of appropriate cut-offs for ESAS and the development of strategies to implement a sustainable integration of early interventions of palliative care in hematology units and to prevent/reduce the burden of physical symptoms and emotional distress.

P1087

EFFICACY OF FENTANYL IN COMPARISON TO KETAMINE IN ANALGESIC EFFECT FOR HEMATOLOGY /ONCOLOGY PROCEDURES IN CHILDREN. A RANDOMIZED, DOUBLE-BLINDED, CROSSOVER, PLACEBO-CONTROLLED TRIAL

C Traivaree[1,*], C Monsereenusorn[1], P Rujkijyanont[1], P Thaoyot[1], R Lumkul[1]
[1]Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background: Children often require relief of pain and anxiety when undergoing painful procedures.
Aims: The purpose of this study was to determine the differences in the comparison between Fentanyl and Ketamine used in cancer-diagnosed children undergoing painful procedures. These include the degree in satisfaction, painfulness and nausea and vomiting.
Methods: The study was conducted with fifty-five children undergoing painful procedures (intrathecal chemotherapy and/or bone marrow aspiration/biopsy) at department of pediatrics, Phramongkutklao Hospital. The informed consents and assents were obtained. Patients were randomly assigned in a double-blinded fashion to receive either intravenous Fentanyl or Ketamine at 1 mcg/kg/dose and 1 mg/kg/dose, respectively. Each patient acted as his or her own control, and each patient was studied at two time points. The result in effectiveness of the drug was measured using 3 parameters. The first parameter was satisfaction score ranging from 0 to 10. Secondly perception of procedural pain using FLACC scale, Wong-Baker FACES Pain Rating Scale and Visual Analog Scale in patient age 3 month to 4 years, 4 to 8 years and more than 8 years old, respectively. Finally, the last studied parameter was nausea score and the frequency of vomiting.
Results: Period effect, sequence effect and carry over effect were not demonstrated. The satisfaction in patient receiving Fentanyl was significantly greater than Ketamine (P=0.007) in the age group more than 8 years old (P=0.005). In addition, both painful and nausea/ vomiting were significantly less in the patient receiving Fentanyl (P=0.002 and P<0.001, respectively**).** No child required admission to hospital and there were no serious complications.
Summary and Conclusions: This study demonstrated that intravenous Fentanyl had a superior efficacy in satisfaction, decreased painful and nausea/ vomiting with no significance side-effects over Ketamine. Fentanyl may also be recommended as a reasonable option before undergoing oncology procedures (intrathecal chemotherapy and/or bone marrow aspiration/biopsy) in children with cancer.

P1088

IS SCREENING FOR MALNUTRITION USEFUL IN OLDER PATIENTS WITH AGGRESSIVE HAEMATOLOGICAL MALIGNANCIES?

A Velghe[1,*], L Noens[2], R Demuynck[1], M Petrovic[1]
[1]Geriatrics, [2]Haematology, Ghent University Hospital, Ghent, Belgium

Background: Treating older patients with haematological malignancies is a challenging task. The age- and gender-specific incidence rates increase dramatically over the age of 70 for Acute Myeloid Leukaemia (AML), Myelodysplastic Syndromes (MDS), Non-Hodgkin's Lymphoma (NHL) and Multiple Myeloma (MM). Malnutrition is a common feature in many types of cancer and is responsible not only for a poor quality of life and poor response to chemotherapy, but also for a

shorter survival time. Patients with haematological malignancies have specific challenges associated with eating and nutrition because of the intensive and aggressive treatments they endure. However, studies focusing on this aspect in older haematological patients are very scarce. Comprehensive geriatric assessment (CGA) is a multidisciplinary systematic approach using validated instruments and aiming at assessing nutritional status, physical functioning, co-morbidity, cognition, mood and polypharmacy in older patients. CGA is strongly recommended as part of the evaluation of older patients with cancer.
Aims: To establish the usefulness of screening for malnutrition in older patients considered for intensive chemotherapy against an aggressive haematological malignancy.
Methods: The patients, 70 years or older, with a new diagnosis of AML, intermediate or high grade MDS, MM or high grade NHL, referred to the haematology department of a tertiary hospital, were enrolled in the current study after providing a written consent. Before the start of therapy, a geriatric assessment measuring nutritional status, physical functioning, hand grip strength, co-morbidity, cognition, mood, quality of life, polypharmacy and falls was completed for each patient. CGA was repeated 2 months after the start of therapy. We used the Mini Nutritional Assessment Short Form, as part of the CGA, to screen for malnutrition. The study was approved by the local Ethical Committee.
Results: Fifty patients were included. Median age was 76 years (range 70-87). Patient characteristics are summarized in Table 1. Eighty four percent of the patients (n=42) had a BMI ≥23. Remarkably, 16% of the patients (n=8), assessed by MNA SF, were malnourished and 66% of the patients (n=33) were at risk for malnutrition. Of the malnourished patients, 50% (n=4) had a BMI>23. Apart from their haematological diagnosis, recent weight loss and declined food intake were the most important MNA SF parameters predicting (risk of) malnutrition. For 12 patients (29%), (risk of) malnutrition was the only impairment detected by CGA on initial evaluation. On the second evaluation, 2 months later, 6 more patients scored positive on MNA SF (1 malnourished, 5 at risk).

Table 1.

		No. of patients	%
Multiple myeloma		5	10
Non-Hodgkin lymphoma		19	38
Myelodysplastic syndrome		9	18
Acute myeloid leukemia		17	34
Female		25	50
G8 ≤ 14		39	78
Dependent in activities of daily living (ADL)		12	24
Dependent in instrumental ADL (iADL)		19	38
ECOG performance score	0 – 1	38	76
	≥ 2	12	24
4-item Geriatric Depression Scale ≥ 2		15	30
MMSE	< 24	2	4
	missing	5	10
At least 1 fall in the previous year		16	32
> 3 medications		33	66

Summary and Conclusions: The prevalence of malnutrition or risk for malnutrition in older patients with severe (aggressive) haematological malignancies is high, even before the start of treatment. Intensive treatment will further increase this risk. Therefore, instead of screening for malnutrition, we recommend nutritional assessment by a dietician with individualised dietary advice and follow up during treatment to become an integral part of the treatment plan in this group of older patients.

P1089

IMPAIRED HEALTH-RELATED QUALITY OF LIFE IN ACUTE MYELOID LEUKEMIA SURVIVORS

A Leunis[1,*], W Redekop[1], C Uyl-de Groot[1], B Löwenberg[2]
[1]institute for Medical Technology Assessment, Erasmus University Rotterdam, [2]Department of hematology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands

Background: Prognosis of acute myeloid leukemia (AML) has progressively improved in the last decades. As a consequence of the increasing number of AML survivors it is becoming more important to assess the impact of AML and its treatments on health-related quality of life (HRQOL).
Aims: The aim of this study was to assess the impact of AML on HRQOL by comparing the HRQOL of AML survivors with the HRQOL in the general population. We also examined which patient characteristics were associated with HRQOL in AML survivors.
Methods: HRQOL was measured with the EQ-5D-5L and the EORTC QLQ-C30. Questionnaires were sent to 103 patients diagnosed with AML between 1999 and 2011 at a single academic hospital and still alive in 2012. The HRQOL in the general population was derived from previously published studies. T-tests were used to test for differences in mean scores on the QLQ-C30 scales and the EQ-VAS between AML survivors and the general population. Multivariate linear regression was used to identify factors associated with HRQOL. The study was approved by a local medical ethics committee.
Results: Questionnaires were returned by 92 of the 103 patients (89%). AML survivors had significantly lower scores on the functioning scales of the QLQ-C30, reported significantly more fatigue, pain, dyspnea and appetite loss and had significantly lower EQ-VAS scores than the general population. Impaired HRQOL in AML survivors was mainly found in survivors aged <65 years without a paid job. Other factors associated with a poor HRQOL were allogeneic hematopoietic stem cell transplantation and absence of social support.
Summary and Conclusions: The HRQOL in AML survivors can return to levels comparable with the HRQOL in the general population. However, a subgroup of AML survivors continues to experience symptoms and functioning problems which complicate the return to work. HRQOL in these patients can be improved by adequately treating and preventing fatigue, pain, dyspnea and appetite loss.

P1090

VALIDATION OF THE G8 IN OLDER HAEMATOLOGICAL PATIENTS

A Velghe[1,*], M Petrovic[1], S Debuyser[1], R Demuynck[1], L Noens[2]
[1]Geriatrics, [2]Haematology, Ghent University Hospital, Ghent, Belgium

Background: Given the increased age- and gender-specific incidence rates for Acute Myelogenous Leukaemia (AML), Myelodysplastic Syndromes (MDS), Non-Hodgkin's Lymphoma (NHL) and Multiple Myeloma (MM) over the age of 70, haematologists are more and more confronted with necessity of decision making in older patients. However, the group of older patients is very heterogeneous with more comorbidities, more often a poor performance status at diagnosis and less tolerance to intensive therapy.
Comprehensive geriatric assessment (CGA) is a multidisciplinary systematic approach using validated instruments and aiming at assessing nutritional status, physical functioning, co-morbidity, cognition, mood and polypharmacy in older patients. CGA is strongly recommended as part of the evaluation of older patients with cancer to identify frail patients for whom a tailored treatment might be imperative. As CGA can be very time-consuming, a screening tool is necessary to select those patients in need of a CGA. In the literature the G8 was validated as a screening tool for older patients in oncology.
Aims: In this study, we tested the performance of the G8 as a screening tool in identifying older haematological patients who would benefit from CGA.
Methods: Patients, 70 years or older, with a new diagnosis of AML, intermediate or high grade MDS, MM or high grade NHL, referred to the haematology department of a tertiary hospital, were enrolled in the current study after providing a written consent. For each patient both the G8 and the geriatric assessment were completed before therapy was started. For the CGA validated scales were used, measuring nutritional status, physical functioning, hand grip strength, co-morbidity, cognition, mood, quality of life, polypharmacy and falls. Patients were considered frail when scoring abnormal for at least one CGA domain. ROC-curve analysis was used to determine inherent validity of G8. The study was approved by the local Ethical Committee.
Results: Fifty patients were included. Median age was 76 years (range 70-87). The AUC-value of 0.949 (95% CI 0.889–1.00) indicates that the G8 tool has a high diagnostic accuracy to identify disabilities. At the cut-off score proposed in the literature (G8 ≤14), a sensitivity of 88.6% and a specificity of 100% was obtained. Overall, one or more impairments were detected by CGA in 88% of patients with a majority of patients scoring positive on (risk for) malnutrition. A comparison of our results with the literature is summarized in Table 1.

Table 1.

	Screening tool	CGA	Sensitivity (%)	Specificity (%)	Prevalence (%)
Velghe A. et al, 2013	G8 ≤ 14	At least 1 abnormal score	88.6	100	88
Soubeyran P. et al, 2011	G8 ≤ 14	At least 1 abnormal score	76.6	64.4	80.1
Pottel L. et al, 2011	G8 ≤ 14	At least 1 abnormal score	85.7	75	68.6
Bellera C. et al, 2012	G8 ≤ 14	At least 1 abnormal score	85	65	94

Summary and Conclusions: Our results show that the G8, at the proposed cut-off of ≤14, can be used as a valid screening tool for older patients with aggressive haematological malignancies who would benefit from CGA.

P1091

PSYCHOLOGICAL ASSESSMENT OF SIBLINGS OF PATIENTS WITH CHILDHOOD CANCER: A FORGOTTEN GROUP

F Mohamed[1], E Aziz[1], I Ragab[2,*], A Abdel-Aziz[3]
[1]Pediatric psychiatry, [2]Pediatric hematology- oncology, [3]Pediatrics, Ain Shams University, Cairo, Egypt

Background: The disruption created by diagnosis of cancer in a child within a family reach beyond the diagnosed child to impact the entire family. It is no surprise, that siblings within these families are at risk for emotional, behavioral and academic problems, and hence it is important to understand their consequences and develop feasible interventions to reduce their distress and promote their adjustment.
Aims: Our aim was to assess of psychological state of siblings of children with cancer.
Methods: A cross-sectional study included 100 children with age range (6-18 years). Group 1 included 70 siblings of 39 patients with cancer attending the oncology unit at Ain Shams University- Pediatrics Hospital. Any child receiving prior treatment for depression or anxiety, having chronic illness, mentally handicapped and siblingsof patients on end of life care program were excluded from participation. Group 2(control) included 30 healthy children from 13 families without any childhood chronic illness. Children receiving treatment for depression or anxiety and mentally handicapped were excluded from participation. Participants were subjected tohistory taking with special emphasis on the onset of the oncological disease in their sick sibling, duration and frequency of hospitalization, socioeconomic standards (SES) and educational level as well as the presenting symptoms, diagnosis and treatment stage of the ill child was collected from patient records.Psychological assessment for depression using children depression inventory (CDI),for anxiety using revised children's manifest anxiety scale (RCMAS) and for personal compatibility using Child Behavior Checklist (CBCL)
Results: Mean age for group1 was 11.36±3.48 years, and group 2 11.77±3.28 years with no significant difference as regard the distribution of sex, SES, educational leveland parental divorce (P>0.05). 65.7% of siblings had depression compared to 40% in group 2 (P=0.046) yet no significant difference was found in mean depression and anxiety scores (P>0.05), and a significantly lower mean score of personal compatibility in group 1 (375.03±33.56) compared to control group(411.6±43.79) (P<0.05). No statistical significant difference was found as regardlow self-esteem, anorexia and sleep disorder (P>0.05).
As regard the effect of gender, there was significantly higher scores and grades of depression in females when compared to males (P<0.05); a significantly higher rate of loneliness, insecurity and low self-esteem in females when compared to males (P<0.05). There was no significant difference between different SES or levels of education in psychological tests (P>0.05). There was no significant association between duration of cancer therapy and psychological tests. We further divided group1 participants into 2 groups (hospital admission more and less than twice per month), significantly lower score and grades of anxiety, lower rate of nervousness and insecurity, lower score and grades of depression, lower rate of low self esteem and sleep disorder in siblings of patients admitted <twice per month when compared to those admitted ≥twice per month (P<0.05); however no statistical significant difference was found in the total personal compatibility score.
Summary and Conclusions: Depression and impaired personal compatibility represent an appreciable problem in siblings of patients with childhood cancer which become more evident in the settings of frequent hospitalization; readjustment of these problem may have a positive impact on the whole family.

P1092

HEALTH-RELATED QUALITY OF LIFE AMONG LONG-TERM SURVIVORS OF ADOLESCENT HODGKIN'S LYMPHOMA TREATED WITH PEDIATRIC APPROACH

S Semochkin[1,2,*], E Arshanskaya[3], T Tolstykh[1], V Ivanova[3], A Rumiantsev[1,2]
[1]Russian National Research Medical University n.a. N.I. Pirogov, [2]Federal Research Center for Pediatric Hematology, Oncology and Immunology, [3]City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation

Background: Reduced health-related quality of life (QoL) and late complications after curative treatment of Hodgkin's lymphoma (HL) are of special relevance because most of the cured are young adults.
Aims: The purposes of the present study were to compare QoL of HL survivors with that of health young adults and to evaluate the relationships between disease/treatment features and QoL in the HL survivors.
Methods: Fifty sex (male - 22, female - 34) survivors of HL with a median ages 27.5 years (range, 22-41) were evaluated. For comparison 94 (male - 44, female - 50) health subjects with a median ages 28.0 years (range, 22-46) was drawn to the study of QoL. All HL survivors were treated with modified pediatric protocol DAL-HD-90 in 1997-2007 in our clinic. Patients are allocated to three treatment groups (TGs). The original protocol is modified in the following positions: (1) procarbazin was replaced by dacarbazin; (2) young adults received vinblastin instead vincristin; (3) all patients with advanced stages received 2 cycles of ODPA independently from gender; (4) doses of involved field radiotherapy were increased from 20-25 Gy to 30 Gy. QOL was assessed by the Short Form 36 (SF-36), which generate 8 separate scales and 2 general scores (0=worst health state, 100=best health state). All survivors have a time of complete remission (CR) of Hodgkin's lymphoma ≥5 years.
Results: The HL survivors had lower scores than the normal controls on all scales and scores (Figure 1). Statistically significant differences were found in general health - GH (53±3 *vs.* 72 ±2, P<0.001), vitality - VT (55±2 *vs.* 72 ±2, P<0.001) and mental health - MH (57±2 *vs.* 72 ±2, P<0.001). Patients with the international prognostic scores for advanced stages (IPS; Hasenclever, 1998) ≥4 (n=7) had the lowest scores in role physical - RF (29±15 *vs.* 81 ±5, P<0.001) and role emotional limitations - RE (33±15 *vs.* 77 ±5, P=0.006). The adverse events including relapsed disease (n=7) and second malignancies (n=2) correlated with IPS ≥4 and reduced QoL. The patients with ages on moment of HL diagnosis ≥18.5 years (methods of ROC-curves, P=0.047) have reduced QoL when compared to younger patients in GH (48±3 *vs.* 61 ±4, P=0.027), VT (50±3 *vs.* 61 ±4, P=0.013) and physical component scale - PCS (48±1 *vs.* 53 ±2, P=0.046). Time since diagnosis, ages on QoL evaluation, gender, treatment groups (2, 4 or 6 cycles of primary chemotherapy plus radiotherapy), Ann-Arbor stages, bulky disease, current married status and education levels were not associated with statistically significant differences in QoL.

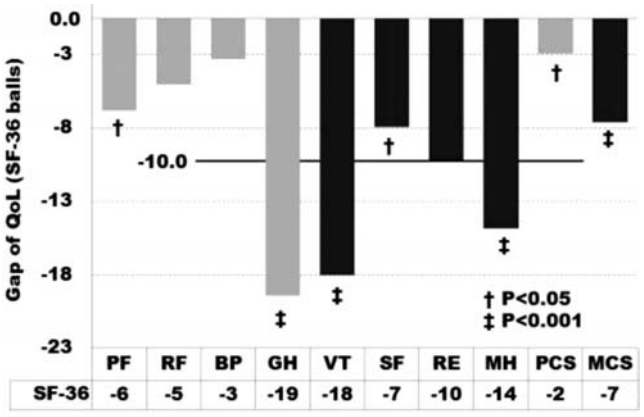

Figure 1. Gap of SF-36 scale-scores for the HL survivors.

Summary and Conclusions: Long-term HL survivors have poorer physical and mental QoL than the general population of young adults. The age on moment of LH diagnosis ≥18.5 years was associated with significant reduced predominantly physical QoL. IPS ≥4, relapsed HL and secondary malignancies were associated mostly with the deterioration of role physical and emotional functioning, which may indicate a lack of confidence in the future health.

P1093

THE PATIENT-REPORTED BURDEN OF ADVERSE EVENTS RELATED TO DASATINIB VERSUS OTHER BCR-ABL INHIBITORS, FROM A PATIENT PERSPECTIVE

S Gupta[1], M Calandriello[2], A Goren[3], M Lees[4,*]
[1]Health Outcomes Practice, Kantar Health, New York, United States, [2]Health Economics and Outcomes Research, BMS, Rome, Italy, [3]Health Outcomes Practice, Kantar Health, Princeton, United States, [4]Health Economics and Outcomes Research, BMS, Rueil-Malmaison Cedex, France

Background: The tyrosine-kinase inhibitors (TKIs) imatinib,dasatinib and nilotinib have improved clinical outcomes in patients with chronic myeloid leukemia (CML). While the prevalence of adverse events (AEs) for each TKI has been widely reported, the impact of these AEs from the patient perspective is less widely documented.
Aims: The study assessed the patient-reported prevalence, bothersomeness and severity of AEs associated with TKIs. Based upon these data, the study aimed to identify differences in patient-reported prevalence, bothersomeness and severity of AEs between the different TKIs.
Methods: Patients with chronic-phase CML were identified from the National Health and Wellness Survey and the Lightspeed Research Chronic Illness panel in the US and EU (United Kingdom, Spain, France, Italy, Germany). Respondents were aged ≥18 years, receiving a TKI or on a drug holiday with an intention to return to treatment. An Internet-based self-administered survey assessed prevalence of AEs, bothersomeness of AEs (1=not present, 2=present, 3=most bothersome) and severity of AEs in the past 24 hours using the MDASI-CML (0=AE not present to 10=bad as you could imagine). Prevalence,

bothersomeness and severity of AEs were compared between dasatinib and the other TKIs in a series of bivariate analyses, using Chi-square tests and independent sample t-tests for categorical and continuous variables, respectively.

Results: Among 303 patients in the study, 208 were on imatinib (3.4% on a drug holiday), 38 on dasatinib (7.9% on holiday) and 49 on nilotinib (2.0% on holiday). Compared with imatinib, dasatinib (imatinib reported first) was associated with lower diarrhoea (43.8% *vs.* 23.7%; P=0.021), muscle cramps (62.0% *vs.* 26.3%; P<0.001), stomach pain (28.4% *vs.* 13.2%; P=0.049) and tear production (19.2% *vs.* 5.3%; P=0.035), but higher constipation (9.6% *vs.* 23.7%; P=0.013) and lost sexual appetite rates (25.5% *vs.* 44.7%; P=0.016). Dasatinib patients experienced significantly lower bothersomeness associated with abnormal kidney function (P=0.003), abnormal liver function (P<0.001) and muscle cramps (P<0.001) than imatinib patients; severity of numbness/tingling (P=0.014), diarrhea (P=0.007), muscle cramps (P=0.002) and swelling (P=0.028) was lower with dasatinib. When compared with nilotinib (nilotinib reported first), dasatinib was associated with fewer abnormal kidney tests (10.2% *vs.* 0.0%; P=0.043) and liver tests (16.3% *vs.* 0.0%; P=0.009) but was associated with more patients showing weight gain (18.4% *vs.* 39.5%; P=0.029). Dasatinib patients showed significantly lower bothersomeness for abnormal kidney function (P=0.031), abnormal liver function (P=0.006) and skin irritation (P=0.039) than nilotinib patients. No differences were reported in AE severity between dasatinib and nilotinib.

Summary and Conclusions: The analysis suggests that patients regard individual AEs associated with dasatinib as equally or less bothersome, and equally or less severe, than the same AEs for other TKIs. Muscle cramps and diarrhea appear to affect dasatinib less than imatinib. Further research is ongoing to assess the impact of these AEs on quality of life and resource use in larger, better-powered samples of dasatanib and nilotinib users.

P1094

EARLY SUPPORTIVE/PALLIATIVE CARE INTEGRATED WITH STANDARD HEMATOLOGICAL CARE (SIMULTANEOUS CARE) IN MULTIPLE MYELOMA PATIENTS

V Federico[1,*], A Levi[1], E Meloni[1], F Gentilini[1], P Finsinger[1], M Petrucci[1], R Foà[1], C Cartoni[1]
[1]Hematology, "Sapienza" University of Rome, Rome, Italy

Background: Patients with multiple myeloma (MM) have a substantial symptom burden at the onset of the disease. We have recently set up a multi-disciplinary team aimed at introducing early supportive/palliative care integrated with standard hematological care (simultaneous care).

Aims: The goal of the current study was to examine the effect of early simultaneous care on health-related quality of life and symptom assessment in MM patients. The primary endpoint was the change in quality of life.

Methods: Quality of life and symptom assessment were evaluated using the M.D. Anderson Symptom Inventory (MDASI: where scores range from 0 to10, with higher scores indicating worse symptoms) at baseline, on days 7 and 28, and every month. The simultaneous care ambulatory team consists of a palliative care physician, a hematologist, a counselor, a psychologist and a social worker. Specific attention was paid to pain, by assessing both physical and psychosocial symptoms, establishing goals of care, assisting in the decision making process regarding treatment, and coordinating care on the basis of the individual needs of the patient.

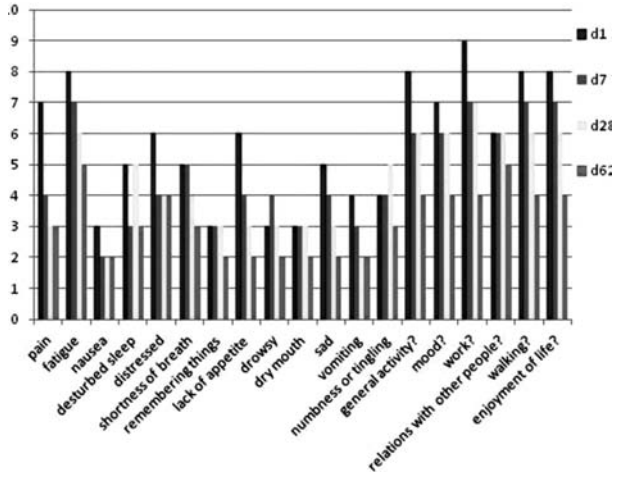

Figure 1.

Results: Between November 2011 and January 2013, 65 MM patients were followed by the simultaneous care team. The clinical characteristics were: median age 67 years (range 40-78); 21 men and 44 women; 40 and 25 patients were, respectively, in Durie and Salmon stages I-II and III. Forty patients were undergoing first line treatment, 13 were in relapse and 17 in advanced stage. The symptoms most frequently reported at baseline were: pain in 83% of patients, fatigue in 92%, anxiety in 67%. The actions taken included pain management in 56 patients; among these, 37% were treated with opioids and NSAIDs, and 63% with strong opioids at the third level of the WHO pain ladder. Oral transmucosal fentanyl delivery technologies were used in 35% of patients for the management of breakthrough cancer pain. Psychosocial interventions were carried out in 18 patients. Among the 17 patients with advanced phase, 12 were assigned to early palliative home care. The MDASI questionnaire scale showed a significant reduction in the median value of all symptoms reported by patients after 2 month (Figure 1).

Summary and Conclusions: Our study demonstrates the feasibility of early palliative care integrated with the standard hematologic care through a multiprofessional team dedicated to the management of symptoms in patients with MM. Based on the reduction in the intensity of symptoms and improvement of the quality of life score, the effectiveness of this type of organization should be emphasized.

P1095

WHAT DO PRELIMINARY ANALYSES HIGHLIGHT AS THE KEY FEARS AND WORRIES OF CHILDREN AND YOUNG PEOPLE WITH SICKLE CELL DISEASE AND WHAT CAN WE DO TO SUPPORT THEM?

B Inusa[1], F Bristow[1,*], H Appleby[1], H Jones[1]
[1]Evelina London Children's Hospital, Guy's & St. Thomas' NHS Foundation Trust, London, United Kingdom

Background: SCD children are now living longer and over 95% survive into adulthood (Telfer *et al.*, 2007; Quinn *et al.*, 2004). As a result, improved survival issues that require psychological input are becoming apparent. Access to a psychology service is not universal for families living with a chronic illness and SCD children may be adversely affected by the inability to address some unique issues they encounter. From audit data and clinical observations it is apparent that despite providing evidenced-based, protocol-driven care to these families, there are gaps in our understanding as clinicians as to what families are most concerned about and opportunities for us to learn from them. In a single centre setting we set out to highlight what these priorities may be and suggest implications and lessons to be learned from them, alongside objectives for future research.

Aims: We qualitatively explore the fears and worries reported by adolescents with SCD and discuss these in relation to team clinical observations of younger children, with the aim of understanding what most affects families living with SCD and how clinicians can best support them.

Methods: The data presented is from a retrospective study using a convenience sample of adolescents attending a London Children's Hospital. A semi-structured questionnaire jointly developed by doctors, psychologists, nurses and teenagers was administered as part of a service evaluation to 41 adolescent sickle cell patients. The questionnaire consisted of 4 sub-sections. For the purpose of this analysis, we focus on the 'impact on life' sub-section, specifically the free-text question, 'What are your fears about having sickle cell disease?' Participants were 24 males and 17 females aged 12 to 19 years (mean 15yr5m). 31 patients had HbSS, 9 had HbSC, and 1 had $HbSb^0$.

Results: 36 adolescents (87.8%) responded to the question in the survey. Of these, 11 adolescents (30.5%) reported not having any fears about SCD. Free-text answers provided were analysed qualitatively using thematic analysis (Braun & Clarke, 2006). Data provided produced 10 codes which led to the emergence of 3 overarching themes (see Figure 1). Themes were interrelated and highlighted a range of fears reported by the adolescents. Most prevalent were fears of death and dying (26.2%), having a crisis (14.63%), stroke (7.31%) and illness (7.31%).

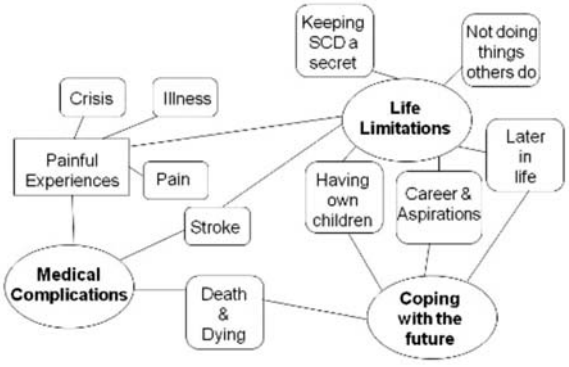

Figure 1. Thematic Map showing 3 main themes to describe adolescents' reported fears of SCD.

Summary and Conclusions: This survey shows that adolescents with SCD have wide ranging fears in relation to medical and psychosocial issues. The adolescents are clearly thinking ahead to their futures and are acutely aware of illness, stroke and death. The results demonstrate a need to incorporate these reported fears into transition planning and provide coping strategies as our adolescents move into adult services. Furthermore, our clinical observations of a younger cohort of patients aged 10-14 attending psycho-educational groups run by the team indicate that younger children also have similar fears and worries to the adolescent cohort, including death and dying, pain, limitations to activities and are also thinking about the future. Clinical observations also highlight parents as sharing similar fears. We propose two objectives for future studies: to examine the direction of the relationship between the fears of parents and children; and to explore the developmental trajectory of reported fears and worries throughout the lifespan. This information would enable us to address such fears both during transition and when determining the support provided to younger children.

P1096

COMPREHENSIVE ANALYSIS OF CLINICALLY RELEVANT IMPROVEMENT IN PROGRESSION-FREE SURVIVAL IN HEMATOLOGIC MALIGNANCY FROM THE VIEWPOINT OF REVISED EMA'S GUIDELINE ON ANTICANCER MEDICINAL PRODUCTS

S Nagai[1,*]
[1]Office of New Drug V, Pharmaceuticals and Medical Devices Agency, Tokyo, Japan

Background: Whether prolongation of progression-free survival (PFS) for a short term means clinically significant benefit has been a major concern regarding marketing authorization of some anticancer drugs for solid tumors. The European Medicines Agency's (EMA's) revised guideline on the evaluation of anticancer medicinal products was released this January. Concerning this revised guideline, the Committee for Human Medicinal Products (CHMP) scientific advisory group (SAG) for oncology suggested that improvement in median PFS in the order three to four months or larger is generally considered adequate if the prognosis is in the order of two to three years overall survival (OS) or less.
Aims: Each of the Pharmaceuticals and Medical Devices Agency (PMDA) in Japan and the EMA reviews drug applications for market approval. In order to examine relevance of the EMA's guideline to hematologic malignancy and what clinically relevant improvement in PFS is, the effect of hematologic anticancer drugs approved in the European Union (EU) or Japan on improvement in PFS as the primary endpoint and OS as the secondary endpoint in pivotal trials was analyzed in this research.
Methods: 38 indications of 28 hematologic anticancer drugs approved in Japan after the year of 2000 and 36 indications of 24 hematologic anticancer drugs which were granted central marketing authorization by the European Commission listed in the EMA's website were examined. Information was obtained from the PMDA's review reports and the European public assessment reports.
Results: All the pivotal trials in which the primary endpoint was PFS were randomized comparative trials, as both the EMA's guideline and the FDA's guidance concerning endpoints requested. Of these indications, the pivotal trials in which OS as the secondary endpoint was significantly improved are as follows. Rituximab as maintenance therapy for relapsed or refractory follicular lymphoma (FL) prolonged median PFS for 27.9 months. Rituximab for newly diagnosed chronic lymphocytic leukemia (CLL) extended median PFS for 7.6 months. On the other hand, the pivotal trials in which significantly improved OS as the secondary endpoint was not observed are as follows. Ibritumomab tiuxetan for newly diagnosed FL extended median PFS for 23.5 months. Rituximab for relapsed or refractory CLL prolonged median PFS for 10.0 months. Rituximab as maintenance therapy for newly diagnosed FL extended median PFS for 191 days. Temsirolimus for relapsed or refractory mantle cell lymphoma prolonged median PFS for 2.9 months. In addition, all these indications were approved in the EU but not Japan while bortezomib and lenalidomide for multiple myeloma (MM) approved in Japan as well as the EU prolonged both time to progression (TTP) as the primary endpoint and OS as the secondary endpoint, suggesting that TTP may be worthy to examine in MM.
Summary and Conclusions: There are few trials of hematologic anticancer drugs in which the primary endpoint was PFS and drugs for lymphoma or CLL were examined in these trials. All the drugs examined in this analysis prolonged PFS for more than 80 days, which was considered to be nearly adequate improvement by the CHMP SAG. Therefore, this research suggests that the revised EMA's guideline is relevant to hematologic anticancer drugs and that more efforts to conduct comparative trials are globally necessary. Because this analysis also shows that it is difficult to define a minimum relevant difference in PFS which leads to improved OS, however, it is important to at least rule out a detriment in terms of OS.

P1097

PREGNANCY ROLE IN THE OCCURRENCE OF MALIGNANT HEMATOLOGICAL DISEASES REMISSION

M Vinogradova[1,*], E Polushkina[2], R Shmakov[2]
[1]hematology, [2]obstetrics, Federal State Budget Institution «Research Center for Obstetrics, Gynecology and Perinatology», Moscow, Russian Federation

Background: In recent years treatment of several malignant hematological diseases (MHD) has improved considerably thanks to more profound understanding of the pathogenesis, implementation of new medicines and optimization of accompanying therapies. For this reason the issues pertaining to the realization of reproductive function in this category of patients are becoming an ever more topical subject.
Aims: Pregnancy planning, evaluation of the disease prognosis and creation of protocols for management of pregnancy and childbirth, all this serves to improve the quality of life of such patients. Research Center for Obstetrics, Gynecology and Perinatology has been developing the optimal strategy for management of pregnant patients with MHD.
Methods: From 1986 to 2012, we have analyzed 158 pregnancies in 149 women remaining in remission after MHD, including 117 patients with Hodgkin lymphoma (HL), 19 patients with non-Hodgkin lymphomas (NHL) and 13 patients with acute leukemia (AL). All of them underwent the treatment of hematological disease to achieve remission. The median time from the moment of achieving remission to the onset of pregnancy was 6 years in patients with HL, 3.2 years in patients with NHL and 7.4 years in patients with AL.
Results: In pregnant women with full MHD remission the progression of the disease was registered in 3 (23%) patients with AL and 2 (1.7%) patients with HL. All patients with diagnosed disease relapse needed the resumption of special chemotherapy. 152 (96.2%) of pregnancies ended up with a birth of full-term healthy infants without birth defects. Premature birth occurred in 5 (3.2%) cases. Neonatal mortality occurred in 1 (0.6%) newborn with unfavorable nervous system defect (anencephaly). In 1 (0.6%) patient pregnancy was terminated for medical reasons in the 2nd trimester. The mode of delivery was determined by the obstetric conditions in all cases. No thrombotic or hemorrhagic complications during labor or postpartum period have been observed.
Summary and Conclusions: Therefore, pregnancy does not influence on the progression of lymphoproliferative diseases in patients with long-lasting remission. Patients with lymphomas could be recommended to plan a pregnancy in 3 years after achieving the remission. Pregnant women in remission after AL are at a considerably higher risk for relapse, hence, the pregnancy planning in this category of patients is feasible but no sooner than in 5 years since the moment of achieving full remission, and only after detailed examination including the molecular and cytogenetic methods, in order to rule out the minimal residual disease. There is no difference between the health of infants born by mothers in MHD remission and the newborns from general population.

P1098

VALIDATION OF A COMPREHENSIVE HEALTH STATUS ASSESSMENT SCALE IN OLDER PATIENTS (≥65 YEARS) WITH HEMATOLOGICAL MALIGNANCES. GAH STUDY

S Bonanad[1,*], I Oiartzabal[2], C Fernández-Lago[3], B González[4], C Marrero[5], M Gironella[6], D Valcárcel [6], J Rivas[7], Z Ripa[8], C Olivier[9], J Rubia[10], P Abrisqueta[6], C Muñoz[11], J Sarrá[12], C Encinas[13], O Salamero[6], M Durán [14], M Marcos[14], S López[14], A Cruz-Jentoft[15]
[1]Hospital La Ribera, Alzira, [2]Hospital de Txagorritxu, Vitoria, [3]Complejo Hospitalario Universitario de A Coruña, A Coruña, [4]Hospital Universitario de Canarias, La Laguna, [5]Hospital Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, [6]Hospital Vall de Hebrón, Barcelona, [7]Hospital Infanta Leonor, Madrid, [8]Hospital de Navarra, Pamplona, [9]Hospital de Segovia, Segovia, [10]Hospital La Fe, Valencia, [11]Hospital Puerta de Hierro, Madrid, [12]Hospital Durán i Reynals, Barcelona, [13]Hospital Gregorio Marañón, [14]Celgene S.L.U., [15]Hospital Ramón y Cajal, Madrid, Spain

Background: Cancer affects mainly older people. The US National Comprehensive Cancer Network and the International Society of Geriatric Oncology have recommended that some form of geriatric assessment should be conducted to help oncologists to determine the best treatment for older patients, in order to identify current health problems and to guide interventions to reduce adverse outcomes and optimize the functional status. Currently, the main tool for assessing older patients is a comprehensive geriatric assessment, although its complexity and duration may hinder its regular use in daily practice as a tool for clinical decision making. Several attempts have been made to assess comorbidities in the specific field of mielodysplasia, but they focused mainly on organic damage rather than global assessment.
Aims: To develop and validate an assessment scale (called Geriatric Assessment in Haematology, GAH) for use in older patients with hematological malignancies (myelodysplasic syndrome (MDS), acute myeloblastic leukemia (AML), multiple myeloma (MM) and chronic lymphocytic leukemia (CLL), that, while integrating the essential dimensions of geriatric assessment, is easier to apply,

accessible, does not interfere with daily clinical practice and could be useful in clinical decision making.
Methods: After item-pool generation, stakeholder consultation and content validation, a brief scale with selected items of several domains has been created. Feasibilty was confirmed in 83 hematological patients in a previous exploratory experience. After that, a multicenter, observational, prospective study has been started in 18 hospitals in Spain, expecting to enroll 360 treatment-naïve, newly diagnosed patients belonging to one of the three groups of study (MDS or AML, MM and CLL). The scale validation process integrates the analysis of criterion validity, concept validity internal reliability, test-retest reliability, as well as the evaluation of intraclass correlation coefficient (ICC) and factor analysis. After psychometric validation phase, further studies will be carried out in order to evaluate its clinical use for prognosis and clinical decision making.
Results: Currently, 75 patients fulfilling inclusion criteria have been enrolled in the study, 51.5% men, median age at diagnosis 76 years (70-80). According to diagnosis, 44% of patients had MDS or AML, 36% had MM and 20% had CLL. Median time for filling in the questionnaire was 12 (10-15) min. In the initial testing, GAH showed satisfactory test-retest reliability. ICC was statistically significant for each dimension, being greater than 0.66 for 6 of the 8 dimensions ($P<0.05$). Factor analysis will be conducted when recruitment is completed. Some differences have been found in subjects with different diseases, although no statistical analysis has been made yet. Based on rough proportions, GAH shows a great potential in terms of sensitivity, specificity and reproducibility between trained observers.
Summary and Conclusions: To our knowledge, this is the first study performed to develop and validate a comprehensive health status assessment in older patients with hematological malignances, which could be used in clinical practice to help haematologists to improve decision making processes in older patients.

P1099

PSYCHOLOGICAL MORBIDITY FOLLOWING THE DIAGNOSIS OF A HAEMATOLOGICAL MALIGNANCY

B Kevane[1,*], M Crowley[1], A Bowler[2], M Mohamad[2], O Gilligan[1], E Cassidy[2]
[1]Haematology, [2]Psychiatry, Cork University Hospital, Cork, Ireland

Background: It has been shown that psychological morbidity occurs frequently following the diagnosis of a haematological malignancy. A number of factors may contribute to the development of mental health issues in this patient group including exposure to new medications and prolonged periods of isolation as well as multiple other physical & emotional factors. Cork university hospital (CUH) is one of the largest teaching hospitals in the Republic of Korea Ireland, serving a population of over 1 million people. The Haematology department within CUH acts as a regional tertiary referral centre for the treatment of acute leukaemia and other complex haematological disorders. A specialist psycho-oncology/liaison psychiatry service has been in operation in CUH since 2006. In cases where there is a clinical suspicion of a mental health issue, the clinical haematology team submits a referral directly to the psycho-oncology service, following which the patient is assessed and recommendations for further specific interventions made if appropriate.
Aims: The purpose of this study was to examine the nature of mental health issues among patients that were diagnosed with a haematological malignancy within our institution.
Methods: Data with regard to mental health assessment, diagnosis and therapy were obtained from a database that was compiled prospectively on all referrals to the liaison Psycho-oncology service from August 2006 to August 2011 in CUH.

Table 1.

Psychological assessment/Mental Health diagnosis	% of Patients (N=254)
Declined assessment/ Referral cancelled	8% (20)
Reaction to severe stress/Adjustment disorder	24% (61)
No mental health diagnosis	19% (49)
Stable mental state (history of psychiatric disorder)	9% (23)
Organic mood/anxiety disorders a) Secondary to steroids b) Not secondary to steroids	15% (38) a) 9% (23) b) 6% (15)
Mood and anxiety disorders	14% (36)
Delirium/Dementia	7% (18)
Mental retardation or Autistic Spectrum Disorder	0.8% (2)
Mental disorders due to psychoactive substance use	1% (3)
Not specified	1% (3)
Disorders of adult personality and behaviour	0.4% (1)

Results: During the study period, 254 patients (146 male, 108 female) with a haematological malignancy were referred for assessment to the liaison psycho-oncology service. The mean age at time of referral was 52 (SD+/-15.4, range 19-85) years. The most frequent haematological diagnosis within the cohort was myeloma (27.6%) followed by non-Hodgkin lymphoma (27.1%). Patients with acute leukaemia accounted for 26.4% of the cohort, with the remainder comprising of patients with chronic leukaemias, myelodysplastic syndromes and myeloproliferative neoplasms. The majority of referrals were prompted for assessment of "low mood" (32%), "anxiety/insomnia" (25%), "poor coping" (14%) and for review with regard to a "past psychiatric history" (14%). No referrals were initiated specifically for assessment of suicidal ideation or behaviour, however, one patient was re-referred following an episode of suicidal behaviour on the haematology ward. Each patient was requested to complete a modified Roth distress thermometer questionnaire. The median distress score was 5 (range 0-10). 75% of patients recorded a score of 4 or greater, which has been validated as being highly sensitive and specific for detecting high levels of psychological distress. Table 1 illustrates the outcome of the initial mental health assessments. Following assessment and diagnosis, a recommendation for either further active observation or specific interventions was made in 84% of cases, including medication change (52%), anxiety management/psychotherapy (38%) and psychoeducation (16%).
Summary and Conclusions: Psychological wellbeing is often adversely affected following the diagnosis of a haematological malignancy. Organic mental disorders, including steroid induced mental disorders, represent a significant component of the morbidity observed. Access to specialized psychiatric assessment is vital in order to make an accurate diagnosis and to identify patients who may benefit from specific therapy.

P1100

QUALITY OF LIFE OF THE PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

L Gritsay[1,*], T Pospelova[1], I Necnunaeva [2], A Mishenin[2]
[1]Novosibirsk State Medical University, [2]Municipal Clinical Hospital №2, Novosibirsk, Russian Federation

Background: The evaluation of quality of life (QOL) is widely used in medical practice, as it allows to assess QOL of patient to get the most complete picture of his health, before starting and during treatment.
Aims: *The Aim* of this study was to determine quality of life of the patients with hematological malignancies (HM) at the time of diagnosis, at the time of chemotherapy (PCT) and during complete clinical remission (CCR).
Methods: Surveyed group were 170 patients (77 patients with non-Hodgkin's lymphoma, 57 - Hodgkin's lymphoma and 36 patients with acute leukemia. Mean age is 44.5±3.75 years. Gender distribution was: women–89 (52.4%) and men–81 (47.6%). The control group consisted of 170 persons, representing the "healthy" population. The average age of respondents was 46±4.6 years: women of them–93 (54.7%) and men–77 persons (45.3%). QOL was estimated by the SF-36.
Results: We noticed a significant reduction of QOL for all investigated scales of the SF-36 in HM group before treatment compared with the control group. During the chemotherapy program QOL of patients with HM were significantly lower compared with the control group on the such scales as: physical functioning (PF)–63.1±2.26 points in the group of patients at the time of chemotherapy and 87,2±1,13 points in the control group, role physical functioning (RFF)–39.4±3.51 points in the patients with HM during treatment and 59.5±2.82 points in the control, general health (GH)–45±1.68 points compared with 56.5±1.35 points respectively, vitality (V)–43±2.09 points in the group of patients at the time of chemotherapy and 58.4±1.54 points in the control group, social functioning (SF)–54.7±2.51 points in HM during treatment and 69.3±2.02 points in the control, role social functioning (RSF)–49.8±3.54 points and 54.5±3,12 points respectively, mental health (MH)–54.5±1.57 points in the group of patients at the time of chemotherapy and 59.7±1.45 points in the control group. At the same time, the analysis of QOL of patients with HM during the course of induction and consolidation of remission showed a significant increase QOL compared with patients before treatment for the pain scale (P) (due to reduction of pain), GH and V: V–66.1±2.36 points in the group of treated patients in comparison with 53.2±2.38 points in the group of patients before treatment, GH–45±1.68 points in the patients during treatment and 39±1, 68 points in the patients at the time of diagnosis, V–43±2.09 37±1.77 points respectively. Comparative analysis of QOL during the therapy and CCR showed the significant increase QOL for all investigated scales of the SF-36, but in comparison with the control group, QOL of the patients with HM were significantly lower for majority of the studied scales: FF–76.2±1.45 points in the patients with CCR and 87.2±1.13 points in the control group, RFF–50±3.25 points in patients in remission and 59.5±2.82 points in the control, GH–44.8±1.77 points and 56.5±1.35 points respectively, V–49.8±1.67 points in patients during CCR and 58.4±1.54 points in the control group, PH–53.5±1,32 points in the patients in remission and 59.7±1.45 points in the control group.
Summary and Conclusions: The study showed the reduction of quality of life for patients with HM before therapy. Chemotherapy and radiation therapy in patients with HM can improve quality of life. During the period of clinical remission QOL was increasing on many studied scales of the SF-36, but the results of QOL on the GH, PH and V scales was significantly lower in comparison with the control group.

ULTRA-DEEP SEQUENCING WITH COMPUTED THRESHOLDS FOR SENSITIVE MUTATION ANALYSIS IN THE KINASE DOMAIN OF BCR-ABL: FOCUSED ON DEEP MUTATION DETECTION IN CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

A Brouckova[1], S Soverini[2], V Kulvait[3,4], A Kohlmann[5], M Jaruskova[1], C de Benedittis[2], H Klamova[1], M Trneny[1], T Haferlach[5], M Baccarani[2], G Martinelli[2], K Polakova[1,*]

[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [2]Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology "L. e A. Seragnoli" University of Bologna, Bologna, Italy, [3]First Faculty of Medicine and Center of Experimental Hematology, Charles University in Prague, Prague, [4]PersMed, Dolni Brezany, Czech Republic, [5]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Sanger sequencing (SS) is widely used for mutation detection in the BCR-ABL kinase domain (KD) with a sensitivity of 15-20%. Due to its clonal nature, next generation sequencing (NGS) improves resolution through ultra-deep sequencing (UDS) of targeted genes. It is necessary to have tools separating errors produced in NGS pipeline from true mutational events.
Aims: 1) We develop a model for error correction and estimating thresholds for detection of mutations in the KD of BCR-ABL by UDS of an amplicon library that was prepared using BCR-ABL plates developed within the IRON-II study (Roche Applied Science). 2) We applied the thresholds in a retrospective UDS analysis of BCR-ABL mutations associated with resistance under TKI treatment in CP-CML patients to assess applicability to future clinical practice.
Methods: *BCR-ABL*mutations were analyzed in 129 samples from 15 CP-CML patients by UDS on a 454 platform (Roche Applied Science). Each patient received 2 or 3 lines of TKIs. BCR-ABL oligonucleotide primer plates containing fusion primers were used to create 4 partially overlapping amplicons covering the KD coding region. For estimation of SNS (Single Nucleotide Substitution) error rates, we used 8 samples from healthy donors. The SNS caller and software framework for estimation of errors was written in Java. We estimated error rates using the Lea Coulson distribution. The distribution parameter was estimated by the maximum likelihood method (Foster, PL in DNA Repair, 2006, Part B, Vol409). If the probability, that the same or higher count of SNS reads from single base occur in error distribution, is less than 1% then we call this SNS significant mutation. On the level of 1% for each nucleotide substitution we also set a threshold.
Results: 1) The SNS error frequency was much higher for nucleotide transitions *vs.* transversions (*e.g.*, mean 2.2 SNS events for T/C *vs.* 0.1 for T/A per 3000 reads). Therefore, computations for each type of nucleotide substitution were performed separately and resulted in higher thresholds for transitions, resulting in *e.g.* T315I and Y253H with 77 (2.57%) and 96 (3.20%) mutations per 3000 reads, respectively, in contrast to transversions, resulting in *e.g.* V299L with 10 (0.3%) per 3000 reads. 2) Using the computed thresholds UDS revealed insignificant mutations at the time of diagnosis that subsequently developed under TKIs in 8/15 patients. We examined, if UDS can outperform SS in detecting mutations earlier considering significant mutations only. UDS detected 5 mutations 3 months earlier, 4 mutations 4 months earlier and 2 mutations 17 months earlier during imatinib treatment. UDS detected other minor mutant populations (G250R, L387F, L364I, Y253H) in 4 patients. In 3 patients, UDS, but not SS, revealed minor populations with F317L, Y253H and T315I before therapy switch that emerged under selected 2nd TKI. Finally, we compared the level of baseline mutations detected by UDS and SS after TKI switch. Baseline mutations were still detectable by UDS in 2 patients who achieved MMR at the time of analysis.
Summary and Conclusions: Since enzymes create errors during library preparation, the threshold computation is essential for relevant interpretation of BCR-ABL KD mutations detected with the highly sensitive UDS technology. Higher SNS error rate was found for nucleotide transitions. UDS outperformed SS in detection sensitivity and thus provided more information. For future reference, we suggest using UDS even for critical clinical applications provided that the precise methods for error management presented here are utilized.

S1102

IKAROS DELETION AND LEVELS OF FULL-LENGTH TRANSCRIPT ARE CRITICAL FOR CML BLAST CRISIS TRANSFORMATION

L Wang[1,2,*], A Howarth[2], R Clark[2]

[1]Department of Haematology, Royal Liverpool University Hospital, [2]Section of Haematology, Department of Molecular and Cancer Medicine, the University of Liverpool, Liverpool, United Kingdom

Background: The *IKZF1* gene encodes Ikaros, a zinc finger protein which acts as a master regulator of lymphoid and myeloid development as well as a tumour suppressor. Deletions of *IKZF1* coding exons 3 to 6 can result in the expression of dominant-negative short forms of *IKZF1* (*Ik6*, *Ik9* and *Ik10*). *IKZF1* deletions have been reported in blast crisis (BC) of chronic myeloid leukaemia (CML).
Aims: To investigate the role of Ikaros as a predictor of BC in CML, we investigated the expression of *IKZF1* variants and the expression levels of the full length *IKZF1* transcript in chronic phase (CP), accelerated phase (AP) and BC.
Methods: The following cases were studied: 53 cases of BCR-ABL1+ acute leukaemia (25 myeloid, 22 lymphoid, 3 biophenotypic and 3 of unknown lineage), 27 cases of AP CML, 52 cases of CP CML who failed imatinib, nilotinib or dasatinib and 25 cases of newly diagnosed CP CML. RNA was extracted and cDNA synthesised from whole blood white cells. PCR was performed using various combinations of primers to detect *IKZF1* variants. Real-time quantitative RT-PCR was applied to quantify the gene expression levels of the full-length *IKZF1* on a LightCycler.
Results: *Ik6/Ik10* were detected in 9/53 (17%) of BCR-ABL1+ leukaemia including 8 cases with *Ik6* and one case with *Ik10*. These were found at a higher incidence in BCR-ABL1$^+$ ALL (7/22; 32%) and biphenotypic BC (1/3; 33%) than in BCR-ABL1$^+$ AML (1/25; 4%). Strikingly, all 9 cases with *Ik6/Ik10* variants had major *BCR-ABL1* transcripts; while none of the 10 cases of *de novo* BCR-ABL1+ ALL with minor or other *BCR-ABL1* variant had *Ik6/Ik9/Ik10*. Analysis of *Ik6/Ik10* in serial CP CML samples prior to BC transformation showed that no *Ik6/Ik10* was detected when patients were responding to treatment. *Ik6/Ik10* was only detected when the patients progressed from CP to BC. No dominant-negative form of *IKZF1* was detected in any CP or AP case. *IKZF1* isoforms *Ik5*, *Ik7* and *Ik8* with no crucial zinc finger motifs were also screened in all samples, but no consistent expression patterns were seen for particular disease subgroups. Surprisingly, expression levels of full length *IKZF1* were greater in BCR-ABL1$^+$ acute leukaemia patients (n=39) than those in CP CML (n=20) (P=0.001; M-W test). For BC cases without shorter dominant-negative *IKZF1* isoforms, the full length *IKZF1* levels were also higher than those in CP CML (P=0.001, M-W test). Expression levels of full length *IKZF1* levels were not significantly different between lymphoid (n=11) and myeloid BC (n=18) of CML, nor between CML BC with and without *Ik6/Ik10* or between imatinib responders and non-responders (n=8).
Summary and Conclusions: This study shows that 1) dominant negative isoforms of *IKZF1* are more prevalent in lymphoid BC of CML than in *de novo* BCR-ABL1$^+$ ALL; 2) BCR-ABL1$^+$ ALL without dominant-negative *IKZF1* isoforms have greater levels of full length *IKZF1* transcript. However, we do not find that IKZF1 dominant negative isoforms are useful in CP CML as a biomarker of BC. Further study is warrantied to investigate the role of full length Ikaros in BC transformation.

S1103

DEEP MOLECULAR RESPONSE (MR4.5) IS REACHED BY THE MAJORITY OF CML PATIENTS, PREDICTS BETTER SURVIVAL, AND IS ACHIEVED FASTER BY OPTIMIZED HIGH DOSE IMATINIB - RESULTS FROM THE RANDOMIZED CML-STUDY IV

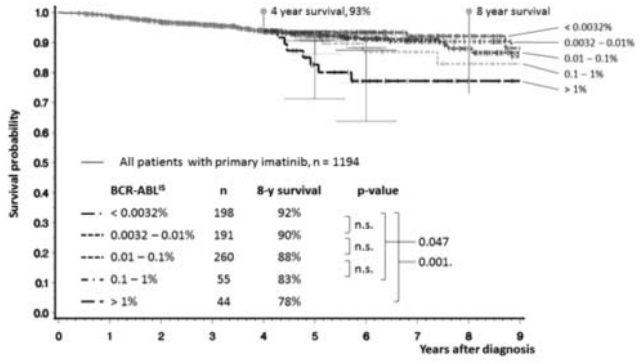
R Hehlmann[1,*], M Müller[1], M Lauseker[2], B Hanfstein[1], A Fabarius[1], A Schreiber[1], U Proetel[1], N Pletsch[1], M Pfirrmann[2], C Haferlach[3], S Schnittger[3], H Einsele[4], J Dengler[5], C Falge[6], L Kanz[7], A Neubauer[8], M Kneba[9], F Stegelmann[10], M Pfreundschuh[11], C Waller[12], K Spiekermann[13], G Baerlocher[14], G Ehninger[15], D Heim[16], H Heimpel[10], C Nerl[17], S Krause[18], D Hossfeld[19], H Kolb[20], J Hasford[2], S Saußele[1], A Hochhaus[21]

Medizinische Klinik und Poliklinik, Universitätsklinikum Eppendorf, Hamburg, [20]III. Medizinische Klinik, Klinikum rechts der Isar der Technischen Universität, München, [21]Klinik für Innere Medizin II, Universitätsklinikum, Jena, Germany

Background: Deep molecular response (MR$^{4.5}$) defines a subgroup of CML patients who may stay in unmaintained remission after treatment discontinua-

tion. It is unclear, how many patients achieve $MR^{4.5}$ and whether $MR^{4.5}$ predicts survival.
Aims: Determine proportion of CML patients who achieve deep molecular responses, analyse predictive power of $MR^{4.5}$for survival, determine whether $MR^{4.5}$is achieved faster by optimized high-dose imatinib.
Methods: Patients from CML-Study IV (Hehlmann *et al.*, JCO 2011, 29:1634-42), a five arm randomized comparison of imatinib in three combinations and two dosages, were analyzed for confirmed $MR^{4.5}$ which was defined as ≥4.5 log reduction of BCR-ABL on the international scale (IS) and determined by RT-PCR in two consecutive analyses. Landmark analyses were performed to evaluate the impact of $MR^{4.5}$on survival at various time points.
Results:1,524 of1,551 randomized patients were evaluable. After a median observation time of 67.5 months 6-year overall survival was 88.2%. The cumulative incidence of $MR^{4.5}$ after 9 years was 70%, of confirmed $MR^{4.5}$ 54%. $MR^{4.5}$ was reached significantly faster with optimized high-dose imatinib than with imatinib 400 mg. Independent of treatment approach confirmed $MR^{4.5}$ at 4 years predicted significant higher survival probabilities than >1% IS (8 years survival 92% *vs.* 78%, P=0.001) and than 0.1–1% IS which corresponds to complete cytogenetic remission (8 years survival 83%, P=0.047, Figure 1). The interim levels of 0.01–0.1% IS defined as major molecular remission (MMR, 8 years survival 88%) and of 0.0032–0.01% IS defined as MR^4 (8 years survival 90%) were not significant compared to $MR^{4.5}$or 0.1-1% IS. Early MMR predicted $MR^{4.5}$. No patient with confirmed $MR^{4.5}$ has progressed.

Figure 1.



Summary and Conclusions: $MR^{4.5}$ is a new molecular predictor of long-term outcome, is reached by a majority of imatinib-treated patients and is achieved faster with optimized high-dose imatinib. Optimized high-dose imatinib may provide an improved therapeutic basis for treatment discontinuation in CML.

S1104

NON-ADHERENCE IN CHRONIC MYELOID LEUKEMIA: RESULTS OF A GLOBAL SURVEY OF 2546 CML PATIENTS IN 79 COUNTRIES

G Sharf[1,2,*], V Hoffmann[3], F Bombaci[4], M Daban[5], F Efficace[6], J Guilhot[7], J Pelouchová[8], E Dziwinski[9], J Jong[10], A Gavin[11], J Geissler[1,12]
[1]Leukemia Patient Advocates Foundation, Bern, Switzerland, [2]Israeli CML Patients Organisation, Netanya, Israel, [3]Institute of Medical Information Sciences, Biometry and Epidemiology (IBE), LMU, Munich, Germany, [4]Gruppo AIL Pazienti Leucemia Mieloide Cronica, Rome, Italy, [5]LMC France, Marseille, France, [6]Data Center and Health Outcomes Research Unit, Italian Group for Adult Hematologic Diseases (GIMEMA), Rome, Italy, [7]Inserm CIC 0802, University Hospital of Poitiers, Poitiers, France, [8]Diagnoza CML, Prague, Czech Republic, [9]Polish Nationwide Association for CML Patients Aid, Warsaw, Poland, [10]Stichting Contactgroep Leukemie, Utrecht, Netherlands, [11]Leukaemia CARE, Worcester, United Kingdom, [12]LeukaNET e.V., Riemerling, Germany

Background: Optimal adherence to oral chronic myeloid leukemia (CML) therapy is of key importance to maximise treatment effectiveness. Non-adherence as well as its biological effect on CML has been observed in clinical research, but data on potential driving factors of non-adherence are lacking in the scientific literature.
Aims: The aim of this study is to investigate motivations and behavioural patterns of adherence in CML and subsequently support hematologists and patients to improve adherence and develop suitable adherence tools.
Methods: A European workgroup of the CML Advocates Network, a network of leukemia patient groups in 55 countries, has conducted a large international study enrolling patients from 09/2012 to 01/2013 in 12 languages. The study was also supported by CML investigator groups in Germany, Italy and France. An *ad hoc* questionnaire was developed for the purpose of this study and this included questions on potential factors associated with non-adherence and other aspects related to patients' perception of disease and treatment burden. Also, medication taking behavior was assessed with the 8-item Morisky Medication Adherence scale (MMAS-8). This scale allows classification of patients into their level of adherence to treatment (*i.e.* low, medium and high adherence). Patients completed this questionnaire online. An additional sample of patients were given this questionnaire, along with a pre-stamped envelope, by their own treating physicians in hospital with the request to completing it at home. These questionnaire were then returned to an independent Data Center for analyses. Differences in adherence groups were determined by χ^2 tests, differences of mean adherence were determined with Mann Whitney U tests and Kruskal Wallis tests.
Results: Overall 2546 questionnaires filled in by CML patients from 79 countries were analyzed. 2151 were completed online, 395 were returned by patients invited to participate in hospital, all others (N=2151) were filled in online. 52.4% of participants were male. Mean age of participants was 50.4 years (range 18-96) and 52.4% of these were male. According to the MMAS-8, 33% of participants could be classified as highly adherent, while 47% and 21% were respectively in the medium and low adherence group. Several factors influenced adherence: Men were more often highly adherent than women (57.3% *vs.* 42.7%, P<0.001). Mean age was higher in the more adherent groups (low 44.8 years, medium 50.6, high 58.8; P<0.001). Patients who live with a partner or family member (85.7%, P=0.006) are more adherent, suggesting that adherence tools should support not only patients but also their relatives. 27.1% of patients on Nilotinib treatment categorized into the low adherence group, compared to only 18.8% of patients on other CML therapies (P<0.001). This might also be due to the fact that most patients (91.2%) have to take Nilotinib twice a day while Imatinib and Dasatinib are mostly administered only once per day (86.8% and 92.5% respectively). Frequency of medication is a major factor of influence on adherence (P<0.001). 51.6% of participants accidentally missed at least one dose of medication within the last year. Main reasons were forgetting (41%) and interruption in the daily routine (27%). As reminder tools, 43% are reminded by family members, 40% use pill dispensers and 24% use cellphones. The majority of patients (85.7%) are aware of the importance of CML therapy to their health. However 19.5% of patients consciously decided to miss a dose during the last year. Main reasons were not feeling well (35%) and the wish to reduce side effects (26%), of which 79% state gastrointestinal events as the reason. Patients state that CML medication impacts their work life (26%) and their social life (23.5%), which both influence adherence to treatment schedules (P<0.001). Patients managed by an approachable doctor providing sufficient information on disease and medication were more adherent than patients with lower satisfaction with their doctor (P<0.001). Doctor's support in managing side effects was also driving adherence (P<0.001).
Summary and Conclusions: This is the most comprehensive study conducted to date to gain knowledge about motivations behind non-adherence in CML. Better information on disease, medication and management of side effects, supported by hematologists, is key to improve adherence.

S1105

INDIVIDUAL EARLY DYNAMICS OF BCR-ABL TRANSCRIPTS, BUT NOT BCR-ABL TRANSCRIPT LEVELS AT BASELINE PREDICT SURVIVAL IN PATIENTS WITH CHRONIC PHASE CML

Background: Early assessment of molecular and cytogenetic response at 3 months of imatinib treatment has been shown to predict survival and might trigger treatment intensification in slow responders at risk of treatment failure. The use of Beta-Glucuronidase (GUS) as a reference gene allows a linear measurement of high BCR-ABL transcript levels at diagnosis and after 3 months of treatment. A ratio of 3 month and baseline levels might best reflect individual

response kinetics. The linear transcript scale is a prerequisite for the optimization of cut-off levels as predictive landmarks.
Aims: Evaluation of the prognostic significance of 1) BCR-ABL/GUS at diagnosis, 2) the individual reduction of transcripts given by (BCR-ABL/GUS at 3 months)/(BCR-ABL/GUS at diagnosis), 3) BCR-ABL/GUS at 3 months and 4) the established 10% BCR-ABL/ABL^{IS}landmark.
Methods: A total of 408 patients (pts) were investigated. 58 pts with imatinib onset before initial blood sampling within the study were excluded from the analysis. A total of 350 evaluable patients (median age 52 years, range 17-85, 42% female) were treated with an imatinib-based therapy consisting of imatinib 400 mg/d (n=84), imatinib 800 mg/d (n=146) and combinations of standard dose imatinib with interferon alpha (n=101) and low-dose cytarabine (n=19). Median follow-up was 4.8 years (range 1-10). Transcript levels of BCR-ABL, ABL and GUS were determined by quantitative RT-PCR from initial samples, taken before imatinib onset ("at diagnosis") and 3 month samples. Only patients expressing typical BCR-ABL transcripts (b2a2 and/or b3a2) were considered. Disease progression was defined by the incidence of accelerated phase, blastic phase or death from any reason. A landmark analysis was performed for progression-free survival (PFS) and overall survival (OS) after dichotomizing patients by a cut-off with optimized hazard ratio and sensitivity.
Results: Disease progression was observed in 26 patients (7.4%), 18 of them died (5.1%). The median BCR-ABL/GUS ratio was 15% at diagnosis (0.07-107) and 0.70% at 3 months (0-84) reflecting a decline to the 0.05 fold (1.3 log decline). With regard to the above described parameters the following findings were observed: 1) At diagnosis no prognostic cut-off level could be identified. 2) A reduction to the 0.35-fold of the initial BCR-ABL transcript level at diagnosis (0.46 log reduction) was identified as single best cut-off according to a maximal hazard ratio (HR) of 6.4 for OS and separated a high-risk group of 64 pts (18% of pts, 8-year PFS 77%, 8-year OS 80%) from a good-risk group of 286 pts (82% of pts, 8-year PFS 93%, 8-year OS 94%, P<0.001, respectively). 3) At 3 months, four BCR-ABL/GUS cut-offs with comparably high hazard ratios were identified: 6%, HR 5.6; 10%, HR 6.0; 14%, HR 6.5 and 21%, HR 7.0. The 6% cut-off was used for further analysis due to its superior sensitivity including the largest proportion of high-risk patients. This optimized cut-off separated a high-risk group of 86 pts (25% of pts, 8-year PFS 79%, 8-year OS 83%) from a good-risk group of 264 pts (75% of pts, 8-year PFS 93%, 8-year OS 94%, P<0.001, respectively). 4) When the established 10% BCR-ABL^{IS} landmark at 3 months was investigated, 88 pts were high-risk (25% of pts, 8-year PFS 83%, 8-year OS 86%) and 262 good-risk (75% of pts, 8-year PFS 92%, 8-year OS 93%, P=0.007 for PFS, P=0.008 and HR=3.4 for OS).
Summary and Conclusions: The individual reduction of BCR-ABL transcripts to the 0.35-fold of baseline levels and a 6% BCR-ABL/GUS cut-off at 3 months identify patients at risk more precisely than the 10% BCR-ABL^{IS} landmark.

Myelodysplastic syndromes - Clinical

IS IT POSSIBLE TO CURE SEVERE APLASTIC ANEMIA REFRACTORY TO IMMUNOSUPPRESSIVE THERAPY WITHOUT TRANSPLANT? A LONG TERM FOLLOW UP ANALYSIS OF A PHASE II STUDY OF ELTROMBOPAG

R Desmond[1,*], D Townsley[1], M Olnes[2], P Scheinberg[3], B Dumitriu[1], A Parikh[4], K Broder[1], K Calvo[5], C Wu[6], N Young[1], C Dunbar[1]
[1]Hematology, National Heart Lung and Blood Institute, Bethesda, [2]Hematology, Alaska Native Medical Center, Anchorage, United States, [3]Hospital Sao Jose - Hospital Beneficencia Portuguesa de Sao Paulo, Sao Paulo, Brazil, [4]Eastern Regional Medical Center, Philadelphia, [5]Laboratory Medicine, National Institute of Health, [6]Biostatistics Research, National Heart Lung and Blood Institute, Bethesda, United States

Background: About one quarter of patients with severe aplastic anemia are refractory to immunosuppressive therapy. Management of this population is challenging with no standard therapies available. Our group has shown that eltrombopag has good efficacy with minimal toxicity in this setting (Olnes MJ NEJM 2012; 367:11-19). In this pilot, phase II, non-randomized study patients received eltrombopag at a dose of 50 mg with dose escalation every 2 weeks to a maximum of 150 mg. The primary endpoint was improvement in blood counts with defined responses for each lineage. Forty-four per cent (11/25) of patients had a hematological response after 12-16 weeks, with responses in all three lineages seen. The majority of responders became transfusion-independent for platelets (9/11), 6 had erythroid responses with 3 patients previously dependent on red cell transfusion becoming transfusion -independent. Nine of 11 responders had increased neutrophil counts.
Aims: The aim of this analysis is to report updated safety and efficacy data in a larger patient cohort, and ask whether eltrombopag can be discontinued in patients with severe aplastic anemia achieving robust count recovery.
Methods: This current analysis includes 37 patients with refractory severe aplastic anemia, including 25 from the initial cohort and an additional 12 patients, enrolled in a second cohort of 18 patients, who have reached time to response assessment. Patients reaching response criteria at 12-16 weeks were offered continued therapy in an extended access study. Patients with robust blood count recovery (platelets >50,000/ul, Hb >10 gr/dL in the absence of RBC transfusion, and neutrophils >1,000/ul for more than 8 weeks) had eltrombopag tapered and discontinued.
Results: Median age was 44 years (range 18-77). Median number of prior courses of immunosuppression was 2 (range 2-4) and median time since last immunosuppression was 10 months (range 6-55). Thirty-eight per cent (14/37 patients) had a response in at least one lineage: 10 patients had platelet responses; 8 had erythroid responses, and 9 neutropenic patients had increased neutrophil counts. One non-responder who had drug stopped prematurely because of hepatitis B infection was retreated off protocol and attained red cell- and platelet-transfusion independence. Of the 11 patients who entered the extension study, 7 have and continue to maintain trilineage responses. We discontinued study drug because of sustained and robust counts (platelets >50,000uL, Hb >10 gr/dL in the absence of transfusion and neutrophils >1,000 for more than 8 weeks) in 4/7 patients and all have maintained stable counts with a median follow up of 7.5 months (range 7-9) off drug. Five non-responders had cytogenetic evolution, all found at response assessment with 3 developing monosomy7, 1 trisomy 21, and 1 trisomy 8. A 77 year old male who was enrolled in the extended access study with a non-robust response developed monosomy 13 after 14 months on eltrombopag. Baseline reticulocytes counts continued to be predictive of response (45.22 per cubic millimeter in responders *vs.* 24.45 per cubic millimeter in non-responders, P=0.015). There was no increased reticulin noted in bone marrow biopsies performed at response assessment and thereafter every 6 months on drug.
Summary and Conclusions: Eltrombopag is an effective treatment for refractory severe aplastic anemia. Continued exposure to drug may not be required for a sustained remission in those with robust count recovery. As in all patients with BM failure syndromes, serial BM biopsies are recommended to monitor for cytogenetic or morphologic evolution. Patients treated with eltrombopag for marrow failure states should be enrolled in clinical trials to allow data collection regarding risk of progression to clonal hematopoiesis. We are currently investigating patients who evolved with comparative genomic hybridization to assess whether unbalanced chromosomal abnormalities existed prior to treatment.

S1107

A RANDOMISED STUDY OF LENALIDOMIDE (LEN) +/- EPO IN RBC TRANSFUSION DEPENDENT (TD) IPSS LOW AND INT-1 (LOWER RISK) MYELODYSPLASTIC SYNDROMES (MDS) WITHOUT DEL 5Q RESISTANT TO EPO

A Toma[1,*], S Chevret[2], O Kosmider[3], J Delaunay[4], A Stamatoullas[5], C Rose[6],

O Beyne-Rauzy[7], A Banos[8], A Guerci-Bresler[9], E Jourdan[10], V Sardnal[3], D Caillot[11], K Laribi[12], B de Renzis[13], D Bordessoule[14], B Slama[15], L Sanhes[16], M Fontenay[3], P Fenaux[17], F Dreyfus[3]
[1]Hopital Henri Mondor, Creteil, [2]Hopital Saint Louis, [3]Hopital Cochin, Paris, [4]CHU, Nantes, [5]Centre Henri BECQUEREL, Rouen, [6]Hôpital Saint Vincent de Paul, Lille, [7]CHU Purpan, Toulouse, [8]Hôpital de la Cote Basque, Bayonne, [9]CHU Brabois, Vandoeuvre, [10]CHU, Nimes, [11]CHU, Dijon, [12]CHU, Le Mans, [13]CHU, Clermont Ferrand, [14]CHU, Limoges, [15]CH, Avignon, [16]CH, Perpignan, [17]Hopital Avicenne, Bobigny, France

Background: ESAs, the first line treatments of anemia in non del 5q lower risk MDS, yield only 40-50% responses. LEN gives RBC transfusion independence (TI) in about 25% of ESA resistant (or relapsing) TD lower risk MDS without del 5q (Raza, Blood, 2008), and a gene expression signature can predict response (Ebert, Plos Med 2008).
Aims: We randomized in this patient population LEN alone and LEN+EPO.
Methods: In this prospective multicenter open-label phase II study (NCT01718379), lower risk MDS patients without del 5q, with TD (≥4 RBC units during the previous 8 weeks (w)) and with ESA resistance or relapse after a response were randomized between LEN alone, 10mg/d × 21 d/4 w (L arm) or LEN (same schedule)+EPO beta, 60 000 U/w (LE arm). The primary endpoint was erythroid response (HI-E, IWG 2006 criteria) after 4 treatment cycles. Secondary objectives included identification of biomarkers of response.
Results: Between July 2010 and June 2012, 132 patients (pts, 66/arm), median age 73 (range 46-88), M/F: 88/44 were enrolled. Median TD was 6 RBC units/8w (range 2-18). IPSS was Low in 45% and Int-1 in 55% pts. Pretreatment characteristics did not differ between the 2 groups. All but 3 pts, who withdrew consent (2L+1LE), were evaluable for response. In this ITT population, HI-E was obtained in 15 pts (23.4%) in L arm and 26 (40.0%) in LE arm (RR=1.7, P=0.043, chi2 test), and TI in 9 (14.1%) *versus* 16 (24.6%) pts (RR=1.7, P=0.13). In the 99 pts who completed 4 treatment cycles, 41 achieved HI-E, including 15/49 (30.6%) in L arm *versus* 26/50 (52.0%) in LE arm (P=0.03), and TI in 9 (18.4%) *versus* 16 (32.0%) pts (RR=1.7, P=0.12). Side effects (cytopenias and 1 DVT/arm) were similar in the 2 arms. A 29-gene expression profile signature predicting HI-E to L or LE, different from that previously published, was identified and a polymorphism in the CRBN gene (Kosmider, submitted) was significantly associated with HI-E in the entire cohort (P=0.034)
Summary and Conclusions: LEN+EPO yielded a significantly better erythroid response than LEN alone in lower risk MDS patients with anemia resistant to ESA alone. A gene expression signature and a CRBN gene polymorphism correlated with the erythroid response.

Background: Patients (pts) with advanced myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML) often develop platelet (plt) transfusion-dependent thrombocytopenia. Eltrombopag (EPAG), an oral thrombopoietin receptor agonist, increases plts in chronic immune thrombocytopenia, hepatitis C virus-associated thrombocytopenia, and severe aplastic anemia.
Aims: To evaluate the safety and tolerability of EPAG in thrombocytopenic pts with advanced MDS and AML (primary end point). Secondary end points include plt transfusions, plt response, and overall survival (OS).
Methods: Pts with relapsed/refractory MDS or AML ineligible for antileukemic therapies, with 10%>50% bone marrow (BM) blasts and plts <30 Gi/L were randomized 2:1 to EPAG 50 mg qd (increases q2 weeks in pts without a plt response, up to 300 mg [150 mg for Asian pts]) or placebo (PLB) for 6 months. Standard supportive care and disease-modifying treatments were permitted at the investigator's discretion.
Results: Overall, 98 pts were enrolled (EPAG: n=64; PLB: n=34). Most pts had AML (Table 1) and received ≥1 prior antileukemic treatments, including hypomethylating agents (EPAG: 24 [38%]; PLB: 11 [32%]) and chemotherapy (EPAG: 10 [16%]; PLB: 3 [9%]). Most pts received the maximum dose (EPAG: 36 [56%]; PLB: 20 [59%]). Mean treatment duration was 102 days for EPAG and 78 days for PLB; 9 (14%) pts on EPAG continued treatment >6 mo *versus* 1 (3%) pt on PLB. Twenty-one (33%) EPAG and 17 (50%) PLB pts died on therapy or <30 days from the last dose; primary cause of death in both arms was underlying disease. The most common (≥20% in the EPAG arm) adverse events (AEs) on therapy +30 days were pyrexia, nausea, diarrhea, fatigue, decreased appetite, and pneumonia. Serious AEs in ≥5% of pts in either arm included sepsis, pyrexia, febrile neutropenia, and pneumonia. Hepatobiliary events were reported in 11 (17%) EPAG and 5 (15%) PLB pts; 3% (EPAG: 2; PLB: 1) reported thromboembolic events. Of 26 pts with MDS (WHO criteria) at baseline, 14 (EPAG: 9; PLB: 5) had postbaseline BM examination results available; 8 (EPAG: 5 [56%]; PLB: 3 [60%]) of 14 pts developed BM blasts ≥20% during treatment. Plt transfusion independence for ≥8 weeks was reported for 24 (38%) EPAG and 7 (21%) PLB pts (*P*=0.0979). Ten (16%) EPAG and 9 (26%) PLB pts had ≥Grade 3 hemorrhages (*P*=0.1472). More EPAG *versus* PLB pts started antileukemic/palliative treatment during the study (26 [41%] *versus* 11 [32%], respectively), including hypomethylating agents and salvage chemotherapy. Median OS was 27 weeks for EPAG *versus* 15.7 weeks for PLB (hazard ratio=0.71, *P*=0.1931). During treatment weeks 5-12, fewer pts receiving EPAG experienced clinically relevant thrombocytopenic events (plt counts <10 Gi/L, plt transfusions, or ≥Grade 3 hemorrhagic events) per week than PLB (weighted average [range]: EPAG: 38% [30%>48%]; PLB: 66% [56%>88%]).

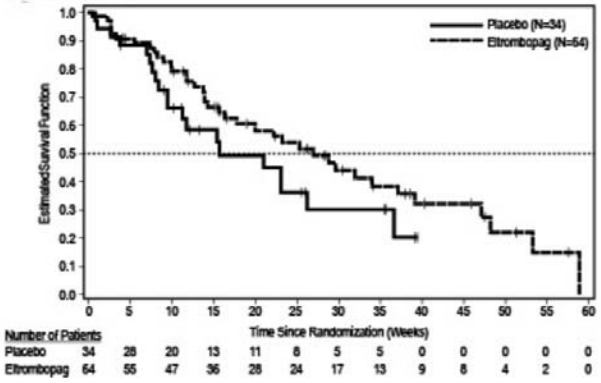
Table 1.

Baseline Disease Characteristics

	Placebo (N=34)	Eltrombopag (N=64)
WHO criteria, n (%)[a]		
MDS	11 (32)	15 (23)
AML	22 (65)	48 (75)
French-American-British criteria n, (%)[b]		
MDS	15 (44)	23 (36)
AML	19 (56)	41 (64)
Poor prognosis karyotype, n (%)	14 (41)	19 (30)
Received prior treatments, n (%)[c]	21 (62)	46 (72)
	Median (range)	
Absolute neutrophil count, Gi/L	0.55 (0-9.8)	0.85 (0-17.6)
Hemoglobin, g/dL	8.5 (6.0-11.2)	8.8 (4.3-13.2)
Platelets, Gi/L[d]	12 (2-38)	17 (2-71)
% BM blasts	20 (10-50)	26 (10-50)

[a]Two pts (1 PLB, 1 EPAG) had missing information. [b]FAB criteria assessed by local morphology review. [c]Excludes palliative treatments (eg, hydroxyurea). [d]Baseline platelet count was derived using an average of platelet counts during screening, excluding within 3 days of a transfusion.

Overall Survival



Summary and Conclusions: EPAG ≤300mg was well tolerated in pts with advanced MDS or AML. Pts treated with EPAG showed a trend toward fewer plt transfusions, fewer ≥Grade 3 hemorrhages, and improved OS compared with PLB. Additional studies with EPAG to evaluate potential antileukemic activity in advanced MDS or AML are warranted.

S1109

PROGNOSTIC VALUE OF DISTINCT ABERRANCIES IN ANTIGEN EXPRESSION AS ASSESSED BY MULTIPARAMETER FLOW CYTOMETRY IN PATIENTS WITH SUSPECTED MDS

W Kern[1,*], C Haferlach[1], T Alpermann[1], S Schnittger[1], T Haferlach[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Multiparameter flow cytometry (MFC) is increasingly used to diagnose myelodysplastic syndromes (MDS). The prognostic impact of distinct aberrancies in antigen expression remains to be clarified yet.
Aims: Evaluate the respective impact of distinct aberrancies in antigen expression on overall survival (OS) in pts with suspected MDS in relation to cytomorphology (CM) and cytogenetics (CG).
Methods: 804 pts with suspected MDS were analyzed in parallel by CM, CG and MFC (median age 70 yrs, range 2-89; median OS 6.2 yrs, median follow-up 3.2 yrs). Results of CM indicated MDS in 493 (61.3%) pts; in 170 (21.1%) pts CM revealed evidence of dysplasia but which was not sufficient to diagnose MDS; CM excluded MDS in 141 (17.5%) pts. Karyotypes were good/intermediate/poor according to IPSS in 684 (85.1%)/89 (11.1%)/31 (3.9%) pts. MFC was performed following ELN recommendations (Westers, Leukemia 2012) in myeloid progenitor cells (MPC), granulocytes, monocytes and erythroid cells. MFC parameters included increased or decreased antigen expression, expression of normally not expressed antigens, aberrant expression pattern of antigen pairs and expression of lymphatic antigens.
Results: The first set of analyses is based on the total of 804 pts, *i.e.* regardless of confirmation of MDS by CM. 11 MFC parameters were significantly associated with OS: MPC >5% (P<0.001, hazard ratio (HR) 2.5), expression of CD5 (P<0.001, HR 4.1), CD56 (P=0.043, HR 2.0), CD7 (P=0.015, HR 2.2) in MPC; reduced side-scatter signal (P<0.001, HR 1.9), aberrant CD13/CD16 expression pattern (P=0.007, HR 1.4), aberrant CD11b/CD16 expression pattern (P=0.003, HR 1.6), CD56 expression (P<0.001, HR 2.1), reduced CD33 expression (P=0.018, HR 1.6) in granulocytes; CD56 expression (P<0.001, HR 1.6) in monocytes; reduced CD71 expression (P<0.001, HR 2.1) in erythroid cells. A flow score was devised calculating for each pt the sum of all HRs for the respective parameters found positive. Pts were separated into 4 groups: group 1 (n=263 pts), score of 0; group 2 (n=259), score >0 and below the median (2.1); group 3 (n=149), score above the median and below the 75th percentile (5.0); group 4 (n=133), score above the 75th percentile. 4-yr-OS in groups 1/2/3/4 was 82.4%/67.1%/54.7%/36.2%, respectively (P=0.001 1 *vs*2, P=0.022 2 *vs*3, P=0.003 3 *vs*4, P<0.001 all other comparisons). Cox analysis of MFC score revealed a significant association with OS (P<0.001, HR 1.4 per group). Other parameters univariately related to OS were: diagnosis of MDS by CM (P<0.001, HR 2.2),% bone marrow blasts by CM (P<0.001, HR 1.9 per 10% increment), cytogenetic IPSS-group (P<0.001, HR 5.1 per group), WBC count (P<0.001, HR 1.2 per 10 G/L increment), hemoglobin level (P<0.001, HR 0.8 per g/L), platelet count (P<0.001, HR 1.4 per 100 G/L increment), and age (P<0.001, HR 1.5 per decade). Multivariate Cox analysis including flow score and established diagnostic markers as covariates revealed an independent impact on OS for all of them: flow score (P<0.001, HR 1.3), diagnosis of MDS by CM (P=0.003, HR 1.4), bone marrow blasts by CM (P=0.015, HR 1.4), and cytogenetics (P<0.001, HR 2.9). The flow score was still indenpendently related to OS when age and peripheral blood counts were included as covariates. The second set of analyses was performed in subgroups of patients according to results of CM. In cases with MDS proven by CM flow score was confirmed independently associated with OS (P=0.001, HR 1.2). Interestingly, even in cases with signs of dysplasia by CM, which are not sufficient to diagnose MDS, the 4 groups derived from the flow score differed significantly in OS (2-year-OS 85.9%/76.4%/73.0%/62.9%, P=0.024), Furthermore, multivariate analysis confirmed the independent impact of the flow score on OS (P=0.016, HR 1.3) within this cohort.
Summary and Conclusions: MDS-related findings by MFC in MDS provide prognostic information not just in pts with MDS proven by CM but also in a comprehensive cohort of pts being diagnosed for suspected MDS. Furthermore, even in pts with evidence of dysplasia not sufficient to diagnose MDS by CM a prognostic impact of MFC was demonstrated. This data thus suggests to integrate MFC into the diagnostic work-up of pts with suspected MDS.

Antonio e Biagio e Cesare Arrigo, Alessandria, [16]Hematology, Ospedale Sant'Andrea, Rome, [17]Hemaology, A.O. Bianchi-Melacrino-Morelli, Reggio Calabria, [18]Hematology, Ospedali Riuniti, Ancona, [19]Hematology, Policlinico Universitario Umberto I, Roma, [20]Hematology, Ospedale Civile, Pescara, [21]Hematology, Policlinico Universitario Umberto I, Rome, Italy
Background: Low and Int-1 International Prognostic Scoring System (IPSS) risk MDS patients may experience severe thrombocytopenia associated with risk of hemorrhage. Eltrombopag is an oral agonist of the thrombopoetin-receptor (TPO-R) indicated for treating chronic immune thrombocytopenic purpura. Eltrombopag's potential in increasing PLT counts in lower risk MDS has not been evaluated. We present interim results of a Phase II, multicentre, prospective, placebo-controlled, single-blind study (EQoL-MDS).
Aims: Primary endpoints are safety and efficacy of eltrombopag in low and intermediate-1 IPSS risk. Secondary endpoints include changes in quality of life (QoL), PLT transfusion requirement, incidence and severity of bleeding, and survival.
Methods: Adult patients (N=171) are being included if: PLT<30 Gi/L; ECOG performance status <4; ineligible for, relapsed or refractory to other treatments; and naive to TPO-R agonists. Eltrombopag/placebo (2:1) will be administered at a 50 mg daily starting dose with 50 mg increases every 2 weeks to maximum 300 mg to target PLT 100 Gi/L. Dose interruptions or reductions are required for PLT >200 Gi/L or adverse events. PLT response is defined as Response (R) if: 1) baseline PLT>20 Gi/L: absence of bleeding and PLT≥50Gi/L; 2) baseline PLT<20 Gi/L: PLT>20 Gi/L and increase by at least 100%, not due to PLT transfusions; and Complete Response (CR) if PLT≥100 Gi/L and absence of bleeding. Peripheral and bone marrow blood morphology (centralized and blind) and cytogenetics are performed throughout the study. QoL scores are evaluated by EORTC QLQ-C30 and QOL-E instruments.
Results: Thirty-one patients (21 on eltrombopag–Arm A), have been randomized and 5 are in screening at the time of this report. Mean age is 66 (SD 12) years, male/female 18/13. Baseline mean PLT count was 16 (SD 8) Gi/L. Three cases in Arm A and 1 in Arm B had significant bleeding requiring PLT transfusions. Fifteen patients have reached a 12-week follow-up: 12 out of 15 cases in Arm A have obtained PLT responses at median 100 mg dosing associated with disappearance of bleeding and PLT transfusion independence. There were no responses in Arm B. At 12 weeks, PLT count increased from baseline by mean 64 (SD 77) Gi/L (P=0.006) in Arm A *versus* no significative changes in Arm B. Fatigue and general QoL improved significantly from baseline in Arm A. Grade III-IV unrelated adverse events occurred in 4 patients in Arm A (infectious complications, arthritis, heart diseae). Bone marrow blasts reduced in 3 cases during treatment in Arm A, *versus* 2 progressions in Arm B.
Summary and Conclusions: Preliminary results in low and Intermediate-1 risk IPSS MDS patients with thrombocytopenia suggest safety and efficacy of eltrombopag in terms of response rates and improvements in quality of life.

Background: Ruxolitinib is a potent JAK1/JAK2 inhibitor that has demonstrated rapid and durable improvements in splenomegaly, MF-related symptoms and quality of life in the 2 phase 3 COMFORT studies. COMFORT-II is a randomized, open-label study comparing ruxolitinib with BAT in patients (pts) with MF. Two-year follow-up of COMFORT-II confirmed that spleen volume reductions were sustained and ruxolitinib treatment remained tolerable with long-term use. This 3-year follow-up presents longer-term survival data and updates the long-term efficacy and safety findings of COMFORT-II.
Aims: To update the efficacy and safety findings of COMFORT-II with 3 years of follow-up (cutoff date: 01 Dec 2012).
Methods: Patients (n=219) with intermediate-2 or high-risk MF were randomized (2:1) to receive ruxolitinib (15 or 20 mg bid, based on baseline platelet count [100-200 or >200×10^9/L, respectively]), or BAT. Efficacy results are based on an intention-to-treat analysis. A spleen response was defined as a reduction ≥35% from baseline in spleen volume; a loss of response was defined as a spleen volume increase >25% over on-study nadir that was no longer a ≥35% reduction from baseline. Overall survival was estimated using the Kaplan-Meier (KM) method.

Results: After 3 years (median follow-up, 151 wk), 45.2% of patients in the ruxolitinib arm remain on treatment. All patients randomized to BAT discontinued treatment: 45 pts (61.6%) crossed over to receive ruxolitinib with 22 (48.9%) of these pts ongoing in the extension phase. Primary reasons for study discontinuation were AEs (16.4%) and disease progression (15.1%) in the ruxolitinib arm and withdrawal of consent and other (12.3% each) with BAT. The median duration of exposure was 136 wk to ruxolitinib (randomized and extension phases) and 45 wk to BAT (randomized treatment only). Overall, 75 pts (51.4%) treated with ruxolitinib achieved a ≥35% reduction from baseline in spleen volume, and 6 of these pts achieved a ≥35% reduction after the primary analysis at 48 wk. Reductions in spleen volumes were sustained with continued ruxolitinib therapy (median duration not yet reached; Figure 1). Overall, 51 patients died: 29 (19.9%) in ruxolitinib arm and 22 (30.1%) in BAT arm; there was a 52% reduction in risk of death in the ruxolitinib arm compared with BAT (HR=0.48; 95% CI, 0.28-0.85; log-rank *P*=.009 [unadjusted for multiple comparisons]; Figure 2). The estimated probability of being alive at 144 wk was 81% in ruxolitinib arm and 61% in BAT arm. With longer treatment duration (median exposure: ruxolitinib, 136 wk; BAT, 45 wk), there were no newly reported or unexpected AEs among those that were most common. Consistent with ruxolitinib's mechanism of action and previous reports, the most common AEs were anemia (ruxolitinib, 50.0%; BAT, 16.4%) and thrombocytopenia (50.7%; 13.7%). The most common non-hematologic AEs were peripheral edema (ruxolitinib, 36.3%; BAT, 28.8%), diarrhea (32.2%; 17.8%), asthenia (24.0%; 12.3%), dyspnea (23.3%; 20.5%), pyrexia (24.0%; 9.5%) and fatigue (23.3%; 11.0%). Five (3.5%) pts and 4 (5.5%) pts developed leukemia in the ruxolitinib and BAT arms, respectively.

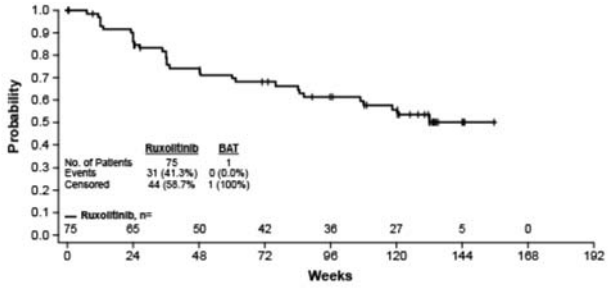

Figure 1. Kaplan-Meier analysis of maintenance of spleen response with Ruxolitinib treatment.

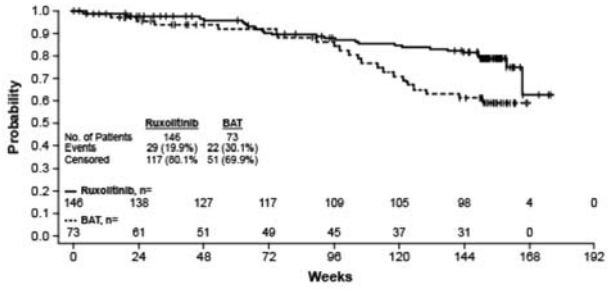

Figure 2. Kaplan-Meier analysis of overall survival.

Summary and Conclusions: This long-term analysis shows that ruxolitinib continues to be well tolerated and provides rapid and durable reductions in splenomegaly that are sustained for ≥3 years of treatment. Ruxolitinib-treated patients showed a longer survival over those receiving BAT, consistent with the survival advantage observed in previous analyses of COMFORT-II (Cervantes *et al. Blood.* 2013*)* and COMFORT-I (Verstovsek *et al. NEJM.* 2012).

Myeloproliferative neoplasms - Clinical

S1112

IMETELSTAT: A NOVEL APPROACH WITH ROBUST HEMATOLOGIC AND MOLECULAR RESPONSES IN A PHASE 2 STUDY IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET) WHO ARE REFRACTORY OR INTOLERANT TO PRIOR THERAPY

G Baerlocher[1,*], E Leibundgut[1], G Spitzer[2], O Ottmann[3], O Odenike[4], A Röth[5], M McDevitt[6], S Verstovsek[7], K Nishimoto[8], C Ayran[8], T Shih[8], X Wang[8], D Morfeld[8], D Snyder[9]
[1]Hematology, University Hospital and University of Bern, Bern, Switzerland, [2]Upstate Oncology Associates, Greenville, SC, United States, [3]Hematology and Oncology, Johann Wolfgang Goethe Universität, Frankfurt, Germany, [4]University of Chicago, Chicago, IL, United States, [5]University of Duisburg-Essen, Essen, Germany, [6]The Johns Hopkins University, Baltimore, MD, [7]University of Texas MD Anderson Cancer Center, Houston, TX, [8]Geron Corporation, Menlo Park, CA, [9]Hematology and HCT, City of Hope, Duarte, CA, United States

Background: Myeloproliferative neoplasms (MPNs), such as essential thrombocythemia (ET), are driven by neoplastic progenitor cells. Telomerase is upregulated in neoplastic progenitor cells and sustains indefinite replication. Imetelstat is a first in class, potent, specific inhibitor of telomerase. *In vitro* studies suggest that imetelstat selectively inhibits spontaneous CFU-megakaryocyte growth from the blood of pts with ET but not from healthy individuals. In addition, imetelstat inhibited the proliferation of neoplastic clonogenic cells in ET pts. An update of the ongoing phase 2 study is presented here.
Aims: Primary endpoint was best overall hematologic response (HR) with complete response (CR) and partial response (PR) defined as platelet (plt) counts ≤400E3/µl and ≤600E3/µl (or >50% reduction from baseline), respectively, for ≥4 consecutive weeks (wks) in the absence of new thromboembolic events. A key secondary endpoint was molecular response (MR), which includes measurement of the JAK2V617F allele burden by allele-specific quantitative real-time PCR.
Methods: This study enrolled pts with ET who had failed or were intolerant to ≥1 prior therapy, or refused standard therapy. During the induction phase, pts were treated with imetelstat 7.5 mg/kg or 9.4 mg/kg IV weekly until attainment of plt count approximately 250-300E3/µl. Maintenance phase was then commenced with dosing titrated to plt count.
Results: As of 11 Jan 2013, 18 pts with ET were enrolled of which 16 (7 JAK2V617F-positive pts) were treated. Median age and yrs since initial diagnosis were 60 yrs and 7.2 yrs, respectively. Median initial plt count was 832E3/µl (range 521-1359E3/µl). Best overall HR was 87.5%, with 14 of 16 pts achieving confirmed HR (13 CR, 1 PR) after a median of 6.1 wks (range 5.1-14.1 wks). Both pts without HR received ≤3 cycles of imetelstat. Hematologic disease progression (PD) is defined as having plt count >600E3/µl for 2 consecutive cycles on the maximum 11.7 mg/kg/wk dose. Despite some fluctuations in plt count, 15 of 16 pts remain on imetelstat therapy (median time 33.1 wks) without PD, including five pts with >1 yr of treatment. Dosing frequency on maintenance therapy was generally reduced with time. A decrease in JAK2V617F allele burden was observed in 6 of 7 JAK2-positive pts (see Table 1). Five pts had a partial MR (≥50% reduction of JAK2V617F allele burden from baseline) with a 2-22 fold decrease within 3 months. One pt reached a partial MR after 12 months and no pt lost partial MR (up to 1.5 yrs treatment) despite less frequent imetelstat dosing. Long-term administration of imetelstat was generally well tolerated. Common adverse events reported were mild to moderate gastrointestinal toxicities, cytopenias, and fatigue. Early onset self-limiting grade 1 increases in alanine aminotransferase were often observed with concurrent grade 1 increases in aspartate aminotransferase, though the latter often persisted with treatment. With longer dosing new onset grade 1 increases in alkaline phosphatase were observed in 7 of 16 pts, associated with unconjugated hyperbilirubinemia (up to grade 2) in 4 pts.

Table 1.

Pt #	Baseline	3 mo	6 mo	9 mo	12 mo	15 mo	18 mo
1	26.4%	***7.7%***	6.1%	1.8%	8.3%	1.0%	2.6%
2	53.3%	52.2%	43.7%	44.5%	44.6%	43.4%	40.7%
3	10.8%	11.2%	14.3%	6.5%	***4.4%***	3.0%	
4	31.1%	***14.8%***	5.6%	n/a	6.5%		
5	10.8%	***1.2%***	3.0%	0.9%			
6	19.7%	***5.7%***	6.2%	3.5%			
7	26.7%	***1.2%***					

n/a: not available
Italic highlight: first tested time point with a partial molecular response

Summary and Conclusions: Imetelstat induced rapid and complete HR in 13 of 16 pts with ET who failed or were intolerant to conventional therapies while having acceptable safety and tolerability. All pts who achieved HR continue on imetelstat without PD. Six of 7 pts with JAK2V617F achieved and maintained a partial MR throughout treatment, confirming durable inhibition of the neoplastic clonogenic cells. Therefore, telomerase inhibition by imetelstat could have the potential to modify the underlying biology of MPNs. Additional and new data on pts with ET and polycythemia vera, respectively, will be presented from this ongoing study.

S1113

UPDATED RESULTS FROM A RANDOMIZED PHASE 2 DOSE-RANGING STUDY OF THE JAK2-SELECTIVE INHIBITOR SAR302503 IN PATIENTS WITH INTERMEDIATE-2 OR HIGH-RISK MYELOFIBROSIS (MF)

M Talpaz[1,*], C Jamieson[2], N Gabrail[3], C Lebedinsky[4], G Gao[4], A Patki[4], F Lui[4], A Tefferi[5], A Pardanani[5]
[1]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [2]Department of Medicine, Moores UCSD Cancer Center, La Jolla, [3]Gabrail Cancer Center, Canton, [4]Sanofi Oncology, Cambridge, [5]Division of Hematology, Department of Internal Medicine, Mayo Clinic, Rochester, United States

Background: We previously reported that treatment with 3 cycles of the JAK2-selective inhibitor SAR302503 at doses of 300, 400, or 500 mg reduced splenomegaly and disease-related symptoms with acceptable toxicity in patients with MF enrolled in a phase 2 study (NCT01420770; *Blood* 2012;120:21 Abs 2837).
Aims: We assessed efficacy and safety in this study after 6 treatment cycles (24 weeks).
Methods: Patients ≥18 years old with intermediate-2 or high-risk primary, post-polycythemia vera, or post-essential thrombocythemia MF and splenomegaly (length ≥5 cm by palpation) were eligible. SAR302503 was administered orally, once daily as consecutive 4-week cycles until disease progression or unacceptable toxicity. Spleen response (≥35% reduction in spleen volume *vs* baseline) was assessed by MRI/CT with blinded independent central review. Symptom response was defined as either a 2-point improvement or resolution of the symptom. All patients provided written informed consent.
Results: A total of 31 patients were enrolled (300 mg n=10; 400 mg n=10; 500 mg n=11). Risk status was balanced in all but the 300 mg group (70% high risk). Most patients were *JAK2*V617F positive (90%) and blood transfusion independent (81%). Spleen response rates at the end of 6 cycles of treatment (secondary endpoint) were 30% (3/10) in the 300 mg group, 60% (6/10) with 400 mg, and 55% (6/11) with 500 mg compared with end of cycle (EOC) 3 rates of 30%, 50%, and 64%, respectively. One patient in the 500 mg group who had a spleen response at EOC 3 (39% reduction) but not at EOC 6 (25% reduction) had dose reductions to 200 mg due to anemia. The median number of cycles was 13 (range 2–17) and 24 patients have been on treatment for >12 months. SAR302503 reduced baseline constitutional symptoms at EOC 3 in all dose groups, with the greatest symptom responses seen for night sweats in 14/15 patients (93%), itching 10/14 (71%), early satiety 10/18 (56%), and abdominal pain 10/18 (56%). Most common adverse events across all doses were anemia and diarrhea, with grade 3/4 rates of 58% and 13%, respectively. The incidence of diarrhea tended to decrease after the first 2 treatment cycles. The rate of grade 3/4 thrombocytopenia was 16%. There was no grade 3/4 neutropenia. There have been no reports of withdrawal syndrome after stopping SAR302503. Median *JAK2*V617F allele burden was 93% at baseline, 87% at EOC3, and 78% at EOC 6 in 19/26 patients with all available samples. The expression of 22 of 97 cytokines was significantly regulated (≥1.5-fold difference; P<0.05) after cycle 1.
Summary and Conclusions: In this phase 2 trial, continued treatment with SAR302503 was associated with clinically meaningful reductions in splenomegaly. SAR302503 was generally well tolerated in this trial and adverse events were consistent with the known safety profile. Updated symptom and long-term outcome data will be reported at the meeting.

S1114

LONG-TERM OUTCOMES IN 62 PATIENTS TREATED WITH PEGYLATED INTERFERON ALPHA2A: EXPERIENCE OF THE FIM.

Background: To date, the only curative treatment for patients with myelofibrosis is still allogeneic stem cell transplantation. Few of palliative therapies could act on both proliferative and cytopenic phases of the disease. Pegylated Interferon α2a (Peg-Ifn α2a) seemed able to do so *(Ianotto et al, 2009 and Ianotto et al, 2013 under submission)*. In a recent study, the French Intergroup of Myeloproliferative Diseases (FIM) proved the real efficiency of Peg-Ifn α2a by proceeding of an analysis of FIM (France Intergroupe des Syndromes Myéloprolifératifs) cases.
Aims: We reported here the long-term analysis of 62 identified patients treated for primary or secondary myelofibrosis and treated with Peg-Ifn α2a.
Methods: From December 2006 to April 2011, we identified 62 patients treated with Peg-Interferon-α2a in 19 different French and Belgian centres affiliated to the FIM. Characteristics of the patients were collected at diagnosis, clinical and biological parameters were collected every 3 months: doses of Ifn, palpable spleen size, constitutional symptoms, transfusion needs, leukocytes, myelemia, haemoglobin, platelets, circulating CD34+ cells, erythroblasts and quantification of $JAK2^{V617F}$ allele burden. Responses were assessed by the International Working Group for Myelofibrosis Research and Treatment criteria (IWG-MRT).
Results: The patients were aged from 33 to 81 years at the beginning of the Peg-Ifn α2a and were 36 males and 26 females. Twenty-nine of them were primary myelofibrosis, 19 were post-PV and 14 post-ET myelofibrosis. Forty patients were $JAK2^{V617F}$ positive. Forty-two patients received previous cytoreductive treatment (almost hydroxyurea). Concerning the best global results obtained, the reduction of the spleen size was observed in 46% (with 50% of complete response: CR), the debiliting symptoms disappeared in 82%, leukocytes abnormalities were reduced from 73% (100% of CR), anaemia was reduced in 64% (91% of CR), platelets abnormalities were reduced from 78% (90% of CR). The median duration of the study was 34.5 months for the global population and 26.5 months for patients still on therapy. At the time of the study-point, 25 patients were still under Peg-Ifn α2a among the 42 patients still alive. Twenty patients died during the study, almost from GVHd (5), evolution of myelofibrosis (4) or acute leukaemia (4). Among the 25 patients still under Peg-Ifn α2a, we did not seen any global CR because of the absence of bone marrow biopsy (at this time), we observed 40% of PR, 30% of CI and 15% of SD. Thirty-seven patients stopped the drug due to evolution of myelofibrosis (43%), cytopenia (16%) or psychiatric side effects (16%). The initial median dose of Peg-Interferon-α2a was 135µg/wk and decreased to 45µg/wk at the time of the evaluation.
Summary and Conclusions: We report here the results of the largest study of patients with primary and secondary myelofibrosis treated with Peg-Ifn α2a. We could observe that this drug is effective and safety in this indication, even for old patients. The positive effects could be maintained over years.

S1115

SYNERGISTIC EFFECT OF RUXOLITINIB AND PANOBINOSTAT TO OVERCOME DRUG RESISTANCE RELATED TO BM STROMA MICROENVIRONMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

B De Angelis[1,*], C Quintarelli[1], S Errichiello[1], S Caruso[1], N Esposito[1], M Raia[2], N Pugliese[3], G Battipaglia[3], V Martinelli[3], F Pane[3]
[1]Dipartimento di Medicina Clinica e Chirurgica, University of Naples Federico II, Italy, [2]Medicina Molecolare e Biotecnologie Mediche, Ceinge - Biotecnologie Avanzate, [3]Dipartimento di Medicina Clinica e Chirurgica, University of Naples Federico II, Italy, Operative Unit of Haematology-II Policlinico Naples, Naples, Italy

Background: The $JAK2^{V617F}$ constitutively deregulate signaling of the JAK/STAT pathway conferring proliferative and survival advantages in the chronic $Ph^{neg.ve}$Myeloproliferative Neoplasms (MPNs). MPNs do not evolve merely from hematopoietic progenitor cells intrinsic defects; rather they are heavily influenced by genetic and epigenetic events affecting the Bone Marrow (BM) niche. Many drugs target different pathways critical for MPN development, like JAK inhibitorruxolitinib, known to decrease spleen size and alleviate constitutional symptoms in myelofibrosis (MF). Other drugs work through remodeling of chromatin with a key role in epigenetics, like the pan-histone deacetylase inhibitor panobinostat. This drug in phase I study for patients with MF, showed to be clinically active, regardless of JAK2 V617F status.However several lines of evidence suggest that in MF, stromal cells are primed by the malignant hematopoietic clone, which, in turn, influences the stroma to create a "favorable" pathologic microenvironment that nurtures and protects the malignant cells. Then, humoral factors secreted by BM niche, may protect MPNs clones from JAK2 or HDAC inhibitortherapy.

Aims: In this study, we evaluate whether combination therapy with HDAC and JAK2 inhibitors has a potential value to overcomethe "protective effects" of the stroma BM on MPN cell lines or primary CD34+ progenitor cells derived from MPN patients.
Methods: $JAK2^{V617F}$ tumor cell lines HEL and SET2 were maintained in culture with RPMI medium, defined as regular media (RM). The human stroma cell line HS-5 serum-free supernatant, named HS5/Stroma Conditioned Media(HS5/SCM), was used to mimic BM microenvironment. Cell lines were incubated for 72hrs in the presence of panobinostat or/and ruxolitinib before the specified analysis. Apoptotic rate was evaluated by Annexin-V staining. Cell cyclewas assessed by BRdU Assay. IC50 was calculated based on the level of viable cells residual after treatment with increasing doses of drugs in the presence or absence of HS-5/SCM.
Results: Treatment with panobinostat or ruxolitinib induced a significant apoptosis in SET2 and HEL cells in a dose-dependent manner. Indeed, when SET2 cells are treated with 30nM panobinostat or 300nM ruxolitinib in the presence of HS-5/SCM, the drug-related apoptosis is significantly reduced (40% ±18% and 30%±8%, respectively) respect to cell line treated in RM (79% ±15% and 58%±12%, respectively; $P<0.05$). Similar results have been achieved for HEL cell line. Serial dilutions of HS-5/SCM, ranging from 50% to 0.1%, showed that the resistance was dose dependent. The IC50 of SET2 cells treated with panobinostat or ruxolitinib is significantly increased in the presence of HS-5/SCM (32nM and 1261nM, respectively) *versus* the IC50 in RM (15nM and 281nM, respectively). Co-treatment of panobinostat and ruxolitinib strongly synergize, increasing SET2 (96%±1%) and HEL (73%±5%) apoptosis, regardless HS5/SCM exposition. Finally co-treatment of MPN-CD34+ cells with panobinostat and ruxolitinib strongly decrease CFU counting in a stroma-independent manner.
Summary and Conclusions: Disrupting the cross-talk between the malignant clone and its BM milieu is an attractive therapeutic strategy in MPNs. Here, we present evidence that, combination therapy with HDAC and JAKinhibitors has a potential value to overcomethe "protective effect" of the stroma BM on the $JAK2^{V617F}$ cells.

Non-Hodgkin lymphoma - Biology

GENETIC ANALYSIS OF SPLENIC MARGINAL ZONE LYMPHOMAS REVEALS NOVEL CHANGES IN PATHWAYS IMPLICATED IN CARCINOGENESIS

M Parry[1,*], M Rose-Zerilli[1], J Gibson[2], H Parker[1], Z Davis[3], A Gardiner[3], J Forster[1], S Ennis[2], R Walewska[3], A Collins[2], D Oscier[1], J Strefford[1]
[1]Cancer Sciences, [2]Human Development and Health, University of Southampton, Southampton, [3]Pathology, Royal Bournemouth Hospital, Bournemouth, United Kingdom

Background: The pathogenesis of Splenic Marginal Zone Lymphoma (SMZL) remains largely unknown. Deletions and mutations in *TP53*, as well as deletions of 7q and gains of 3q, are recurrent in SMZL but their role in disease pathogenesis and their clinical significance remains unclear. Recent whole exome sequencing (WES) studies have identified recurrent mutations in key pathways, and most notably *NOTCH2* mutations in >25% of patients. These studies are based on small, heterogeneous discovery cohorts, and therefore only captured a fraction of the genomic lesions present in SMZL. Considerable research therefore remains necessary to accurately describe the genetic landscape of SMZL.
Aims: To identify novel somatic mutations in a biologically-homogeneous (7q abnormalities and/or *IGHV*1-2*04 usage) cohort of eight SMZL patients.
Methods: High molecular weight genomic tumour DNA was extracted from purified peripheral blood lymphocytes or spleens, and matched with germ-line DNA from saliva. PCR for each patient's clonal *IGHV*-sequence was used to ensure germ-line DNA purity. WES (Agilent SureSelect enrichment and Illumina HiSeq2000 sequencing) and copy number profiling (Affymetrix SNP6.0) were performed. Sequence reads were aligned to the human reference genome (Hg19, Novoalign), then merged and compiled (SAMtools), prior to removal of duplicate reads (Picard). Finally, non-synonymous somatic variants were identified (Varscan 2), prioritised (somatic P-value), and annotated against the COSMIC, dbSNP and 1000 genomes databases using Annovar. The presence of somatic variants was confirmed using Sanger sequencing.
Results: Our analysis identified 74 somatic variants, including 66 non-synonymous or frame-shift mutations and eight splice-site mutations, with an average of 9/patient (2-17). Copy number analysis revealed 28 somatic copy number alterations, with an average of 3.5/tumour (0-9/tumour). Two gains of 3q (28.5Mb; 170.8-199.3) and a trisomy 12 were also found. A 12.2Mb MDR was identified at 7q32.3-34 (130.6-142.8) in seven patients. We identified mutations in several genes previously reported in SMZL, such as *MAP3K14* [n=2], *NOTCH2* [n=1] and *TNFAIP3* [n=1]. Importantly, our study identified two novel recurrently mutated genes, *CREBBP* and *CBFA2T3*, both in two cases. The CREB binding-protein, *CREBBP*, is involved in chromatin remodelling and transcription factor recognition, and the same mutation (Y1450C) occurs in other lymphoma subtypes. *CBFA2T3* is a core-binding factor that facilitates transcriptional repression and is targeted by the t(16;21) translocation in AML. We also identified mutations in *BRPF1*, *FAT4*, *SDK1*, *TRPM6* and *AMOTL1* in single cases that can now be considered recurrent, as they have also been observed in other studies [*JEM (2012); 209(9): 1553-63/1537-51*]. Pathway analysis identified involvement of MAPK signalling (*MAP3K14, FLNC, CACNA1E*), cell cycle control (*CREBBP, CUL1*) and Notch signalling (*NOTCH2, NOTCH4*).
Summary and Conclusions: This current study expands our understanding of the molecular pathogenesis of SMZL. We are currently extending this work by re-sequencing approximately 600 candidate genes, known or predicted to be involved in SMZL pathogenesis, in 300 patients (Haloplex, Agilent Technologies). This is an international collaborative project that will ultimately establish the frequency and clinical importance of gene mutations in SMZL, pushing forward our understanding of the disease and validating the clinical utility of these lesions to establish a stratified approach to care.

S1117

EPIGENETIC DEREGULATION OF MIRNA IN MALIGNANT LYMPHOMAS

M Yamagishi[1,*], K Nakano[1], H Katano[2], A Utsunomiya[3], Y Ota[4], T Hishima[5], S Okada[6], K Yamaguchi[7], K Uchimaru[8], S Ogawa[9], T Watanabe[1]
[1]Graduate School of Frontier Sciences, The University of Tokyo, [2]Department of Pathology, National Institute of Infectious Disease, Tokyo, [3]Department of Hematology, Imamura Bun-in Hospital, Kagoshima, [4]Department of Pathology, Toranomon Hospital, [5]Department of Pathology, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, [6]Center for AIDS Research, Kumamoto University, Kumamoto, [7]Department of Safety Research on Blood and Biologics, National Institute of Infectious Disease, [8]Institute of Medical Science, [9]Faculty of Medicine, The University of Tokyo, Tokyo, Japan

Background: One of the most significant recent advances in biomedical research has been the discovery of the 22-nt-long class of non-coding RNA designated miRNA. The miRNAs are pleiotropic molecules that can regulate multiple genes expression and consequently control cell fate. miRNA imbalance is observed in the pathogenesis of a range of diseases including lymphomas, in

which survival and proliferation signaling cascades are abnormally sustained. It is now unclear how miRNAs regulate lymphoma-specific signaling activation.
Aims: Elucidation of miRNA signature and its functional involvement in malignant lymphomas.
Methods: By integrated analyses of primary adult T-cell leukemia (ATL) cells, we uncovered unique molecular characteristics that include profiles of mRNA expression, DNA copy number, and miRNA signature. In addition, we also addressed miRNA abnormality and its functional roles in diffuse large B-cell lymphoma (DLBCL).
Results: Although crucial roles of miRNA in cancers have begun to emerge, detailed studies with ATL patients have not been achieved. Using 40 primary ATL samples and 22 samples of normal CD4+ T cells, we determined the ATL miRNA signature, *i.e.*, all ATL samples showed abnormal downregulated miRNA expression (Yamagishi *et al.*, Cancer Cell, 2012). Especially, microarray and qRT-PCR revealed drastic loss of miR-31, which has been reported as a metastasis-associated miRNA in breast cancer. Given that all ATL cases invariably showed undetectable or very low level of miR-31, the loss of miR-31 appears to be involved in ATL development. As a novel miR-31 target gene, we identified NF-κB inducing kinase (NIK) that plays central roles in noncanonical signaling and constitutive activation of NF-κB pathway in various cancers, including malignant lymphomas. Restoration of miR-31 decreased the levels of NIK expression and NF-κB activity, resulting in reduction of malignant phenotypes, including proliferative index, anti-apoptosis, and chemotaxis in ATL cells. Furthermore, lentivirus-introduced miR-31 could induce strong apoptosis in primary tumors freshly isolated from ATL patients, clearly indicating pivotal functions of miR-31 as a tumor suppressor. We also found that genetic loss and polycomb-mediated epigenetic deregulation directly involve in the silencing of miR-31. Knockdown of polycomb repressive complex restored the miR-31 expression and consequently inhibited NIK-dependent NF-κB cascade, leading to strong apoptosis in ATL cell lines as well as in primary patient samples. These findings illustrated that genetic and epigenetic abnormalities link to NF-κB activation through the loss of miR-31. Of note, we and other research groups have demonstrated that this novel molecular interconnection is well conserved in other cancers such as breast and prostate cancers, melanoma, and B cell lymphomas, in which polycomb and NF-κB are both activated. Thus, miR-31 downregulation appears to be one of the crucial molecular hallmarks of cancers. By comprehensive analysis of primary DLBCL samples and *in vitro* experiments, we also discovered specific miRNAs downregulation in DLBCL. We show that epigenetic silencing of some miRNAs contributes to chronic signaling activation and cell proliferation in B cell lymphoma cells.
Summary and Conclusions: Considering aberrant epigenomics associated with cancers, the emerging relationship provides us a conceptual advance in understanding the broad-acting oncogenic signaling and molecular hallmarks of malignant lymphomas.

S1118

REDUCED TET2 FUNCTION CONTRIBUTES TO DEVELOPMENT OF PERIPHERAL T-CELL LYMPHOMA THROUGH IMPAIRMENT OF EPIGENETIC REGULATION

M Sakata-Yanagimoto[1,*], H Muto[1], G Nagae[2], Y Miyake[1], T Enami[1], Y Kamada[1], T Kato[1], H Nishikii[1], K Suzukawa[1], N Nakamura[3], H Aburatani[2], S Ogawa[4], S Chiba[1]
[1]Department of Hematology, University of Tsukuba, Ibaraki, [2]Genome Science Division, RCAST, the University of Tokyo, Tokyo, [3]Department of Pathology, Tokai University School of Medicine, Kanagawa, [4]Cancer Genomics Project, the University of Tokyo, Tokyo, Japan

Background: TET family proteins convert methylcytosine (mC) to hydroxymethylcytosine (hmC). Loss-of-function mutations in *TET2* were initially reported in various types of myeloid malignancies, and later also in specific subtypes of lymphoid malignancies. *TET2* mutations are found more frequently in angioimmunoblastic T cell lymphoma (AITL) and peripheral T cell lymphoma, not otherwise specified (PTCL-NOS) with AITL-like features than PTCL-NOS without those or other types of lymphomas. The tumor origin of AITL is thought to be follicular helper T cells (Tfh). *Tet2* knockout mice demonstrated premalignant status of myeloid lineages, implicating that loss-of-function mutations of *TET2* play an important role in myeloid malignancies; however, there are no clues how impaired *Tet2* function provokes T-cell lymphomas.
Aims: We analyzed Tet2 gene trap mice to analyze the role of TET2 in T-cell lymphomagenesis.
Methods: The $Tet2^{gt}$ locus has a trapping vector inserted into the second intron of *Tet2* locus. Bone marrow, spleen, and tumors when developed were analyzed in adult $Tet2^{gt/gt}$ mice by flow cytometry and immunohistochemical staining. The comprehensive gene-expression profiles of tumors were assayed by microarray and the data was analyzed by Gene Set Enrichment Analysis (GSEA). The patterns of hmC were analyzed by hmDIP, followed by high throughput sequencing.
Results: Adult mice were obtained after crossing $Tet2^{+/gt}$ mice under the following ratio; $Tet2^{+/+}$:$Tet2^{+/gt}$:$Tet2^{gt/gt}$=48:52:25. The TET2 mRNA expression level in $Tet2^{gt/gt}$ Lin- FL cells was reduced to 20% of that in WT Lin- FL cells, while the hmC level to around a half of that in WT cells. In the spleen of 40 week-old mice, the proportion of CD4+/PD1+/CXCR5+ cells, immunophenotypically similar to Tfh, was significantly increased in $Tet2^{gt/gt}$ mice compared to $Tet2^{+/+}$ mice ($P=0.022$). Five out of the 7 $Tet2^{gt/gt}$ mice aged 60 weeks or older (median, 67 weeks) developed marked splenomegaly with swollen lymph nodes and multi-nodular tumors in liver and lungs. Histological examination of the enlarged spleen and swollen lymph nodes in these 5 mice demonstrated completely destroyed follicular structures and infiltration of morphologically abnormal lymphocytes, which showed the CD4+/PD1+/CXCR5^{dull} phenotype. CD4+ cells purified from the tumors revealed restricted rearrangement patterns of T-cell receptor gamma gene, implying a signature of T-cell lymphoma. CD4+ cells purified from the lymphomas represented similar gene-expression profiles with Tfh cells, *i.e.*, high expression of Bcl6 and c-Maf, two key transcription factors of Tfh. The patterns of hydroxymethylation were distinct between CD4+ cells purified from $Tet2^{gt/gt}$ mice and those from control mice.
Summary and Conclusions: Our observations indicate that reduced expression of TET2 leads to proliferation of Tfh cells and eventually to development of lymphomas that pathologically recapitulate PTCL-NOS with characteristics of Tfh in humans. These data suggest that TET2 serves as a gatekeeper of lymphoid malignancies in addition to myeloid malignancies.

S1119

A KEY ROLE FOR EZH2 IN EPIGENETIC SILENCING OF HOX GENES IN MANTLE CELL LYMPHOMA

M Kanduri[1,*], B Sander[2], K Stamatopoulos[3], C kanduri[4], R Rosenquist[5]
[1]Department of Clinical Chemistry and Transfusion medicine, Institute of Biomedicne, Gothenburg University, Gothenburg, [2]Department of Laboratory Medicine, Division of Pathology, Karolinska University Hospital, Huddinge, Sweden, [3]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [4]Department of Medical and Clinical Genetics, Gothenburg University, Gothenburg, [5]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: HOX genes play a central role in body formation during early embryonic development, while deregulation of these genes adversely affects development and may also lead to malignancy. Using 27K methylation microarrays, we recently reported differential methylation of a number of HOX genes (n=13) in one of the most the aggressive lymphomas *i.e.* mantle cell lymphoma (MCL) *versus* the more indolent disease chronic lymphocytic leukemia (CLL). Interestingly, we observed that though differentially methylated, *i.e.* hypermethylated in MCL and hypomethylated in CLL, HOX genes remained unexpressed in both diseases, indicating that both DNA methylation-dependent and independent mechanisms operate to silence HOX genes.
Aims: We here characterized the differential mechanisms underlying the epigenetic silencing of HOX genes (specifically, HOXA cluster genes) in MCL *versus* CLL using representative cell lines and primary samples.
Methods: In order to investigate if HOXA genes could carry other epigenetic modifications in their upstream regulatory regions, we performed chromatin immune purification (ChIP) assays in MCL and CLL cell lines (Granta 519 and HG3) using antibodies for the repressive histone mark H3 lysine 27 trimethylation (H3K27me3) and its methyl transferase, EZH2. The DNA methylation status was analyzed using pyrosequencing and bisulfite sequencing assays, while the mRNA and protein expression levels were measured using RQ-PCR and western blot analysis respectively. Furthermore, siRNA transfection and EZH2 inhibitor (3-Deazaneplanocin A (DZNep)) treatment experiments were performed to investigate the direct role of EZH2 in DNA methylation.
Results: Overall, our results for the first time highlights the epigenetic silencing mechanisms underlying differential HOXA genes (*i.e.* HOXA2, HOXA7, HOXA 9 and HOXA13) regulation in MCL *versus* CLL. More specifically, we demonstrate that the chromatin modifier, EZH2, catalyzed repressive H3K27me3, which was sufficient to silence HOX genes in CLL, whereas in MCL both H3K27me3 and DNA methylation were required for efficient silencing of the HOXA genes. More importantly, HOXA gene promoters were more enriched with EZH2 in MCL compared to CLL, which in turn correlated with increased DNMT1 recruitment and CpG methylation, indicating that EZH2 levels indeed determine the levels of DNA methylation through DNMTs. Finally, the crucial role of EZH2 in orchestrating HOX gene silencing in MCL was underscored by our siRNA and EZH2 inhibitor experiments, whereby DNA methylation occurs as a secondary event following EZH2 recruitment to the HOX promoter.
Summary and Conclusions: These novel observations implicate EZH2 in long-term silencing of HOX genes in MCL, and this could form the basis for epigenetic therapy targeting EZH2 with potential clinical implications.

DEEP SEQUENCING REVEALS SMALL SUBCLONES OF STAT3 MUTATIONS IN LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

H Rajala[1,*], P Ellonen[2], S Lagström[2], M Clemente[3], T Olson[4], E Andersson[1], S Eldfors[2], A Jerez[3], D Zhang[4], A Awwad[4], O Kallioniemi[2], K Porkka[1], C Heckman[2], T Loughran[4], J Maciejewski[3], S Mustjoki[1]
[1]Hematology Research Unit, University of Helsinki, [2]Institute for Molecular Medicine Finland, Helsinki, Finland, [3]Department of Translational Hematology

and Oncology Research, Taussig Cancer Institute, Cleveland, [4]Penn State Hershey Cancer Institute, Hershey, United States

Background: Large granular lymphocytic (LGL) leukemia is a clonal disorder of either cytotoxic CD8+ T-cells or NK-cells. We recently discovered that 40% of LGL leukemia patients with monoclonal Vbeta expansions harbor somatic mutations in the SH2 domain of *STAT3* gene. The found mutations cause constitutive activation of STAT3.
Aims: The purpose of the current project was to study the LGL leukemia samples with ultra-deep amplicon sequencing to discover the clonal architecture and mutation spectrum of expanded lymphocytes.
Methods: DNA samples from 190 T-LGL and 38 NK-LGL leukemia patients (both with the mono-and oligoclonal expansions) who met the diagnostic criteria of WHO2008 were included in the study. Locus-specific primers for *STAT3* exon 21 were used in the amplicon sequencing and up to 10 000× coverage was achieved with Illumina Miseq platform. The data was analyzed with Illumina MiSeq Reporter.
Results: The frequency of *STAT3* mutations in the whole study cohort was 21% (48/228) by capillary sequencing, whereas the amplicon sequencing revealed 27 additional patients with mutations (total freq. 33%, Figure 1). The most common mutations found were Y640F (38%) and D661Y (27%). In addition to previously described mutations, 4 novel *STAT3* mutations were discovered by amplicon sequencing (Q643H, I659L, K658H, and K658N). In total, 12 patients had multiple *STAT3* mutations: in 8 cases the mutations were in different clones and in 4 cases in the same clone. As extreme examples, two patients had 3 different *STAT3* mutations in different clones (Y640F, D661Y and I659L; D661Y, N647I and Y640F). Patients with single *STAT3* mutation had typically one large clone, whereas in patients with multiple *STAT3* mutations, small subclones were discovered in addition to main clone. As in some LGL leukemia patients a clonal drift (ie. change of the major Vbeta clone) has been described, we analyzed one T-LGL leukemia patient who had multiple lymphocyte expansions during the disease course in detail. At diagnosis, 40% of CD3+ cells expressed TCR-γδ, and *STAT3* amplicon sequencing of mononuclear cell (MNC) fraction revealed mutations Y640F (5%) and D661Y (20%) in different clones. After one year of treatment with cyclosporine and danazol, the patient had two new Vbeta expansions (Vβ14 18% and Vβ16 17%), whereas only 4% of CD3+ cells were γδ+. We sorted MNCs into 4 different CD3+ cell subsets: CD3+αβ+, CD3+γδ+, CD3+Vβ14+, and CD3+Vb16+ cells and sequenced the fractions with amplicon sequencing method. Both *STAT3* mutant clones had survived the therapy and were found in the small CD3+γδ+ fraction (Y640F 23% and D661Y 9%). However, no mutations were discovered in the expanded Vbeta fractions suggesting that they were only reactive clones and no real clonal drift had occurred.

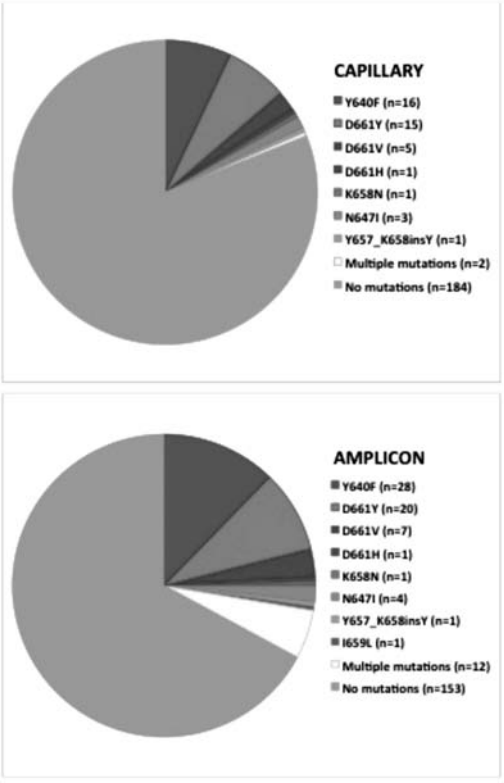

Figure 1.

Summary and Conclusions: With the ultra-deep amplicon sequencing method we were able to discover small lymphocyte clones with STAT3 mutations in LGL leukemia patients and reveal clonal heterogeneity in some patients. The total frequency of mutations found (33%) was lower than in the original LGL leukemia cohort with monoclonal expansions suggesting that some patients included may have reactive LGL proliferation. The multiple STAT3 mutations in individual patients suggest that STAT3 pathway plays a central role in the LGL leukemia pathogenesis and further studies are needed to understand the initial transforming events.

Background: The karyotype is an important predictor of outcome in adults with acute lymphoblastic leukemia (ALL). Some groups have reported a negative prognostic value of complex karyotype (CK, defined as ≥5 unrelated chromosomal abnormalities) in adult ALL (Moorman *et al.*, Blood. 2007; 109: 3189-97). On the other hand, monosomal karyotype (MK, defined as ≥2 distinct autosomal chromosome monosomies or 1 single monosomy in the presence of structural abnormalities; Löwenberg *et al.*, JCO. 2008; 26: 4791-7) has been associated with a worse outcome in patients with acute myeloid leukemia.
Aims: We aimed to assess the prognostic value of CK and MK in adults with ALL treated with risk-adapted protocols of the Spanish PETHEMA Group.
Methods: The karyotypes of 881 adult ALL patients from 65 Spanish centers treated according to the protocols of the PETHEMA Group between 1993 and 2012 were reviewed. Central review of karyotype reports was performed for this study. Patients with t(9;22), t(v;11q23), t(1;19), t(8;14), and t(14q32) rearrangements were not considered for the analysis of CK according to the Moorman's criteria. All karyotypes were included for the analysis of the prognostic value of MK. A specific analysis for patients with t(9;22) was performed. Outcome measures were complete remission (CR) rate, CR duration, overall survival (OS) and event-free survival (EFS).
Results: The median age of the series was 33 years (range 15-82) and 498 patients (56.5%) were male. The karyotypes of 636 out of 881 patients were evaluable after review: 163 patients (19.5%) presented normal karyotype, 33 out of 364 evaluable patients without t(9;22), t(v;11q23), t(1;19), t(8;14), and t(14q32) rearrangements (9.1%) had CK, and 68 out of 535 evaluable patients (12.7%) had MK. The CR rate and the probabilities of CR duration, OS and EFS are shown in the Table 1.

Table 1.

Group	N (%)	CR rate	CR duration (6 years)	OS (6 years)	EFS (6 years)
CK	33 (9.1)	79%	55±13%	36±18%	33±17%
No CK	170 (46.7)	89%	52±10%	37±8%	35±8%
Normal	161 (44.2)	89%	52±10%	39±9%	39±9%
MK	68 (12.7)	82%	66±15%	40±14%	43±12%
No MK	467 (87.3)	87%	48±6%	33±5%	33±5%
Ph+ MK	15 (15)	79%	86±26%[1]	22±34%	40±28%
Ph+ no MK	85 (85)	84%	35±17%[1]	30±11%	20±12%
Ph+ (imatinib) MK	10 (19.6)	89%	100%	62±35%	55±34%
Ph+ (imatinib) no MK	41 (80.4)	93%	56±24%	45±18%	39±18%

No significant differences on comparison between groups except [1]p=0.08

Summary and Conclusions: Our study shows that CK and MK were not associated with a worse prognosis in adult patients with ALL treated with risk-adapted or subtype-oriented protocols from the PETHEMA group. In patients with Ph+ ALL MK did not have impact on prognosis irrespective to imatinib treatment.
Supported in part with Grants PI10/01417 from FIS and RD12-0036-0029 from RTICC. Instituto Carlos III, Spain.

S1122

IDENTIFICATION OF NEW PROGNOSTIC FACTORS PREDICTIVE OF EXTRAMEDULLARY RELAPSE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

D Launaij[1,*], J de Vries[2], J Voerman[1], M de Bie[1], C Eckert[3], V de Haas[4], E Sonneveld[4], J van Dongen[1], V van der Velden[1]
[1]Immunology, Erasmus MC, Rotterdam, [2]The Netherlands Cancer Institute-Antonie van Leeuwenhoek, Amsterdam, Netherlands, [3]Paediatric Oncology/Haematology, Charite Medical University Berlein, Berlin, Germany, [4]Dutch Childhood Oncology Group, Den Hague, Netherlands

Background: Acute lymphoblastic leukemia (ALL) is the most common cancer diagnosed in children. With the discovery and implementation of new drugs and a better risk stratification, survival rates in pediatric ALL patients increased over the last decades, and currently at least 80% of childhood ALL are cured, indicating that a relatively large proportion of the children suffer from relapse. Extramedullary (EM) involvement is defined as leukemic infiltration in EM sites like the central nervous system (CNS), testis, gut or skin. EM involvement at diagnosis is rare (1-4%) in childhood ALL patients, but is more frequent at relapse (~40%) suggesting that ALL cells at EM sites more easily escape from treatment. Because of the still developing and maturing of the CNS in children, the applied treatment modalities have a high change to induce late sequelae.To reduce the side effects of CNS-directed therapy and to prevent CNS relapses, it is important to predict which patients are at high risk of a CNS relapse. These patients will receive intensified treatment, while patients at low risk may receive less treatment, thereby improving quality of life at later age.
Aims: To find cellular and molecular characteristics of EM-derived cells and hypothesize that at diagnosis a subpopulation of ALL cells with such "EM signature" might already be present in bone marrow (BM), allowing early identification of ALL patients at risk of developing an EM relapse.
Methods: Microarray study was performed using Affymetrix GeneChip Human Genome U133 Plus 2.0 Array. Differential expression of genes as identified by microarray analysis was confirmed by realtime quantitative PCR (RQ-PCR). Differential gene expression between ALL cells derived from BM *versus* extramedullary locations was confirmed at protein level by flow cytometric analysis. Bio-plex pro human cytokine 20-plex assay was performed according to the manufacturer's protocol.
Results: Gene expression profiling was performed on B-cell precursor (BCP) ALL samples isolated from cerebrospinal fluid (CSF) or BM. Principal Component Analysis (PCA) and hierarchical clustering analysis showed that CSF-derived ALL samples perfectly cluster into one separate branche, indicating that ALL cells from the CNS show distinct gene expression profiles as compared to BM-derived ALL cells. Selection of potentially interesting genes was performed based on the following criteria: highest differential expression (FC) between CSF and BM samples in both the paired and the unrelated analysis; highest statistical significance; expression at the cell membrane; presence of (monoclonal) antibodies and biological relevance and confirmed by RQ-PCR. Genes involved in cell growth, survival, proliferation (ARHGAP18, RASA1), differentiation (RASA1), migration and cell adhesion (OPN, ARHGAP18), showed a significant increase in CNS localization compared to BM localization. Diagnostic BM and/or PB cells from four BCP-ALL patients with an isolated CNS relapse were analyzed by flow-cytometry for (sub) populations of ALL cells. Preliminary data show that minor ALL populations expressing the proteins encoded by these genes can be identified in diagnostic BM samples from patients with EM relapse.
Summary and Conclusions: We conclude that EM-derived and BM-derived BCP-ALL cells show distinct gene expression profiles. The presence of a small ALL population with an EM signature at diagnosis may be associated with a higher chance of EM relapse. In future, the identification of proteins and involvement of specific pathways in EM involvement may contribute to targeted therapies.

S1123

IKZF1 DELETION STATUS DISCRIMINATES FOR OUTCOME IN IMATINIB-TREATED BCR-ABL1-POSITIVE CHILDHOOD ALL

A Van Der Veer[1,*], M Zaliova[2], F Mottadelli[3], P De Lorenzo[4], G Te Kronnie[5], C Harrison[6], H Cave[7], J Trka[8], V Saha[9], M Schrappe[2], R Pieters[1], A Biondi[3], M Valsecchi[4], M Stanulla[2], M Den Boer[1], G Cazzaniga[3]
[1]Pediatric Oncology, Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands, [2]Pediatrics, University Medical Center Schleswig-Holstein, Kiel, Germany, [3]Centro Ricerca Tettamanti, Clinica Pediatrica, [4]EsPhALL Trial data Center, University of Milano-Bicocca, Milano, [5]Women's and Children's Health, University of Padova, Padova, Italy, [6]Leukaemia Research Cytogenetics Group, New Castle University, Newcastle upon Tyne, United Kingdom, [7]Genetics, University Paris Diderot, Paris, France, [8]Childhood Leukemia Investigation Prague (CLIP), Charles University and University Hospital Motol, Prague, Czech Republic, [9]Children's Cancer Group, University of Manchester, Manchester, Netherlands

Background: The *BCR-ABL1*-translocation (Philadelphia-chromosome) predicts for an unfavorable outcome in childhood acute lymphoblastic leukemia

(ALL). *BCR-ABL1*-positive ALL is characterized by a high frequency (70%) of *IKZF1* deletions. *IKZF1* deletions are correlated to an unfavorable outcome in *BCR-ABL1*-negative ALL.
Aims: We studied the prognostic value of *IKZF1* deletions in children with *BCR-ABL1*-positive ALL who were treated with and without Imatinib.
Methods: The *IKZF1*-status was evaluated by multiplex ligation-dependent probe amplification in 191 newly diagnosed patients; 84 cases were diagnosed before the introduction of Imatinib and 107 cases were enrolled in the European Philadelphia-chromosome positive ALL trial. 63 EsPhALL cases were stratified in the good-risk arm and were randomized for Imatinib, 44 EsPhALL cases were stratified in the poor-risk arm and all received Imatinib.
Results: 66% (126/191) of the *BCR-ABL1*-positive patients had an *IKZF1* deletion; 36.5% of these deletions resulted in haplo-insufficiency (covering monoallelic loss of at least exon 2), 52.4% had an exon 4-7 deletion that resulted in a dominant-negative variant. The frequency of hematopoietic stem cell transplantation (HSCT) did not differ between the *IKZF1*-deleted and wild-type group (both ~70%). In patients that were treated before the introduction of Imatinib, *IKZF1*-deleted patients had a poor 4-yr disease free survival (DFS) (30.0±6.8%) compared to wild-type patients (57.5±9.4%; P=0.01). *IKZF1*-deleted patients treated according to the EsPhALL good-risk protocol had a poor 4-yr DFS (51.9±8.8%) compared to wild-type patients (78.6±13.9%; P=0.03), and this was also evident for those who received Imatinib (4-yr DFS 55.5±9.5% for *IKZF1*-deleted *versus* 75· 0±21.7% for *IKZF1* wild-type good-risk patients, P=0.05).
Summary and Conclusions: This is the first study demonstrating that *IKZF1* deletions are correlated to a poor outcome in a relative large cohort of childhood *BCR-ABL1*-positive ALL. We advocate that *IKZF1*-deleted patients need a more intensified or alternative therapy. In addition, since *IKZF1* wild-type *BCR-ABL1*-positive patients treated with Imatinib have a good outcome comparable to *BCR-ABL1*-negative ALL, the absence of an *IKZF1* deletion may be used as marker to exclude HSCT.

FRENCH RESULTS WITH THE EWALL CHEMOTHERAPY BACKBONE IN OLDER PATIENTS WITH PHILADELPHIA CHROMOSOME-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA. A GRAALL REPORT.

P Schwartz[1,*], M Hunault-Berger[2], P Chevallier[3], F Dreyfus[4], E Raffoux[5], X Thomas[6], V Cacheux[7], J Malfuson[8], Emanuelle Tavernier[9], P Rousselot[10], C Bonmati[11], K Bilger[12], S Leprêtre[13], M Sauvezie[1], N Ifrah[2], H Dombret[5], T Leguay[1]
[1]Service d'hématologie clinique et de thérapie cellulaire, CHU de Bordeaux, Pessac, [2]CHU d'Angers, Angers, [3]CHU de Nantes, Nantes, [4]Hôpital Cochin, [5]Hôpital Saint-Louis, Paris, [6]CHU de Lyon, Lyon, [7]CHU de Clermont-Ferrand, Clermont-Ferrand, [8]Hôpital Antoine Béclère, Clamart, [9]CHU de Saint-Etienne, Saint-Etienne, [10]CHU de Versailles, Versailles, [11]CHU de Nancy, Nancy, [12]CHU de Strasbourg, Strasbourg, [13]CHU de Rouen, Rouen, France

Background: Philadelphia chromosome (Ph)-negative acute lymphoblastic leukemia (Ph-neg ALL) occurring after 60 years of age is associated with a poor prognosis.
Aims: In order to test novel therapeutic interventions, the European Working Group for Adult ALL (EWALL) has developed a common chemotherapy backbone adapted to older patients.
Methods: After a dexamethasone (DEX) prephase, patients received two induction cycles, comprising DEX, vincristine and idarubicin for cycle1, followed by cyclophosphamide and cytarabine for cycle2, starting after hematological recovery or at d29. Consolidation included 6 cycles alternating intermediate-dose methotrexate and L-asparaginase (odd cycles) and intermediate-dose cytarabine (even cycles). Patients aged more than 70 years received half-dose of chemotherapy during consolidation. Maintenance therapy comprised then 6 cycles. Treatments are detailed in the Table 1.
Results: We report here the results of 59 patients with Ph-neg ALL treated with this backbone between 2007 and 2013 in 12 GRAALL centers. Median age was 65 years (60.9-82.5) and median follow-up was 13.9 months (2.3-64). After induction, 45 patients (76%) achieved CR, 10 (17%) were alive with resistant disease (RD). Four patients (7%) died during induction. Five patients who reached CR after the first induction cycle did not received the second one. Among the 45 CR patients, 29 died (25 after ALL recurrence). Among the 10 RD patients, 8 died. Median overall survival (OS) was 11.3 months. The probability to be alive at 1 year and 3 years were 49.9% and 24%, respectively. Median disease free survival (DFS) was 9.6 months with 1-year and the 3-years DFS estimation at 43% and 19%, respectively. We used the EWALL backbone to test two treatment intensification approaches. First, 9 of these 59 patients (median age, 64 years) received 6 additional infusions of6,000UI/m^2 L-asparaginase during each induction course. In these patients, we observed 6 CR (67%), two toxic-deaths due to encephalopathy and one RD. Their median DFS and OS were 15 and 16.7 months, respectively. Comparatively 39 CR (78%), two toxic-deaths, and 9 RD were observed in the 50 patients who received recommended induction, with 8.6 months median DFS and 11.3 months median OS. These differences were not statistically significant. Secondly, we tested consolidation intensification in 6 CR eligible patients (median age, 64 years). These patients received consolidation, late intensification (with 6 infusions of 6.000UI/m^2 L-asparaginase) and maintenance according to the GRAALL2005 protocol designed for younger adults. With median follow-up of 9.9 months, none of them relapsed, nor died in CR. Comparatively median DFS was 8.6 months in the 39 patients who received recommended consolidations, but had a longer median follow-up of 37.9 months. The difference was not statistically significant.

Prephase		
DEX	D-5 à D1	10 mg/m²/d
METHOTREXATE IT	D-5	15 mg

METHYLPREDNISOLONE IT	D1	40mg
Consolidation course n°2, n°4 and n°6 (D1=D21)		
CYTARABINE	D1, D3, D5	1000 mg/m²/12h or 500mg/m²/12h*
Maintenance D1=D60 during the first 6 months and D1=D90 during 12 last months		
DEX	D1 and D2	40 mg/d
VINCRISTINE	D1	1 mg flat dose
Oral 6-Mercaptopurine	daily	60 mg/m²/d continuously
Oral Methotrexate	weekly	25 mg/m² 1/week continuously

* in patient aged more 70 years old

Figure 1.

Summary and Conclusions: In conclusion, the EWALL chemotherapy backbone yielded a high CR rate (76%) but a poor median survival, due to a high relapse rate during the first year. L-asparaginase seemed too toxic to be recommended during induction in these older patients. However, more intensive consolidations cycles appeared to be an interesting option that could be tested to prolong CR duration in these high-risk patients.

S1125

WEEKLY INOTUZUMAB OZOGAMICIN (INO) IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY CD22-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

DJ DeAngelo[1,*], W Stock[2], AR Shustov[3], R Ananthakrishnan[4], K Luu[5], J Boni[6], A Volkert[4], E Vandendries[4], AS Advani[7]
[1]Dana Farber Cancer Institute, Boston, MA, [2]University of Chicago, Chicago, IL, [3]University of Washington, Seattle, WA, [4]Pfizer, Cambridge, MA, [5]Pfizer, La Jolla, CA, [6]Pfizer, Collegeville, PA, [7]Cleveland Clinic, Cleveland, OH, United States

Background: INO is a humanized anti-CD22 antibody conjugated to calicheamicin. CD22 is expressed on a majority of B-cell ALL. An initial study suggested INO efficacy and tolerability in ALL (*Lancet Oncol* 2012;13:403-11).
Aims: To optimize the INO dose and weekly schedule, and evaluate safety and efficacy in CD22+ relapsed/refractory ALL.
Methods: This phase1, dose-escalation study enrolled pts aged ≥18 y with CD22+ refractory/relapsed ALL and no central nervous system disease. INO was administered in 28-d cycles (Table 1), up to 6 cycles. The final dose was to be determined based on dose-limiting toxicities (DLT) and efficacy, using EffTox V2.10 software during dose escalation. Adverse event (AE) severity was assessed per CTCAE V3. DLTs included the following INO-related events in Cycle 1: gr ≥4 nonhematologic toxicity; prolonged myelosuppression (absolute neutrophil count [ANC] <500/μL or platelets <25,000/μL in bone marrow) with no evidence of leukemia persisting >45 d from last dose; gr 3 nonhematologic toxicity persisting ≥7 d from last dose; gr ≥3 increased alanine aminotransferase (ALT), aspartate aminotransferase (AST), or bilirubin persisting >7 d; or any toxicity resulting in permanent INO discontinuation. Complete response (CR) was defined as <5% bone marrow blasts with absence of peripheral blasts, ANC ≥1,000/μL, platelets >100,000/μL, and no extramedullary disease; incomplete CR (CRi) permitted ANC <1,000/μL and/or platelets ≤100,000/μL.
Results: We report data for 24 pts (Table 1): median age was 47.5 y (range 23-69 y); 71% were male; 10 (42%) pts were in salvage1, 6 (25%) in salvage2, and 8 (33%) in salvage ≥3; 5 (21%) pts had prior allogeneic stem cell transplant

(SCT); 4 (17%) pts were Ph+; median CD22+ blasts was 98% (by central lab); median WBC was $3.9\times10^3/mm^3$ (range $0.5\text{-}29.1\times10^3/mm^3$). Median follow-up among surviving pts was 4.1 mo (range 0.5-12.6 mo). Twenty-three pts discontinued INO: 10 proceeded to SCT, 6 due to disease progression, 4 due to AEs (gr 3 acute renal failure, gr 2 ascites, gr 2 increased gamma-glutamyl transpeptidase [GGT], and gr 5 graft failure), and 3 due to other causes. One DLT of transient gr 4 elevated lipase occurred at INO dose level 3. The most frequent (≥20% of pts) treatment-related AEs were thrombocytopenia (38%; 33% with gr 3/4), increased AST (33%), nausea (25%), neutropenia (25%; 21% with gr 3/4), fatigue (21%), and increased GGT (21%). Fourteen (58%) pts had dose delays due to AEs; 5 (21%) pts had dose reductions due to AEs. Eight deaths were reported, including 1 death on Day 14 due to disease progression and 7 deaths during the post-treatment follow-up due to sepsis following transplant (n=3), ALL (n=3), and graft failure (n=1). Responses were observed for all INO doses (Table 1). The remission rate was 79% (n=19; 11 pts with CR, 8 pts with CRi); median time to remission was 28 d (range 20-78 d). A total of 18/19 (95%) pts with a CR or CRi achieved negative minimal residual disease (MRD; <1 blast out of 10^4 mononuclear cells by flow cytometry); median time to MRD negativity was 33.5 d (range 22-141 d). Minimum INO concentrations in responders were higher than in pts failing treatment.

Table 1.

	INO dose level			
	1 (n = 3)	2 (n = 12)	3 (n = 9)	Total (N = 24)
Total dose/cycle, mg/m²	1.2	1.6	1.8	
Day 1, mg/m²	0.8	0.8	0.8	
Day 8, mg/m²	0	0.4	0.5	
Day 15, mg/m²	0.4	0.4	0.5	
Day 28	Bone marrow aspirate and/or biopsy for disease assessment			
DLTs	0	0	1	1
Median no. of cycles initiated (range)	4 (1-6)	2 (1-4)	3 (1-4)	2 (1-6)
Response rate (CR + CRi + PR), n (%)	2 (67)	11 (92)	8 (89)	21 (88)
Remission rate (CR + CRi), n (%)	2 (67)	9 (75)	8 (89)	19 (79)
MRD negative, n/n with remission (%)	2/2 (100)	8/9 (89)	8/8 (100)	18 (95)
Median time to MRD negativity (range), d	98.5 (98-99)	32 (22-64)	30 (22-141)	33.5 (22-141)

Summary and Conclusions: INO had a tolerable safety profile consistent with prior reports, primarily characterized by hematologic, gastrointestinal, and hepatic AEs. Single-agent INO demonstrated encouraging clinical activity in this relapsed/refractory population; preliminary efficacy results appear dynamically related to exposure and circulating blasts. Further exploration in CD22+ ALL is warranted.

Myeloid leukemogenesis

S1126

A STUDY OF THE LEUKEMOGENIC INTERACTION BETWEEN MUTANT NPM1 AND NRASG12D IN CONDITIONAL KNOCK-IN MICE

O Dovey[1,*], C Grove[1], J Cooper[1], A Mupo[1], P Wright[2], A Bradley[3], G Vassiliou[1]
[1]Haematological Cancer Genetics, Wellcome Trust Sanger Institute, [2]Department of Pathology, University of Cambridge, Addenbrooke's Hospital, [3]Mouse and Zebrafish genetics, Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Very recently, whole genome and targeted sequencing of individual cases of AML have raised the possibility that in many instances as few as three specific mutated genes may be sufficient to promote leukaemia. Appreciation of the biological synergy between the complement of leukaemogenic mutations in driving disease progression is key to the development of new treatments. The largest subgroup of AML which constitutes 35% of all cases, namely a karyotypically normal sub-group of AML, exhibits a mutation in the Npm1 gene ($Npm1^c$). A humanised conditional knock-in mouse model of the main form of $Npm1^c$ mutations, Type A, has lately been described in which one third of mice developed AML after a long latency (median17.5 months), suggesting a requirement for cooperating mutations. An insertional mutagenesis screen in the same mice revealed rapid onset AML ~80% of mice (median days 99) with activating insertions in in *Csf2*, *Flt3*, *Rasgrp1* or *Kras*, suggesting that activation of these downstream pathways are key in leukaemogenesis. Furthermore, the aforementioned human sequencing studies, including the first AML genome to be sequenced, reveal commonly co-occurring mutations in Npm1 and Nras ($Nras^{G12D}$, which results in a constitutively active form of the protein). Notably, only ~25% of mice genetically engineered to harbour the $Nras^{G12D}$ ($NRAS^{LSL\text{-}G12D}$) mutation develop AML.
Aims: Comprehensive analysis of the molecular synergy between the leukaemogenic mutations, $Npm1^{cA}$ and $NRAS^{G12D}$, in the development of AML.
Methods: To analyse the combined effects of $Npm1^c$ with $Nras^{G12D}$ we crossed conditional $Npm1^{flox\text{-}cA/+}$; Mx-1^{Cre} with NRAS $^{LSL\text{-}G12D}$ mice to generate $Npm1^{flox\text{-}cA/+}$; NRAS $^{LSL\text{-}G12D}$; Mx-1^{Cre} double conditional heterozygous mice (RNMX mice). Mice were aged until moribund, tissue samples collected and preserved for histopathology and nucleic acid extraction. Comparative analysis of haematopoietic cell compartments in younger mice (*i.e.* 4 weeks post mutation induction) from combined and singular mutant cohorts was performed using standard FACS techniques. Similar comparative analyses were performed on bone marrow cell extracts on the Lineage^{-ve} transcriptome and on self-renewal, using microarrays and serial re-plating assays respectively.
Results: Histopathological analysis of RNMX mice revealed the development of AML with ~80% penetrance. These mice have a median survival of 89 days, much reduced when compared to $NRAS^{G12D/+}$ (250 days) or $Npm1^{cA/+}$mice (400 days). Peripheral blood counts of aged RNMX mice revealed significantly elevated leukocyte counts and reduced platelets. Cells isolated from diseased RNMX aged mice tested so far, were all transplantable. Subsequent EXOME analysis of RNMX AMLs so far, have revealed the accrual of yet further mutations including a particular instance of $IDH1^{R132Q}$, synonymous to the $Idh1^{R132H}$ mutation associated, and known to co-occur with $Npm1^{cA}$ and $NRAS^{G12D}$, in human AML. Analysis of younger mice reveals $Npm1^{cA}$ dependent skewing toward the myeloid lineage and a general increase in haematopoietic cells concomitant with the $Nras^{G12D}$ mutation. Combined, in RNMX mice, myeloid expansion is responsible for statistically significant increased haematopoietic cellularity. *In vitro* self-renewal properties of bone marrow cells are also enhanced in RNMX mice compared to other cohorts. Global transcriptome analysis has, so far, revealed a previously identified $Npm1^{cA}$ signature of HOX gene overexpression, absent from NRAS mice, but persistent in the RNMX cohort.
Summary and Conclusions: These observations in RNMX mice specifically emphasise the role of combinatorial somatic driver mutations particular to AML and provides a rationale for the co-occurrence of $Npm1^{cA}$ and $Nras^{G12D}$ mutations (given that, in isolation, $Npm1^{cA}$ or $Nras^{G12D}$ mutations have relatively subtle effects on mouse haemopoiesis and a prolonged latency/frequency of AML). Combined with the observed spontaneous accrual of other known co-occurring somatic mutations (IDH1), this model presents a valuable tool in studying the pathogenesis and treatment of AML.

S1127

MOLECULAR SYNERGY BETWEEN MUTANT NUCLEOPHOSMIN AND FLT3-ITD TO DRIVE ACUTE MYELOID LEUKEMIA IN MICE

A Mupo[1,*], L Celani[2], O Dovey[1], J Cooper[1], C Grove[1], R Rad[1], P Sportoletti[2], B Falini[2], A Bradley[1], G Vassiliou[1]
[1]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [2]University of Perugia, Perugia, Italy

Background: Acute myeloid leukemia (AML) is the commonest myeloid malignancy, yet there has been little therapeutic progress for this disease in decades. Recently, advances in DNA sequencing have led to the identification of recur-

rent somatic mutations in AML, but have also demonstrated that individual cases are driven by a small number of co-occurring mutations. Our ability to interpret these findings and address this important medical need relies on an improved understanding of the pathways corrupted by such mutations and particularly the basis of the molecular synergy between them. Here, we report that the two most commonly co-occurring somatic mutations in AML, namely NPM1 exon 12 mutations (NPM1c) and internal tandem duplications of FLT3 (FLT3-ITD), cooperate explosively to induce AML. Mice succumbed to AML after a median of 49 days, and also many cases exhibited loss-of-heterozygosity for Flt3, as seen in human AML. In revealing this striking molecular synergy, our work offers a basis for the frequent co-occurrence of these two mutations and provides a model for the detailed study of AML.

Aims: To study the combined effects of NPM1c with FLT3-ITD we crossed conditional Npm1flox-cA/+ with constitutive Flt3ITD/+ to generate Npm1flox-cA/+; Flt3ITD/+ double heterozygous mice.

Methods: Mice strains have been previously described.

Mouse blood, femurs and spleens were stained with Gr1-PE and CD11b-FITC, B220-APC-Alexa750, CD3-PerCP-Cy5.5 and cKit-APC, run on a BD Fortessa cytometer and analysed with FlowJo 7.6.5. Bone marrow cells were plated in M3434 and colonies counted after 7-10 days. For re-plating, 30,000 bone marrow cells were plated and counted after 8 days.

Results: In this study we observed universal and rapid emergence of AML in *Npm1c;FLT3ITD* mice. All mice developed AML and became moribund aged 31-68 days (Figure 1).Weekly blood showed a progressive increase in blood leukocyte counts in Npm1c/Flt3-ITD mice, to more than 25-fold that of control littermates, whilst hemoglobin and platelet counts were significantly reduced. Flow analysis of blood samples demonstrated, in Npm1c/Flt3-ITD mice, a population of blast cells and a large number of single Mac1+ precursors. Additionally, we also observed an increased number of mature myeloid (Gr1+/Mac1+) cells in Npm1c/Flt3-ITD mice indicating that any maturation block was incomplete.To assay their self-renewal potential, bone marrow cells were studied in serial re-plating assays. Npm1c/Flt3-ITD cells gave rise to significantly more colonies than any other genotype demonstrating their increased self-renewal potential. Interestingly, Npm1c/Flt3-ITD littermates often progressed to AML at different rates or developed more/less aggressive disease. To explain this we hypothesized that, as seen in human AML, LOH for Flt3 may be responsible. We found significant spontaneous loss of the wild-type Flt3 allele in blood samples from Npm1c/Flt3-ITD mice and a tendency for higher blood leukocyte counts when LOH was present. LOH was also seen in bone marrow and spleen but not tail DNA, in keeping with somatic loss of the wild-type allele in leukemic cells.

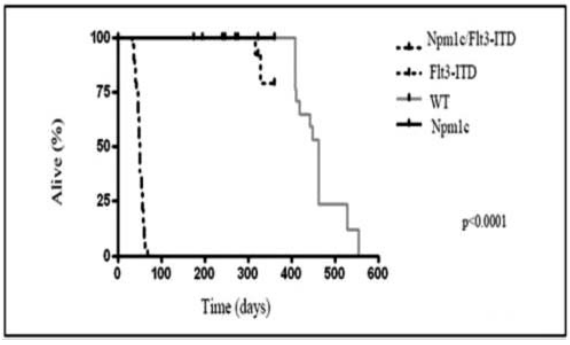

Figure 1.

Summary and Conclusions: Recent studies have revealed that AML heterogeneity is derived, to a large extent, from the specific combinations of somatic driver mutations. Here, we show that the combination of Npm1c and Flt3-ITD, is rapidly and universally leukemogenic in knock-in mice These findings are particularly striking in light of the fact that, in isolation, both Npm1c and Flt3-ITD mutations have relatively subtle effects on mouse haemopoiesis.

Our observations emphasize the remarkable complementarity between Npm1c and Flt3-ITD. In the context of a stochastic model for AML pathogenesis, this potent molecular synergy goes some way towards explaining why NPM1c and FLT3-ITD co-occur so frequently and makes the model described here a valuable tool for the study of the pathogenesis and treatment of AML

S1128

UNDERSTANDING THE PHYSIOLOGICAL FUNCTION OF THE TWO RNA-BINDING PROTEINS MSI1 AND MSI2 INVOLVED IN HETAMOLOGICAL MALIGNANCIES

J Hoell[1,*], S Duggimpudi[1], P Muench[2], K Hezaveh[1], C Tusche[2], A McHardy[2], A Borkhardt[1]

[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Center for Child and Adolescent Health, [2]Department of Algorithmic Bioinformatics, Heinrich Heine University Duesseldorf, Duesseldorf, Germany

Background: Musashi homolog 2 (MSI2) is an RNA-binding protein (RBP) that was first associated with myeloid malignancies when it was shown to form a fusion protein with HOXA9 in chronic myeloid leukemia (CML). Subsequently it was found that MSI2 expression is highly uP-regulated during CML progression into blast crisis. Since then, high levels of MSI2 have been described in various malignancies including prostate cancer, pulmonary carcinomas and AML, in which it is predictive of unfavorable outcome.

Aims: Gene expression in mammals is extensively controlled at the post-transcriptional level by RBPs modulating all stages of the mRNA life cycle. This is achieved by covalent binding between RBPs and mRNAs depending on the unique RNA-recognition element (RRE) of each RBP. Neither the mechanism by which the overexpression of MSI2 contributes to leukemogenesis nor its physiological function is well understood. By identifying its transcriptome-wide mRNA targets we wish to uncover the physiological function of MSI2. This will allow us to understand the consequences of its deregulation in malignancies.

Methods: We applied PAR-CLIP, a method that was developed to identify the transcriptome-wide RBP binding sites by incorporation of a photoreactive nucleoside into nascent mRNAs, to MSI2. Next-generation sequencing (NGS) then allows the mapping of the exact crosslink sites by mapping thymidine to cytidine transitions (T2C) in the cDNAs of PAR-CLIP libraries. To approach the several tens of millions obtained NGS reads, extensive bioinformatic analysis was performed followed by biochemical methods to validate the findings.

Results: Since RBPs within the same protein family often have overlapping mRNA targets, we included MSI1 into our study as it is closely related to and highly co-expressed with MSI2. The roughly 200-300 million NGS reads of each PAR-CLIP library gave rise to around12,000 single linkage clusters meeting stringent quality criteria: (1) more than 25 overlapping reads and (2) at least one T2C transition in at least 20% of the cluster reads. We found that both MSI1 and MSI2 -despite their cytoplasmic localization- bind intronic, exonic and 3'UTR mRNAs at roughly equal distribution. We defined the RRE for MSI1 and MSI2 using a motif discovery approach (MEME). In both proteins it consists of the six nucleotides *TTTTAG*. As expected -given the shared RRE- the targeted genes of MSI1 and MSI2 overlap to a large degree (~75%). We recombinantly expressed MSI2 to perform biochemical validations. Gene ontology analysis of both the RRE and the targeted mRNAs separately indicated a role for MSI2 in MAPK and TGF-beta signaling. We also performed siRNA knockdowns of both MSI1 and MSI2 and correlated the regulated genes with those carrying PAR-CLIP clusters. This resulted in 136/70 genes for MSI1/MSI2, respectively. These genes are currently subject to further functional analysis.

Summary and Conclusions: The RBP MSI2 is frequently overexpressed in (hematological) malignancies. Its physiological function remains unclear since its mRNA targets are unknown. By applying PAR-CLIP to MSI1 and MSI2 we defined their respective direct mRNA targets as well as their RRE. We included MSI1 in our study since RBPs of the same protein family often target identical mRNAs. Gene ontology analysis indicated a role for MSI2 in MAPK and TGF-beta signaling pathways. Knockdown analysis revealed a total of 136/70 regulated genes for MSI1/MSI2, respectively. As predicted, the target genes of MSI1 and MSI2 overlap to a large extent (~75%). So far, neither MSI1 expression nor mutational states in MSI2-related malignancies have been analyzed. However, this might be of interest, considering that overlapping target genes are associated with similar biological functions.

S1129

HES1 IS RESPONSIBLE FOR NOTCH SIGNALING-MEDIATED SUPPRESSION OF ACUTE MYELOID LEUKEMIA DEVELOPMENT

T Kato[1,*], M Sakata-Yanagimoto[1], Y Miyake[1], H Nishikii[1], H Muto[1], Y Yokoyama[1], Y Asabe[1], K Suzukawa[1], N Obara[1], S Chiba[1]

[1]Department of Hematology, University of Tsukuba, Ibaraki, Japan, Tsukuba, Japan

Background: The transcription factor Hairy enhancer of split1 (Hes1) is well characterized as a downstream target of Notch signaling. Hes1 is a basic helix-looP-helix-type protein, and represses target gene expression. Notch signaling has been proposed to play both pro- and anti-tumorigenic roles; it promotes development of T-cell acute lymphoblastic leukemia (T-ALL), while serves as a tumor suppressor for acute myeloid leukemia (AML). Meanwhile, Hes1 has been proven as an essential mediator of Notch signaling in T-ALL development, but its mediator for AML suppression remains to be elucidated.

Aims: To explore whether Hes1 is responsible for Notch signaling-induced suppression of AML development.

Methods: Common myeloid progenitors (CMPs) purified from RBP-J$^{f/f}$ mouse bone marrow (BM) were serially transduced with MLL-AF9 and Cre recombinase (iCre) using retroviral vectors, and transplanted into lethally irradiated syngenic mice. CMPs from Hes1$^{-/-}$ mouse fetal liver were also retrovirally transduced with MLL-AF9 and transplanted after multiple rounds of replating, Expression levels of downstream targets were evaluated by cDNA array and quantitative RT-PCR.

Results: Mice transplanted with MLL-AF9/RBP-J$^{-/-}$ cells developed leukemia at shorter latencies than those with MLL-AF9/RBPJ$^{+/+}$cells (MLL-AF9/RBPJ$^{-/-}$, 3-8 weeks, n=14 *vs* MLL-AF9/RBPJ$^{+/+}$, 4-10 weeks, n=13; P<0.01). MLL-AF9-transduced Hes1$^{-/-}$ cells formed higher number of colonies at third replating compared to MLL-AF9-transduced Hes1$^{+/+}$ cells. When infused into irradi-

ated syngenic mice, MLL-AF9/Hes1$^{-/-}$ cells developed leukemia at shorter latencies than MLL-AF9/ Hes1$^{+/+}$cells (MLL-AF9/Hes1$^{-/-}$, 7-10 weeks, n=18 *vs* MLL-AF9/Hes1$^{+/+}$, 10-14 weeks, n=18; P<0.001). Both MLL-AF9/Hes1$^{-/-}$ and MLL-AF9/Hes1$^{+/+}$ leukemia cells prepared from bone marrow of the first recipients were transplantable and caused leukemia in the secondary recipients. When Hes1 was retrovirally re-expressed in MLL-AF9/Hes1$^{-/-}$ cells, these cells developed leukemia in recipient mice at longer latencies than mock-transduced MLL-AF9/Hes1$^{-/-}$ cells (Hes1/MLL-AF9, 12 weeks, n=8 *vs* Mock/MLL-AF9, 5-7 weeks, n=7 P<0.001). Taken together, these results indicate that Notch signaling indeed suppresses MLL-AF9-triggered AML development and that Hes1 is a definitive downstream mediator for this Notch function. MLL-AF9/Hes1$^{-/-}$ and MLL-AF9/Hes1$^{+/+}$ leukemia cells were then compared for mRNA expression by cDNA microarray. Among the genes with different expression levels between MLL-AF9/Hes1$^{-/-}$and MLL-AF9/Hes1$^{+/+}$ leukemia cells, Flt3 was expressed at significantly higher levels in MLL-AF9/Hes1$^{-/-}$ leukemia cells. It was also demonstrated that Flt3 was phosphorylated with Flt3 ligand stimulation in the MLL-AF9-immortalized cells specifically with the Hes1$^{-/-}$ background.
Summary and Conclusions: Canonical Notch signaling serves as a tumor suppressor in MLL-AF9-induced AML through upregulation of Hes1.Hes1 is an essential Notch signaling mediator for AML suppression. At least a part of Hes1 function might be explained by repression of Flt3.

S1130

AML1-ETO COLLABORATES WITH THE TALE HOMEOBOX GENES MEIS1 AND MEIS2 IN INDUCING AML

M Vegi[1,*], J Klappacher[1], F Oswald[2], R Claus[3], M Mulaw[1], A Mandoli[4], V Thiel[2], J Martens[4], V Rawat[1], L Quintanilla-Fend[5], C Plass[6], K Döhner[7], H Döhner[7], W Hiddemann[8], H Stunnenberg[9], M Feuring-Buske[7], C Buske[1]
[1]Institute for Experimental Cancer Research, CCC and University Hospital of Ulm, [2]Department of Internal Medicine I, University Hospital of Ulm, Ulm, [3]Department of Internal Medicine I, Freiburg, Germany, [4]Department of Molecular Biology, Nijmegen Centre for Molecular Life Sciences, Nijmegen, Netherlands, [5]University of Tübingen, Institute of Pathology, Tübingen, [6]Division of Epigenomics and Cancer Risk Factors, German Cancer Research Center (DKFZ), Heidelberg, [7]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [8]Department of Medicine III, Klinikum Grosshadern, LMU, Munich, [9]Department of Molecular Biology, Nijmegen Centre for Molecular Life Sciences, Nijmegen, Germany

Background: *AML1-ETO (AE)* is the most frequent fusion gene in human AML. Previously, we and others have demonstrated that the fusion is not able to cause leukemia on its own in experimental murine models, but that it needs as a class II mutation collaborative partners such as *FLT3-length mutation* (class I) to generate AML in the murine bone marrow transplantation model (BMT model) (Schessl *et al*., JCI 2005).
Aims: We aimed at determining the functional role of the Hox co-factors *Meis1* and *Meis2* belonging to TALE family of homeodomain proteins. Meis1 is one of the strongest known co-factors for Hox associated leukemogenesis, but was not linked to CBF leukemias so far. There are no data so far on the role of Meis2 in human AML.
Methods: Taqmann analysis was done for AE positive samples to determine the expression of both MEIS genes. Expression of Meis genes and of AE were achieved by retroviral gene transfer. To test the functional relevance of *MEIS* genes in AE positive AML, lethally irradiated mice were transplanted with BM cells solely expressing the fusion gene (n=8), EGFP (n=8, control) or with BM expressing both genetic alterations AE+Meis1 (n=14) and AE+Meis2 (n=4). To test dependence of human AE positive AML cell lines on MEIS expression lentiviral based knock down of *MEIS1* & *2* were performed. DNA binding of AE in human AML cell lines with or without MEIS depletion was assessed by ChIP-Seq.
Results: Gene expression analysis revealed that *MEIS1* is expressed at high levels in a subgroup of AE positive AML patients. Furthermore, *MEIS2* was highly and aberrantly expressed virtually in all AE patients (n=70) compared to normal bone marrow. Expression patterns of both *MEIS* genes correlated with their promoter methylation in the t(8;21) patients and cell lines. Murine transplantation experiments showed that none of the mice in the AE as well as in the control group developed disease. In contrast, mice transplanted with BM co-expressing AE+Meis1 and AE+Meis2 developed lethal disease after a median latency of 102 and 255 days respectively. AE+Meis1 induced MPS in three, AML in seven and ALL in three cases, whereas AE+Meis2 induced AML in all cases. Functional relevance of *MEIS* expression was further confirmed in human AML cell lines as shRNA mediated depletion of *MEIS1* as well as *MEIS2* impaired cell growth in AE positive AML cell lines and so far one primary AE AML sample. To understand the mechanisms of AE/MEIS collaboration co-immunoprecipitation assays were performed documenting interaction of Meis1 as well as Meis2 with AE. ChIP-Seq has been performed and data on changes in DNA binding of AE in dependence of MEIS expression will be presented.
Summary and Conclusions: Our data demonstrate for the first time that AML1-ETO can collaborate with Meis1/2 and identify a novel collaborative partner in t(8;21) positive AML. It furthermore shows that a class II mutation can be converted into an overt oncogene by collaborating with its own class.

Lymphoid leukemogenesis

Molecular Biomedical Research, VIB, Ghent University, [2]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Ghent, Belgium, [3]Institut Universitaire d'Hématologie and U944 INSERM, Hopital Saint-Louis, Paris, France, [4]Center for Medical Genetics, Ghent University, Ghent, Belgium, [5]Mouse & Animal Pathology Laboratory, Università degli Studi di Milano, Milan, Italy, [6]Department of Development and Regeneration, K.U.Leuven, Leuven, Belgium, [7]Department of Internal Medicine III, Hematology and Oncology, University of Bonn, Bonn, Germany, [8]Department of Pediatric Oncology/Haematology, Erasmus MC Rotterdam - Sophia Children's Hospital, Rotterdam, Netherlands

Background: Zeb2 is a member of the ZEB family of transcriptional regulators. Its expression was correlated with the formation and/or function of cancer stem cells in solid tumors. We have previously demonstrated that Zeb2 is highly expressed in the hematopoietic system and evidence from mouse retroviral mutagenesis studies points to a role for Zeb2 in initiation and/or progression of leukemia/lymphoma.
Aims: Here, we examined the roles of Zeb2 in the hematopoietic system and in leukemia formation through a conditional gain-of-function approach.
Results: Bi-allelic overexpression of Zeb2 from the ROSA26 locus resulted in altered T cell development: a delay and partial block in differentiation was observed at the DN3 pre-T cell stage. In addition, Zeb2 overexpressing mice spontaneously develop thymic lymphomas starting at 5 months of age, indicating that Zeb2 acts as a driver in T cell malignancies. Next we have bred these mice onto a tumor-prone background (p53$^{flox/flox}$) and observed a significant decrease in tumor latency and an increase of the stem/progenitor markers c-Kit and CD44, suggesting an increase in leukemic stem cells. Using a minimal dilution series of tumour cells into NOD/SCID mice we could demonstrate a 10-100 fold increase in leukemia-initiating cells in the Zeb2 overexpressing tumors. To assess the relevance of these findings with human disease, we screened a cohort of T-ALL patients and found increased expression of ZEB2 predominantly associated within immature/ETP-ALL patients. Importantly, we could identify two ETP-ALL patients who presented a unique chromosomal translocation t(2;14)(q22;q32) on karyotype. This new translocation involves the ZEB2 locus and the BCL11B locus as confirmed by FISH analysis. Such BCL11B-associated translocations lead to the overexpression of the partner gene, thereby identifying ZEB2 deregulation as a molecular driving force for the development of ETP-ALL in these two patients.
Summary and Conclusions: In conclusion, we have shown that Zeb2 overexpression affects early T cell development and predisposes mice to develop an aggressive form of T-ALL with increased stem cell properties. This mimics patients with aggressive ETP-ALL driven by ZEB2 translocations, demonstrating that the EMT regulator ZEB2 is an oncogene for T-ALL.

S1132

ETV6-RUNX1 ALL, INSIGHTS FROM INTEGRATIVE GENOMIC ANALYSIS

E Papaemmanuil[1,*], Y Li[1], N Potter[2], L Alexandrov[1], P Van-Loo[1], D Wedge[1], T Ford[2], M Stratton[3], M Greaves[2], P Campbell[1]
[1]Cancer Genome Project, Wellcome Trust Sanger Institute, Cambridge, [2]Hemato-oncology, Institute of Cancer Research, London, [3]Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Approximately 25% of pediatric B-cell precursor ALL are characterized by the *ETV6-RUNX1* fusion and are associated with a favorable prognosis. Monozygotic twin studies with concordant ALL and 'backtracking' studies using archived neonatal blood spots established that *ETV6-RUNX1* is a likely initiating event arising prenatally in a committed B-cell progenitor. However, the fusion gene is not sufficient on its own to cause overt leukemia and a number of subsequent studies have now provided strong evidence that additional mutations, arising post-natally, are essential for the clinical development of ALL.
Aims: To obtain a detailed portrait of the composite genetic events that, in concert with the *ETV6-RUNX1* fusion gene, drive this subtype of ALL, we have carried out extensive genomic analysis in patients with ETV6-RUNX1 ALL.
Methods: A total of 57 cases with diagnostic (leukemic) cell DNA paired with matched, remission samples as a source of constitutive DNA were used for exome sequencing (n=56) and low-depth whole genome sequencing for structural variation analysis (n=51). Integrative analysis of exome and whole genome

data was performed and data were evaluated for recurrent gene mutations, copy number alterations and genomic rearrangements. Signatures of somatic mutation and structural variation were studied for insights into operative mutational processes and exposures that may drive *ETV6-RUNX1* pathogenesis. Single cell analysis in two patients was performed using a PCR-based, microfluidic platform, to study timing of mutational processes and how these affect the patterns of subclonal segregation of mutations and clonal phylogeny.
Results: We confirmed 775 somatic substitutions and 16 indels across 715 protein coding genes and 3 micro RNAs. Each patient had on average 14 gene coding mutations consistent with the low number of acquired somatic mutations identified by systematic sequencing screens of haematological malignancies and other childhood cancer. Whole genome profilings identified 524 SVs (average:11, range 0-49) including 34 tandem duplications, 66 inversions, 106 intrachromosomal translocations and 317 deletions. Oncogenic mutations in *KRAS*, *NRAS*, *CTCF*, *DAXX*, *EZH2*, and *KDM6A* are described as well as patterns of complex rearrangement including the balanced chain of chromosomal rearrangements seen in prostate cancer. Most mutations are subclonal to *ETV6-RUNX1*. Integrative analysis of whole-genome and exome data identify genes with deletions and inactivating mutations including *MGA* and *ZMYM2* that would have not been identified by either dataset alone. Sequence context analyses on the observed mutations identifies two distinct mutational signatures that are operative in *ETV6-RUNX1* ALL, and collectively account for the majority of the acquired mutations observed.
Summary and Conclusions: We report the identification of a novel spectrum of somatic mutations in *ETV6-RUNX1* ALL and present the first detailed characterization of the genomic landscape of this common ALL subtype. We provide new insights into the molecular pathogenesis of *ETV6-RUNX1* ALL and discuss the potential biological and clinical implications.

S1133

THE ROLE OF JAK3 MUTATIONS IN THE DEVELOPMENT OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: DEVELOPMENT OF IN VITRO AND IN VIVO MODELS

S Degryse[1,2,*], L Cox[1,2], V Gianfelici[1,2], O Gielen[1,2], N Mentens[1,2], K Jacobs[1,2], C De Bock[1,2], J Cools[1,2]
[1]Center for the Biology of Disease, VIB, [2]Center for Human Genetics, KU Leuven, Leuven, Belgium

Background: JAK3 is a tyrosine kinase that associates with the common gamma chain in different cytokine receptors in which JAK1 tyrosine kinase is an essential signaling protein. In acute lymphoblastic leukemia (ALL) and acute megakaryoblastic leukemia mutations have been identified in JAK1 and JAK3. In our exome sequencing study of 67 T-ALL cases, we identified six patients with heterozygous mutations in the pseudokinase or kinase domain of JAK3. Two samples showed evidence for bi-allelic JAK3 mutation.
Aims: The aim of this work was to determine the signaling properties of these JAK3 mutant proteins, to study their *in vitro* and *in vivo* leukemogenic properties, and to test the efficacy of JAK kinase inhibitors for the inhibition of the different mutants.
Methods: We selected six JAK3 pseudokinase domain mutations (A573V, R657Q, A572T, V674A, V678M, M511I), and one JAK3 kinase domain mutation (L857Q). We expressed these proteins in Ba/F3 (B-cell) and MOHITO (T-cell) models through viral transduction. We performed western blot experiments to evaluate downstream signaling, and tested the efficacy of the kinase inhibitors tofacitinib and ruxolitinib for the inhibition of JAK3. RNAi experiments were used to identify essential components for the transforming capacities of the JAK3 mutants.In order to study the effect of JAK3 mutations on T-cell development *in vivo*, we expressed the mutant JAK3 proteins in mouse hematopoietic cells through viral transduction.
Results: Expression of the JAK3 kinase mutant and the six JAK3 pseudokinase mutants in Ba/F3 and MOHITO cells resulted in transformation to IL3 or IL7 independent growth. All mutants led to phosphorylation of JAK1, STAT5 and ERK, while only some mutants showed strong phosphorylation of the JAK3 kinase. Expression of the JAK3 mutant proteins in cells lacking the common gamma chain receptor did not result in auto-phosphorylation of the JAK3 mutant proteins. Based on RNAi experiments and the expression of JAK1 kinase deficient proteins, we were able to show that JAK1 kinase activity is essential for the transforming capacities of all except one (L857Q) JAK3 mutant. The JAK kinase inhibitors tofacitinib and ruxolitinib were able to inhibit the proliferation of the transformed cells with IC50 values around 300 nM and 150 nM, respectively. The kinase domain mutation was significantly less sensitive to ruxolitinib compared to the other JAK3 mutants, while such difference was not observed with tofacitinib. To determine the *in vivo* transforming properties of the JAK3 mutants, we performed bone marrow transplant assays. Mice that received bone marrow cells transduced with JAK3 mutants, developed a fatal T-cell leukemia within 100 days post transplant. The disease was characterized by increased white blood cells counts (>60,000/mm^3) and splenomegaly, with massive infiltration of CD8 single positive T-cells in bone marrow, spleen and thymus. Secondary transplanted mice developed leukemia within three weeks post transplant, confirming the disease to be an acute leukemia.
Summary and Conclusions: *In vitro* and *in vivo* experiments confirm the oncogenic properties of JAK3 mutant proteins and show that JAK1 is an essential kinase for most JAK3 mutants. Therefore, both JAK1 and JAK3 specific inhibitors could be tested for the treatment of JAK3 mutation positive leukemias. We demonstrate the efficacy of tofacitinib and ruxolitinib for the inhibition of various JAK3 mutants.

S1134

LEUKEMIA INITIATING CELLS (LICS) IN ACUTE LYMPOBLASTIC LEUKEMIA (ALL) ARE ENRICHED IN EARLY CELL CYCLE

L Trentin[1,*], M Queudeville[1], S Eckhoff[1], M Herrmann[1], S Miller[1], N Hasan[1], K Debatin[1], L Meyer[1]
[1]Department of Pediatrics and Adolescent Medicine, Ulm University, Ulm, Germany

Background: Leukemia initiating cells (LICs) in acute lymphoblastic leukemia (ALL) were initially supposed to be organized in a hierarchical fashion similarly to acute myeloid leukemia (AML) with only a minority of phenotypically defined cellular sub-fractions that are able to propagate leukemia in immunodeficient mice. Recent data have challenged this view and clearly showed that LICs in ALL are not restricted to few phenotypically defined cells but that both immature and mature B-cell precursor (BCP) -ALL cells are equally able to reconstitute leukemia *in vivo* pointing to a stochastic model for the LICs in ALL. Nevertheless, the identification of a distinct leukemia initiating cell population in ALL is still an open issue.
Aims: In order to further characterize LICs in BCP-ALL we employed an alternative approach to determine leukemia initiating activity of ALL cells of distinct cell cycle stages by xenotransplantation assays using our NOD/SCID/huALL mouse model.
Methods: Patient derived xenograft B-cell precursor (BCP-) ALL samples were simultaneously stained for their DNA and RNA content and sorted according to distinct cell cycle phases, *i.e.* G0/G1 and G2-M. Sorted cells were transplanted onto NOD/SCID mice (10^5cells per recipient, 3 recipients per cell cycle subgroup). In addition, sorted cells were analyzed for surface expression of CD19, CD45, CD10, CD38, CD34 and Ly-5.
Results: No difference in the surface expression of markers earlier reported to characterize ALL initiating cells such as CD10, CD38, CD34 and CD19 was detected comparing BCP-ALL cells sorted according to distinct phases of the cell cycle. Most interestingly, functionally all ALL cell subpopulations showed leukemia initiating activity irrespective of their cell cycle stage and led to development of leukemia in the recipient mice. However, among the 4 cell cycle compartments analyzed, the cells isolated from the G0/G1 phase showed the shortest time to leukemia appearance in the recipients compared to cells from later/G2-M cell cycle phases. Importantly, cells belonging to the G2-M phase were always the last engrafting in the recipient mice. Even more interestingly, the differences in the engraftment activity were maintained also when cells were further transplanted onto secondary recipients: cells (unsorted) isolated from primary mice transplanted with G0/G1 cells engrafted earlier compared to cells (unsorted) isolated from mice primarily transplanted with G2/M cells. This increased leukemia initiating activity of ALL cells originating form G0/G1 phases clearly indicates an enrichment of cells with ALL initiating and propagating activity within early cell cycle phases.
Summary and Conclusions: In summary, ALL cells of all cell cycle phases are able to reconstitute leukemia in the recipient animals indicating LIC activity irrespective of cell cycle phases and do not differ in expression of surface markers. This is in line with recent findings describing that LICs in ALL are ubiquitous and frequent. Importantly, despite leukemia reconstitution by cells of all cell cycle subphases, a higher leukemia repopulating activity of cells within G0/G1 was identified indicating an enrichment of LICs in this early phase of the cell cycle which was maintained upon secondary transplantation. Taken together, these data indicate that all BCP-ALL cells posses leukemia initiating potential with cells in the G0/G1 phase representing the driving leukemia initiating cell compartment.

S1135

TISSUE AND DIFFERENTIATION STAGE-SPECIFIC EXPRESSION OF THE CALM/AF10 FUSION PROTEIN IS REQUIRED FOR LEUKEMOGENESIS

S Dutta[1,*], A Krause[2], M Schneider[3], M Dahlhoff[3], B Tizazu[1], E Wolf[3], S Bohlander[4]
[1]Hämatologikum, Department of medicine III, Ludwig Maximilians Universität München,Clinical Cooperative Group "Leukemia", National Research Center for Environmental Health,Helmholtz Zentrum München, Munich, Germany, [2]Stem Cell Laboratory, Department of Small Animal Medicine,Federal University of Santa Maria, RS, Brazil, [3]Molecular Animal Breeding and Biotechnology, Gene center, LMU, Munich, [4]Center for Human Genetics, Philipps University Marburg, Marburg, Germany

Background: The translocation t(10;11)(p13;q14), which results in the formation of the CALM/AF10 fusion gene, is associated with variety of hematological malignancies including T-cell acute lymphoblastic leukemia (T-ALL), acute myeloid leukemia (AML), undifferentiated leukemia, and T cell lymphoma. In most cases, this translocation is associated with a very poor prognosis.

Aims: To study the mechanism of leukemic transformation by the CALM/AF10 fusion, we established tissue-specific knock-in mouse models.
Methods: In the Rosa26-CALM/AF10 mouse line, the CALM/AF10 cDNA preceded by a loxP flanked transcriptional stop cassette is integrated into the Rosa26 locus. Using tissue restricted or inducible expression of the Cre recombinase, the stop cassette can be removed, resulting in the expression of the CALM/AF10 fusion from the Rosa26 promoter.
Results: We crossed the Rosa26-CALM/AF10 mouse line with a Vav-Cre transgenic line to express CALM/AF10 in the entire hematopoetic compartment starting in the fetal liver, and with Cd19-Cre and Mb1-Cre lines to express CALM/AF10 in early and mature B cells. Expression of CALM/AF10 using Vav-Cre-mediated recombination led to the development of AML with a median latency of 1 year and 100% penetrance. Leukemic mice showed splenomegaly, leukocytosis, and diffuse infiltration of myeloperoxidase positive blast cells in several organs. In 40-50% of the cases the leukemic cells had a biphenotypic character, staining positive for both the myeloid marker Mac1 and the B lymphoid marker B220. In the leukemic cells, we could detect overexpression of *Hoxa* cluster genes (*Hoxa5*, *Hoxa7*, *Hoxa9*, *Hoxa10*) and the *Hox* cofactor *Meis1*. Stable expression of CALM/AF10 from the Rosa26 locus in B cells starting from the very early pro B cell stage using Mb1-Cre and Cd19-Cre-mediated recombination did not result in leukemia development in any of the animals after more than 1.5 years. CALM/AF10 expressing B cells from those healthy mice do not show *Hoxa* gene or *Meis1* overexpression.
Summary and Conclusions: This study demonstrates that CALM/AF10 is only leukemogenic when expressed at the right stage of hematopoetic development in the correct cell type and that the overexpression of *Hoxa* genes and of *Meis1* plays important roles in the leukemic transformation. Furthermore, the relatively long median latency of 1 year in the Vav-Cre induced cohort strongly supports the hypothesis that CALM/AF10 requires additional genetic lesions for leukemia development.

Platelets

S1136

T-CELL GENE EXPRESSION PROFILING SUGGESTS THAT "ACUTE" AND CHRONIC ITP ARE TWO SEPARATE DISEASE ENTITIES

M Jernas[1,*], I Nookaew[2], F Celind[3], K Mellgren[3], H Wadenvik[4], B Olsson[5]
[1]Dept of molecular and clinical medicine, UNIVERSITY OF GOTHENBURG, [2]Department of Chemical and Biological Engineering, Chalmers University of Technology, [3]Department of Paediatrics, The Queen Silvia's Hospital for Children and Adolescents, [4]Internal Medicine, [5]Psychiatry and Neurochemistry, University of Gothenburg, Göteborg, Sweden

Background: Immune thrombocytopenia (ITP) is an organ specific autoimmune disease where platelets and megakaryocytes are targeted. Although the immunopathogenic cause of ITP has not been fully clarified, there is overwhelming evidence to suggest that a dysfunction of autoreactive T cells could represent the critical event in ITP. A substantial fraction of children with ITP undergo spontaneous remission within 6 months after the initial diagnosis. These patients have formerly been referred to as "acute" while those with persistent low counts beyond 12 months are referred to as chronic ITP. However, it is still unclear if chronic ITP is a natural course of the "acute" form or if these conditions are two different and distinct disorders.
Aims: T-cell dependent processes are central in the pathophysiology of ITP. Our aim was to study if the global gene expression signatures in T-cells differ between "acute" and chronic ITP in childhood.
Methods: Heparin-anticoagulated peripheral blood was obtained from 8 acute (2 boys, 6 girls, mean age 4.9±1.6 yrs; mean time to CR 1.7±0.3 month) and 9 chronic (7 boys, 2 girls, mean age 10.6±2.3 yrs; mean disease duration:56±14 month) ITP-patients and 7 healthy controls (6 boys, 1 girl, mean age 9.9±1.7 yrs). T-cells were isolated by immunomagnetic cell sorting (Miltenyi Biotec, Surrey, UK) and RNA was prepared using the Chomczynski method, followed by RNeasy mini-elute clean-up (Qiagen, Hilden, Germany). Twenty ng RNA was amplified with the Ovation RNA Amplification System V2 (NuGEN Techn., Inc, San Carlos, CA), and cDNA was synthesized using the Encore Biotin Module kit (NuGEN Techn., Inc, San Carlos, CA). After standard labeling, each sample was hybridized to Affymetrix U133Plus 2.0 Human Genome array (Santa Clara, CA). We verified some differentially expressed genes and corresponding protein with real-time PCR and ELISA.
Results: In the DNA microarray analysis we identified 4194 differentially expressed genes in "acute" and 168 in chronic childhood ITP *versus* controls, respectively. From these genes, 125 genes were differently expressed in both ITP forms compared with controls. Interestingly, 4069 and 43 differently expressed genes between ITP patients and controls were specific to "acute" and chronic ITP, respectively. A dendrogram plot showed that the two forms of ITP clustered separate from each other. Functional enrichment analysis based on GO classifications identified several pathways that differed between "acute" and chronic ITP patients compared with controls. Since ITP is an autoimmune disease we focused on immune related genes classified according to Immune Systems Gene Ontology. The analysis showed that enriched T-cells genes in "acute" ITP patients compared with controls were involved in T-cell receptor signaling pathway and regulation of T-cell activation. In chronic ITP patients compared with controls genes involved in regulation of macrophage and neutrophil chemotaxis were found. The GO classifications identified increased T-cells genes in "acute" ITP patients compared with controls such as IL-16 and CX3CR1 and real-time PCR confirmed the regulation. We also measured protein levels of TGFB1, which showed significant regulation between "acute" and chronic ITP compared with controls.
Summary and Conclusions: Our findings show that genes involved in T-cell receptor signaling and activation are differently expressed in "acute" ITP patients compared with chronic ITP. Furthermore, the clustering of T-cell gene expression profiles suggests that "acute" and chronic ITP are two separate disease entities.

S1137

DIFFERENTIAL REGULATION OF THE APOPTOTIC MACHINERY DURING MK DIFFERENTIATION AND PLATELET PRODUCTION BY IAP LIVIN

I Elrahman[1,*], V Deutsch[2], M Pick[1], T Neuman [3], R Perlman[1], Di Ben-Yehuda[1]
[1]Hematology, Hadassah - Hebrew University Medical Center, Jerusalem, [2]Hematology, The Hematology Institute, Tel Aviv Medical Center, Tel-Aviv, [3]Pathology, Hadassah - Hebrew University Medical Center, Jerusalem, Israel

Background: The exact mechanism of platelet production is poorly understood. A relationship between activation of the apoptotic cell machinery and the formation of pro-platelets has been established. In this study we show that Livin plays a role in this process. Livin is a member of the Inhibitor of Apoptosis Proteins (IAP) family of intracellular anti-apoptotic proteins that acts by binding and inhibiting caspases. We found that Livin is unique among the IAP members as upon strong apoptotic stimuli it is specifically cleaved by caspases to produce a truncated protein (tLivin) with a paradoxical pro-apoptotic activity.

Aims: To explore Livin expression during MK differentiation and better understand its role inplatelet production
Methods: In this work we studied Livin expression in normal bone marrow (BM) and in BM from patients with hematological diseases using immunohistochemistry (IH) staining. To evaluate the potential role of Livin in thrombopoiesis we used cord blood CD34+ cells that were grown under MK differentiating conditions (SCF and TPO). In addition, an *in vitro* model was established to evaluate the potential role of Livin in thrombopoiesis. The human BCR-ABL positive cell line, LAMA-84, was induced by a phorbol ester (PMA) to differentiate to MK. Increased cell size, ploidy and DNA synthesis, all markers of MK differentiation, were detected by flow cytometry (FACS).
Results:: Interestingly, Livin protein is clearly detected in MK in normal mature BM (by IH staining) and is expressed in platelets. *Down-regulation of Livin* in $CD34^+$ progenitor cells and LAMA-84 decreased the ability of MKs to produce functional platelets. Upon differentiation induced by PMA, LAMA-84 cells formed pro-platelets and produced functional platelets capable of aggregation. This differentiation of LAMA-84 cells into MKs was accompanied by Livin protein expression. In contrast to Livin, the levels of the anti-apoptotic proteins Bcl-2, XIAP and Survivin decreased upon MK differentiation. Livin over-expression in $CD34^+$ progenitor cells induced differentiation of these cells into MK and increased the ability of these primary MK to produce platelets. At the terminal stage of differentiation we observed accumulation of the pro-apoptotic tLivin concomitant with increased caspase 3 activity and apoptosis.
Summary and Conclusions: The IAP Livin is upregulated upon MK differentiation and is then cleaved to pro-apototicc tLivin at the end of this process to produce functional platelet. We suggest that Livin plays a role in thrombopoiesis by regulating the apoptotic cell machinery in MK.

S1138

X-LINKED THROMBOCYTOPENIA WITH THALASSEMIA (XLTT) DISPLAYS INCREASED BONE MARROW FIBROSIS AND ANGIOGENESIS–COMPARISONS WITH PRIMARY MYELOFIBROSIS AND GATA1LOW MICE

M Åström[1,*], V Hahn-Strömberg[2], E Zetterberg[3], M Merup[4], K Hultenby[5], A Migliaccio[6], J Palmblad[4]
[1]Section of Hematology, Department of Medicine, [2]Section of Pathology, Department of Laboratory Medicine, Örebro University Hospital, Örebro, [3]Department of Hematology and Coagulation, Skåne University Hospital, Malmö, [4]Departments of Medicine and Hematology, [5]Department of Laboratory Medicine, Karolinska Institutet, Karolinska University Hospital Huddinge, Stockholm, Sweden, [6]Tisch Cancer Institute, Mount Sinai School of Medicine, New York, United States

Background: GATA1 is a transcription factor that controls erythropoiesis and thrombopoiesis by binding to DNA targets directly or via its co-factor FOG-1. In man, several hypomorphic mutations in the *GATA1* gene localized on the X-chromosome are associated with thrombocytopenia and anemia. In mice, the hypomorphic $Gata1^{low}$ mutation causes a phenotype similar to human primary myelofibrosis (PMF) with thrombocytopenia, defective megakaryocyte (MKC) maturation with increased proliferation, progressive bone marrow (BM) fibrosis, and increased angiogenesis with dilated BM micro-vessels (MV). Although *GATA1* mutations have not been detected in PMF as yet, MKC from these patients exhibit abnormalities similar to MKC from $Gata1^{low}$ mice and have low expressions of GATA1 by immuno-histochemistry (IHC)/immuno-electronmicroscopy. X-linked thrombocytopenia with thalassemia (XLTT) is a rare inherited disorder caused by the 216 R>Q mutation in exon 4 of *GATA1*. The phenotype of male patients includes macrothrombocytopenia, splenomegaly and a beta-thalassemia trait. We describe two families with XLTT in whom three males were initially falsely diagnosed withPMF and all five investigated males showed BM fibrosis ranging grades I-II/III.
Aims: To enhance diagnostic accuracy and improve the knowledge on mechanisms of BM fibrosis by comparing the natural course of BM fibrosis and features of BM angiogenesis between XLTT patients, PMF patients and $Gata1^{low}$ mice.
Methods: Members of the two apparently non-related XLTT families (5 M reported here, 2 F not reported here) were studied. Red blood cell and platelet indices were measured with Siemens ADVIA 2120. BM biopsies from the five XLTT males, varying numbers of patients with PMF or post-PV or –ET-MF with grade II or III BM fibrosis, healthy controls and $Gata1^{low}$ micewere stained by IHC/immuno-fluorescence for several markers.
Results: BM fibrosis never exceeded grades I-II/III in the XLTT males who were aged 29-67 years at sampling, with increased reticulin staining but no collagen fibers (negative van Gieson staining). Also spleen sizes seemed stable over time (lengths by ultrasound 13-20 cm). Mild anemia, anisocytosis, reticulocytosis and low MCV (median 78 fL, ref 82-98 fL) were typically seen. Platelet counts were mostly in the range 22-87 $\times$ 10^9/L (ref 145-387$\times10^9$/L), with high MPV 11.1-12.0 fL (ref 7-9 fL) and PDW 63-74%. Some platelets were pale, and deficiency of alpha-granule was verified by EM. Blood CD34+ cells were increased. MKC were increased in BM, sometimes hypolobulated and showed reduced expressions of GATA1, VEGF and AGGF1 (angiogenic growth factor-1) but normal CD61. PMF MKC had reduced GATA1 expression but increased VEGF and CTGF (connective tissue growth factor). High micro-vessel density (MVD) in XLTT BM, with small MV and poor pericyte coverage of the vessel walls contrasted with large MV having high pericyte coverage in PMF and $Gata1^{low}$ mice. AGGF1 and CTGF were expressed in pericytes as shown by double-stainings for CD34, SMA-alpha and the growth factors. None of the XLTT patients showed the *JAK2* 617 V>F mutation.
Summary and Conclusions: Apparently non-progressive BM fibrosis is a clinically important feature in two XLTT families. Other findings in XLTT were low VEGF and AGGF1 expressions in MKC and enhanced angiogenesis with small MV and low pericyte coverage, as opposed to large MV and high pericyte coverage in PMF. These features together with mutation analyses may aid in the differential diagnosis against PMF.

S1139

MUTATIONS RESPONSIBLE FOR ANKRD26-RELATED THROMBOCYTOPENIA INCREASE THE RISK OF HEMATOLOGICAL MALIGNANCIES BUT ARE NOT FREQUENTLY INVOLVED IN *DE NOVO* ACUTE LEUKEMIAS

Seràgnoli", University of Bologna, Bologna, Italy, [9]Department of Medical Genetics, University of British Columbia, Vancouver, Canada, [10]Department of Internal Medicine, San Paolo Hospital, Milan, [11]Department of Clinical and Biological Science, University of Turin, Orbassano, [12]Department of Internal Medicine, IRCCS Policlinico San Matteo-University of Pavia, Pavia, [13]Laboratory of Genetics, Institute for Maternal and Child Health, IRCCS Burlo Garofalo-University of Trieste, Trieste, [14]Medical Genetics Unit, Department of Gynaecological, Obstetric, and Paediatric Sciences, University of Bologna, Bologna, Italy, [15]Armand Trousseau children hospital, Paris and Inserm U1009, Villejuif, Paris, France

Background: It has been recently shown that mutations in the 5'UTR of *ANKRD26* result in an autosomal dominant form of thrombocytopenia with normal size platelets that has been named *ANKRD26*-Related Thrombocytopenia (*ANKRD26*-RT) (Am J Hum Genet 2011;88:115-20). Gene overexpression seems to be the consequence of mutations. It has been suggested that *ANKRD26*-RT is one of the less rare forms of inherited thrombocytopenias in that it was identified in 21 of 210 families with genetically transmitted low platelet counts (Blood 2011;117:6673-80). Analysis of 78 patients revealed that thrombocytopenia and bleeding tendency were usually mild or moderate, and bone marrow examination suggested that thrombocytopenia was derived from dysmegakaryopoiesis. Unexplained high values of hemoglobin and leukocytes were observed in some cases. The most important clinical remark of *ANKRD26*-RT was the association with acute leukemia, which affected 6% of patients.
Aims: The purpose of this study was to confirm the clinical and laboratory characteristics of *ANKRD26*-RT that have been identified in the first case series of patients. In particular, we wanted to confirm that the disease increases the risk of hematological malignancies. Moreover, we wanted to ascertain whether the 5 'UTR of *ANKRD26* is mutated in *de novo* acute leukemias.
Methods: We searched for mutations in the 5'UTR of *ANKRD26* in patients with inherited thrombocytopenias who had remained without a definite diagnosis at the end of the diagnostic procedure. The search for mutations in the 5'UTR of *ANKRD26* was also performed in 254 subjects with acute leukemia.
Results: We identified 11 heterozygous single nucleotide substitutions and 1 small deletion in the 5'UTR of *ANKRD26* in 65 patients from 21 pedigrees with inherited thrombocytopenia. Four of these mutations (c.-116C>G, c.-126T>C, c.-127delAT, c.-128G>C) had not been detected previously. Bleeding tendency was mild (most patients with grade 1 or 2 of the WHO bleeding scale), platelet count was moderately reduced (mean value/SD: 51/29 $\times10^9$/L) and mean platelet volume was usually normal (mean value/SD: 9/2 fL). Hemoglobin and leukocyte levels higher than normal were observed in 5 and 13 cases, respectively. Considering also 27 affected family members who died before our study, the extended series of 92 patients includes 6 subjects with AL, 3 with myelodysplastic syndrome (MDS) and 2 with chronic myelogenous leukemia (CML). Mutation screening in patients with *de novo* acute leukemias identified mutations in the 5'UTR of *ANKRD26* in one subject. However, medical history revealed that he was thrombocytopenic before developing leukemia and that other family members were known to be affected by *ANKRD26*-RT.
Summary and Conclusions: Our study brings the number of families with *ANKRD26*-RD described in the literature to 42 and makes this form of inherited thrombocytopenia one of the most frequently reported. Analysis of this new case series confirmed that the typical picture of *ANKRD26*-RT is that of an autosomal dominant disorder characterized by moderate thrombocytopenia with normal sized platelets and mild bleeding diathesis. It also confirmed

that mutations in 5'UTR of *ANKRD26* predispose to hematological malignancies, in that 11 of 92 affected subjects developed AL, MDS or CML. However, our study excluded that these mutations are frequently involved in *de novo* AL.

S1140

EXTENT AND CLINICAL RELEVANCE OF BONE MARROW FIBROSIS IN IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS TREATED WITH THROMBOPOIETIN RECEPTOR AGONISTS (TPO-RA)–A SINGLE CENTRE LONG-TERM FOLLOW-UP

W Ghanima[1,2,*], J Geyer[3], L Boiocchi[4], C Lee[2], A Miller[2], A Orazi[5], J Bussel[2]
[1]Medicine, Østfold Hospital Trust Fredrikstad, Fredrikstad, Norway, [2]Department of Pediatric Hematology/Oncology, [3]Pathology and Laboratory Medicine, [4]Weill Cornell Medical College/New York Presbyterian Hospital, New York, United States, [5]Pathology and Laboratory Medicine, Weill Cornell Medical College/New York Presbyterian Hospital, New York, United States

Background: Treatment of ITP patients with TPO-RA increases platelets through stimulation of the TPO receptor. One reported side effect of TPO-RAs is induction of bone marrow fibrosis (BMF)
Aims: To determine the magnitude and clinical significance of BMF and risk of developing phenotypical and/or karyotypic clonal abnormalities in TPO-RA-treated ITP patients
Methods: This single-centre study was carried out at the Platelet Disorders Centre of Weill Cornell Medical College (WCMC), New York, USA. Eligibility criteria were the presence of ITP diagnosis, treatment with TPO-RA and availability of at least one bone marrow biopsy (BMB) performed on treatment with one of the following TPO-RA: romiplostim, eltrombopag, AKR 501/E5501 (Eisai) or the Shionogi agent. BMB were performed every 1–2 years as part of the standard follow-up procedure for ITP patients on TPO-RA. The grade of BMF was assessed in 121 BMBs (13 pretreatment, 103 on-treatment, 5 post-treatment) acquired from 64 patients. Forty disease-free staging BMBs served as controls. All BMBs were separately reviewed by 3 pathologists to assess the grade of marrow fibrosis (MF); discordant cases were reviewed simultaneously to reach consensus. Fibrosis was graded from MF-0 to MF-3 according to the European Consensus Grading System. No additional bone marrows were performed as part of the study. The study was approved by the IRB of the WCMC; informed written consent to include their previously obtained material was acquired from all patients.
Results: Median age (interquartile range=IQR) of 64 patients (33 males/31 females) at the time of first BMB was 38 years (IQR 18-63). Twenty-six patients had ≥2 BMBs. The distribution of MF-grades is shown in the Table 1. The proportion of MF-0 decreased from 70% in pretreatment biopsies to 22% in the first set of BMBs (P=0.03) indicating that TPO-RA induces reticulin in the BM of most treated patients. Despite stable dosing, there was a significantly greater number of MF-2/MF-3 in the last available BMBs as compared to control BMBs, in which no MF-2/MF-3 was found (P=0.003). In the 26 patients having two or more BMBs the number of MF2/3 increased from 2 (8%) in BM1 to 8 (30%) in the last available BMB (P=0.03), which indicates progressive fibrosis in some patients. At time of last available BMB, median hemoglobin level, absolute neutrophils counts, platelet counts and lactic dehydrogenase in those with MF0/1 were 13.6 g/dl, 4.6×10^9/L, 98×10^9/L, 225 U/L and in patients and with MF-2/3 were 12.5 g/L, 6.6×10^9/L, 139×10^9/L, 223 U/L, respectively. No statistically significant differences were found. Comparing factors as age, duration of disease, duration of treatment, splenectomy status, type and dose of agent, only age was found to be significantly higher in patients with MF-2/3 as opposed to MF0/1 at time of last BMB [54 y *vs.* 38 years in (P=0.02].

Table 1.

	TPO-RA treated ITP patients						Controls
	BM 0 n=13	BM 1 n=64	BM 2 n=26	BM 3 n=10	BM 4 n=3	BM Last n=64	n=40
Median (IQR) duration of treatment in years		1.3 0.9-1.7	2.5 1.9-3.4	3.6 2.6-3.7	5.5 5.0-5.8	1.9 1.3-3.5	
MF-0	9 (70%)	14 (22%)	4 (15%)	1 (10%)	0	14 (22 %)	20 (50%)
MF-1 (%)	3 (23%)	45 (70%)	14 (54%)	5 (50%)	1 (33%)	39 (61 %)	20 (50%)
MF-2 (%)	1 (8%)	4 (6%)	7 (27%)	3 (30%)	2 (67%)	11 (17 %)	-
MF-3 (%)	0	1(2%)	1 (4%)	1 (10%)	0	0	-
Trichrome (n +/-)	0/10	1/64	1/26	2/8	0/3		
Karyotype (n of abnor/nor)	0/3	2/25	0/12	0/7	0/2		
Immunophenotype (n of abnor/nor)	0/6	0/41	0/16	0/6	0/2		
BM 0 = pretreatment biopsies; BM 1= 1st set; BM 2 = 2nd set; BM 3 = 3rd set; BM 4= 4th set; BM last= last available BM biopsy							

Summary and Conclusions: This large single centre experience indicates that TPO-RAs induce some degree of BMF, which although it was progressive in some, remained stable in the majority of patients and within the range that is found in normal individuals. The high grades of BMF (MF-2/3) observed in some did not appear to be clinically significant. Age was the only factor associated with higher grades of fibrosis. No neoplastic immunophenotypic or karyotypic abnormalities emerged during treatment with TPO-RA. Annual follow-up with BMB is recommended in TPO-RA-treated patients. Discontinuation should be considered in those who develop MF-3 or possibly even MF-2.

Cellular immunotherapy and vaccination

EXPLORING LEUKEMIA- AND VIRUS-SPECIFIC HUMAN CD8+ T LYMPHOCYTES WITH STEM-CELL-LIKE AND CENTRAL MEMORY PROPERTIES FOR EFFECTIVE IMMUNOTHERAPY USING HUMANIZED MICE

U Hartwig[1,*], Y Xu[1], A Mades[1], S Khan[1], M Theobald[1]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive transfer of *in vitro* generated tumor- and virus- reactive T cells has evolved as a promising strategy in cellular immunotherapy to treat cancer and virus-associated neoplasia such as Epstein-Barr Virus (EBV)-mediated post-transplant lymphoproliferative disorder (PTLD) observed after solid organ and hematopoietic stem cell transplantation. However, terminally differentiated, high avidity effector T cells exhibit limited homing and self-renewal capacity to establish sustained memory.
Aims: In this study we thus explored the modulation of the canonical Wnt-signaling pathway previously shown to affect T cell differentiation to generate HLA-A*0201 restricted, EBV- and Wilms Tumor 1 (WT1) antigen-specific cytotoxic T lymphocytes (CTL) from naïve $CD8^+$ $CD45RA^+$precursors with stem-cell (T_{SCM}) and central-memory (T_{CM}) properties.
Methods: Naïve $CD8^+$ T cells isolated from peripheral blood mononuclear cells (PBMCs) of healthy donors using the *Naive CD8⁺ T-Cell Isolation Kit* (Miltenyi Biotec) were first primed by autologous dendritic cells loaded with EBV-peptides (LMP2, BRLF1, BMLF1) or WT1-peptides ($WT1_{126-134}$ or WT1 PepMix® (Jerini Peptide Technology)) and then restimulated using peptide presenting autologous PBMCs or $HLA\text{-}A2^+$ T2-cells in the presence of an optimized cytokine cocktail comprising interleukin (IL)-12, -7, -15, and -21. To modulate Wnt-signaling the glycogen synthase kinase-3β (Gsk-3β) inhibitor TWS119 was added to the culture. Phenotypic and functional analyses were performed by flow cytometry, IFN-γ ELISpot and ^{51}Cr-release assays, respectively, at different time points of culture. In addition, homing and persistence of different T cell subsets was tested in NOD/scidIL2Rcg-null (NSG) mice while adoptive transfer studies to evaluate antitumor reactivity of these T cells were performed in NSG recipients engrafted with autologous EBV-transformed B cells (B-LCL) or patient-derived AML blasts prior to T cell transfer.
Results: Upon repetitive stimulation we obtained strong expansion of EBV- and WT1-reactive CTL expressing a $CD8^+CD45RA^+CD45RO^-CD95^+CD27^+CD28^+CD62L^+CCR7^+$ T_{SCM} and $CD8^+CD45RA^-$ $CD45RO^+CD95^+CD27^+CD28^+CD62L^+CCR7^+$ T_{CM} phenotype when compared to CTL stimulated without TWS119. In support of our phenotypic analyses additional studies revealed elevated ß-catenin mRNA and eomesdermin expression levels suggesting a Tcf-7 mediated transcriptional effect on T cell differentiation. Interestingly, whereas both TWS119 treated and control CTL populations elicited comparable reactivity against B-LCL *in vitro* as shown by IFN-y ELISPOT and chromium-release assays, adoptive transfer of EBV-reactive, TWS119-treated CTL in B-LCL engrafted NSG mice resulted in potent reduction of EBV-induced B-cell hyperplasia and prolonged engraftment as compared to non TWS119 treated controls. Similar *in vivo* studies of WT1-specific CTL using AML-engrafted NSG mice are currently in progress.
Summary and Conclusions: In conclusion, this study demonstrates that stem-cell-like and central memory EBV- and WT1-reactive CTLs with enhanced survival and sustained effector functions can be generated from naïve $CD45RA^+$ T cells by modulating Wnt-signaling for improved immunotherapy.

A NOVEL METHOD FOR SUBRETINAL TRANSPLANTATION OF HUMAN ADULT BONE MARROW MESENCHYMAL STEM CELLS AMELIORATES THE DETERIORATION OF RETINAL STRUCTURE AND FUNCTION IN A RAT MODEL OF RETINAL DYSTROPHIES

Y Rotenstreich[1,2,*], A Tzameret[1,2], I Sher[1], M Belkin[1,2], A Treves[3], A Nagler[4]
[1]Goldschleger Eye Research Institute, Sheba Medical Center, Tel Hashomer, [2]Goldschleger Eye Research Institute, Tel Aviv University, Tel Aviv, [3]Cancer Research Center, [4]Hematology Division, Sheba Medical Center, Tel Hashomer, Israel

Background: Retinal dystrophies, including age related macular degeneration (AMD) and retinitis pigmentosa (RP) are the leading cause of vision incapacitation and blindness worldwide. Currently, there are no effective treatments for most of these progressive diseases. Stem cell-based therapies represent a promising treatment avenue, with recent studies in animal models demonstrating enhanced retinal function following subretinal transplantation of adult or embryonic human stem cell. Preliminary results in clinical trials showed some promising positive effects. However in both animal models and patients, transplanted cells were confined to the injection area, significantly limiting the potential therapeutic effect.
Aims: To develop an improved subretinal transplantation system of human-derived bone marrow mesenchymal stem cells (hBM-MSCs).
Methods: hBM-MSC cells (CD73+; CD90+, CD105+, CD45-) from healthy human donors were transplanted into the sub-retina of one eye of 69 RCS rats at p28 (0.25 million cells/eye). Ten RCS rats were subretinally injected with medium as control. Retinal function was tested by electroretinogram before and following transplantation for 22 weeks. Visual function was examined by an object recognition test. Eyes were inoculated for histology and immunofluorescence analyses. To demonstrate efficiency and safety of the new transplantation method in a large animal model, cells were transplanted in New Zealand White Rabbits and Spectral Domain Optical Coherence Tomography (SD-OCT, Heidelberg) was used for eye imaging and detection of transplanted cells.
Results: Transplanted cells were identified shortly after transplantation as a nearly continuous sheet of cells covering most of the subretinal surface and in the choroid in the rat model. One week after transplantation, cells were confined to the subretinal space. A prolonged (up to p168) and statistically significant enhancement of retinal function following hBM-MSCs transplantation was demonstrated by electroretinogram analysis. Transplanted rats demonstrated improved visual performance following cell transplantation. These results correlated with histological analysis that revealed a significant preservation of retinal structure. Thus, increased number of photoreceptors were observed in the outer nuclear layer along most of the retina with concomitant preservation of rod photoreceptor cell structure. No immunosuppressants were used and long-term safety analysis demonstrated no gross or microscopic adverse effects of cell transplantation. Experiments in rabbits demonstrated efficient subretinal transplantation, with transplanted cells forming a uniform sheet of cells covering most of the subretinal surface. A shallower and less traumatic retinal detachment was produced by cell injection (Figure 1).

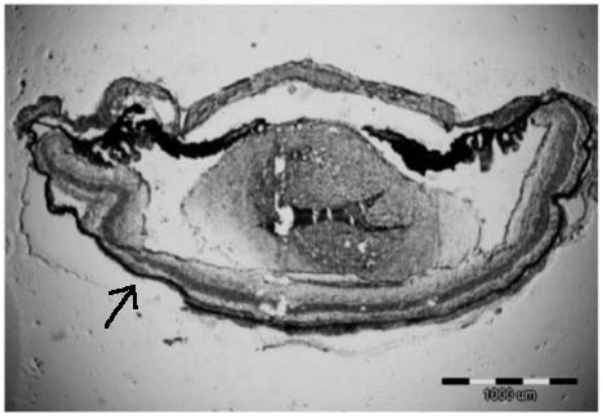

Figure 1. DiI-labeled (arrow) transplanted cells in rat eye.

Summary and Conclusions: In this study we showed for the first time that transplanting hBM-MSCs as a thin homogenous sub-retinal layer resulted in long-term protection of visual functions and significantly delayed photoreceptor degeneration throughout the retina. This new transplantation method may enhance host-graft interaction, cause less trauma to the host tissue and shallower retinal detachment. Our findings suggest that transplanting the cells as a thin layer enhances the therapeutic effect of these cells and safety of transplantation.

DENDRITIC CELL VACCINATION AS A POST-REMISSION TREATMENT IN ACUTE MYELOID LEUKEMIA: A REPORT OF 29 PATIENTS

Z Berneman[1,*], A Van de Velde[1], S Anguille[1], Y Willemen[1], W Schroyens[1], I Vrelust[1], A Gadisseur[1], G Nijs[1], B Stein[1], V Van Tendeloo[1], E Smits[1]
[1]Hematology, Antwerp University Hospital, Edegem, Belgium

Background: Relapse remains a major problerm in acute myeloid leulemia (AML), especially in the majority of older patients who cannot undergo allogeneic hematopoietic stem cell transplantation. We have reported on the induction of complete and molecular remissions in 5/10 AML patients, following vaccination with dendritic cells (DC), electroporated with mRNA encoding the full-length sequence of the Wilms' tumor protein WT1 (PNAS 2010;107:13824-9). This clinical effect was correlated with CD8+ T-cell response directed against WT1.
Aims: We hypothesized that we could improve the clinical effects by inducing anti-WT1 CD4+ T-cell response in addition to the anti-WT1 CD8+ T-cell response already observed previously.
Methods: In addition to the original construct with the full-length WT1 (construct 1), we also used 2 other constructs, one with a Sig-DC-LAMP MHC class II-skewing signal and a deletion of the WT1 nuclear localization signal (construct 2) and one similar to it, but codon-optimized (construct 3). mRNA, derived from these 3 constructs by *in vitro* transcription, was electroporated into monocyte-derived DC.

Results: When mRNA derived from the 2 new constructs (constructs 2 and 3) with the MHC class II-skewing signal was electroporated into DC, there was a higher cytoplasmic WT1 protein expression and a stronger stimulation of WT1-specific CD8+ T-cells as compared to the original full-length sequence without MHC class II-skewing signal (construct 1). DC electroporated with mRNA derived from constructs1, 2 and 3 were used to vaccinate respectively13, 6 and 10 AML patients, at very high risk of relapse and who were in remission following chemotherapy and pre-DC vaccination. In those 3 groups, the clinical response rate, as measured by a normalization of *WT1* mRNA tumor marker levels in blood and/or marrow, occurred in respectively 7/13, 1/4 and 0/6 patients. In addition, there were 4 patients with evidence of stable disease, some of it late, during DC vaccination. All patients, who did not normalize the *WT1* mRNA tumor marker level relapsed and/or died. Globally, 8/29 patients have not relapsed yet. Of those 8 patients, 5 had an increased *WT1* mRNA tumor marker level which normalized following DC vaccination, 3 of them now more than 5 years after the start of DC vaccination and most probably cured. One of those 3 patients, was in partial remission of AML following chemotherapy and was brought into complete and molecular remission by the DC vaccination only. Mono- or poly-epitope WT1-specific tetramer-positive T cells were detectable in all evaluable patients, with the highest frequency in patients who remained in complete remission after DC vaccination.
Summary and Conclusions: In conclusion, *WT1* mRNA-transfected DC vaccination is emerging as a non-toxic and effective strategy to prevent relapse in AML. Contrary to expectations, the original full-length *WT1* construct without MHC class II skewing signal has demonstrated the highest clinical activity so far.

S1144

INHIBITION OF PROTEIN GERANYLGERANYLATION SPECIFICALLY INTERFERES WITH CD40-DEPENDENT B CELL ACTIVATION RESULTING IN A REDUCED CAPACITY TO INDUCE T CELL IMMUNITY

A Shimabukuro-Vornhagen[1,*], S Zoghi[2], T Liebig[3], K Wennhold[3], M Kochanek[3], C Scheid[3], S Theurich[3], M Hallek[1], M von Bergwelt-Baildon[3]
[1]Department I of Internal Medicine, University Hospital of Cologne, Cologne, [2]University of Bonn, Bonn, [3]University Hospital of Cologne, Cologne, Germany

Background: Antibody-independent effector functions of B cells, such as antigen presentation and cytokine production, have been shown to play an important role in a variety of immune-mediated conditions such as autoimmune diseases, transplant rejection and graft-*versus*-host disease. Most current immunosuppressive treatments target T cells and are relatively unspecific and result a profound immunosuppression that places the patients at an increased risk of severe infections and development of cancer. Therapeutic strategies which interfere with B cell activation could therefore be a useful addition to the current immunosuppressive armamentarium.
Aims: The aim of this study was to identify novel immunomodulatory agents, which could be used to inhibit B cell activation and effector functions.
Methods: Human B cells were stimulated with CD40L, which is one of the most potent B cell-activating stimuli and strongly enhances the antigen-presenting function of B lymphocytes. The gene expression profiles of the CD40-activated B cells were compared to the those of resting B cells in order to determine pathways which were upregulated after CD40-activation.
Results: The transcriptomic analysis revealed that many of the of the genes which belong to the mevalonate pathway were upregulated following CD40-mediated activation of B cells. Inhibition of 3-hydroxy-3-methylglutaryl coenzyme A reductase, the rate limiting enzyme of the mevalonate pathway, by lipophilic statins such as simvastatin and atorvastatin resulted in a specific inhibition of B cell activation via CD40 and impaired their ability to act as stimulatory APC for allospecific T cells. Furthermore, statin-treated B cells acquired tolerogenic features and preferentially expanded regulatory T cells. Mechanistically, the inhibitory effect resulted from the inhibition of protein geranylgeranylation subsequent to the depletion of mevalonate, the metabolic precursor for geranylgeranyl.
Summary and Conclusions: Inhibition of geranylgeranylation either directly through geranylgeranyl transferase inhibitors or indirectly through statins represents a promising therapeutic approach for the treatment of diseases where antigen-presentation by B cells plays a role.

S1145

CELLULAR DYNAMICS OF THE INDUCTION OF T CELL-MEDIATED ANTITUMOR IMMUNITY BY A B CELL-BASED CANCER VACCINE

A Shimabukuro-Vornhagen[1,*], N Gonzalez[2], T Liebig[2], S Grabbe[3], M von Bergwelt-Baildon[2]
[1]Department I of Internal Medicine, [2]University Hospital of Cologne, Cologne, [3]University Hospital Mainz, Mainz, Germany

Background: B cell-based cellular vaccines are a promising platform for cancer immunotherapy. Compared to dendritic cells little is known about the precise mechanisms of the induction of CD8 T cell responses by B cells.
Aims: The aim of this study was to determine the safety and effectiveness of B cell-based tumor immunotherapy in the murine B16 melanoma tumor model and to analyze the dynamics of the T cell-B cell interactions with regard to the clinical application of B cell-based cancer vaccines.
Methods: The kinetics of T-B cell interactions in a 3-D collagen matrix was studied using time lapse videomicroscopy. Mice where vaccinated by injection of *ex vivo* generated CD40-activated B cells either subcutaneously or intravenously.
Results: CD40-activated B cells express the full lymph node homing triad including CD62L, CCR7/CXCR4 and LFA1. Murine and human CD40-activated B cells migrate towards cognate ligands such as CCL19, CCL21 and CXCL12. Furthermore, such CD40-activated B express several T-cell chemoattractants and induce T-cell chemotaxis *in vitro*. To dissect T cell/APC interaction on a single cell we analyzed three-dimensional migration in collagen matrix. Interestingly, antigen-loaded CD40-B differ from immature and mature DC by displaying a rapid migratory pattern undergoing promiscuous, short-lived (7.5min) but stable interactions with cognate T cells. Furthermore, upon injection GFP+ CD40-activated B cells home to secondary lymphoid organs. Taken together, these data suggest that CD40-B are equipped with the receptors and migratory capacity necessary to home to secondary lymphoid organs and have the property to attract and enter into stable contacts with T cells. Preclinical evaluation of CD40-actived B cell-based tumor immunotherapy demonstrated the safety and effectiveness of this approach. Even the injection of high numbers of CD40-activated B cells did not result in any detectable toxicity. Furthermore, the B cell-based vaccine led to the induction of antigen-specific antitumor immunity.
Summary and Conclusions: In summary, we show fundamental differences in the mechanisms of cytotoxic T cell activation induced by DC and B cells. T cell stimulation by CD40-activated B cells, unlike T cell activation induced by DCs, primarily takes place through short-lived sequential interactions.we demonstrate that vaccination with peptide-loaded CD40-activated B cells elicits antigen-specific T cell-mediated antitumor immunity without causing toxicity. Thus CD40-activated B cell-based immunotherapy represents a promising approach to cancer immunotherapy.

Chronic lymphocytic leukemia - Clinical studies

THE BCL-2 INHIBITOR ABT-199 (GDC-0199) IS ACTIVE AND WELL-TOLERATED IN ULTRA HIGH-RISK RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

A Roberts[1,*], M Davids[2], J Pagel[3], B Kahl[4], W Wierda[5], T Miller[6], J Gerecitano[7], T Kipps[8], M Anderson[1], D Huang[1], D Darden[9], L Gressick[9], C Nolan[9], J Yang[9], T Busman[9], A Graham[9], E Cerri[9], S Enschede[9], R Humerickhouse[9], J Seymour[10]
[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Dana-Farber Cancer Institute, Boston, MA, [3]University of Washington, Seattle, WA, [4]University of Wisconsin, Madison, WI, [5]University of Texas, Houston, TX, [6]University of Arizona, Tucson, AZ, [7]Memorial Sloan-Kettering Cancer Center, New York, NY, [8]University of California San Diego, San Diego, CA, [9]AbbVie Inc., North Chicago, IL, United States, [10]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Patients (pts) with CLL and deletions of chromosome 17p (del(17p)) or whose disease is refractory to fludarabine (F) are considered to have ultra high-risk CLL. The median life expectancy of these pts is less than 2 to 3 years with standard therapy; therefore novel agents are urgently needed, particularly for this subgroup. Overexpression of BCL-2 and failure to trigger upstream pro-apoptotic pathways underpin resistance to apoptosis in these patients. *In vitro*, this block to apoptosis can be overcome by targeting mitochondria through BCL-2 inhibition. The first-generation BCL-2 inhibitor, navitoclax, achieved partial remissions (PRs) in 35% of pts with relapsed/refractory (R/R) CLL, however concomitant inhibition of BCL-X_L resulted in dose-limiting thrombocytopenia (TCP). ABT-199 is a second generation inhibitor with greater affinity for BCL-2, but 500-fold less affinity for BCL-X_L, than navitoclax. We hypothesized that selective BCL-2 inhibition with ABT-199 would demonstrate significant clinical efficacy, including in pts with ultra high-risk disease.
Aims: The primary objectives of this phase-I dose-escalation study are to evaluate the safety and pharmacokinetics (PK) of ABT-199, determine a maximum tolerated dose and recommended phase-2 dose, and assess efficacy and biomarkers in pts with R/R CLL. In this analysis, we have sought to determine if pts with ultra-high risk CLL have similar response rates to the overall study population.
Methods: Pts with ECOG performance status ≤1 and adequate marrow function received a single dose of ABT-199 on Week1 Day -3 or -7 (W1D-3, W1D-7), followed by continuous once-daily dosing from W1D1, until disease progression or unacceptable toxicity. After cohort1, the initial dose was reduced and daily dosing modified to include a 2 or 3 step dose-escalation to the target dose for each cohort. Evaluations included adverse events (AE; NCI-CTCAE-V4), PK parameters and disease response (IWCLL 2008).
Results: As of January 2013, 56 pts have been enrolled (see Table 1) in cohorts assessing doses from 150mg to 1200mg. Sixteen (29%) had del(17p) and 18 (32%) F-refractory CLL (see Table 1). The most common non-haematologicalAEs (>15% pts) were nausea (36%), diarrhea (30%), fatigue (25%), upper respiratory tract infection (23%), and cough (16%). Grade 3/4 AEs occurring in ≥5 pts were neutropenia 21(38%), thrombocytopenia 6 (11%) and tumour lysis syndrome (TLS) 5 (9%). The thrombocytopenia was not dose-related. With initial dosing, TLS occurred in 3/3 pts in cohort 1 and 2/53 pts with the modified dosing schedule (both were DLTs). Additionally, 1 fatal AE occurred within 48 hrs of dose-escalation to 1200 mg in a pt with laboratory evidence of TLS (DLT). 13 pts have discontinued, 7 due to progression, 6 for other reasons: TLS (2), other illness (2), thromboembolic event (1), consent withdrawal (1). After a single dose of ABT-199 with a low-fat meal, T_{max} and $T_{1/2}$ values were approximately 7 and 17 hrs, respectively, a pattern supporting daily dosing. Preliminary efficacy data are summarised (Table 1).

Table 1.

Characteristic	All CLL n=56	del (17p) n=16*	F-refractory n=18*
Age (yr)†	67 [36-86]	69 [47-80]	66 [36-78]
Male#	41 (73)	11 (69)	12 (67)
Number of prior therapies†	3.5 [1-10]	4 [2-9]	5 [1-10]

RANDOMISED COMPARISON OF FCR-LITE AND CLR (CHLORAMBUCIL PLUS RITUXIMAB) REGIMENS IN ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E Nikitin[1,*], D Kisilichina[2], O Zakharov[3], S Lugovskaya[2], E Varlamova[4], T Obukhova[5], B Biderman[6], I Kaplanskaya[7], E Naumova[2], M Pochtar[2], A Sudarikov[6], E Domracheva[5], V Ivanova[8], L Kovaleva[1], V Ptushkin[9]
[1]Outpatient department, Hematology Research Center of Russia, [2]Department of Clinical Laboratory Diagnostics, Russian Medical academy of postgradual education, [3]Outpatient department, City Hospital N150, [4]Laboratory of immunochemistry, [5]Laboratory of Cytogenetics, [6]Laboratory of Molecular Hematology, [7]Department of Pathology, Hematology Research Center of Russia, [8]Outpatient department, City hospital named after Sergei Botkin, [9]Oncology and hematology dpt. for adolescents and young adults, Federal Scientific and Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitriy Rogachev, Moscow, Russian Federation

Background: Chlorambucil is still considered as standard of care in elderly and physically unfit patients with chronic lymphocytic leukemia (CLL). However, a considerable number of patients have insufficient or short responses to chlorambucil and there is a need to develop safe and more efficacious treatment approaches. Two regimens have been proposed for treatment of patients with comorbidities and elderly patients: FCR-Lite and CLR, both showing relatively high efficacy and good tolerability.
Aims: To compare in randomized trial FCR-Lite and CLR regimens in treatment of elderly patients with chronic lymphocytic leukemia.
Methods: Untreated CLL patients older than 71 years and physically unfit patients aged 61–70 years with cumulative illness rating score (CIRS) 7 and more were included into the trial. After Informed consent the patients were randomly assigned to receive either FCR-Lite (F oral 32 mg/m2 for three days, C oral 150 mg/m2 for three days) or CLR (Chl 10 mg/m2 for 7 days). Rituximab was given once in each cycle in both regimens (375 mg/m2 i.v. day 0 at first cycle and 500 mg/m2 day 1 all subsequent cycles). Cycles were repeated every 4 weeks.
Results: 97 patients have been included into the study. The patient's characteristics were relatively well balanced between arms with regard to age, stage, genomic aberrations and VH status. 72% were Binet B, 16% Binet C and 12% Binet A. The median age was 71 years (range 60 to 84), 47 patients were females (48%), the median CIRS score was 8 (range 1-18). The overall incidences of trisomy 12 and abnormalities of 13q, 11q23, and 17p13 detected by FISH were8,5%, 50%, 21,3%, and6,4%, respectively, with no statistically significant differences between treatment arms. One patient withdraw consent, 1 patient died from pneumonia before initiation of treatment, and 3 patients discontinued treatment due toxicity or worsening of concomitant condition. Ninety two patients were available for assessment. At the time of analysis, February 2013, the median observation time was 29.8 months. A mean number of 5.1 courses was given in the CLR arm *versus* 5.3 courses in the FCR-Lite arm. 72% (FCR-Lite) and 66% (CLR) of patients received 6 cycles. There was no significant differences in grade III–IV myelotoxicity in FCR-Lite and CLR arms: neutropenia was observed in 36% patients and 34% patients, anemia 4% and2,6% and thrombocytopenia in 8% and 13%, respectively. The incidence of CTC grade 3 or 4 infections was also not significantly different (17,7% in FCR-Lite arm *versus*14,8% in the CLR arm (P=0.9). The overall response rate of the FCR-Lite arm was 93% as compared to 85% in the CLR arm (P<0.35). The complete response rate was significantly higher in the FCR-Lite arm (42%; 19/45) compared to CLR (10,6%; 5/47) (P=0.001). Forteen patients (31%) in FCR-Lite arm achieved an MRD-negative CR while in CLR arm there were no MRD-negative cases. Median PFS in CLR arm was 25,3 months, while in FCR-Lite arm it was not reached (P=0,0042). PFS at 2 years in FCR-Lite arm was 72,6%. To date, 80 patients remain alive and 17 patients (17%) have died. In LR arm 6 patients died from progression, 2 from secondary tumors and 3 from other causes. In FCR-Lite arm there have been no deaths from progression, 3 patients died from secondary tumors and 3 from other causes.
Summary and Conclusions: Preliminary results show that FCR-Lite is more efficacious in terms of response and progression free survival without significant increase of toxicity.

S1148

RESULTS OF THE RANDOMISED PHASE II NCRI ADMIRE TRIAL OF FCR AND FCM-R IN PREVIOUSLY UNTREATED CLL: ORAL FCR IS HIGHLY EFFECTIVE AND SAFE BUT THE ADDITION OF MITOXANTRONE DOES NOT IMPROVE RESPONSES

P Hillmen[1,*], C Pocock[2], A Rawstron[3], L McParland[4], A Chalmers[4], A Varghese[1], A Smith[4], C Collett[4], M Hamblin[5], A Bloor[6], A Pettitt[7], C Fegan[8], J Blundell[9], J Gribben[10], W Gregory[4], D Phillips[4], D Cohen[4]

[1]Haematology, St James's Institute of Oncology, Leeds, [2]Haematology, East Kent Hospitals, Canterbury, [3]HMDS, St James's Institute of Oncology, [4]Clinical Trials Research Unit, University of Leeds, Leeds, [5]Haematology, Colchester Hospital University NHS Foundation Trust, Colchester, [6]Haematology, The Christie NHS Foundation Trust, Manchester, [7]Haematology, Royal Liverpool University Hospital, Liverpool, [8]Haematology, University Hospital of Wales, Cardiff, [9]Haematology, Royal Cornwall Hospital, Truro, [10]Barts and The London NHS Trust, London, United Kingdom

Background: Fludarabine, cyclophosphamide and rituximab (FCR) results in improved progression free (PFS) and overall survival (OS) compared to FC. Initial evidence from non-randomised Phase II trials suggest the addition of mitoxantrone to FCR improves remission rates. We previously demonstrated that the addition of mitoxantrone and rituximab to oral FC (FCM-R) was safe and potentially effective in previously treated patients with CLL.
Aims: To compare the primary end-point (complete response (CR) rates) and the short-term secondary endpoints (Minimal Residual Disease (MRD), ORR and safety) for FCR and FCM-R in previously untreated CLL.
Methods: ADMIRE was a phase IIB, randomised, controlled, parallel group trial in previously untreated CLL performed in 29 UK centres. 218 patients were planned to be randomised on a 1:1 basis to FCR or FCM-R, to provide 80% power to detect a 20% improvement in CR rate. Patients required therapy by IWCLL criteria and were considered fit for fludarabine-based therapy. The schedule for oral FCR was equivalent to iv FCR with iv rituximab given on Day 1 of each cycle (375mg/m^2 Cycle 1; 500mg/m^2 Cycles 2-6), oral fludarabine at 24mg/m^2/day for 5 days (Days 1-5) and oral cyclophosphamide at 150mg/m^2/day for 5 days (Days 1-5). FCM-R included intravenous mitoxantrone (6mg/m^2/day on Day 1 of each cycle). Six cycles were planned 28 days apart. Patients with neutropenia delaying any cycle of therapy received G-CSF (lenograstim 263mcg/day; Days 7-13) on all subsequent cycles. All patients received prophylaxis with co-trimoxazole and acyclovir.
Results: 215 patients were recruited June 2009 to April 2012 with 107 receiving FCR and 108 FCM-R. The treatment arms were well balanced for the following: median age of 62 (range 33–77) and 66% (n=141) under 65; 76% (n=163) male; 12% (n=26) progressive stage A, 52% (n=111) stage B and 36% (n=78) stage C; 56% (100/177) had unmutated Ig genes; 5% (10/187) were 17p deleted; and 19% (36/187) were 11q deleted. More 17p deleted patients were randomly allocated to FCR (8 *vs* 2). 28% (61/215) discontinued therapy early including 23% (n=25) for FCR and 33% (n=36) for FCM-R. Overall, 10% (n=21) received 1-3 cycles, 8% (n=8) FCR and 12% (n=13) FCM-R. 60% (n=128) of patients received G-CSF during therapy with a higher proportion on FCM-R compared with FCR (68% *vs* 60%). 62% (n=134) of patients experienced some form of dose modification including 61% for FCR and 64% for FCM-R; the most common modification was dose delay. 150 SAE's were reported from 95 patients; 69 events from 42 receiving FCR and 81 from 53 receiving FCM-R. 91 patients (43%) were hospitalised due to an SAE, 41 (39%) FCR compared with 50 (47%) FCM-R. There were no treatment related deaths. At the time of writing 172 patients (80%) had undergone independent central review for response, with 36 outstanding and 7 being ineligible or withdrawn. 151 patients are currently included in the primary endpoint analysis; with 21 excluded due to good clinical responses but missing trephine biopsies so that CR could not be assessed. 70% (105/151) of available patients achieved a CR; 71% (53/75) FCR and 68% (52/76) FCM-R. ORR was 97% (n=145/150) in available patients, 96% (72/75) FCR and 97% (73/75) FCM-R. MRD by flow cytometry (sensitivity<10^{-4}) in the bone marrow was assessed at 3 months post-therapy; of those assessable 57% (106/186) had undetectable MRD, 62% (58/93) FCR compared to 52% (48/93) FCM-R.
Summary and Conclusions: Oral FCR is well tolerated with acceptable toxicity. Dose intensity was supported with G-CSF in 60% of patients. The complete remission rate (CR+CRi) at 70% and the MRD negativity rate of 62% were very high compared to previous collaborative group trials. There was no improvement in the CR rate with the addition of mitoxantrone, fewer patients achieved an MRD negative remission and there was slightly increased toxicity; concluding that the addition of mitoxantrone to FCR will not be taken forward into a Phase III trial. The higher than predicted CR and MRD negativity rates for FCR compared to previous reports may be due to an increased use of growth factor support, close attention to dose intensity, routine use of prophylactic antibiotics and/or the use of oral fludarabine and cyclophosphamide.

Background: Hairy cell leukemia (HCL) is a rare hematologic disorder. Purine analogues (pentostatin and cladribine) have transformed the course of the disease with similar overall responses obtained in more than 85% of patients, with median relapse-free survival up to 15 years. With prolonged survival, HCL patients tend to develop further malignancies. Isolated case reports and single center series described the different malignancies observed.
Aims: We conducted a large, multi-center, retrospective survey in France to determine the frequency of malignancy in HCL patients (pts) and their families, and to analyze the long-term effects of the established purine nucleotide analogs (PNA) cladribine (C) and pentostatin (P).
Methods: Physician members of the Société Française d'Hématologie were surveyed on their management of HCL pts over the past 30 years. Clinicians completed a form that collected data concerning personal and familial medical history of pts, with particular focus on hematologic malignancies, solid tumors, clinical and biological presentation at HCL diagnosis, therapeutic options, response to treatment, time to relapse, second malignancies and cause of death.
Results: We studied 487 HCL patients (mean patient age 59y; range 29–90y) from 36 French clinical centers. HCL diagnosis was established after examination of peripheral blood and/or bone marrow and by immunophenotyping. Eighty-eight patients (18%) had familial history of cancers, with one familial HCL case. Forty-one patients (8%) presented solid tumors and hematologic malignancies before HCL diagnosis with a median time of 89 months (range 2–529). Twenty-three patients (5%) received no treatment. Three hundred and forty-five patients (71%) received just one first-line treatment (C: 235 pts, P: 82 pts, interferon: 13 pts, other: 15 pts), and 119 pts (24%) received two-to-seven lines of therapy. After first-line treatment, although complete response (CR) rates and median relapse free survival (RFS) were similar between C (CR:85.1%, RFS:164mo) and P (CR: 85.3%, RFS:159mo), overall survival (OS) is better with C than P (respectively 97% *versus* 89%, at 5 years). Whereas more patients achieved CR in second-line treatment with C than P, RFS and OS are significantly better when patients received P. Twenty-nine pts (6%) died (11 HCL-related, 6 related to second malignancies). Forty-eight pts (10%) developed second malignancies (34 solid tumors, 10 hematologic malignancies, 4 both) after a median time of 74 months (2-375). Excess of incidence of second malignancies, including solid and hematologic malignancies, is observed with a standardized incidence ratio (SIR) at 1.86 (IC95%: 1.34-2.51) with no significant difference between the two PNAs. SIR for second hematologic malignancies was particularly increased at 5.32 (IC95%: 2.90-8.92).
Summary and Conclusions: This study highlights the high frequency of cancers in HCL pts (18%) and their family members, suggesting a role for genetic factors in the development of the disease. First-line treatment based on PNAs, P or C, is very efficient with OS at 5 years at 95%. Frequency of second malignancies is particularly increased (10%) with a SIR at 1.86, especially concerning hematologic malignancies (SIR=5.32). The respective role of P and C in the development of second malignancies is debatable. PNA remains the reference treatment in HCL, as long as secondary effects, especially second malignancies, of emerging therapeutics are not clearly evaluated. Indeed secondary mutations in RAS pathway have been described in patients treated with BRAF inhibitors. We recommend the use of PNAs in first-line, reserving BRAF inhibitors exclusively in very high-risk HCL patients.

S1150

UPDATE ON A PHASE 1 STUDY OF THE SELECTIVE PI3K-DELTA INHIBITOR, IDELALISIB (GS-1101) IN COMBINATION WITH OFATUMUMAB IN PATIENTS WITH RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

S Coutre[1,*], J Leonard[2], R Furman[2], I Flinn[3], S De Vos[4], K Rai[5], M Schreeder[6], N Wagner-Johnston[7], J Sharman[8], T Boyd[9], N Fowler[10], Y Kim[11], L Holes[11], D Johnson[11], R Dansey[11], T Jahn[11], J Barrientos[5]
[1]Stanford University Cancer Center, Stanford, CA, [2]Weill Cornell Medical College, New York, [3]Sarah Cannon Research Institute, Nashville, TN, [4]University of California Los Angeles, Los Angeles, [5]Hofstra North Shore-LIJ School of Medicine, Hyde Park, NY, [6]Clearview Cancer Institute, Huntsville, AL, [7]Washington University, St. Louis, MO, [8]Willamette Valley Cancer Institute/US Oncology Research, Springfield, OR, [9]Yakima Valley Memorial Hospital/North Star Lodge Cancer Care, Yakima, WA, [10]M. D. Anderson Cancer Center, Houston, [11]Gilead Sciences, Seattle, United States

Background: PI3K-delta (δ) is critical for activation, proliferation and survival of B cells and plays a role in homing and retention in lymphoid tissues. Ide-

lalisib is a first-in-class, targeted, highly selective, oral inhibitor of PI3Kδ that has shown considerable monotherapy activity in patients with heavily pretreated CLL.

Aims: The primary objective of this study was the assessment of safety and the secondary objective was the evaluation of clinical response: overall response rate (ORR), progression-free survival (PFS), duration of response (DOR), overall survival (OS). The study is ongoing.

Methods: The study evaluated idelalisib (GS-1101) for relapsed/refractory CLL continuously given at 150 mg BID in combination with a total of 12 infusions of ofatumumab (O, 300 mg initial dose either on Day 1 or Day 2 relative to the first dose of idelalisib, then1,000 mg weekly ×7, then1,000 mg every 4 wks × 4). Pts who were benefitting from therapy after the 48 weeks of the primary study were eligible to continue idelalisib on an extension study. Clinical response was evaluated according to published criteria (Hallek 2008; Cheson 2012).

Results: 21 pts (6F/15M) with a median (range) age of 66 (43-79) years and a WHO performance status of 0 (13, 62%) or 1 (8, 38%) were enrolled. Adverse disease characteristics (n,%) included bulky lymphadenopathy (12, 57%), refractory disease (7, 33%), multiple prior therapies (median:2, range: 1-6). Almost all patients (20, 95%) had at least 1 prior therapy containing rituximab (R), and 9 (43%) were refractory to R. 3 (14%) had received prior O. Prior therapies also included alkylating agents (18, 86%, [bendamustine:11, 52%]) and purine analogs (16, 76%, [fludarabine:15, 71%]). 8/21 (38%) pts had evidence of del17p, and data available from 13 pts showed that 10 (77%) had unmutated IGHV. As of 22 Feb 2013, the median (range) treatment duration was 11 (0-18) months. 10/21 (48%) pts have completed the primary study and enrolled into the extension study. 8/21 (38%) discontinued: 3 for reasons of AE and 2 for other reasons. There were 3 deaths that occurred on study. 7/21 (33%) pts are continuing idelalisib treatment on the extension study. The ORR (ITT, as assessed by investigators) was 76% (16/21), with 3 CRs (14%, 1 unconfirmed), and a median (range) time to response of 1.9 (1.8-8.3) months. Median progression-free survival and duration of response were 17.8 months and 15.9 months, respectively. Median overall survival (OS) has not been reached; OS at 11 months was 80%. The most common TEAEs (any Grade/≥Gr3, regardless of causality) included diarrhea (48%/5%), cough (43%/0%), pyrexia (38%/0%), dyspnea (33%/0%), nausea (24%/0%), pneumonia (19%/19%), fatigue (19%/0%), and rash (19%/0%). Elevation of liver transaminases (TA, any Grade/≥Gr 3) was seen in 29%/14%. Of those, only 1 pt discontinued the study because of (recurrent) TA elevation.

Summary and Conclusions: The combination of idelalisib with ofatumumab represents a non-cytotoxic regimen with a favorable safety profile and high activity resulting in durable tumor control in pts with high-risk pretreated relapsed/refractory CLL. Phase 3 trials evaluating the efficacy of idelalisib in combination with therapeutic anti-CD20 antibodies such as ofatumumab or rituximab are ongoing (NCT01659021, NCT01539512).

Clinical studies in multiple myeloma 2

S1151

EFFICACY, SAFETY, AND QOL IN MM-003, A PHASE3, MULTICENTER, RANDOMIZED, OPEN-LABEL STUDY OF POMALIDOMIDE (POM)+LOW-DOSE DEXAMETHASONE (LODEX) VS HIGH-DOSE DEXAMETHASONE (HIDEX) IN RRMM

Background: Relapsed/refractory multiple myeloma (RRMM) patients (pts) who are refractory to bortezomib (BORT) and lenalidomide (LEN) treatment (Tx) have a poor prognosis with short overall survival (OS) and reduced quality of life (QOL). HiDEX is commonly used to treat RRMM. POM was recently approved by the US FDA for the treatment (Tx) of RRMM patients who have received at least 2 prior therapies, including BORT and LEN.

Aims: MM-003 study compared POM+LoDEX *vs.* HiDEX in RRMM pts who failed BORT and LEN and progressed on their last Tx.

Methods: Pts must have been refractory to last prior Tx (progressive disease [PD] during or within 60 days) and failed BORT and LEN after ≥2 consecutive cycles (C) of each (alone or in combination). Pts were randomized 2:1 to receive 28-day C of POM 4 mg D1-21+LoDEX 40 mg (20 mg for pts aged >75 y) weekly or HiDEX 40 mg (20 mg for pts aged >75 y) D1-4, 9-12, and 17-20. Tx continued until PD or unacceptable toxicity. The primary endpoint was progression-free survival (PFS) and secondary endpoints included OS, overall response rate (ORR; ≥partial response [≥PR]), duration of response, safety, and QOL. For pt-reported QOL outcomes, change scores and minimal important differences were calculated as meaningful change from baseline through C5 (1 standard error of measurement) for the 5 clinically relevant EORTC QLQ-C30 domains (Global Health Status, Physical Functioning, Fatigue, Emotional Functioning, and Pain). Time to QOL worsening was compared between arms by the Kaplan-Meier method.

Table 1.

	POM + LoDEX (n = 302)	HiDEX (n = 153)	*P* Value	
All patients				
ORR, %	21	3	<.001	
Median duration of response, mos	10.1	Not estimable		
Pts ≥ 6 Mos Post-Enrollment	**n = 204**	**n = 99**		
ORR, %	24	3	<.001	
Median duration of response, mos	10.1	Not estimable		
Survival Outcomes, mos	**n = 302**	**n = 153**	**HR**	**Log-Rank *P* Value**
Median PFS	3.6	1.8	0.45	<.001
Median OS	Not reached	7.8	0.53	<.001
Median Time to First Worsening in QOL Domains, days (95% CI)			**Log-Rank *P* Value**	
Global Health Status	114 (71-143)	85 (37-140)	.058	
Physical Functioning	174 (123-288)	106 (57-NE)	.088	
Fatigue	113 (71-169)	60 (57-113)	.038	
Emotional Functioning	190 (145-361)	124 (64-235)	.023	
Pain	147 (89-NE)	113 (58-NE)	.203	

Results: 455 pts were randomized to POM+LoDEX or HiDEX. The median number of prior Tx was 5 (range 1-17). 72% were refractory to LEN and BORT. Median follow-up was 4 mos. POM+LoDEX significantly extended median PFS and OS *vs.* HiDEX, despite 29% of HiDEX pts receiving POM after PD (Table 1). At

this point, the Data Monitoring Committee recommended crossover from HiDEX to POM±LoDEX. As of Nov9, 2012, the ORR remained significantly higher for POM+LoDEX *vs.* HiDEX (Table 1). The most frequent grade 3-4 adverse events (AEs) for POM+LoDEX *vs.* HiDEX were neutropenia (42% *vs.* 15%), anemia (27% *vs.* 29%), and infection (24% *vs.* 23%); discontinuation due to AEs was infrequent (7% *vs.* 6%). Regarding QOL, favorable trends were observed for POM+LoDEX *vs.* HiDEX in each of the 5 relevant domains. QOL in responders *vs.* patients who have progressed by arm indicated statistically significant differences favoring POM+LoDEX responders in Physical Functioning (*P*=.005) and Fatigue (*P*=.032). In all pts, by Kaplan-Meier estimation, POM+LoDEX extended median time to meaningful symptom and QOL worsening *vs.* HiDEX for all 5 domains (Table 1). Updated results will be presented at the meeting.
Summary and Conclusions: POM has shown activity in MM pts refractory to LEN and BORT. In this study, POM+LoDEX significantly extended PFS and OS *vs.* HiDEX and resulted in improvements in clinically relevant QOL measurements over the course of Tx. POM+LoDEX should become a standard of care in these pts.

S1152

LENALIDOMIDE ASSOCIATED WITH CYCLOPHOSPHAMIDE AND DEXAMTHASONE (CRD) IS AN EFFECTIVE NON TOXIC OPTION FOR NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS

A Brioli[1,2,*], F Davies[1], W Gregory[3], S Hinsley[3], C Pawlyn[1], M Cavo[2], R Owen[4], G Jackson[5], N Russell[6], G Morgan[1]
[1]Haemato-Oncology Research Unit, Institute of Cancer Research, London, United Kingdom, [2]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [3]Clinical Trials Research Unit, University of Leeds, [4]St James's Institute of Oncology, St James's University Hospital, Leeds, [5]Department of Haematology, University of Newcastle, Newcastle Upon Tyne, [6]Clinical Haematology, Nottingham City Hospital, Nottingham, United Kingdom

Background: The advent of new drugs used in triplet combinations with alkylating agents and steroids has dramatically improved the outcome of MM patients, however peripheral neuropathy (PN) and the potential for myelosuppression and second primary malignancies (SPMs) have made their use in some settings difficult. Among the new drugs, lenalidomide (Len), due to his oral availability and the lack of treatment related PN, is particularly attractive.A recent phase III study has combined Len with Melphalan and Prednisone followed by Len maintenance (MPR-R) obtaining good results, but myelosuppression and SPMs were seen.[1] Combining Len with Cyclophosphamide (Cy) and Dexamethasone (Dex) is particularly attractive because of its reduced cytotoxicity and mutagenicity. We investigated the CRD triplet in relapsed patients in phase I/II studies.[2-3] A total of 52 heavily pre-treated patients were treated in the 2 studies with good response rate (CR+PR 65%>81%) and manageable toxicities (Table 1).

Table 1.

	Phase I	Phase I/II	Phase III
AR	% pts	% pts	% pts
Neutropenia	38%		24.9%
Thrombocytopenia	NA	32%*	7.6%
Anemia	NA		12.9%
Infections	29%	6%	NA
PN	NA	0%	0.6%
DVT/PE	14%	6%	5.6%
Others	NA	19%	30.9%**

*all cytopenias
**including infections

Aims: The positive results of these studies led us to design a phase III study (MRC Myeloma XI trial) which compared CTD with CRD in newly diagnosed MM patients. As part of the safety analysis we have looked at the toxicity of pts receiving CRD.
Methods: The trial is ongoing and has recruited 1054 patients (pts) in the younger intensive pathway and 828 in the non intensive one. Based on the dose finding studies CRD doses were: Cy 500 mg on days 1 and8, Len 25 mg on days 1-21 and Dex 40 mg on days 1-4, 12-15 given for a minimum of 4 to 6 cycles until maximum response or unacceptable toxicity. Older or frail pts received attenuated doses of Dex (20 mg on days 1-4 and 15-18). The response rates with the combination in studies up to know have been excellent, with OR rates of 81% and CR rates of 29% in relapsed patients, with maximum response developing in a median of 3 cycles. Response rates in presenting patients will be higher and updated results will be presented.
Results: Of the 1882 pts that entered the trial 937 have been randomised to CRD treatment. Data for pts receiving at least 1 cycle are available on 711 pts (75.9%), of which 495 (69.6%) have completed induction. Mean number of cycles received has been 4.8 (±1.99), with a median of 5 (range 1-18). A dose modification of any of the 3 drugs was needed in 62.2% of pts (Cy in 27.6%, Len in 47.4% and Dex in 40.6%), but only 39 pts (5.5%) stopped induction due to toxicity before receiving the minimum number of cycles required. More than 60% of the pts (63.3%) were able to receive the prescribed therapy without any delay. Grade 3-4 hematologic adverse events were reported in 24.9% (neutropenia), 7.5% (thrombocytopenia) and 12.6% (anaemia) of the patients, respectively. The incidence of any extra-hematologic adverse reaction (AR) grade 3-4 was 30.3%. No grade 4 PN was reported; PN grade 3 (sensory or motor) was seen in 0.6% of the patients. Deep vein thrombosis (DVT) was reported in 3.3% of patients and the incidence of pulmonary embolism (PE) was 2.3%. SAEs are available for all the randomized population, and were reported in 535/937 pts (57.1%). About half of the SAEs were related to at least one of the study drugs; the most frequent were infections (39.1%) and cytopenias (18.5%). Treatment related mortality was 0.6%. With a median follow up of 1.3 years from beginning of therapy the incidence of SPMs has been 0.3% (n=3).
Summary and Conclusions: Overall our data confirm that CRD treatment has a good safety profile, and is therefore a valid option for both young and old newly diagnosed MM patients.

Background: Three large randomized trialsrecently reported an increased risk of second primary malignancies (SPMs) in newly diagnosed myeloma (MM) patients treated with lenalidomide. However, patients with MM have multiple risk factors for SPM and the excess risk with lenalidomide compared with non-lenalidomide has not been described.
Aims: We performed an individual patient data meta-analysis to estimate the incidence of SPM according to lenalidomideexposure.
Methods: Relevant studies, from PubMed and ASCO/IMW/ASH abstracts (after 2000), that met the following criteria were included: (1) randomized trials of newly diagnosed MM patients; (2) randomization to treatment with lenalidomide in at least one arm (lenalidomide-trials); (3) randomization to treatment to at least one new drug but not lenalidomide (no-lenalidomide-trials); (4) available data of SPMs. The primary aim was the cumulative incidence of SPMs,that was estimated accounting for competing events (Gooley *et al.*).
Results: 6383 patients were included in the analysis. The median follow-up was 30 months. Median age was 69 years, 45% of patients aged 65-74 years and 22% ≥75 years. Total cases of SPMs were 420 (6.6%), including 188 (2.9%) hematologic and 232 (3.6%) solid cancers. The cumulative incidence at 3 and 5 years of SPMs and of death were summarized in the Table 1. 3218 patients were enrolled in the lenalidomide-trials and were available for adirect comparisons between lenalidomide *vs* non-lenalidomide treatments.Solid

tumors occurred with similar incidence in all treatment groups. The risk of hematologic SPM was significantly higher in patients receiving lenalidomide (5-year cumulative incidence 3.2% *vs* 1.1%, P=0.04) and increased linearly over time. Therisk is limited to patients receiving lenalidomide plus melphalan (4.1, 95%CI: 2.4-5.8) with no excess in other combinations (lenalidomide without melphalan: 1.2, 0.0-2.6; melphalan without lenalidomide: 1.1, 0.0-2.7) (P=0.003).The risk of death for adverse events and for progression was higher than the risk of SPM.

Table 1. Cumulative incidence (%) at 3 and 5 years of SPMs and death (95% CI).

The source trials have been registered with the following identifier numbers: EudraCT 2005-004714-32; EudraCT 2007-004007-34; ASTAT 2004-000665-36; ISRCTN 90632740; NCT 00551928; NCT 01160107; NCT 01091831; NCT 00134101; NCT 00098475; NCT 01093136; NCT 00232934; NCT 00378105; NCT 00405756; NCT 00218855; NCT 01063179.

Summary and Conclusions: An increase of SPMs was observed in patients receiving lenalidomide compared with controls. The observed difference was attributed to the increased occurrence of hematologic SPMs, mainly with combination including lenalidomide plus melphalan. In the context of the observed survival benefit, the benefit/risk profile of lenalidomide treatment remains positive.

S1154

SUBCUTANEOUS VELCADE PLUS PREDNISONE (VP) OR PLUS CYCLOPHOSFAMIDE (VCP) OR PLUS MELPHALAN (VMP) IN FRAIL, ELDERLY, NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: A PHASE II COMMUNITY-BASED STUDY.

A Larocca[1,*], S Oliva[1], M Offidani[2], A Levi[2], C Musolino[2], A Falcone[2], C Conticello[2], T Caravita[2], D Rossi[2], O Villani[2], C Nozzoli[2], G Benevolo[2], T Guglielmelli[2], A Liberati[2], D Derudas[2], F Morabito[2], A Carella[2], P Caraffa[2], M Astolfi[1], C Palladino[1], V Montefusco[2], F Cavallo[1], M Petrucci[2], M Boccadoro[1], P Sonneveld[3], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Turin, Turin, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, Italy, [3]Erasmus Universal Medical Center, Rotterdam, Netherlands

Background: Bortezomib-Melphalan-Prednisone (VMP) is the standard of care for the treatment of newly diagnosed elderly multiple myeloma (MM) patients. Subcutaneous and weekly bortezomib infusions were both associated with a significant reduction in adverse events (AEs), such as peripheral neuropathy, without affecting efficacy. Frail elderly patients are more susceptible to AEs with subsequent treatment discontinuation that significantly affect efficacy and dose-intensity, thus suggesting the need for a reduced-dose strategy.
Aims: To assess the safety and the efficacy of 3 reduced-dose intensity subcutaneous (sc) bortezomib-based treatments in elderly, frail, newly diagnosed MM patients unsuitable for protocol with standard inclusion criteria.
Methods: Treatment included nine 28-day cycles of bortezomib 1.3 mg/m^{2}sc days1,8,15, 22 plus oral prednisone 50 mg every other day (VP) or VP plus oral ciclophosphamide 50 mg every other day (VCP) or oral melphalan 2 mg every other day (VMP) for 28 days, followed by maintenance with sc bortezomib every 2 weeks until progression.
Results: A total of 152 patients were enrolled, including 51 patients in the VP, 51 in the VCP and 50 in the VMP group. Median age was 78, 76 and 77 years, and 40%, 24% and 30% of patients were older than 80 years in the VP, VCP, and VMP groups, respectively. Overall, 76%, 71% and 72% had ISS stage II/III disease and 18%, 21% and 20% of the patients were defined at high risk by FISH with at least one chromosomal abnormalities among del17, or t (4;14), or t(14;16). Frail patients defined as Charlson comorbidity index ≥2 or Activity of Daily Living score (ADL) ≤4 or Instrumental Activity of Daily Living score (IADL) ≤5 or age ≥80 years were 66%: 78% in the VP, 57% in the VCP and 62% in the VMP group. Median follow-up was 10 months. Patients received a median of 6 VP, 8 VCP, and 7 VMP treatment cycles. All three induction regimens exhibited substantial activity, with an overall response rate (≥partial response) of 60% in the VP, 60% in the VCP, and 70% in the VMP group (P=0.67). At least 1 grade 3-5 adverse event was reported in 31% of patients in the VP group, 41% in the VCP group and 42% in the VMP group (P=0.41). Hematologic grade 3 AEs occurred in less than 10% patients in all groups. The incidence of non hematologic grade 3 AEs was similar in the 3 groups and were mainly infective (12%), cardiovascular (8%), and neurologic (7%), including 5% of peripheral neuropathy. Discontinuation rate due to AEs was 14% in the VP, 16% in the VCP and 22% in the VMP group (P=0.30, VP *vs* VMP). In frail patients, the overall response rate was 60% in VP, 52% in VCP, and 77% in the VMP group (P=0.13). At least 1 grade 3-5 adverse event was reported in 30% of the VP, 52% of the VCP and 48% of the VMP group (P=0.14). Discontinuation rate due to AEs was 15% in the VP, 21% in the VCP and 23% in the VMP group (P=0.53, VP *vs* VMP) (Table 1).

Table 1.

	Fit (N=52)			Frail* (N=100)		
	VP (N=11)	VCP (N=22)	VMP (N=19)	VP N=40	VCP N=29	VMP N=31
≥PR	82%	68%	58%	60%	52%	77%
At least 1 grade 3-5 adverse event	36%	27%	32%	30%	52%	48%
Discontinuation rate for toxicity	9%	9%	21%	15%	21%	23%

* Charlson comorbidity index ≥2 or Activity of Daily Living score (ADL) ≤4 or Instrumental Activity of Daily Living score (IADL) ≤5 or age ≥80 years.

Summary and Conclusions: In frail elderly newly diagnosed MM patients, the doublet VP regimen showed a similar efficacy compared to VCP and VMP triplet combinations. Rate of discontinuation due to AEs was lower in the VP group. Longer follow-up is needed to assess long-term outcomes.

Giovanni Battista - University of Torino, Torino, [15]Hematology, DRMM, University of Udine, Udine, [16]Hematology, University La Sapienza, Rome, Italy, [17]Asklepios Klinik Altona, Hamburg, Germany

Background: Over the last decade, integration of novel agents into ASCT for younger patients with newly diagnosed MM has significantly improved their clinical outcomes. However, whether the novel agents are able to improve or overcome the adverse prognosis related to several genomic aberrations is still an open question.
Aims: The European cooperative groups HOVON/GMMG, IFM, PETHEMA/GEM and GIMEMA conducted 4 phase III studies aimed to compare bortezomib-based (B-b) induction regimens (VD or VTD or PAD) *vs* non-bortezomib-based (nB-b) ones (VAD or TD) before single or double ASCT. We performed an integrated analysis of data from these studies to evaluate the role of B-b ASCT *vs* nB-b ASCT, in particular in patients with or without cytogenetic abnormalities (cyto pos or neg) detected by FISH.
Methods: Out of a total of 2169 patients who were enrolled, 74% had available data on the percentage of cyto pos or neg CD138-purified plasma cells and were included in the current analysis. A high-risk cytogenetic profile (HR-cyto) was defined by the presence of t(4;14) and/or del(17p).
Results: In comparison with control treatment, B-b induction significantly increased the rate of CR before ASCT in the overall population (4% *vs* 15%, P<.001) and in the HR-cyto subgroup (0% *vs* 18%, P<.001). With a median follow-up of 37 months, median PFS was significantly longer for patients randomly assigned to receive B-b ASCT (41.5 mos *vs* 33 mos for the control group) (HR=0.76, P<.001), a gain retained across subgroups lacking (HR=0.79, P=0.010) or carrying HR-cyto (HR=0.58, P<.001). A marginal OS benefit favoring B-b ASCT was observed in comparison with nB-b ASCT (HR=0.85,

P=0.058). In a stratified multivariate analysis, PFS and OS in the overall population were favorably influenced by the lack of the following variables: cytogenetic abnormalities, thrombocytopenia and high β2-m. Additional independent variables significantly predicting for extended PFS and OS in the overall population included achievement of CR after induction therapy (HR=0.46 and 0.44 for PFS and OS), double ASCT (HR=0.46 and 0.33 for PFS and OS) and B-b ASCT (HR=0.74 and 0.79 for PFS and OS). These latter variables independently affected PFS and OS in the HR-cyto subgroup (CR after induction: HR=0.49 and 0.43 for PFS and OS; double ASCT: HR=0.34 and 0.25 for PFS and OS; B-b ASCT: HR=0.61 and 0.69 for PFS and OS). B-b ASCT was independently associated with prolonged PFS (HR=0.60), but not with OS, in patients with positive del(17p) but negative t(4;14). Within the group assigned to receive B-b ASCT, patients who carryied both t(4;14) and del(17p) (ultra HR-cyto) had the worst outcomes (median PFS: 21 mos) and in a multivariate analysis were likely to mostly benefit from novel-agent-based double ASCT (HR=0.13 and 0.28 for PFS and OS).

Summary and Conclusions: Results from this integrated analysis of different studies including different B-b induction regimens demonstrated the superiority of B-b ASCT over nB-b ASCT in terms of higher rate of CR and extended PFS in newly diagnosed MM. PFS benefit with B-b ASCT was retained across subgroups of patients with and without HR-cyto. In comparison with the control group, B-b ASCT significantly improved the outcome of patients with HR-cyto, but did not overcome the adverse prognosis related to t(4;14) and/or del(17p). Results of OS analysis should be cautiously interpreted due to the still short follow-up. Finally, apparent benefits observed with novel agents integrated into double ASCT in the subgroup of patients with HR-cyto and ultra HR-cyto need to be confirmed in prospective randomized studies.

Non-Hodgkin lymphoma - Clinical 2

SINGLE-AGENT LENALIDOMIDE IN PATIENTS WITH RELAPSED/ REFRACTORY MANTLE CELL LYMPHOMA FOLLOWING BORTEZOMIB: EFFICACY, SAFETY AND PHARMACOKINETICS FROM THE MULTICENTER PHASE II MCL-001 "EMERGE" TRIAL

A Goy[1,*], R Sinha[2], J Vose[3], H Adler[4], S Bernstein[5], M Robertson[6], N Chen[7], L Zhang[7], S Cicero[7], T Fu[7], T Witzig[8]
[1]John Theurer Cancer Center at HUMC, Hackensack, [2]Emory University Winship Cancer Institute, Atlanta, [3]Nebraska Medical Center, Omaha, [4]Lynn Cancer Institute/Boca Raton Regional Hospital, Boca Raton, [5]University of Rochester Medical Center, Rochester, [6]Indiana University Medical Center, Indianapolis, [7]Celgene Corporation, Summit, [8]Mayo Clinic, Rochester, United States

Background: Patients (pts) with relapsed/refractory mantle cell lymphoma (MCL) have limited treatment options, particularly when progressing after bortezomib. Lenalidomide is an immunomodulatory agent with antitumor activity in B-cell non-Hodgkin lymphoma, including a subset of relapsed/refractory MCL pts previously treated with bortezomib.

Aims: A phase II multicenter, single-arm, open-label trial evaluated the efficacy, safety, and pharmacokinetics (PK) of lenalidomide in pts with MCL who relapsed or were refractory to bortezomib.

Methods: Pts were treated with lenalidomide 25 mg/day PO days 1-21 every 28 days. Eligible pts had received prior rituximab, cyclophosphamide, and anthracycline (or mitoxantrone) and relapsed or progressed within 12 months of last bortezomib dose or were refractory to bortezomib (at least 2 cycles). The primary endpoints were overall response rate (ORR) and duration of response (DOR), assessed by independent central review committee. Secondary endpoints included complete response (CR)/unconfirmed CR (CRu), time to response (TTR), progression-free survival (PFS), overall survival (OS), and safety. PK analysis was an exploratory endpoint. Response and time-to-event data were evaluated according to modified International Working Group criteria and Kaplan-Meier estimates, respectively. Optional blood samples for PK analysis were obtained 1-12 hours post-lenalidomide days2,4, and 15 for cycle 1 and on day 15 of cycle 2. Plasma concentration data were combined with data from multiple myeloma (MM) and myelodysplastic syndrome (MDS) pts, analyzed using population PK methodology.

Results: 134 pts (median age 67 years; range, 43-83) were enrolled; 2/3 of pts were ≥65 years, and 93% had stage III or IV disease. Pts had received a median of 4 prior therapies (range, 2-10); 78% had ≥3 prior chemotherapy regimens, and 60% were refractory to prior bortezomib. ORR was 28% (CR/CRu in 7.5%), with a median DOR of 16.6 months (95% CI, 7.7-26.7). Median TTR was 2.2 months (range, 1.7-13.1), and median PFS was 4.0 months (95% CI, 3.6-5.6). With a median follow-up of 9.9 months, estimated median OS was 19.0 months (95% CI, 12.5-23.9). Mean lenalidomide dose intensity was 20 mg/day, and median treatment duration was 94.5 days (range, 1-1,002). The most common grade ≥3 AEs (reported in >10% of pts) included neutropenia (43%), thrombocytopenia (28%), and anemia (11%). A total of 24 MCL pts were included in the population PK analysis. In these pts, mean lenalidomide clearance and central distribution volume were estimated to be 9.5 L/h and 46.1 L, respectively. Terminal half-life was 3.4 hours. Creatinine clearance was the only significant covariate predictive of lenalidomide clearance, while age and sex did not affect lenalidomide clearance. The lenalidomide PK profile in MCL was similar to MM and MDS pts. Among 24 pts in the PK study, 6 pts had grade 3/4 neutropenia; no apparent relationship was observed between lenalidomide exposure and grade 3/4 neutropenia.

Summary and Conclusions: Single-agent lenalidomide treatment showed rapid and durable responses in heavily pretreated pts with MCL who were relapsed/refractory to bortezomib. The PK profile of lenalidomide in MCL pts was comparable to that in other patient populations.

Hospital, Grenoble, [11]Department of Hematology, University Hospital, Angers, [12]Department of Hematology, University Hospital, Brest, [13]Department of Hematology, University Hospital-Saint Antoine, Paris, [14]Department of Hematology, Centre Henri-Becquerel, Rouen, [15]Department of Hematology, Saint Louis, Paris, [16]Department of Hematology, Institut de Cancerologie de la Loire, Saint Etienne, [17]Department of Hematology, University Hospital, Besancon, France

Background: Induction poly-chemotherapy plus rituximab followed by autologous stem-cell transplantation (ASCT) for newly diagnosed young patients with mantle cell lymphoma (MCL) is current standard of care. However, transplanted patients remain highly exposed to relapse. Reduced intensity conditioning allogeneic stem-cell transplantation (RIC-allo) is among therapeutic options for these young relapsed/refractory patients.
Aims: Several retrospective studies addressed the question of RIC-allo in MCL but authors reached to various conclusions. In addition, any study addressed the question of RIC-allo in the setting of previously auto-transplanted patients. Therefore, we performed a national survey conducted on behalf of the SFGM-TC (société française de greffe de moëlle et de thérapie cellulaire).
Methods: Inclusion criteria were as followed: patients with MCL who relapsed after ASCT and for whom RIC-allo has been performed. Patients who underwent RIC-allo within 3 months after ASCT were excluded. Local investigators were asked to confirm diagnosis and update follow-up. All SFGM-TC centers (except one) accepted to participate.
Results: According to the SFGM-TC database, 105 patients matched these criteria. Patients' characteristics were as followed: median age at diagnosis was 54y [range, 30-65], 68% patients were male, 93% of patients presented with stage IV disease at diagnosis. Median PFS after ASCT was 4y [range, 0.4-10]. Median age at RIC-allo was 60y [range, 39-68] and median time from ASCT to RIC-allo was 4y [range, 0.4-10]. Before RIC-allo, 85% of patients had received at least 2 lines of treatment. Sources of donor were a matched related donor in 35 cases (33%), a matched unrelated donor in 50 cases (38%) or a mismatched donor in 20 cases (19%). Conditioning regimens for RIC-allo were cyclophosphamide-based, fludarabine-based or busulfan-based in 20%, 33% and 47%, respectively. A low-dose TBI (Maximum dosing of 2Gy) was used in 27 patients. At time of RIC-allo, 63% (n=63) of patients were in CR, 7% (n=7) in PR and 20% (n=20) with Progressive Disease (data missing in 10%). Twenty patients (19%) experienced grade III/IV aGVHD and Extensive cGVHD was reported in 17 cases (16%). After RIC-allo, 81 (94%) patients reached at least PR. Median FU after RIC-allo was 52 months [range, 12.6-166]. At time of the present analysis, median PFS was 21 months whereas median OS calculated from time of RIC-allo was 51months. Median PFS and OS according to disease status at transplantation were 59m and 62m for patients in CR; 10m (PFS and OS) for patients in PR, 4.1m and 5m for patients in PD; respectively. Seventeen patients (17%) relapsed. Median time from RIC-allo to relapse was 6 months [range, 2-57] and 46 patients (44%) died. Causes of death were related to toxicity in 29 cases, lymphoma progression in 9 patients and other causes in 6 patients (missing data=2).
Summary and Conclusions: Our ongoing analysis shows that incidence of relapse after RIC-allo remains high for MCL patients who have previously relapsed after ASCT. As expected, patients in CR at time of RIC-allo experience a longer PFS duration, underlying that new salvage therapies are highly warranted prior to RIC-allo.

RESPONSE RATES USING STANDARD CRITERIA, FDG-PET AND MRD MEASUREMENT AFTER 4 COURSES OF R-DHAP AND AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN MCL, RESULTS FROM THE LYMA TRIAL

S Le Gouill[1,*],E Macintyre[2], M Callanan[3], C Bodet-Milin[1], M Meignan[4], A Moreau[1], A Traverse-Glehen[5], M Béné[6], H Maisonneuve[7], P Solal-Celigny[8], H Zerazhi[9], S Bologna[10], T De le Chapelle[11], H Tilly[12], M Delfau-Larue[4], O Hermine[2]
[1]CHU de Nantes, Nantes, [2]Hopital Necker APHP, Paris, [3]CHU de Grenoble, Grenoble, [4]Hopital Henri Mondor, APHP, Creteil, [5]CHU de Lyon, Lyon, [6]CHU de Nantes, Nanes, [7]CHD La Roche-Sur-Yon, La Roche-Sur-Yon, [8]Clinique Victor Hugo, Le Mans, [9]CH Avignon, Avignon, [10]CHU de Nancy, Nancy, [11]CHU de Rennes, Rennes, [12]CRLCC Henry Becquerel, Rouen, France

Background: Induction chemotherapy followed by autologous stem cell transplantation (ASCT) is the current standard of care in younger patients with mantle cell lymphoma (MCL) (<65 years). Cytarabine-containing chemotherapy regimens (R-DHAP) plus R-CHOP prior to ASCT are associated to longer overall survival (OS) (Hermine *et al.*, ASH 2012). Response rates before and after ASCT can predict patients' outcome. Therefore, induction chemotherapy has a major impact.
Aims: We analyzed response rates after 4 courses of R-DHAP and after ASCT in the Lyma trial, a prospective phase III trial.
Methods: In 2008, the GOELAMS and GELA groups (now Lysa) launched a prospective phase III trial addressing the question of rituximab maintenance after ASCT (Lyma trial) in younger MCL patients. Before ASCT, all patients were planned to receive 4 courses of R-DHAP (without R-CHOP). Transplanted patients were randomized between two study arms (rituximab maintenance *versus* observation). After 4 courses of R-DHAP and after ASCT, patients were monitored for response according to the Cheson 99 criteria. At the same time points, minimal residual disease (MRD), assessed by quantitative PCR, was measured in peripheral blood (PB) and bone marrow (BM). FDG-PET analysis was also performed. From September 2008 to August 2012, 299 patients were enrolled.
Results: Herein, we present response rates for the first 200 patients enrolled in the trial (response assessment for the 99 remaining patients are ongoing and will be presented at the time of the meeting). Patients presented the following characteristics: Median age,57.2 years; male, 79.5%; MIPI score, low (l-MIPI) 53%, intermediate (i-MIPI) 27% and high (h-MIPI), 20%. Blastoid variant was diagnosed in 12.5% of the patients.. 182 patients (91.5%) received 4 courses of R-DHAP and 164 (82%) proceeded to transplant. 156 (78.5%) patients were randomized. After 4 courses of R-DHAP, CR/CRu rate was 76.5% (l-MIPI 74.5%, i-MIPI 83.5%, H-MIPI 70%) while 13% of the patients reach PR. 162 patients underwent FDG-PET and no abnormal FDG uptake was observed for 79.6% of the patients (l-MIPI 83%, i-MIPI 81%, H-MIPI 66.6%). Regarding MRD status, 79.2% and 64.4% of patients reached negativity in PB and BM,respectively. After ASCT, CR/CRu rate was 93.5% (l-MIPI 93%, i-MIPI 98%, H-MIPI 89,5%) and 95.3% of transplanted patients reached MRD negativity in PB *versus* 78.1% in BM. According to FDG-PET (n=121). CR after ASCT was 89%.
Summary and Conclusions: These results show for the first time that CR/CRu and MRD negativity rates after only 4 courses of R-DHAP are similar to those reported after 6 courses of R-CHOP/R-DHAP. Furthermore, the Lyma trial is the first large phase III trial that prospectively evaluates FDG-PET response in MCL. Because it has been demonstrated that response before and after ASCT can predict response duration after ASCT, response rates after 4xR-DHAP alone are warranted to design next generation clinical trials in MCL.

Background: PET/CT is widely used in the definition of response and as a prognostic indicator, in Hodgkin lymphoma and diffuse large B cell lymphoma, but its role in PMLBCL remains to be defined.
Aims: The IELSG 26 study was defined to prospectively evaluate the role of PET, after rituximab and anthracycline-containing immunochemotherapy (R-CHT) in patients (pts) with PMLBCL.
Methods: Between 2007 and 2010, 125 pts gave their consent to be enrolled and were treated with R-CHOP(-like) (20 pts), R-VACOP-B (34 pts) or R-MACOP-B (71 pts) regimens; consolidation radiotherapy (RT) as indicated by local guidelines was allowed. PET/CT scans were planned at baseline, at 3-4 weeks after R-CHT and at 12 weeks after RT. Central PET/CT review was performed at the end of treatment using the Deauville score (Meignan *et al.* Leuk Lymphoma 2009) and complete metabolic response (mCR) was defined as a negative PET scan or one having minimal residual uptake lower than mediastinal blood pool (MBP) activity in regions which were positive at baseline, according to the IHP criteria (International Harmonization Project in Lymphoma, Juweid *et al.* JCO 2007).
Results: Treatment was administered as initially planned in 119 pts; there were 6 early withdrawals and central PET/CT review was done in 115/119 pts; 102 of 115 had consolidation RT. PET/CT visual assessment at 3-4 weeks post-R-CHT showed mCR in 54/115 pts (47%; 95% CI, 36%>56%): in 12 cases (10%; 95% CI, 6%>18%) PET/CT scan was completely negative (Deauville score 1), while in 42 (37%; 95% CI, 28%>46%) there were small residual masses with an uptake less than MBP (score 2). PET/CT scans showed a positive residual

mass after R-CHT in 61/115 pts (53%; 95% CI, 44%>62%). The residual uptake was higher than MBP but below the liver uptake (score 3) in 27 pts (23%; 95% CI, 16%>32%), slightly higher than the liver uptake (score 4) in 24 pts (21%; 95% CI, 14%>29%) and markedly higher than the liver uptake (score 5) in 10 pts (9%; 95% CI, 4%>15%). Despite only 47% of pts achieving a mCR by IHP criteria after R-CHT, at a median follow-up of 3 years, the estimated 5-year overall survival (OS) and progression-free survival (PFS) rates in the whole population (n=125) is 92% (95% CI, 86%>96%) and 86% (95% CI, 79%>91%), respectively. The achievement of a mCR by the IHP criteria at 3-4 weeks after R-CHT predicted a longer PFS (P=0.004) and OS (P=0.029) with high sensitivity but poor specificity. Pts with Deauville score 3 had a clinical outcome identical to that of 'PET negative' (score 1-2) pts and ROC analysis suggested that moving the cut-point for the definition of mCR from the MBP to the liver uptake, will increase specificity while maintaining sensitivity. Indeed, the liver uptake as a cut point is a better predictor for both PFS (P<0.001) and OS (P=0.003) (Figure 1).

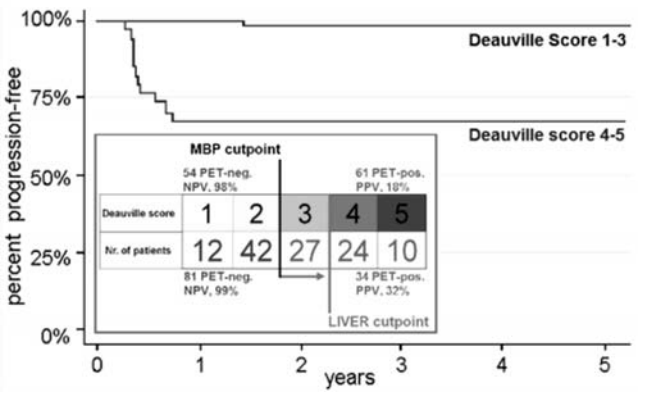

Figure 1.

Summary and Conclusions: This study provides the first prospective validation on the use of a 5-point visual scale, the Deauville criteria, for the PET response definition after R-CHT in large cell non-Hodgkin lymphomas. Using the MBP cut-point, the mCR rate after R-CHT in PMLBCL was lower than reported in DLBCL, but approximately 90% of pts are projected to be alive and progression-free at 5 years post-treatment and only the pts with score 4 and 5 had a significantly worse outcome. Hence, the liver uptake may represent a more appropriate cut-point than MBP to identify poor-risk pts who may need early intensification. The design of this study precludes any conclusion about the RT role, but the ongoing IELSG-37 randomized trial will assess whether RT can be safely omitted in PMLBCL pts in mCR after R-CHT.

EXTRALYMPHATIC CRANIOFACIAL DIFFUSE LARGE B-CELL LYMPHOMA: ROLE OF RADIOTHERAPY AND INTRATHECAL CNS PROPHYLAXIS

N Murawski[1,*], S Zeynalova[2], G Held[1], M Ziepert[3], B Kempf[4], A Viardot[5], M Haenel[6], M Witzens-Harig[7], C Ruebe[8], J Fleckenstein[8], C Zwick[1], B Glass[9], N Schmitz[9], M Pfreundschuh[1]

[1]Internal Medicine I, Saarland University Medical School, Homburg, [2]IMISE, University Leipzig, [3]IMISE, Saarland University Medical School, Leipzig, [4]Hematology/Oncology, Klinikum Landshut, Landshut, [5]Internal Medicine III, University Hospital Ulm, Ulm, [6]Internal Medicine III, Klinikum Chemnitz/Krankenhaus Kuechwald, Chemnitz, [7]Hematology/Oncology, University Hospital Heidelberg, Heidelberg, [8]Radiooncology, Saarland University Medical School, Homburg, [9]Hematology/Oncology, Asklepios Hospital St. Georg, Hamburg, Germany

Background: The role of radiotherapy and intrathecal prophylaxis in extralymphatic craniofacial involvement of aggressive B-cell lymphoma remains to be determined in the rituximab era.

Aims: To study the relevance of radiotherpay and intrathecal CNS prophylaxis to extralymphatic craniofacial DLBCL.

Methods: In a retrospective subgroup analysis of 9 consecutive prospective DSHNHL trials covering all DLBCL risk groups from 18 to 60 years of age, patients with and without craniofacial involvement were compared with respect to clinical presentation, event-free and overall survival.

Results:: 336 sites of extralymphatic craniofacial involvement were observed in 284/3840 (7.4%) patients (orbita: 30, paranasal sinuses: 90; main nasal cavity: 38, tongue: 26, remaining oral cavity: 99, salivary glands: 53). In a multivariable analysis adjusting for IPI risk factors the addition of rituximab improved EFS and OS in both patients with and without craniofacial involvement. The 141 responding patients who received radiotherapy to sites of craniofacial involvement had a similar 3-year event-free (79% *vs* 79%; P=0.835) and 3-year overall survival (88% *vs.* 85%; P=0.311) when compared with the 56 patients who did not receive radiotherapy. Without rituximab, the 2-year-rate of cumulative risk of CNS disease was increased in 205 patients with compared to 2586 patients without craniofacial involvement (4.2% *vs.* 2.8%; P=0.038), while this difference disappeared in patients who received CHOP(like) chemotherapy in combination with rituximab (1.7% in 77 patients with compared to 2.9% in 946 patients without craniofacial involvement; P=0.868). Of 85 patients with craniofacial involvement who received intrathecal prophylaxis with methotrexate, the 2-year-rate of cumulative risk of CNS disease was 4.3% compared to 2.3% in 189 patients who did not (P=0.995).

Summary and Conclusions: Rituximab eliminates the increased risk for CNS disease in patients with craniofacial involvement. As a practical consequence intrathecal prophylaxis and radiotherapy to sites of craniofacial involvement should not be given any more.

[1]Cancer Genomics Project, The University of Tokyo, Tokyo, [2]Cellular Transplantation Biology, Division of Cancer Medicine, Graduate School of Medical Science, Kanazawa University, Kanazawa, [3]Depertment of Pediatrics, Graduate School of Medecine, Nagoya University, Nagoya, [4]Laboratory of DNA information Analysis, Human Genome Center, [5]Laboratory of Sequence Analysis, Human Genome Center, The University of Tokyo, Tokyo, Japan, [6]Hematology Branch, National Heart, Lung and Blood Institute, Bethesda, United States

Background: Acquired aplastic anemia (AA) is a prototype of idiopathic bone marrow failure, which is caused by autoimmune destruction of hematopoietic progenitors. However, its natural course could be more complicated than expected for a simple autoimmune disease, which is related in large part to the development of apparently clonal disorders such as paroxysmal nocturnal hemoglobinuria (PNH) and myelodysplastic syndrome (MDS) or acute myelogenous leukemia (AML), during its course. In addition, clonality in AA is one of the long standing issues, which is evident from the cytogenetic abnormalities and skewed pattern of X chromosome inactivation in some patients. Although these evidences suggest a pathogeneic link between these disorders, clonal architecture in AA has not been fully explored.
Aims: To genetically define the origin of clonal hematopoiesis in patients with acquired AA in terms of gene mutations.
Methods: We analyzed peripheral blood DNA samples from 192 patients with AA for genetic alterations, in which coding sequences of 51 genes, which include common target of somatic mutations in myeloid malignancies, such as *RUNX1*, *ASXL1*, *TET2*, *IDH1/2*, *DNMT3A* and major components of splicing factors, were captured by liquid phase hybridization and subjected to high-throughput sequencing using Illumina HiSeq 2000. Copy number alterations have been also examined using SNP arrays analysis in all cases.
Results: About 40% were severe or very severe diseases. PNH-type cells and uniparental disomy at short arm of 6th chromosome (6pUPD) were found in 55% and 12%, respectively. Immunosuppressive therapies were performed in 70% of the cases. 32% of the cases had ATG. Response was obtained in 81% of the informative cases. 169 single nucleotide variants (SNV) are detected by target sequencing, which were subjected to deep sequencing. Finally 43 somatic mutations were detected in 34 patients (18%). Mutations were most frequently found in *DNMT3A* (7 mutations), followed by *ZRSR2* (6), *ASXL1* (5), *BCOR* (4), however *TET2* mutations, which are most commonly observed in MDS, were not identified. Mutations were more biased to nonsense (11 mutations), frameshift (6), splice site changes (3) and non-frameshift indel (5), compared to missense (18). There was no significant difference in severity, positive PHN-type cells, 6pUPD, or copy number abnormalities between mutation positive and negative cases. Mutations were associated with older age (P=0.014) and higher response to immunosuppressive therapies (P=0.040). SNP array analysis revealed copy number abnormalities in 24/192 cases (12.5%), in whom 6pUPD were observed most commonly (6.3%), therefore 51/192 cases (26.6%) had evidence of clonal evolution. In most cases with more than 5 years observation periods, no progression to AML or MDS has been reported.
Summary and Conclusions: Although the role of observed mutations in evolution from AA to AML/MDS is still unclear, we revealed a new insight of clonality in AA. In the meeting, we will introduce our findings including clinical course in some typical AA cases with mutations.

Background: Juvenile myelomonocytic leukemia (JMML) is a rare pediatric myelodysplastic/myeloproliferative neoplasm, of which molecular pathogenesis is poorly understood except for mutations of RAS pathway genes including *PTPN11, NF1, N/KRAS* and *c-CBL*. Clinical management of patients with JMML according to genetic status is of great international interest, but remains controversial among researchers.
Aims: To obtain a complete spectrum of gene mutations in JMML.
Methods: Whole exome sequencing was performed for paired tumor-normal DNA from 13 JMML cases. Candidate somatic mutations were detected through in house pipeline for whole exome sequencing. All the candidate germline and somatic nuncleotide changes were validated by Sanger/deep sequencing. A total of 92 JMML tumor specimens were screened for mutations in previously reported genes (*PTPN11*, *NF1*, *KRAS, NRAS*, and *c-CBL*) and newly identified 3 genes with deep sequencing. Moreover, to clarify the clinical significance of aberrant DNA methylation in JMML, we evaluated quantitative CpG methylation pattern of 10 candidate genes by pyrosequencing in the same cohort.
Results: Only 11 non-silent somatic mutations were detected in whole exome sequencing (0.85/sample), of which 6 involved the known RAS pathway genes (2 *PTPN11*, 1 *NRAS*, 1 *KRAS*, and 1 *NF1*). Germline involvement was suspected in 7 cases (54%), of which 6 had germline mutations of RAS pathway genes (2 *PTPN11*, 2 *NF1*, and 2 *c-CBL*). Totally, the RAS pathway mutations were found in 11 out of 13 discovered cases (85%). Five out of the 11 somatic mutations were in three non-RAS pathway genes (3 *SETBP1*, 1 *JAK3*, and 1 *SH3BP1*). The mutation of *SETBP1* has recently been reported in Schinzel-Giedion syndrome (Nat Genet. 2010) and adult atypical chronic myeloid leukemia (Nat Genet 2012). By deep sequencing, RAS pathway mutations were found in 82 out of 92 cases (89%), where *PTPN11* mutations were predominant (n=39, 42%) followed by *N/KRAS* (n=28, 30%), *c-CBL* (n=14, 15%), and *NF1* (n=9, 10%) mutations. The other 10 (11%) patients were negative for known RAS pathway mutations. In addition, genetic mutations of *SETBP1* and *JAK3* were recurrently found in 16 patients (17%). These mutations had lower allele frequencies compared to the accompanying RAS pathway mutations, indicating that they were responsible for disease progression rather than the establishment of JMML. Clinically, these mutations were associated with poor overall survival (P=0.10). By epigenetic analysis, aberrant methylation in any of *CDKN2A, BMP4*, *CALCA*, and *RARB* was also a significant poor prognosis factor for transplantation free survival (P=0.009) (Figure 1).

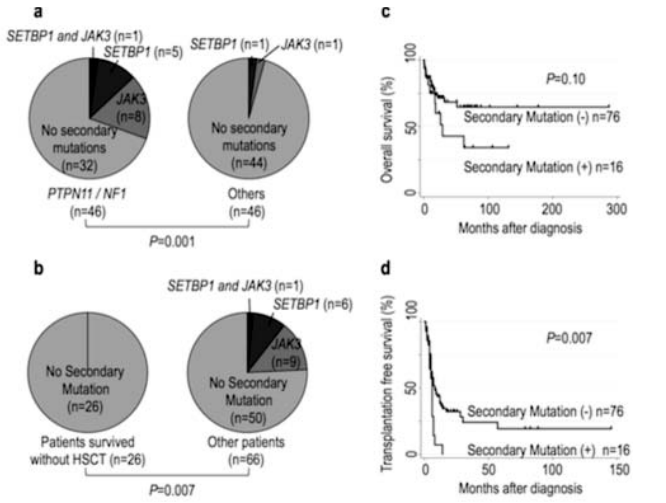

Figure 1. Clinical features of JMML cases with or without secondary mutations.

Summary and Conclusions: Our whole-exome sequencing revealed the spectrum of gene mutations in JMML. Together with high frequency of RAS pathway mutations, the paucity of non-RAS pathway mutations is a prominent feature of JMML. Mutations of SETBP1 and JAK3 were common recurrent secondary events presumed to be involved in tumor progression and associated with poor clinical outcomes. Our finding provides an important clue to understand the pathogenesis of JMML that helps to develop novel diagnostics and therapeutics for this leukemia.

S1163

ABT-737 PROLONGS SURVIVAL IN AN NRASD12/BCL2-MEDIATED MOUSE MODEL OF MYELODYSPLASTIC SYNDROME (MDS) BY TARGETING LEUKEMIA INITIATING CELLS (LIC), PRIMITIVE LIN-/SCA1+/KIT+ (LSK) AND PROGENITORS

[2]Cardiff University School of Medicine, Cardiff, United Kingdom, [3]Service de Médecine Nucléaire - Hôpital Bichat, [4]Genosplice Technology, Paris, France, [5]The University of Texas, M. D. Anderson Cancer Center, Huston, United States, [6]AP-HP, Hôpital Avicenne, Service d'Hématologie Clinique, Univerist Paris13, Bobigny, France

Background: MDS are characterized by apoptosis of bone marrow (BM) progenitors, associated in particular to BCL-2 family gene deregulation. In our transgenic acute myeloid leukemia (AML) mouse model expressing NRAS and BCL2 with 90% BM blasts and reduced apoptosis (Omidvar Cancer Res, 2007), ABT-737, a mimetic inhibitor of the BH3 domain of BCL2 protein family, prolonged mouse survival (Gorombei, ASH 2012).
Aims: Here we address the effect of ABT-737 on survival and LICs in our MDS mouse model with and pro-apoptosis (Omidvar Cancer Res, 2007).
Methods: Transgenic MRP8NRASD12/MMTVLTRtTA/TetoBCL-2 MDS mice were treated or not after genotyping and hBCL-2 expression by flow, and the disease confirmed by blood counts. Treatment consisted of 75 mg/kg ABT-737 (Abbott)×3 /week for 15 injections. Mice (treated or not) were followed for survival (n=27 untreated and n=23 treated) or sacrificed (n=60) and BM harvested and Giemsa stained for BM analysis, by microscopy (n=4 in each group), characterized for LICs by transplantation of spleens into lethally irradiated syngeneic recipients (n=3 per group), primitive cells as Lin-/Sca1+/cKit+ (LSK) by flow cytometry (12 untreated, 8 treated), and for progenitor assays (11 untreated, 5 treated). BM apoptosis was measured by annexin V staining; SPECT (12 untreated, 3 treated) and liver sections examined by TUNEL (n=2). RAS activity was measured by RAS-pulldown assays. RNA was extracted from Sca1+ enriched spleen cells (3 treated and untreated) and assayed for gene expression profiling (GEP) using exon specific arrays (Affymetrix).
Results: Median survival was 15 days in 27 untreated mice and 70 days, (two thirds surviving >60 days) in the 23 treated mice (P<0.0005). This correlated with reduction of marrow blasts from 10±2.1% in untreated to 6±2.8% in treated mice (P<0.05) and clearance of tissue infiltration by myeloblasts. After ABT-737 treatment 2 of 3 transplanted mice remain alive after 5 months whilst the untreated mice died by day 50; the BM LSK cell population decreased to nearly normal levels (normal 1.8±0.6%; 8.5±3.6% in untreated *versus* 4.5±2.4% in treated, P<0.05) with complete restoration of colony growth to normal range (35±10 in wild type normal mice, 45±9 in untreated *versus* 38±8in treated mice p~0.1). In treated mice, increased apoptosis was observed in the bone marrow and liver. RAS-GTP ad BCL-2 expression remained unchanged following treatment. Exon specific gene expression arrays showed 399 genes differentially expressed between treated and untreated mice; 305 and 94 genes were upregulated and downregulated respectively including genes important for stem cell development such as ALDH2, ALDH3B2, CTBP2, possibly reflecting partial restoration of normal stem cell function, consistent with reduced LSK, progenitor cell numbers and apparent transplantation of normal cells. Downregulation of anti apoptotic genes such as Map3K14 and upregulation of pro apoptotic genes such as Apaf1 and Pik3Cg was observed, consistent with increased apoptosis data. Restoration of normal hematopoiesis was confirmed by upregulation of myeloid differentiation genes (CD14, CSF1) and genes involved in the cell cycle (Ccna2, Ccnb2, E2F2, Cdkn2C, Ttk, Ccne2).
Summary and Conclusions: ABT-737 extends lifespan in our mutant NRAS BCL-2 MDS transgenic mice. ABT-737 targets LIC and primitive progenitors, and regulates cell cycle, differentiation and apoptosis pathways. These data suggest that clinical trials with BCL-2 targeting reagents in MDS patients are warranted.

MUTATIONS IN SETBP1 GENE ARE RECURRENT IN MYELODYSPLASTIC SYNDROMES AND OFTEN COEXIST WITH CYTOGENETIC MARKERS ASSOCIATED WITH POOR PROGNOSIS

M Fernandez-Mercado[1], A Pellagatti[1], C Di Genua[1,*], M Jose Larrayoz[2], N Winkelmann[3], P Aranaz[2,3], A Burns[4], A Schuh[4], M Calasanz[2], N Cross[3,5], J Boultwood[1]
[1]NDCLS, RDM, University of Oxford, Oxford, United Kingdom, [2]Department of Genetics, University of Navarra, Pamplona, Spain, [3]National Genetics Reference Laboratory, Salisbury NHS Foundation Trust, Salisbury, [4]NIHR Biomedical Research Centre, University of Oxford, Oxford, [5]Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Background: The molecular basis of disease progression in the myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML) remains poorly understood. SETBP1, a regulator of SET nuclear oncogene, has recently been shown to be mutated in myeloid malignancies, including MDS, secondary AML (sAML) and atypical chronic myeloid leukemia (aCML). aCML patients with *SETBP1* mutations have a poor prognosis.
Aims: We sought to investigate whether *SETBP1* plays a role in disease progression in MDS/CMML. We screened a large series of MDS cases, and sAML cases evolving from MDS/CMML, for *SETPB1* mutations. We also studied serial samples from MDS/CMML cases in evolution to AML.
Methods: DNA was isolated from patient bone marrow or peripheral blood samples. The region surrounding the SKI homology domain was sequenced using standard Sanger-sequencing methods. Serial samples were also screened for mutations in *ASXL1* and *TET2*. In addition, one of the MDS cases in progression to AML with del(7)(q21) from onset was subjected to whole exome sequencing (WES) both at diagnosis and at the leukemic stage.
Results: We screened a cohort of 328 patients with a range of myeloid malignancies (122 MDS, 12 CMML, 2 MDS/MPN, 115 *de novo* AML and 77 sAML) for *SETBP1* mutations. Overall, 4.9% of patients had *SETBP1* mutations and these were all heterozygous and missense. Sixteen mutations were detected in 16 patients; G870S, I871S and R627C alterations were most frequently observed (n=4, n=4 and n=3, respectively), while G870R, P637R, E863K, D868N, T873R were less prevalent (n=1 each). Mutations were detected in 4.1% cases with MDS (5/122), 50% with MDS/MPN (1/2), 16.7% with CMML (2/12), 0.9% with *de novo* AML (1/115) and 9.1% with sAML (7/77). Among the sAML cases, mutations were present in 23.1% of cases secondary to CMML (3/13) and in 6.3% secondary to MDS (4/64). Strikingly, the majority of the *SETBP1* mutations were found in samples with specific cytogenetic features: 8 mutations in cases with monosomy 7 (-7) or del(7q), 3 mutations in cases with abnormalities including isochromosome 17 [i(17)(q10)], and 3 mutations in cases with normal karyotype. The remainder of the patients with *SETBP1* missense mutations had del(20q) or inv16 (Table 1). Chromosome 7 abnormalities [-7/del(7q)] and i(17)(q10) are associated with shortened overall survival in MDS and risk of leukemic evolution. The increased frequency of *SETBP1* mutations observed in these cytogenetic subgroups and in sAML prompted us to analyse serial samples from 22 MDS/CMML cases in transformation to AML. Four of these cases showed *SETBP1* mutations, 3 of which acquired the mutation during leukemic evolution. Notably, in the fourth case the *SETBP1* mutation was detectable before the cytogenetically aberrant clone [harboring a i(17)(q10) marker] arose. In addition to *SETBP1*, we also screened the serial samples for mutations in *ASXL1* and *TET2*. Overall, 15 of the 22 cases (68.2%) showed mutations in at least one of the three genes during the disease course. *ASXL1* and *TET2* were mutated in 11 and 5 cases, respectively, with 3 cases harboring mutations in both genes. *ASXL1* mutations were present in 2 of the 4 cases with *SETBP1* mutations. No clear pattern of mutation acquisition was noted, likely due to the small number of cases with more than one mutation. One MDS case with del(7)(q21) in progression to AML was subjected to WES both at diagnosis and at the AML stage. Only the AML sample showed a G870R somatic mutation.

Table 1.

Karyotype	MDS/CMML	De novo AML	Secondary AML	SETBP1 mutated cases No (%)
monosomy 7/del(7q)	15	2	3	8 (40.0)
i(17)	1	1	2	3 (75.0)
inv16	0	6	0	1 (16.7)
del(20q)	14	2	3	1 (5.3)
normal	34	51	33	3 (2.5)

Summary and Conclusions: Somatic *SETBP1* mutations are recurrent in MDS, CMML and sAML, and frequently coexist with cytogenetic markers associated with poor prognosis. Analysis of serial samples from MDS and CMML cases in transformation showed that nearly 70% of the cases presented mutations in at least one of three genes screened (*SETBP1, ASXL1* and *TET2*). *SETBP1* mutations were frequently acquired during leukemic evolution.

Background: International Prognostic Scoring System (IPSS) Low- or Intermediate (INT)-1 risk (low-risk) myelodysplastic syndrome (MDS) with del(5q) was considered to have an indolent course, but recent data have indicated a subgroup of patients with more aggressive disease and shorter overall survival (OS). Using deep sequencing, it was previously demonstrated that 18% of such patients carry small *TP53* mutated subclones at diagnosis, rendering them at significantly higher risk for disease progression (Jädersten *et al.*, JCO 2011). The presence of *TP53* mutations was associated with strong p53 protein expression by immunohistochemistry (IHC) indicating that p53 IHC may be a sensitive biomarker for outcome in lower-risk MDS.
Aims: To assess the association between p53 protein expression by IHC in patients with lower-risk del(5q) MDS treated with lenalidomide and response to treatment, outcome, and *TP53* gene mutations.
Methods: Bone marrow (BM) biopsies obtained at screening and during follow-up in 85 of 205 (41%) patients from the MDS004 clinical trial (Fenaux *et al.*, Blood 2011) were retrospectively assessed for p53 protein expression by IHC in a blinded fashion by manual and automated image analysis using p53 DO1 and DO7 monoclonal antibodies. Sections were assessed for the percentage and intensity of p53 nuclear staining based on a total count of 1000 BM haematopoietic cells (lymphocytes and lymphoid aggregates excluded) at high magnification (40×/60× objectives), and p53 protein expression was graded as 0 (negative), 1+ (faintly positive), 2+ (moderately positive) and 3+ (strongly positive). Results for strong p53 staining were correlated to clinical outcome and treatment response. A subset of BM samples was reviewed by three independent investigators to test reproducibility. The *TP53* mutational status was assessed by deeP-sequencing in nine patients and in microdissected cells with strong, moderate and negative p53 staining by using pyrosequencing.
Results: Strong p53 protein expression in ≥1% BM cells was detected in 30 of 85 patients (35%). Baseline demographics, clinical characteristics and WHO subgroups did not differ between the IHC cohort and the MDS004 study patients without trephine biopsies. Results for the two p53 monoclonal antibodies, manual *versus* automated measurements, and across three independent investigators were highly concordant (P<0.01, for all three). The presence of ≥1% BM cells with strong p53 expression ($p53^{+++}$) was significantly associated with shorter OS (P=0.0104) and higher risk for progression to AML (P=0.0003). The P53 IHC status showed no association with transfusion independence or response duration (P=0.636 and P=0.4421), but was significantly associated with cytogenetic response (CyR) (complete and partial response taken together) with: 18/35 (51%) CyR for the p53-negative patients as compared to 3/21 (14%) CyR for p53-positive patients (P=0.009). As CyR rates differed for 5 mg *vs* 10 mg lenalidomide (len) in the entire MDS04 study, CyR rates were also specifically evaluated for patients randomized to each dose level. For patients randomized to 10 mg len, CyR occurred in 1 of 8 (13%) and in 16 of 19 (84%) p53-positive and negative patients, respectively. Eight of 21 patients with serial BM samples had an increased percentage of $p53^{+++}$ cells at three months, which was associated with higher risk for progression to AML (P<0.01) and shorter OS (P=0.0005) as compared to patients who remained negative for p53 by IHC. Cytogenetic evolution, including del(17p), was observed in three of the eight patients with increased $p53^{+++}$ by IHC. Pyrosequencing analysis of microdissected, p53-immunolabeled cells confirmed *TP53* mutation in cells with strong p53 staining, while cells with moderate staining where predominantly of wild-type TP53.
Summary and Conclusions: The present study validates p53 IHC as a predictive tool in del(5q) lower-risk MDS patients treated with lenalidomide, and as a biomarker for underlying *TP53* mutations. *TP53* mutational status should be included in risk assessment systems for MDS with del(5q).

Molecular markers in acute myeloid leukemia

WHOLE EXOME SEQUENCING OF PRIMARY REFRACTORY AML PATIENTS REVEALS A DIVERSE MUTATIONAL PATTERN WITH HIGH PREVALENCE OF MDS RELATED MUTATIONS

S Herold[1,*], M Kuhn[2], T Stange[2], I Röder[2], A Dahl[3], J Schetelig[1], M Schaich[1], C Röllig[1], H Serve[4], C Brandts[4], G Ehninger[1], C Thiede[1]
[1]Medizinische Klinik I, Universitätsklinikum Carl Gustav Carus, [2]TU Dresden, Institut für Medizinische Informatik und Biometrie, [3]Biotec Dresden, Deep Sequencing-Group of SFB 655, Dresden, [4]Medizinische Klinik II, Universitätsklinikum Frankfurt, Frankfurt, Germany

Background: A critical step during treatment of patients with acute myeloid leukemia (AML) is the achievement of complete remission (CR). Although the majority of younger patients with AML will achieve CR, about 5-50% will fail to respond sufficiently to induction treatment, with highest CR-rates in CBF leukemias and worst response in complex karyotypes and secondary AML. Treatment of AML patients with induction failure (IF-AML) is difficult and outcome is dismal, with long-term survival mainly restricted to patients who are successfully salvaged and transplanted. The molecular mechanisms of resistance are still poorly understood, especially in patients with normal karyotype, a subgroup mainly associated with good CR rates. Since improved understanding of resistance mechanisms might help to develop novel treatment strategies, we aimed to study genetic alterations in IF-AML patients using whole exome sequencing (WES).
Aims: Since improved understanding of resistance mechanisms might help to develop novel treatment strategies, we aimed to study genetic alterations in IF-AML patients using whole exome sequencing (WES).
Methods: We performed WES (TrueSeq enrichment, Illumina) of FACS-sorted leukemic blasts (CD34/33/117+) and normal T-cells (CD4+; as germline reference) after whole genome amplification (WGA) in 29 patients (median age 44 years; range, 21-63) with *de novo* AML who had IF. Primary refractory disease was defined as failure to achieve CR after conventional double induction chemotherapy using standard anthracycline/cytosine arabinoside containing chemotherapy, with the majority of patients showing blast persistence at high levels or even increased blast counts. Patients had primarily intermediate-risk cytogenetics according to MRC criteria (N=24), of whom 16 patients had a cytogenetically normal (CN) AML. Paired-end 100 bP-sequencing was performed on a HiSeq2000 instrument (Illumina). Bioinformatic analysis included BWA-mapping (Hg19 reference) and somatic single nucleotide variants (SNVs) calling using SAMTOOLS. Only variants not specified as simple nucleotide polymorphisms (SNP) in db135 with a minor allele frequency of >1% were included in the final analysis.
Results: With an average target base coverage of 46- fold (38-56 inter quartile range, IQR) we identified a median number of 22 high confident SNVs per patient (range 9-310). Ongoing validation of SNV-calls using Sanger sequencing confirmed somatic status in the majority of cases. Frequently mutated, recurrently affected known genes included TET2 (24.1%), IDH1 and 2 (27.6%), DNMT3A (13.8%), WT1 (13.7%) and RUNX1 (13.8%); mutations were also less frequently found in SF3B1 (10.3%) and BCOR (10.3%). Rarely found genes in AML include ATM (N=2), BRCA2 (N=2) and MYC (N=2), whereas several novel recurrent alterations currently undergo further validation, *e.g.* CREBBP (N=2), and MYCBP2 (N=2).
Summary and Conclusions: Combining the mutational data, we so far did not identify a specific molecular lesion in IF-AML. However, although we focused on *de novo* AML, we observed a high prevalence of alterations previously associated with MDS, including TET2, RUNX1, SF3B1 and DNMT3A, which might point to an unrecognized underlying secondary development of these leukemias. Especially alterations in epigenetic modifier proteins were common, which might point towards potential new treatment strategies in these patients.

INTERACTIONS BETWEEN GEMTUZUMAB OZOGAMICIN TREATMENT AND ACUTE MYELOID LEUKEMIA PATIENT SUBSETS DEFINED BY CYTOGENETICS, GENE MUTATIONS, AND SINGLE-NUCLEOTIDE POLYMORPHISM ARRAY-BASED KARYOTYPING

ARenneville[1,*], R Abdelali[2], S Chevret[3], O Nibourel[1], M Cheok[4], C Pautas[5], R Duléry[6], T Boyer[1], J Cayuela[2], S Hayette[7], E Raffoux[8], H Farhat[9], N Boissel[8], C Terré[10], H Dombret[8], S Castaigne[9], C Preudhomme[1]
[1]Hematology Laboratory, CHRU of Lille, Lille, [2]Hematology Laboratory, [3]Department of Biostastistics, Saint-Louis Hospital, APHP, Paris, [4]Inserm, U837, Team3, Cancer Research Institute of Lille, Lille, [5]Department of Hematology, Henri Mondor Hospital, APHP, Créteil, [6]Department of Hematology, CHRU of Lille, Lille, [7]Laboratory of Molecular Biology, Lyon Sud Hospital, Pierre Benite, Lyon, [8]Department of Hematology, Saint-Louis Hospital, APHP, Paris, [9]Department of Hematology, [10]Laboratory of Cytogenetics, Versailles Hospital, Le Chesnay, France

Background: We recently reported the results of the ALFA-0701 Phase 3 tri-

al, showing that the addition of fractionated doses of gemtuzumab ozogamicin (GO) during induction and consolidation chemotherapy may significantly improve outcome of acute myeloid leukemia (AML) patients aged 50-70 years. In this trial, as well as in Medical Research Council AML 15 and 16 trials, it appeared that patients with favorable or intermediate cytogenetics, including those with normal karyotype (NK) AML, may benefit from GO, while not those with adverse cytogenetics.

Aims: Our objectives were to evaluate the prognostic impact of molecular abnormalities and lesions detected by single-nucleotide polymorphism array (SNP-A)-based karyotyping on clinical outcome in AML patients treated in the ALFA-0701 trial, and to analyze potential interactions between GO treatment and patient subsets defined by cytogenetics, gene mutations, and SNP-A lesions.

Methods: We performed mutational analysis of 11 genes (*FLT3*, *NPM1*, *CEBPA*, *MLL, RUNX1*, *WT1*, *ASXL1*, *TET2*, *IDH1/2,* and *DNMT3A*), *EVI1* overexpression screening, and 6.0 SNP-A analysis in the diagnostic samples of the 278 patients with previously untreated *de novo* AML enrolled in the ALFA-0701 trial. The screening for *TET2*, *IDH1/2*, and *DNMT3A* mutations was restricted to NK-AML.

Results: Karyotype and SNP-A data were available for 254 and 248 patients, respectively. SNP-A analysis revealed 450 genomic abnormalities (245 losses, 117 gains, 88 uniparental disomies) in 135/248 (54%) patients. In NK-AML (n=146), 38% of the patients had ≥1 SNP-A lesion and 89% had ≥1 molecular abnormality, *NPM1* mutations (52%), *DNMT3A* mutations (34%), and *FLT3* internal tandem duplication (ITD) (25%) being the 3 most frequent molecular abnormalities. The median duration of follow-up from time to randomization was 25 months. As expected, karyotype had a strong influence on overall survival (OS). The presence of SNP-A lesions conferred a significantly shorter OS in the whole cohort (HR, 2.52 [95%CI, 1.68-3.77]; P<0.0001) and in the subset of 132 NK-AML patients analyzed by SNP-A (HR, 2.45 [1.39-4.31]; P=0.002). In the NK-AML subset, *DNMT3A* mutations (HR, 2.33 [1.35-4.01]; P=0.002) and, to a lesser extent, *FLT3*-ITD (HR, 1.77 [1.01-3.1]; P=0.045) were associated with a significantly shorter OS. In multivariate analysis, only the presence of unfavorable karyotype (HR, 2.47 [95%CI, 1.61-3.79]; P<0.001) and SNP-A lesions (HR, 2.05 [95%CI, 1.33-3.10]; P=0.001) were retained as significantly associated with OS in the whole cohort, while the presence of SNP-A lesions (HR, 3.14 [95%CI, 1.74-5.68]; P<0.001), *DNMT3A* mutations (HR, 1.90 [95%CI, 1.08-3.35]; P=0.027), and randomization in the control arm (HR, 2.50 [95%CI, 1.35-4.55]; P=0.003) independently predicted shorter OS in NK-AML patients. The benefit of GO treatment was predominantly observed in NK-AML. In this subset, the negative impact of *FLT3*-ITD was observed in the control arm (HR, 1.77 [95%CI, 1.04-2.99]; P=0.005) but not in the GO arm (HR, 0.89 [0.32-2.44]; P=0.82), while such an effect of GO treatment was not found for SNP-A lesions and *DNMT3A* mutations.

Summary and Conclusions: SNP-A lesions and *DNMT3A* mutations represent adverse independent prognostic factors in AML. Our results suggest that addition of GO to standard chemotherapy might overcome the poor prognosis of *FLT3*-ITD, but not that of SNP-A lesions and *DNMT3A* mutations. However, further studies based on larger patient cohorts are required to formally identify the molecular determinants of response to GO.

S1168

HIGH EXPRESSION OF DNMT3B NEGATIVELY IMPACTS ON CLINICAL OUTCOME OF OLDER PATIENTS (PTS) WITH PRIMARY CYTOGENETICALLY NORMAL (CN) ACUTE MYELOID LEUKEMIA (AML) [CALGB 20202 (ALLIANCE)]

C Niederwieser[1,*], J Kohlschmidt[1,2], K Maharry[1,2], K Mrózek[1], K Metzeler[1], S Volinia[1], P Yan[1], D Frankhouser[1], S Whitman[1], H Becker[1], A Eisfeld[1], S Schwind[1], J Curfman[1], Y Wu[1], M Baer[3], B Powell[4], J. Kolitz[5], J Moore[6], T Carter[7], G Marcucci[1], C Bloomfield[1]

[1]Comprehensive Cancer Center, The Ohio State University, Columbus, [2]Alliance for Clinical Trials in Oncology Statistics and Data Center, Mayo Clinic, Rochester, [3]Greenebaum Cancer Center, University of Maryland, Baltimore, [4]Comprehensive Cancer Center, Wake Forest University, Winston-Salem, [5]Monter Cancer Center, Hofstra North Shore-Long Island Jewish School of Medicine, Lake Success, [6]Duke University Medical Center, Durham, [7]University of Iowa, Iowa City, United States

Background: DNA methyltransferases (DNMT1, DNMT3A, DNMT3B) are involved in DNA methylation and epigenetic gene silencing. Aberrant DNA methylation appears to contribute to leukemogenesis, and increases with age. *DNMT3A* mutations (mut) have been reported to impact negatively on the clinical outcome of AML pts, and it recently was reported that *DNMT3B* overexpression adversely affected outcome of a clinically and cytogenetically diverse cohort of 195 adult AML pts (PLoS One 2012;7:e51527). However, the prognostic impact of *DNMT3B* expression has not yet been evaluated in similarly treated older [≥60 years(y)] pts with CN-AML, especially in the context of a comprehensive panel of molecular prognosticators that include mut in the *DNMT3A, TET2* and *ASXL1* genes, which are implicated in aberrant epigenetics in AML.

Aims: To test the clinical impact of *DNMT3B* expression in a large cohort of similarly treated and molecularly well-characterized CN-AML pts, and to derive *DNMT3B* expression-associated gene-expression (GEP), microRNA-expression (MEP) and gene promoter methylation profiles.

Methods: We analyzed 210 pts aged 60-83 y (median, 68). *DNMT3B, ERG* and *BAALC* expression was assessed by NanoString nCounter assay. Mutation analyses of genes known to affect outcomes of CN-AML were performed using PCR amplification and Sanger sequencing. Pts were dichotomized into low and high *DNMT3B* expressers using a median cut. The GEP (n=177 pts) and MEP (n=162) were assessed using, respectively, the HG-U133plus2.0 and The Ohio State University custom microRNA microarrays. Methylation was measured by the NGS MethylCaP-seq (Blood 2012;120:2466).

Results: High *DNMT3B* expressers had lower complete remission (CR) rates (*P*<.001, 56% v 79%), and worse disease-free (DFS; *P*=.03; 3y-rates, 14% v 21%) and overall (OS) survival (*P*<.001; 3y-rates, 11% v 28%) than *DNMT3B* low expressers. High *DNMT3B* expressers had higher WBC (*P*=.002), and% blood (*P*=.003) and marrow (*P*<.02) blasts, were more often in the European LeukemiaNet (ELN) Intermediate-I Genetic Group (*P*<.007), and had more often *FLT3*-ITD (*P*<.001), *IDH2* R172 mut (*P*=.02), and high *ERG* (*P*<.001) and *BAALC* (*P*=.001) expression. In multivariable analyses, high *DNMT3B* expression associated with worse CR [*P*=.01, hazard ratio (HR)=.42] once adjusted for *BAALC* expression, WBC and age, and shorter OS (*P*=.008, HR=1.52) once adjusted for ELN Groups, *DNMT3A* R882 mut, and *BAALC* expression.

By GEP, we found 2188 genes differentially expressed (*P*<.001, FDR<.01) between high and low *DNMT3B* expressers; 1465 were upregulated concordantly with *DNMT3B* including genes previously implicated in AML (*e.g.*, *KIT*, *FLT3*, *WT1*, *ERG*, *FANCL*, *TP53*, *HOXA6*, *NPM1*, *DNMT3A* and *GATA2*), and 723 downregulated (*e.g.*, *TGFBI*, *CEBPB*, *VEGFA*, *GATA3*, *TLR8* and *TLR4*). In contrast, only 4 *miRs* were differentially (*P*≤.001, FDR<.1) expressed between high and low *DNMT3B* expressers. *miR-133a* and *miR-133b*, targeting *SP1* and *MCL1,* were upregulated, and *miR-148a*, regulating *MITF*, and *miR-122*, repressing *SLC7A1* and modulating interferon-1, were downregulated. Notably, among 134 pts with genome-wide methylation data available, we did not observe any differentially methylated regions in gene promoters.

Summary and Conclusions: High *DNMT3B* expression is independently associated with adverse outcome of older CN-AML pts. The *DNMT3B* expression associated with distinct expression profiles that include many genes, but few *miRs*. Differential expression of these genes does not seem to be related to their methylation status, suggesting that *DNMT3B* may contribute to disease aggressiveness through other mechanisms yet to be elucidated.

Background: Mutations in the *nucleophosmin 1* (*NPM1*^{mut}) gene represent the most common gene mutations in acute myeloid leukaemia (AML), with highest frequency in cytogenetically normal AML. We have previously shown the applicability and prognostic value of *NPM1*^{mut} based RQ-PCR assays for the detection of minimal residual disease (MRD).

Aims: To confirm our previous results on the prognostic relevance of *NPM1*^{mut}-transcript levels in an extended cohort of AML patients (pts) (18 to 77 years) harbouring *NPM1*^{mut} type A, B, D, JT,4, QM or KM, and to assess the impact of concurrent *FLT3* internal tandem duplications (ITD) and *DNMT3A* mutations.

Methods: All pts were enrolled in one of four AMLSG [AMLHD98A, AMLSG 07-04, AMLSG 09-09, AMLSG 16-10] treatment trials. Treatment comprised double induction therapy with ICE (idarubicin, cytarabine, etoposide) with or without ATRA or gemtuzumab ozogamicin or 1 cycle of daunorubicin and cytarabine followed by 1 to 4 cycles of high-dose cytarabine, autologous or allogeneic stem cell transplantation. *NPM1*^{mut} transcript levels (ratio of *NPM1*^{mut}/*ABL1* transcripts×10^4) were determined by RQ-PCR using TaqMan technology; the sensitivity of the assays was 10^{-5}to 10^{-6}.

Results: A total of 2421 samples [bone marrow (BM) n=2397; peripheral blood (PB) n=24] from 407 *NPM1*^{mut} pts were analysed at diagnosis, after each treatment cycle, during follow-up (FU) and at relapse. *NPM1*^{mut} transcript levels at diagnosis varied between 2.9×10^1 and 10.4×10^6 (median, 6.4×10^5). Pretreatment transcript levels were not correlated with clinical characteristics (*e.g.*, age, WBC, BM blasts, *FLT3* mutation status) and did not impact event-free survival (EFS), relapse-free (RFS) and overall survival (OS). In multivariable analyses, *NPM1*^{mut} transcript levels at different time points were significantly associated with shorter remission duration and shorter OS. After double induction therapy, the cumulative incidence of relapse (CIR) at 4 years was 7% for RQ-PCR-negative pts (n=43) *versus* 50% for RQ-PCR-positive pts (n=195) (P<0.00001); the lower CIR translated into a significant better OS (P=0.0003). After completion of therapy, CIR at 4 years was 20% for RQ-PCR-negative pts (n=106) and thus significantly lower compared with 62% in RQ-PCR-positive pts (n=97; P<0.00001). Again, the lower CIR translated into a significantly better OS (P<0.00001). Multivariable analysis at both time points revealed *NPM1*^{mut} transcript levels as a significant marker for shorter remission duration [(HR, 2.05; 2.20, respectively) and shorter OS (HR, 1.65; 1.62, respectively). During FU, 687 BM and 24 PB samples from 209 patients were analysed. The relapse rate at 2 years for pts exceeding the previously defined cut-off value of >200 *NPM1*^{mut} copies was 90%. Finally, we evaluated the impact of concurrent *FLT3*-ITD and *DNMT3A* mutations on *NPM1*^{mut} transcript levels. Following the first induction cycle, the median *NPM1*^{mut} transcript level was significantly lower in pts without concurrent *FLT3*-ITD or *DNMT3A* mutations. This effect could be observed throughout subsequent treatment cycles.

Summary and Conclusions: In our extended cohort we could confirm the two clinically relevant MRD time points, after induction and after completion of therapy, which allow for the identification of pts at high risk of relapse. During the follow-up period, we could confirm our previously defined cut-off value which is highly predictive for relapse. The reduction of *NPM1*^{mut} transcript levels strongly correlates with the *FLT3*-ITD and *DNMT3A* mutation status.

S1170

AMPLIFICATION OF CHROMOSOME 21 AS A MECHANISM FOR ERG OVEREXPRESSION IN PATIENTS WITH MYELOID MALIGNANCIES

S Weber[1,*], C Haferlach[1], L Noel[1], T Alpermann[1], W Kern[1], T Haferlach[1], S Schnittger[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany

Background: *ERG* overexpression was shown to be related to adverse outcome in cytogenetically normal AML (CN-AML). The proto-oncogene *ERG* is situated on chromosome 21 (chr21). Acquired gain of chr21 (+21) is a recurrent cytogenetic abnormality in AML. The pathogenetic impact of +21 remains elusive, but data indicates that +21 could be a mechanism underlying the increased expression of genes located in the respective regions.

Aims: The aim of this study was 1) to ascertain the prognostic impact of *ERG* expression in context of other relevant molecular prognostic markers in CN-AML and 2) to analyze a possible relationship between +21 and variations in *ERG* mRNA expression levels.

Methods: *ERG* mRNA expression was analyzed using a TaqMan real-time PCR assay. 1) *ERG* expression was assessed in a cohort of 331 patients (pts) with *de novo* CN-AML. Female/male ratio was 168/163 and age ranged from 18.3-64.8 years (median, 52.7 years).The median%*ERG*/*ABL1* level was used to distinguish low from high *ERG* expressers. *BAALC* levels were analyzed accordingly. Expression levels were correlated with clinical outcome and with the presence of *FLT3*-ITD (n=124/331), *NPM1* mutations (*NPM1*mut, n=208/331), *RUNX1*mut (n=35/330), *CEBPA*mut (n=29/331), *MLL*-PTD (n=27/331), *ASXL1*mut (n=13/331), *FLT3*-TKD (n=32/331), *IDH1*R132mut (n=41/328), *IDH2*R140mut (n=48/328), *IDH2*R172mut (n=6/328), *NRAS*mut (n=53/329) and *WT1*mut (n=27/330). 2) To address *ERG* expression in relation to +21 the following cohorts were analyzed: 66 AML pts with a complex karyotype and +21 (CK+21); 44 AML pts with +21 as sole cytogenetic abnormality (+21s), 15 pts with different myeloid malignancies (6 *de novo* AML, 5 MDS, 1 s-AML, 2 t-AML,1 t-MDS) showing *ERG* amplification by use of interphase FISH (amp21) and 32 CK-AML pts without +21 (CK). Mean *ERG* expression levels were compared by t-test.

Results: 1) At diagnosis,%*ERG/ABL1* levels ranged from 0.078 to1,016.027 (median: 188.582). High *ERG* expression was associated with lower age (P=0.003), higher white blood cell (WBC) count (P=0.017), *FLT3*mut/wt ratio of at least 0.5 (50/165, 30.3% *vs* 25/166, 15.1%, P=0.001) and high *BAALC* expression (104/164, 63.4% *vs* 60/166, 36.6%, P<0.001), as compared to low *ERG* expression. In contrast, *NPM1*mut (91/165, 55.2% *vs* 117/166, 70.5%, P=0.004) and *IDH1*R132mut (11/164, 6.7% *vs* 30/164, 18.3%, P=0.002) were less frequent in high *ERG* expressers. Kaplan Meier analysis revealed inferior overall survival (OS at 3 years: 50.9% *vs* 67.3%, P=0.035) and event free survival (EFS at 3 years: 34.6% *vs* 42.9%, P=0.048) for high *ERG* expressers as compared to low *ERG* expressers. However, in a multivariate model adjusted for age, WBC, *BAALC* expression, *FLT3*mut/wt ratio of at least 0.5, *MLL*-PTD and *WT1*mut no significant impact of *ERG* expression was observed. 2) Mean±SEM expression levels of *ERG* were higher in pts with +21 (+21s and CK+21 combined, 336±27) as compared to pts with CN-AML or CK-AML (229±10, 177±36; P<0.001 and P=0.001, respectively). Moreover, mean *ERG* expression was even higher in pts with amp21 (613±159) as compared to pts with +21 (336±27, P=0.107), albeit this difference was not significant, probably due to small numbers of pts.

Summary and Conclusions: High *ERG* expression is associated with adverse outcome, as well as with the well established risk factors *FLT3*-ITD, high *BAALC* expression and the lack of *NPM1*mut. Furthermore, high levels of *ERG* observed in pts with +21 and moreover in pts with amp21 indicate ERG as an important factor contributing to the pathogenesis and progression of myeloid malignancies with gain of chr21.

SERUM FERRITIN FOR PREDICTING CLINICALLY RELEVANT LIC THRESHOLDS TO GUIDE MANAGEMENT OF PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMIA TREATED WITH DEFERASIROX: THALASSA STUDY EXTENSION ANALYSIS

A Taher[1,*], J Porter[2], V Viprakasit[3], A Kattamis[4], S Chuncharunee[5], P Sutcharitchan[6], N Siritanaratkul[7], R Galanello[8], Z Karakas[9], D Habr[10], Z Zhu[10], M Cappellini[11]
[1]American University of Beirut, Beirut, Lebanon, [2]University College London, London, United Kingdom, [3]Department of Pediatrics and Thalassemia Center, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]First Department of Pediatrics, University of Athens, Athens, Greece, [5]Ramathibodi Hospital, Mahidol University, [6]Chulalongkorn University and King Chulalongkorn Memorial Hospital, [7]Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [8]Ospedale Regional Microcitemie, Cagliari, Italy, [9]Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [10]Novartis Pharmaceuticals, East Hanover, United States, [11]Universita di Milano, Ca Granda Foundation IRCCS, Milan, Italy

Background: Although liver iron concentration (LIC) assessment by magnetic resonance imaging (MRI) to diagnose iron overload and guide iron chelation therapy is clinically more robust, limited access worldwide makes it practical to also use serum ferritin (SF) assessments. THALASSA assessed efficacy and safety of deferasirox in iron-overloaded non-transfusion-dependent thalassemia (NTDT) patients. Previously, we reported the utility of SF as a predictor of clinically relevant LIC thresholds in screened patients (Taher *et al. Haematologica* 2012;97 [Suppl 1]:abst 0927)–representing a patient population being evaluated for iron overload and considered for iron chelation therapy; these patients had a broad range of LIC and were deferasirox-naïve.
Aims: The objective of this analysis was to further evaluate the relationship between SF and LIC after up to 2-yrs' treatment with deferasirox, to help guide the management of iron chelation therapy in patients receiving treatment at clinically relevant thresholds, ie THALASSA thresholds for stopping treatment (LIC<3mg Fe/g dw) or dose escalation (LIC≥7mg Fe/g dw).
Methods: THALASSA enrolled iron-overloaded NTDT patients (LIC≥5mg Fe/g dw and SF>300ng/mL) aged ≥10 years. Patients completing the 1-yr core study could continue into the 1-yr extension, with placebo patients switching to deferasirox. Data from all patients completing the extension with available SF and LIC at the end of treatment (EOT) were used (EOT was end of extension or earlier if patients stopped treatment when LIC<3mg Fe/g dw [n=22]). A receiver operating characteristic analysis was conducted; positive predictive values (% of patients with LIC≥cutoff in all patients whose SF>cutoff) and negative predictive values (% of patients with LIC).
Results: 130 NTDT patients completed treatment and had SF and LIC measurements at baseline and EOT. There was a moderate-to-strong correlation between SF and LIC at baseline (R=0.6382); the magnitude of correlation increased slightly by EOT (R=0.7214). The predictive value of SF for LIC thresholds at EOT are shown in the Table 1. SF>300 is 86.1% predictive of LIC≥3, indicating a 13.9% probability of LIC<3 leading to potential over-treatment. SF<300 is 40% predictive of LIC<3, hence a 60% probability of LIC≥3 potentially leading to sub-optimal treatment when LIC≥3, but only 13.3% probability of LIC≥5. SF>1700 and >2000 are 100% predictive of LIC≥7. SF<1700 is 61.0% predictive of LIC<7, indicating a 39.0% probability of sub-optimal treatment.

Table 1. End-of-treatment predictive value of serum ferritin cutoffs for clinically relevant LIC thresholds used to guide treatment decisions in THALASSA.

Thresholds	End of treatment	
	PPV	NPV
LIC≥3 mg Fe/g dw		
SF cutoff of 300 ng/mL	86.1	40.0
• *SF>300 is 86.1% predictive of LIC≥3 → 13.9% probability of over-treating with LIC<3* • *SF<300 is 40% predictive of LIC<3 → 60% probability of sub-optimal treatment when LIC≥3*		
LIC≥7 mg Fe/g dw		
SF cutoff of 2000 ng/mL	100	59.5
• *SF>2000 is 100% predictive of LIC≥7 → 100% appropriate dose escalation* • *SF<2000 is 59.5% predictive of LIC<7 → 40.5% probability of sub-optimal treatment when LIC≥7*		
SF cutoff of 1700 ng/mL	100	61.0
• *SF>1700 is 100% predictive of LIC≥7 → 100% appropriate dose escalation* • *SF<1700 is 61.0% predictive of LIC<7 → 39.0% probability of sub-optimal treatment when LIC≥7*		

PPV; positive predictive value = % of subjects with LIC≥cutoff in all subjects whose SF>cutoff
NPV; negative predictive value = % of subjects with LIC<cutoff in all subjects whose SF≤cutoff

Summary and Conclusions: Data from patients exposed to deferasirox treatment for up to 2 yrs indicate that a SF threshold <300 ng/mL for stopping chelation treatment appears adequate to minimize the risk of over-chelation. This threshold potentially leads to some patients stopping chelation prematurely, but only a small proportion of these patients would have LIC≥5 mg Fe/g dw, ie at risk of iron-related complications. Using a SF threshold >1700 ng/mL for dose escalation, all patients would be appropriately dose increased (ie all would have LIC≥7 mg Fe/g dw). However, a good proportion of patients with SF<1700 ng/mL would not be dose-increased despite also having a LIC≥7 mg Fe/g dw. Although this analysis is limited by a small number of patients with the lowest levels of SF and LIC, these results confirm previous observations in screened patients and suggest that, if carefully considered, SF could be useful to guide iron chelation therapy management where LIC monitoring by MRI is limited.

S1172

MORBIDITY RISK IN UNTREATED PATIENTS WITH B-THALASSEMIA INTERMEDIA: A CLOSER LOOK AT THE ROLE OF IRON OVERLOAD

K Musallam[1,*], M Cappellini[1], S Daar[2], M Karimi[3], A El-Beshlawy[4], M Magestro[5], J Wulff[6], G Pietri[6], A Taher[7]
[1]University of Milan, Milan, Italy, [2]Sultan Qaboos University, Muscat, Oman, [3]Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of Korea, [4]Cairo University, Cairo, Egypt, [5]Novartis Pharmaceuticals Corporation, New Jersey, United States, [6]HERON, Luton, United Kingdom, [7]Chornic Care Center, Hazmieh, Lebanon

Background: Patients with β-thalassemia intermedia (TI), a form of non-transfusion dependent thalassemia (NTDT), remain at risk of iron overload due to increased intestinal iron absorption. Although an association between iron overload and morbidity risk in this patient population is suggested by cross-sectional studies, data from longitudinal cohorts are limited.
Aims: To evaluate the association between iron overload and morbidity risk in transfusion-independent and chelation-naive patients with TI followed longitudinally for an extended time and thus representing the natural history of the disease.
Methods: This was a retrospective cohort study of patients from five comprehensive care centers in Italy, Lebanon, Oman, Iran, and Egypt. Beyond diagnosis of TI, inclusion criteria were: 1) no history of liver disease (biopsy confirmed fibrosis, cirrhosis, or cancer), osteoporosis, hypothyroidism, hypoparathyroidism, diabetes, hypogonadism, extramedullary hematopoiesis, thrombosis, or pulmonary hypertension, and 2) no history of transfusion, iron chelation, or fetal hemoglobin induction therapy. Patients were followed for eleven years (2000-2010), and occurrence of any of the aforementioned morbidities was recorded. Serum ferritin (SF) levels were recorded at baseline and annually during follow-up. Clinical outcomes were assessed for three distinct groups of mean SF: ≤300 ng/mL (n=8, 15.4%), >300 to <800 ng/mL (n=17, 32.7%), and ≥800 ng/mL (n=27, 51.9%); which are proposed thresholds for tailoring iron chelation therapy in NTDT patients.

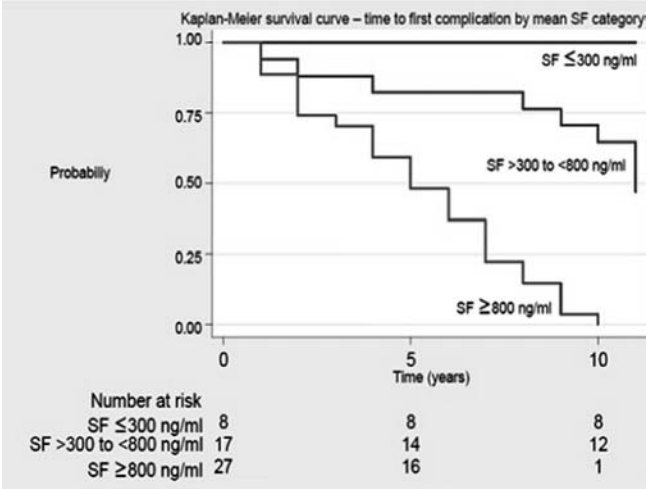

Figure 1.

Results: Fifty-two patients were included in this analysis. Their mean age at baseline was 24.1±1.6 years and 25 (48.1%) were men. No patients died or were lost to follow-up during the study period. There was a steady increase in mean SF level throughout the follow-up period, from a mean±SE of 513.2±51.2 ng/mL at baseline to 1209±103ng/mL at study end (mean annual increase of 9%).%). By study end, 36 (69%) of patients had at least one SF measure ≥800 ng/mL. The cumulative incidence of developing at least one morbidity was significantly higher in patients with mean SF levels ≥800 ng/mL than patients with mean SF levels >300 to <800 ng/mL and ≤300 ng/mL (100% *vs.* 52.9% *vs.* 0%, respectively; Chi-squared test P=0.001). A similar observation was made for

multiple="multiple" morbidity (59.3% *vs.* 5.9% *vs.* 0%, respectively; Chi-squared test P=0.001). Kaplan-Meier plots showed a statistically significant difference in morbidity-free survival between the three mean SF level groups (Figure1, Logrank test, P=0.001). Morbidity-free survival rates at 5- and 10-years were 48.2% and 0% in patients with a mean SF level ≥800 ng/mL, 82.4% and 64.7% in patients with a mean SF level >300 to <800 ng/mL, and 100% in patients with a mean SF level ≤300 ng/mL. A Cox proportional hazard model was developed (stepwise backward selection) that included baseline age and splenecomy status, sex, mean total hemoglobin level and mean SF level observed over the study period. Mean SF level was the only independent and statistically significant risk factor for the occurrence of at least one morbidity (P=0.001) as well as multiple morbidities (P=0.005) during the follow-up period.

Summary and Conclusions: Without chelation, SF levels continue to increase in transfusion-independent patients with TI. SF levels ≥800 ng/mL are associated with a significant increase in long-term morbidity risk; while levels ≤300 ng/mL are not associated with any risk. These data should help guide decisions for iron chelation therapy in this patient population.

S1173

NUCLEOSOMES AND NEUTROPHIL ACTIVATION AS MARKERS OF NEUTROPHIL EXTRACELLULAR TRAP FORMATION DURING SICKLE CELL DISEASE PAINFUL CRISIS

M Schimmel[1,2,*], E Nur[1], S Zeerleder[1], G van Mierlo[3], S Solati[3], D Brandjes[2], H Otten[2], J Schnog[4], B Biemond[1]

[1]Hematology, Academic Medical Center, [2]Internal Medicine, Slotervaart Hospital, [3]Immunopathology, Sanquin Research and Landsteiner Laboratory AMC, University of Amsterdam, Amsterdam, Netherlands, [4]Hematology/Oncology, Sint Elisabeth Hospital, Willemstad, Curaçao

Background: Sickle cell disease (SCD) is characterized by recurrent acute vaso-occlusive painful crisis frequently leading to SCD related complications, like acute chest syndrome. The complex pathophysiology of the vaso-occlusive painful crisis is mediated by activation of endothelial cells, adhesion of sickled erythrocytes and polymorphonuclear neutrophils (PMN), oxidative stress, coagulation activation and an increased release of inflammatory mediators, resulting in ischemic organ damage. Recently, PMN have been demonstrated to form Neutrophil Extracellular Traps (NETs) upon activation. During this process, DNA and DNA-binding proteins are extruded from neutrophils exposing a mesh consisting of nucleosomes, histones and neutrophil proteases. NET formation has been shown to propagate coagulation in sepsis and deep venous thrombosis. Moreover, nucleosomes and histones exposed on NETs have been shown to be highly cytotoxic to endothelial cells. Beside the exposure on NETs, nucleosomes can be actively released into the circulation from dead cells. Circulating nucleosomes detected in sepsis have been reported to correlate with markers of coagulation and inflammation as well as with organ dysfunction and mortality.

Aims: The aim of this case-control study was to assess plasma levels of circulating nucleosomes and neutrophil activation as evidenced by human neutrophil elastase–α_1-antitrypsin (EA) complexes, as indirect measure of NET formation in plasma.

Methods: After obtaining informed consent, nucleosomes and EA complexes were measured using ELISA in blood samples of race matched healthy controls (24), sickle cell patients during steady state (74) and sickle cell patients with painful crisis (70). Markers of inflammation and endothelial activation were also measured. For statistical analysis, patients were divided in two groups: patients with the relatively severe genotypes HbSS and HbSβ^0-thalassemia (HbSS/HbSβ^0-thal) and patients with the relatively milder HbSC and HbSβ$^+$-thalassemia genotypes (HbSC/HbSβ$^+$-thal). The study protocol was approved by the local medical ethical committee.

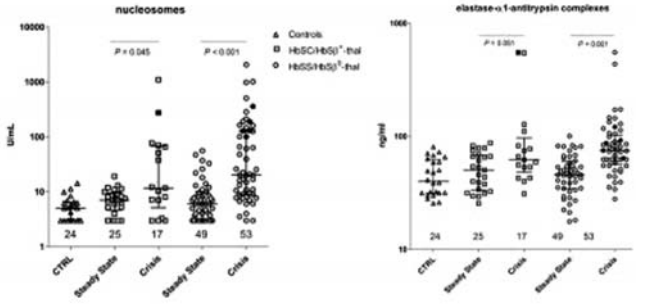

Figure 1.

Results: Plasma levels of nucleosomes in both patients with HbSS/HbSβ^0-thal and HbSC/HbSβ$^+$-thal were significantly higher during painful crisis (median; IQR, 20.2 U/mL; 8.9–129.0, *P*<0.001, and 11.7 U/mL; 5.1–67.7, *P*=0.045) as compared to those in steady state (6.0 U/mL; 3.0–9.8 and 7.1 U/mL; 4.6–9.6). EA levels were higher in HbSS/HbSβ^0-thal and HbSC/HbSβ$^+$-thal patients during painful crisis (75.1 ng/mL: 56.5–102.4, *P*<0.001; 62.0 ng/mL: 48.0–96.7; *P*=0.051) as compared to levels during steady state (45.7 ng/mL; 34.7–59.7 and 50.2 ng/mL; 33.3–67.7), but just failed to reach statistical significance in HbSC/HbSβ$^+$-thal patients. During painful crisis, EA levels correlated strongly with levels of nucleosomes in both HbSS/HbSβ^0-thal (Sr=0.55, *P*<0.001) and HbSC/HbSβ$^+$-thal patients (Sr=0.90, *P*=<0.001). In steady state HbSS/HbSβ^0-thal patients, levels of nucleosomes correlated with endothelial markers sVCAM-1 and vWF:Ag (Sr=0.421, *P*=0.003; Sr=0.452, *P*=0.001). Six patients who developed an acute chest syndrome during painful crisis were among the patients with the highest nucleosome and EA levels. A significant (Sr=0.441, *P*<0.001) correlation was found between levels of nucleosomes and duration of hospitalization (Figure 1).

Summary and Conclusions: We demonstrate for the first time increased levels of circulating nucleosomes in sickle cell patients with painful crisis reflecting NET formation which strongly correlates with PMN activation and disease severity.

S1174

MUTATIONS OF ABCG2 TRANSPORTER AS THE GENETIC BASIS OF HIGH FREQUENCY BLOOD ANTIGEN JUNIOR

M Koszarska[1,*], M Kasza[2], A Bors[1], H Andrikovics[1], ATordai[1], G Varadi[2], A Németh[2], G Scheffer[3], G Szakacs[4], B Sarkadi[5]

[1]Hungarian National Blood Transfusion Cervice, [2]CellPharma Kft, Budapest, Hungary, [3]Free University Medical Center, Amsterdam, Netherlands, [43]Institute of Molecular Pharmacology and Institute of Enzymology, Research Center for Natural Sciences, HAS, [5]Institute of Molecular Pharmacology and Institute of Enzymology, Research Center for Natural Sciences, HAS, Budapest, Hungary

Background: Blood group antigen variants caused by genetic alterations may trigger severe diseases during pregnancy and blood transfusion, such as hemolytic disease of the fetus and newborn (HDFN) or adverse hemolytic transfusion reactions. Membrane proteins, comprising about 30% of the total number of human proteins, are crucial in many diseases, while currently no simple assays are available for the determination of their tissue levels. ABCG2 gene has recently been described as the the genetic basis of one of the high frequency red-blood-cell (RBC) blood group antigens, encoding Junior (Jun) blood group.

Aims: To identify the genetic background of low RBC ABCG2 protein expression level in healthy individuals.

Methods: 61 healthy volunteers (47 unrelated individuals and 14 family members of two volunteer probands with low ABCG2 transporter expression) were enrolled. RBC ABCG2 protein expression was measured by flow cytometry (FACS) using paraformaldehyde fixed RBC stained with three different ABCG2 specific monoclonal antibodies. Using whole genomic DNA, common ABCG2 SNPs V12M (c.34G>A, p.12Val>Met, rs2231137) and Q141K (c.421C>A, p.141Gln>Lys, rs2231142) were genotyped by LightCycler allelic discrimination system, while novel mutations were identified by direct sequencing of exons and flanking intronic regions.

Results: ABCG2 protein expression on RBC did not associate with age or sex. Among the 47 donors, there were 11 individuals with heterozygous Q141K variant (allele frequency: 11.7±6.6%), and 3 individuals with heterozygous V12M variant (allele frequency: 3.2±3.6%) genotypes. Individuals carrying the heterozygous ABCG2 Q141K variant exhibited significantly lower expression of ABCG2 (5.27±1.19) on RBC, as compared to homozygous wild-type individuals (6.13±0.61, P=0.011). There was no significant difference between homozygous wild-type individuals and heterozygous V12M carriers.Two unrelated individuals out of 47 exhibited lower RBC ABCG2 expression (2.65±0.29). Sequencing of the ABCG2 gene in these cases revealed two different heterozygous mutations; a nonsense mutation, causing an arginine to stop codon change in exon 7 (c.706C>T, p.R236X, rs140207606) and a small deletion also in exon 7 (c.791_792delTT, L264HfsX14). Both of these mutations result in premature termination. Low ABCG2 expression phenotypes were segregated in both families with the presence of the respective mutations.

Summary and Conclusions: Based on our results, FACS may be a rapid and reliable assay for the quantitative determination of membrane protein expression in human erythrocytes. We found significant differences between the expression levels of the wild-type ABCG2 protein and the heterozygous Q141K polymorphic variant. Our observations suggest that the ABCG2 genetic variants associated with the absence of high frequency blood group antigens may be more common than previously described.

S1175

THE SAFETY, TOLERABILITY AND EFFICACY OF FBS0701, AN IRON CHELATOR IN CLINICAL DEVELOPMENT FOR TRANSFUSIONAL IRON OVERLOAD: DATA FROM 72 WEEKS OF TREATMENT

Y Aydinok[1,*], R Galanello[2], V Viprakasit[3], A Piga[4], P Harmatz[5], G Forni[6], F Shah[7], R Grace[8], John Porter[9], E Vichinsky[5], J Wood[10], S Krishnan[11], P Zhang[11], W Abi-Saab[12], H Rienhoff [13], E Neufeld[8]

[1]Pediatric Hematology, Ege University Hospital, Izmir, Turkey, [2]Ospedale

Regionale Microcitemie, Università degli Studi di Cagliari, Cagliari, Italy, [3]Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]University of Torino, Torino, Italy, [5]Children's Hospital & Research Center, Oakland, United States, [6]Ospedale Galliera, Genoa, Italy, [7]The Whittington Hospital, London, United Kingdom, [8]Boston Children's Hospital and Harvard Medical School, Boston, United States, [9]University College London, London, United Kingdom, [10]Cardiology, Children's Hospital Los Angeles, Los Angeles, [11]Shire Pharmaceuticals Inc, Wayne, United States, [12]Shire AG, Nyon, Switzerland, [13]Ferrokin BioSciences Inc., San Carlos, United States

Background: Iron overload is a major concern in transfusion-dependent anemias. Many patients are inadequately treated owing to a lack of efficacy at established doses of iron chelators or inadequate dosing resulting from adverse events (AEs) and adherence issues. The efficacy, safety and tolerability of the iron chelator FBS0701 has been reported at 2 doses (16 and 32 mg/kg/day) over 24 weeks, from a randomized study in 51 patients. A clear dose-response shown by changes in liver iron concentration (LIC) from baseline (+3.1 mg/g dry weight [dw] *vs* −0.3 mg/g dw for the low- *vs* high-dose groups, $P<0.03$) was reported (Neufeld *et al. Blood* 2012). Excellent tolerability with the absence of dose-dependent AEs encouraged extension of the study up to a total length of 96 weeks.
Aims: To assess the efficacy, safety and tolerability of FBS0701 in adults with transfusional iron overload treated with assigned fixed doses of chelator for 24 weeks followed by dose adjustments until study end. Here we describe data from 72 weeks' treatment.
Methods: Patients with thalassemia syndromes and sickle cell disease completing the first 24 weeks with LIC ≥2 mg/g dw, serum ferritin (SF) ≥350 ng/mL and cardiac T2* ≥10 ms were eligible for a 24-week extension. Those completing this extension and still meeting eligibility criteria could enter a further 48-week extension. Dose adjustments were allowed based on efficacy parameters at/after week 24, at which point doses up to 60 mg/kg/day were permitted for the remainder of the study. Outcome measures included LIC determined by FerriScan® R2 MRI at weeks12, 24, 48 and 72, monthly SF levels, safety monitoring and laboratory measurements. All patients provided written informed consent.
Results: Fifty-one patients started the study (age, 18–48 years). Forty-two of 49 patients completing the first 24 weeks entered weeks 24–48; 39 completed 48 weeks. Of these, 37 patients entered the extension (weeks 49–96). Of the patients who had LIC measurements at week 72, 10/29 (34.5%) and 19/29 (65.5%) had high (>0.4 mg/kg/day) and low (≤0.4 mg/kg/day) baseline transfusion burden, respectively. LIC until week 72 is shown in the Figure 1. Median (range) SF reduced from 2766 (570–6667) ng/mL at week 24 (n=30) to 2396 (631–7037) ng/mL at week 72 (n=29). AEs related to study drug were reported in 31/51 patients (60.8%; safety set). Serious AEs occurred in 5 patients (9.8%), leading to discontinuation of study drug in 1 patient owing to a treatment-related case of hypoesthesia. Treatment-related increases in transaminases occurred in 8 patients (15.7%); in 3 cases this was due to new onset hepatitis C leading to discontinuation of FBS0701 in 1 patient. The other 5 patients had fluctuating levels that were not clinically significant, while continuing on FBS0701. Common treatment-related AEs were headache and flatulence (both n=6, 11.8%). Gastrointestinal related-AEs included diarrhea (n=3, 5.9%), nausea, constipation and abdominal pain (all <5%). Mean serum creatinine was consistent with baseline levels over the 72 weeks.

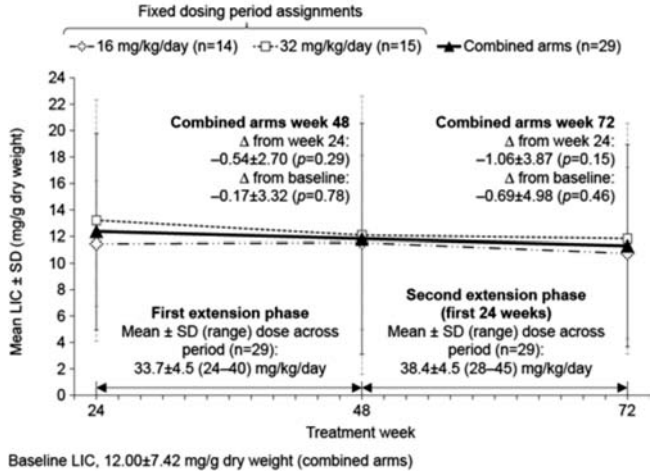

Figure 1. Liver iron concentration (LIC) from weeks 24 to 72 in patients with measurements at week 72.

Summary and Conclusions: FBS0701 doses up to 50 mg/kg/day continued to be well tolerated, with no evidence of renal or hematological effects or other safety concerns. FBS0701 at 32 mg/kg/day has been shown to maintain iron balance during the first 24 weeks. Safety data support making further dose escalations to achieve the ideal endpoint of negative iron balance in all patients.

Novel therapeutics

S1176

HIGH-THROUGHPUT DRUG SENSITIVITY AND RESISTANCE TESTING (DSRT) COMBINED WITH MOLECULAR PROFILING FOR THERAPEUTIC TARGETING OF NUP98-NSD1-POSITIVE AML

M Kontro[1,*], T Pemovska[2], M Majumder[2], H Edgren[2], S Eldfors[2], E Kulesskiy[2], R Karjalainen[2], B Yadav[2], A Murumägi[2], A Parsons[2], T Lundán[3], T Aittokallio[2], O Kallioniemi[2], KWennerberg[2], K Porkka[1], C Heckman[2]
[1]Hematology Research Unit, Helsinki University Central Hospital, [2]Institute for Molecular Medicine Finland, FIMM, University of Helsinki, Helsinki, [3]Department of Clinical Chemistry and TYKSLAB, University of Turku and Turku University Central Hospital, Turku, Finland

Background: The *NUP98-NSD1* fusion gene is a recently discovered recurrent aberration in 17% of pediatric and 2-3% of adult cytogenetically normal (CN) AML patients. The occurrence of the fusion is strongly associated with *FLT3-ITD* mutations. The transforming property of *NUP98–NSD1* involves a block in cellular differentiation and enforced leukemic progenitor self-renewal through persistent overexpression of distinct HOX-genes (*HOXA5, HOXA7, HOXA9, HOXA10* and *MEIS1*). The fusion is associated with very poor outcome and a 4-year event-free survival of less than 10% in both pediatric and adult patients (Iris *et al.* Blood 2011).
Aims: Our aim was to identify novel therapies for *NUP98-NSD1*-positive AML.
Methods: We performed deep molecular profiling (exome and RNA sequencing at multiple time points throughout the disease) and *ex vivo* high-throughput drug sensitivity and resistance testing (DSRT) on a patient with relapsed, chemorefractory CN-AML. DSRT was performed using fresh BM MNCs (>50% blasts) with a panel of all FDA/EMA-approved small molecule and conventional cytotoxic oncology drugs, as well as investigational compounds (n=202) over a10,000-fold concentration range. A leukemia specific drug sensitivity score (sDSS) derived from an area under the dose response curve calculation was used as the efficacy assessment by comparing drug sensitivity profiles of primary leukemia and normal bone marrow cells.
Results: NUP98-NSD1 blasts showed selective sensitivity (measured as sDSS, Figure 1) to the mTOR inhibitor temsirolimus (sDSS 12) and the multi-kinase inhibitors dasatinib (sDSS 15) and sunitinib (sDSS 17). Following treatment with a combination of temsirolimus, dasatinib and sunitinib (TDS), a rapid decrease of the bone marrow blast cell count occurred accompanied with normalization of peripheral blood neutrophil count, but no increase in platelet count (a CRi-response). Within 30 days of treatment, a relapse occurred and repeated DSRT showed loss of sensitivity to the applied drugs (temsirolimus: sDSS1, dasatinib: sDSS 6 and sunitinib: sDSS 4) reflecting good correlation of *ex vivo* and *in vivo* sensitivity and resistance. The *NUP98-NSD1* fusion was detected in all samples, including the diagnostic sample (600_0) suggesting that this was an early initiating event in the development of the patient's disease. Exome sequencing revealed a diverse subclonal clonal architecture highlighted by *FLT3-ITD* and *WT1* mutations. After induction chemotherapy, the predominant *FLT3-ITD* subclone was no longer detectable, while subsequent therapies, including the dasatinib, sunitinib and temsirolimus combination, induced a change in the proportional sizes of different subclones containing *WT1* mutations, as well as appearance of a second *FLT3-ITD*.

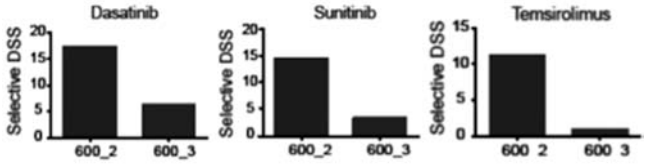

Figure 1.

Summary and Conclusions: The TDS-combination therapy may present a novel targeted therapy option for patients with *NUP98-NSD1*-driven AML and warrants further preclinical and clinical experimentation, which are ongoing in our laboratory. The comprehensive DSRT platform covering the entire cancer pharmacopeia and many emerging agents rapidly identifies individually optimized combinatorial therapies, and when coupled with deep molecular profiling provides insights into the molecular events underlying disease progression in *NUP98-NSD1*-positive and other molecularly defined subgroups of AML.

[1]Hematology, Goethe University, Frankfurt am Main, Germany, [2]Fusion Pharma LLC, Moscow, Russian Federation, [3]Fusion Pharma LLC, Moscow, Germany

Background: Targeting BCR/ABL by ABL-directed kinase inhibitors (AKIs) induces long lasting remissions in many patients with chronic myeloid leukemia (CML), and short remissions in Ph+ acute lymphatic leukemia (ALL). Notably in advanced Ph+ leukemia resistance attributable to either kinase domain mutations in BCR/ABL or non mutational mechanisms remains the major clinical challenge. With the only exception of Ponatinib, a multitargeted kinase inhibitor, all actually approved AKIs are unable to inhibit the "gatekeeper" mutation T315I. On the other hand Ponatinib is unable to overcome non mutational resistance in advanced leukemia. This together with the fact that Ponatinib is the AKI with the broadest spectrum of kinase inhibitions reveals that there is the urgent need for further and more selective therapeutical options in treating therapy-resistant advanced Ph+ leukemia.
Aims: We wanted to develop an AKI, which should have the following qualities: i.) ability to target all known resistance mutations in BCR/ABL but mainly the T315I; ii.) a higher selectivity as compared to Ponatinib in order to reduce undesired side effects; iii.) ability to overcome also non mutational resistance in advanced Ph+ leukemia; iv.) activity not only in chronic phase CML but also advanced Ph+ leukemia, Ph+ ALL or blast crisis CML (BC-CML).
Methods: The preclinical evaluation of PF-114 was performed in direct comparison to Ponatinib on golden standard preclinical models of CML and advanced Ph+ leukemia. Advanced leukemia model were cell lines (K562, KCL22, BV173 for BC-CML, SupB15 and TOM1 for Ph+ ALL), primary patient-derived long term culture (PD-LTC) of Ph+ ALL patients and secondary BCR/ABL-induced murine ALLs for the *in vivo* studies. The effects on mutational resistance was investigated i.) on the factor dependence of Ba/F3 cells expressing BCR/ABL or its clinically most relevant resistance mutants (Y253F, E255K, T315I, F317L); ii.) *in vivo* on the transduction/transplantation model of BCR/ABL- and BCR/ABL-T315I-induced CML-like disease; iii.) on a PD-LTC of a Ph+ ALL patient harboring the T315I. As models for non mutational resistance we used PD-LTCs from Ph+ALL patients with different levels of non mutational drug resistance and the SupB15RT, a Ph+ ALL cell line rendered resistant by the exposure to increasing doses of Imatinib, which exhibits a cross resistance against all approved AKIs.
Results: PF-114 is an orally available AKI, which is more selective than Dasatinib or Ponatinib (number of kinases inhibited at 100 nM of a drug: Nilotinib - 19; PF-114 - 27; Dasatinib - 48; Ponatinib - 80). It efficiently inhibited all tested BCR/ABL mutants in cellular and biochemical assays at dosages of 10-100nM. It also suppressed growth of Ph+ PD-LTC with non mutational resistance as well as the BCR/ABL-T315I-positve PD-LTC in this dosage range. In all models the effect was independent of the presence of either the p210 or the p185 form of BCR/ABL. No effect of PF-114 was seen in PD-LTCs of Ph- ALL. Noteworthy PF-114 (50 mg/kg) prolonged significantly the survival of mice with both BCR/ABL- and BCR/ABL-T315I-driven CML-like disease as compared to Ponatinib (25 mg/kg). Like Ponatinib PF-114 was unable to overcome the non mutational resistance in SupB15RT.
Summary and Conclusions: Our work supports clinical evaluation of PF-114 as a pan BCR/ABL inhibitor for treatment not only for chronic phase CML, but also for advanced and resistant Ph+ leukemia such as Ph+ ALL or BC-CML.

Background: Bruton's tyrosine kinase (BTK) is a central mediator of B-cell receptor (BCR) signaling essential for normal B-cell development. Ibrutinib is an oral BTK inhibitor that induces apoptosis and inhibits migration and adhesion of malignant B-cells. Mantle cell lymphoma (MCL) is an aggressive non-Hodgkin lymphoma subtype, and despite high initial responses to standard therapy, patients often relapse. Preliminary results in 51 evaluable patients demonstrated ibrutinib induced rapid nodal responses in relapsed or refractory MCL (Wang, ASH 2011). Interim results for the fully enrolled study, PCYC-1104, were reported (Wang, ASH 2012), and a longer follow-up resulted in a higher overall response rate (ORR). Updated results of this international, multicenter, phase 2 study of single agent ibrutinib in relapsed or refractory MCL will be presented.
Aims: Objectives of the study were to assess ORR, duration of response (DOR), overall survival (OS), progression free survival (PFS) and the safety and tolerability of ibrutinib as a single agent in relapsed or refractory MCL.
Methods: Relapsed or refractory MCL patients who were either bortezomib-naïve or bortezomib-exposed were enrolled. All patients had the study explained to them prior to their enrollment and voluntarily consented to participate in the study. Ibrutinib 560 mg PO QD was administered continuously until disease progression. Tumor response was assessed every 2 cycles (one cycle=28 days). The study enrolled 115 patients (65 bortezomib-naïve, 50 bortezomib-exposed); 111 patients were treated; 110 were evaluable for response. Baseline characteristics included: median age 68 yrs, median time since diagnosis 42 months, median number of prior treatments 3; bulky disease (>10 cm) 13%, prior stem cell transplant 10%, high risk MIPI 49%.
Results: Safety data is reported for 111 patients. Treatment-emergent adverse events (AEs) seen in ≥20% of patients included: diarrhea (40%), fatigue (36%), URI (23%), nausea (23%), and dyspnea (21%). Grade 3 AEs included neutropenia (13%), anemia (8%), thrombocytopenia (7%), abdominal pain (5%), diarrhea (5%), dyspnea (5%), and pneumonia (5%). Grade 4 treatment-related AEs included: neutropenia (7%), hyperuricaemia (2%), pancytopenia (1%), thrombocytopenia (1%), and sepsis (1%). One Grade 5 pneumonia was reported as treatment-related. Median time on study was 9.2 months; 47% of patients remain on therapy. Median PFS was 13.9 months and DOR has not yet been reached. Boretezomib-naive (n=63): ORR=65%; CR=21%; PR=44%. Bortezomib-exposed(n=47): ORR=72%; CR=23%; PR=49%. Total (all patients, n=110): ORR=68%; CR=22%; PR=46%. Response rates increased with longer treatment. With longer follow-up of the initially reported subset of 51 patientsdescribed at ASH 2011(median time on treatment then was 3.7 months, now 14.7 months), the CR rate increased from 16% to 39%, and the ORR increased from 69% to 75.
Summary and Conclusions: Analysis upon longer follow-up demonstrates the durability of responses and confirms the unprecedented single agent activity of ibrutinib in relapsed or refractory MCL. The treatment-emergent AEs were consistent with safety data previously reported. Pivotal studies in relapsed or refractory MCL have been initiated.

S1179

FIRST CLINICAL TRIALS EMPLOYING SLEEPING BEAUTY SYSTEM AND ARTIFICIAL ANTIGEN PRESENTING CELLS TO GENERATE T CELLS EXPRESSING CD19-SPECIFIC CHIMERIC ANTIGEN RECEPTOR

P Kebriaei[1,*], H Huls[2], H Singh[2], S Olivares[2], M Figliola[2], M Dawson[2], B Jena[2], R Jackson[2], D Bosque[1], G Rondon[1], I McNiece[1], P Hackett[3], E Shpall[1], R Champlin[1], L Cooper[2]
[1]Stem Cell Transplant, [2]Pediatrics, MD Anderson Cancer Center, Houston, [3]Genetics, University of Minnesota, Minneapolis, United States

Background: T cells can be genetically modified *ex vivo* to redirect specificity upon enforced expression of a CAR that recognizes tumor-associated antigen (TAA) independent of human leukocyte antigen.
Aims: We report a new approach to non-viral gene transfer using the *Sleeping Beauty* (SB) transposon/transposase system to stably express a 2nd generation CD19-specific CAR (designated CD19RCD28) in autologous and allogeneic T cells manufactured in compliance with current good manufacturing practice (cGMP) for Phase I/II trials.
Methods: T cells were electroporated using a Nucleofector device to synchronously introduce DNA plasmids coding for SB transposon (CD19RCD28) and hyperactive SB transposase (SB11). T cells stably expressing the CAR were retrieved over 28 days of co-culture by recursive additions of g-irradiated artificial antigen presenting cells (aAPC) in presence of soluble recombinant interleukin (IL)-2 and IL-21. The aAPC (designated clone #4) were derived from K562 cells and genetically modified to co-express the TAA CD19 as well as the co-stimulatory molecules CD86, CD137L, and a membrane-bound protein of IL-15. The dual platforms of the SB system and aAPC are illustrated in Figure 1.
Results: To date we have enrolled 11 patients with multiply relapsed ALL (n=4) or B-cell lymphoma (n=7) on three investigator initiated trials at MD Anderson Cancer Center to infuse thawed patient- and donor-derived CD19-specific T cells in the adjuvant setting after autologous (n=3), allogeneic adult (n=7) and umbilical cord (n=1) hematopoietic stem-cell transplantation (HSCT). Each clinical-grade T-cell product was subjected to a battery of in-process testing to complement release testing. Four adult patients have been treated following allogeneic HSCT (ALL, n=3; NHL, n=1), beginning at a dose of 10^6 and escalating to 10^7 modified T cells/m^2. No toxicities have been noted to date. In our

first dose cohort (10^6T cells/m^2), we could not detect sustained persistence of CAR+ T cells, and the 3 patients in this cohort relapsed. We then infused a higher dose of T cells (10^7T cells/m^2) on a compassionate basis to two of these patients with ALL: One patient relapsed, while one patient obtained a 4th complete remission with B-cell aplasia and persistent expression of the CAR+ T cells as of his last follow-up 4 months after T cell infusion.

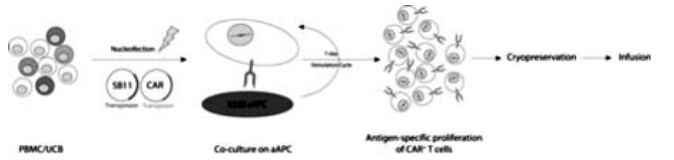

Figure 1.

Summary and Conclusions: We report the first human application of the *SB* system to genetically modify clinical-grade cells, which can be achieved at less cost compared with clinical grade virus. Our data enhance the translational appeal of electroporation of the *SB* system and aAPC-mediated propagation of T cells. Importantly, infusing CD19-specific CAR+ T cells in the adjuvant HSCT setting is feasible and safe and may provide an effective approach for maintaining remission in patients with high risk, CD19+ lymphoid malignancies.

[1]UCLA Medical Center, Los Angeles, [2]National Cancer Institute, Bethesda, [3]Memorial Sloan-Kettering Cancer Center, New York, [4]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [5]Department of Medicine - Hematology/Oncology, University of Wisconsin, Madison, [6]University of Rochester Medical Center, Rochester, [7]Ohio State University Medical Center, Columbus, [8]Department of Medicine, Division of Hematology, University of Washington Medical Center, Seattle, [9]Department of Medicine, Division of Hematology, Stanford University Medical Center, Stanford, [10]Department of Lymphoma/Myeloma, University of Texas MD Anderson Cancer Center, Houston, [11]Oncology/Hematology Division, University of Nebraska Medical Center, Omaha, [12]SAIC Frederick National Laboratory for Cancer Research, Frederick, [13]Pharmacyclics, Inc., Sunnyvale, United States

Background: Diffuse large B-cell lymphoma (DLBCL) has two molecular subtypes: ABC and germinal center B cell-like (GCB). Survival in the ABC subtype is sustained by "chronic active" BCR signaling. Mutations affecting the BCR subunit CD79B occur in 21% of the ABC subtype but only 5% of GCB tumors. A second BCR-related pathway coordinated by MYD88, an adapter for Toll-like receptors, is also relevant. A constitutively active MYD88 mutant (L265P) is frequent in ABC DLBCL tumors (29%) but rare in GCB DLBCL. CD79B and MYD88 L265P mutations often coexist in ABC DLBCL tumors, suggesting oncogenic collaboration, but can also occur alone. We will present updated results of this international, multicenter, phase 2 study of single-agent ibrutinib, a first-in-class inhibitor of BTK, in R/R DLBCL.

Aims: We tested the hypothesis that ibrutinib would be more active in ABC than GCB DLBCL because of the dependence on BCR signaling. However, we also assessed the association of CD79B and MYD88 mutations with response. The primary objective was to assess the overall response rate (ORR) categorized by subtype. Response was investigator-determined using the revised IWG Criteria for NHL. Secondary objectives of the study were to assess the safety and tolerability of ibrutinib in DLBCL.

Methods: Patients received ibrutinib 560 mg PO QD until disease progression. Gene expression profiling of formalin-fixed paraffin-embedded biopsy tissues using Affymetrix arrays was used to identify the subtype; Sanger sequencing was used to identify CD79B and MYD88 mutations. Patients underwent CT and PET scans pre-treatment and every 2 cycles (one cycle=28 days). 70 patients were enrolled; median age 64 yrs (28-92); male 71%; High-Intermediate/High IPI 59%; disease ≥10 cm 23%; median prior treatments 3 (1-7); relapsed 27%, refractory 54%, unknown 19%; prior SCT 23%; median time from diagnosis 19 months (5-332). For analysis of ORR and mutation status, we also included 10 patients with ABC DLBCL treated on an expansion component of the phase I, at the same dose and schedule. All patients had the study explained to them prior to their enrollment and voluntarily consented to participate in the study.

Results: Safety data from 70 patients identified no new safety signals; 66 patients were evaluable for response. In ABC patients, responses were observed in 12/29 patients for an ORR=41% (CR 17%, PR 24%); in GCB, ORR was 5% (1/20) with no CRs; no responses were observed in the unclassifiable cases. Thus, ibrutinib showed a preferential response activity in ABC *versus* GCB DLBCL (P=0.0071, Fisher's exact test). Median overall survival (OS) was 9.76 months for the ABC subtype and 3.35 months for the GCB subtype. Responses were seen in ABC DLBCL with CD79B mutations (71%; 5/7) and wild type CD79B (34%; 10/29), suggesting ibrutinib sensitivity does not require a BCR mutation. Interestingly, 4 of 5 cases with mutations in both CD79B and MYD88 responded indicating that MYD88 status does not preclude response to ibrutinib. However, tumors with only MYD88 mutations (n=5) did not respond (P=0.0476, Fisher's exact test), suggesting a MYD88-dependent but BCR-independent pathogenesis for some ABC DLBCL tumors.

Summary and Conclusions: Ibrutinib showed a clinically meaningful ORR in R/R ABC DLBCL, but not in the GCB subtype. Results are consistent with an essential role of BCR signaling in ABC DLBCL, and future trials will be planned with this subtype.

RECOMBINANT CD95-FC (APG101) PREVENTS GRAFT-VERSUS-HOST DISEASE IN MICE WITHOUT DISABLING ANTI-TUMOR CYTOTOXICITY AND T CELL FUNCTIONS

N Hartmann[1], J Messmann[1], F Leithäuser[2], M Kluge[3], H Fricke[3], K Debatin[1], G Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, [2]Institute of Pathology, University Ulm, Ulm, [3]Apogenix GmbH, Heidelberg, Germany

Background: Graft-*versus*-host disease (GVHD) induced by transplant-derived T cells represents a major complication after allogeneic bone marrow transplantation (BMT). These T cells, however, also support engraftment, early T cell immunity and mediate the graft-*versus*-tumor (GVT) effect. Cytotoxic effector functions and subsequent target cell destruction by transplant-derived allogeneic T cells are predominantly mediated by the CD95/CD95L and the perforin/granzyme system.
Aims: APG101 is a novel human recombinant fusion protein, consisting of the extracellular part of CD95 and the Fc domain of an IgG1 antibody and inhibits CD95L-mediated apoptosis. APG101 was tested for its ability to prevent GVHD in an allogeneic BMT model without abrogating the GVT effect.
Methods: To analyze APG101 treatment on GVHD development, lethally irradiated B6D2F1 (H-2^{bxd}) mice were reconstituted with C57BL/6 (H-2^{b})-derived BM and spleen cells and treated with APG101 starting either one day before or 6 or 13 days after transplantation. By co-injection of either P815 mastocytomas or primary B-ALL cells into transplanted mice, influence of APG101 on GVT effect was tested. Further, effect of APG101 on donor chimerism and phenotype, function, and homing of allogeneic T cells was monitored.
Results: *In vitro*, APG101 treatment inhibited CD95L-mediated T cell apoptosis but did not affect T cell proliferation or development of alloantigen-specific cytotoxic T cells. Treatment of allogeneic BM-transplanted animals starting one day before or 6 days after transplantation efficiently prevented clinical GVHD and increased survival to nearly 100%. No inhibition of GVHD was detected when treatment started 13 days after transplantation. Most importantly, APG101 treatment did not interfere with the GVT-effect since P815 mastocytoma and primary Bcr-Abl-transformed B cell leukemias were completely eradicated by the alloantigen-specific T cells. Donor chimerism of transplanted animals or phenotype, function, and homing of alloantigen-specific T cells was unaltered by APG101 treatment.
Summary and Conclusions: Inhibiting CD95/CD95L interaction by APG101 is an effective therapeutic approach to prevent GVHD while preserving anti-tumor cytotoxicity and early T cell immunity. These data suggest that APG101 could be incorporated into protocols for GVHD prevention and treatment during BMT.

S1182

KREC QUANTIFICATION IS A SUITABLE MARKER TO MONITOR THE DELAY IN EARLY B CELL RECONSTITUTION ASSOCIATED WITH ACUTE GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Mensen[1,*], C Ochs[1], S Demski[1], P Hemmati[2], G Vuong[2], O Penack[2], J Westermann[2], S Fillatreau[3], B Dörken[2], C Scheibenbogen[1], R Arnold[2], I Na[2]
[1]Institute for Medical Immunology, [2]Department of Hematology, Onocology and Tumorimmunology, Charité Berlin CVK, [3]German Rheumatism Research Center, Berlin, Germany

Background: The curative effect of allogeneic hematopoietic stem cell transplantation (alloHSCT) is limited by infectious complications and graft-*versus*-host disease (GvHD). B cell dysfunction following delayed immune reconstitution substantially contributes to an increased risk for life-threatening infections after alloHSCT.
Aims: Whereas chronic GVHD is known to negatively influence the B cell lymphopoiesis, less is known about the impact of acute GvHD on early B cell reconstitution. For this, we investigated B cell subset reconstitution kinetics in adult patients diagnosed with acute leukemia. Patients gave informed consent.
Methods: We phenotypically and functionally determined different B cell subsets by flow cytometry before and within six months after alloHSCT and performed RT-PCR quantification of kappa-deleting recombination excision circles (KREC), which are non-replicative episomal plasmids generated during bone marrow B cell development.
Results: We observed a significant deficiency of CD19+ B cells already pretransplant that proceeded during the first month post transplantation (mean cells/mL blood±SEM: 10±3 pretransplant, 4±1 day14, 3±1 day28 post alloHSCT; 43±8 healthy donor). During that time period, detectable B cells exhibited a highly activated (CD95+ and CD86+) phenotype with significantly reduced expression levels of the survival receptor BAFF-R and the chemokine receptors CCR7, CXCR5 and CXCR4. The predominance of naïve and memory B cell subsets indicated the putative origin from the donor graft. Early onset of bone marrow neogenesis was seen in 52% of patients, characterized by a strong increase of transitional B cells between day 60 and 90 post alloHSCT (120±75 day90). These transitional B cells exhibited normal expression of activation markers, but reduced expression of BAFF-R and CCR7. KREC quantification revealed a highly positive and significant correlation between absolute KREC copy numbers and transitional B cells (Spearman: r=1.00, P=0.003) indicating ongoing B cell neogenesis in patients with an early recovering B cell reconstitution. In contrast, naïve and memory B cells did not significantly correlate to the KREC copy numbers. In those patients, characterized by a late recovering B cell reconstitution (48%), low transitional B cell counts between day 60 and 90 were correlated with low KREC copy numbers (r=0.94, P=0.02). Interestingly, the delay in B cell reconstitution was significantly associated with acute GvHD as well as pretransplant myeloablative conditioning (MAC) compared to patients without GvHD and non-MAC treatment (GvHD: 73% *vs* 29%, Fisher´s exact P=0.047; non-MAC: 45% *vs* 93%, P=0.021). KREC level positively correlated with high transitional B cell counts in patients without GvHD (r=1, P=0.003).
Summary and Conclusions: From our data we conclude, that early onset of B cell reconstitution in alloHSCT patients is characterized by a switch in B cell subset distribution and function, which parallels the shift from graft-derived B cells towards newly regenerating B cells within three months after transplantation. Systemic acute GvHD is significantly associated with delayed B cell reconstitution and potentially reflects the consequence of bone marrow niche destruction by alloreactive T cells and pretransplant conditioning. Furthermore, our data reveal KREC quantification as a suitable marker to monitor early B cell neogenesis after alloHSCT as KREC levels are highly comparable to transitional B cell reconstitution kinetics, allowing to estimate bone marrow output post alloHSCT in dependency on different clinical parameters such as acute GvHD.

S1183

MULTI-GENOTYPE OF MINOR HISTOCOMPATIBILITY ANTIGENS (MHAGS) TO STUDY GRAFT VERSUS HOST DISEASE (GVHD) AND GRAFT VERSUS LEUKEMIA (GVL) EFFECTS IN ALLOGENEIC STEM CELL TRANSPLANTATION

F Cattina[1,*], C Skert[1], S Bernardi[1], E Ottaviani[2], M Bochicchio[2], I Iacobucci[2], S Soverini[2], F Bonifazi[2], M Arpinati[2], M Motta[2], E Toffoletti[3], D Damiani[3], A Santoro[4], F Fabbiano[4], D Pastore[5], G Specchia[5], G Console[6], B Martino[6], V Guadagnuolo[2], C De Benedittis[2], M Malagola[1], C Bergonzi[1], C Filì[1], A Turra[1], R Ribolla[1], V Cancelli[1], E Alghisi[1], S Perucca[1], A Di Palma[1], G Martinelli[2], D Russo[1]
[1]Chair of Hematology, University of Brescia, Brescia, [2]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, [3]Division of Hematology and BMT, Udine, [4]U.O.di Ematologia ed UTMO, Ospedali Riuniti Villa Sofia-Cervello, Palermo, [5]Hematology, A.O.U. Policlinico di Bari, Bari, [6]Azienda Ospedaliera Bianchi Melacrino Morelli, Reggio Calabria, Italy

Background: The outcome of allogeneic stem cell transplantation (Allo-SCT) is closely related to graft *versus* host disease (GvHD) and graft *versus* leukemia (GvL) effects which, in part, are mediated by mHAgs. Twenty-six mHAgs (see Table 1) have been identified and reported to be differently and variably correlated with GVHD or GVL, but a simultaneous method to genotype a so large panel of mHAgs has never been employed.

mHAgs correlated with GvHD	mHAgs correlated with GvL	mHAgs correlated with both GvHD and GvL	mHAs with clinical significance to be determined
UGT2B17	ACC-1, ACC-2, ACC-6, C19orf48, HB-1, LB-ADIR-1, LB-LY75-1K, LB-MR1-1R, LB-MTHFD1-1Q, LB-PTK2B-1T, LRH1	HA-1, HA-2, HA-8, CD31	ACC-4, ACC-5, CTL7A7, DPH1, DRN7, HA-3, HEATR-1, P2RX7, LB-ECGF-1H, UTA2-1

Table 1.

Aims: The aim of this work has been to develop a feasible method to genotype all the 26 mHAgs described so far and to test them for their correlation with GVHD and GVL in a group of donor/recipient pairs submitted to allo-SCT.
Methods: For a multi-genotype of 23 mHAgs we used a Maldi-Tof IPlex Gold technology (3 multiplex). This assay is relatively fast and requires a small amount of DNA. For the other three mHAgs we designed other three assays: two based on capillary sequencing of PCR products (for LB-MR1-1R and LRH1) and the last on PCR alone (for UGT2B17). By these methods, we tested the 26 mHAgs in 70 donor/recipient pairs with 4-digit high resolution typing that underwent allo-SCT (sibling or MUD) because of Philadelphia positive CML (n=46) or ALL (n=24).
Results: Maldi-Tof IPlex Gold technology proved a high degree of efficiency. Out of a total of 3430 SNPs a good genotype was obtained in 3383 (98.6%). As expected, sibling pairs showed most identity of MUD pairs. In the setting of

MUD pairs, some immunogenic differences were correlated with a better disease free survival, suggesting a role in driving GvL reaction. Notably, the presence of these differences did not modify the risk and the incidence of GvHD. Furthermore, we confirmed that mHAg CD31 shows frequently an immunogenic mismatch between recipient and donor with graft *versus* host direction (6 patients/70; 8.6%) and correlates with a better disease free survival.
Summary and Conclusions: Our data generated by a multi-genotype technique confirm the role of mHAgs in addressing GvL (in some cases without GvHD) and suggest that a study of mHAgs could be perfomed before transplant in order to better investigate the role of the known and new mHAgs involved in GvHD and GvL effects. Work supported by Lions Club "Bassa Bresciana" and BCC di Pompiano e Franciacorta Founds.

S1184

ROLE OF ALPHA4BETA7 INTEGRIN AND P-SELECTIN-LIGAND EXPRESSION FOR AGVHD INDUCTION AND AS POTENTIAL PREDICTIVE MARKERS FOR INTESTINAL AGVHD

C Bäuerlein[1,*], A Garrote[1], C Brede[1], A Mottok[2], M Chopra[1], M Ritz[1], M Balz[1], K Mattenheimer[1], C Kiesel[1], P Schlegel[3], H Einsele[1], U Syrbe[4], A Beilhack[1]
[1]Department of Medicine II, University Hospital Würzburg, [2]Department of Pathology, Würzburg University, [3]Department of Pediatrics, University Hospital, Würzburg, [4]Charité University Medicine, Berlin, Germany

Background: Acute graft-*versus*-host disease (aGvHD) is an immune syndrome associated with allogeneic hematopoietic stem cell transplantation (allo-HCT) that is mediated by alloreactive donor T-cells attacking the gastrointestinal tract, liver, and skin of the host. To cause aGvHD, alloreactive T-cells require the expression of appropriate homing receptors to efficiently migrate from secondary lymphoid organs as their priming sites to peripheral target tissues. Previously, we identified $\alpha4\beta7$ integrin and P-selectin-ligand expressed on peripheral blood (PB) alloreactive T-cells in a hyeracute GvHD mouse model. Therefore, we envisioned the development of a predictive test based on the homing receptor expression profile of PB T-cells to identify patients at risk of aGvHD before disease onset and for timely preventive therapeutic interventions.
Aims: To functionally test the relevance of $\alpha4\beta7$ integrin and P-selectin-ligand expression for T-cell homing into aGvHD target organs and to determine the time frame of homing receptor expression on PB T cells and its potency to predict development of aGvHD.
Methods: We employed two well-established allo-HCT mouse models [hyperacute GvHD MHC major mismatch model, C57Bl/6, H-2^b→ Balb/C, H-2^d or clinical relevant aGvHD minor histocompatibility antigen mismatch (miHAg) model, C57Bl/6, H-2^b→ Balb/B, H-2^b]. To induce aGvHD we transplanted C57Bl/6 wild type bone marrow together with T-cells isolated from C57Bl/6 mice of wild type or genetic knock-out mice [deficient for $\alpha4\beta7$ integrin (β7-ko) alone or fucosyltransferase VII (deficient for P-selectin ligand) and β7 (FucT7/β7-dko)]. Intestinal donor T-cell infiltration was assessed by immunofluorescence microscopy. PB was analyzed daily for donor T-cell distribution and homing receptor expression by multi-parameter flow cytometry. Histopathological stainings were used for aGvHD scoring.
Results: Transplanting β7-ko or FucT7/β7-dko donor T-cells resulted in significantly reduced cell numbers in the small bowel compared to recipients of WT donor T-cells (β7-ko: 2.7-fold $CD4^+H\text{-}2K^b+$ and 2.6-fold $CD8^+H\text{-}2K^b+$; FucT7/β7-dko: 3.6-fold $CD4^+H\text{-}2K^b+$ and 3.9-fold $CD8^+H\text{-}2K^b+$ on day+6 after allo-HCT) confirming the importance of these receptors for the homing of alloreactive T-cells into the intestinal tract. Histopathological aGvHD scoring confirmed less tissue damage of the gastrointestinal tract in β7-ko and FucT7/β7-dko donor T-cell recipients compared to recipients of WT T-cells. Daily PB analyses revealed in miHAg allo-HCT recipients that alloreactive donor T-cells can be readily detected 6 to 10 days before the onset of clinically apparent aGvHD symptoms. Relative values as well as absolute numbers of T-cells expressing $\alpha4\beta7$ integrin and P-selectin-ligand significantly exceeded those in syngeneic controls from day+6 on after allo-HCT indicating their potential use as predictive markers.
Summary and Conclusions: Our data demonstrate that $\alpha4\beta7$ integrin and P-selectin ligand expressing T-cells essentially contribute to the pathophysiology of intestinal aGvHD. As $\alpha4\beta7$ integrin and P-selectin ligand expressing donor T-cells can be detected in the PB up to 10 days before aGvHD onset we postulate the detection of $\alpha4\beta7$ integrin and P-selectin-ligand on alloreactive donor T-cells as promising candidates for a predicitive test to identify patients at risk before the clinical manifestation of aGvHD.

S1185

IN VITRO-GENERATED MYELOID-DERIVED SUPPRESSOR CELLS (MDSC) INHIBIT GRAFT-VERSUS-HOST DISEASE (GVHD) IN MICE WHILE MAINTAINING THE GRAFT-VERSUS TUMOR EFFECT

J Messmann[1], M Lutz[2], F Leithäuser[3], K Debatin[1], G Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, [2]Institute of Virology and Immunobiology, Würzburg, [3]Institute of Pathology, University Ulm, Ulm, Germany

Background: Allogeneic bone marrow transplantation (BMT) is a curative treatment modality for hematopoietic malignancies such as acute and chronic leukemias and lymphomas. Mature donor T cells in the allograft support engraftment, promote early T cell immunity of the recipient and mediate the graft-*versus*-leukemia (GVL) effect. However, these donor T cells are also responsible for the induction of graft-*versus*-host disease (GVHD) by attacking recipient tissue such as liver, skin, and bowel leading to significant morbidity and mortality. Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of myeloid precursors suppressing T cell activation and proliferation and might therefore be a putative cellular therapy for GVHD prophylaxis.
Aims: Therefore, we tested whether *in vitro*-generated MDSCs suppress GVHD development without interfering with the GVL effect.
Methods: MDSCs were generated *in vitro* by culturing BM cells in the presence of GM-CSF. After 4 days more than 90% of the cells exhibit the $CD11b^+Gr\text{-}1^+$ MDSC phenotype. To test, whether MDSCs prevent GVHD, C57BL/6 (B6, H-2^b)-derived MDSCs were co-transplanted with allogeneic BM and spleen cells from B6 mice into either lethally irradiated B6D2F1 (H-2^{bxd}) or B6.bm1 (H-k^{bm1}) mice. By co-injecting syngeneic tumor cells together with the BM transplant, the effect of MDSC transplantation was analyzed on the GVL effect. Influence of MDSCs on T cell responses after transplantation was defined by analyzing cytokine levels, activation status and number of allogeneic T cells.
Results: In-vitro generated MDSCs efficiently suppressed alloantigen-specific T cell proliferation *in vitro*. Transplantation of 1×10^7 MDSCs together with allogeneic BM and spleen cells efficiently prevented clinical GVHD. Due to MDSCs injection survival was increased to 100% in the B6 into B6.bm1 BMT model while 70% of the animals survived in the B6 into B6D2F1 BMT model. Effect of MDSCs was dosage dependent since clinical GVHD increased when numbers of transplanted MDSCs were reduced. Histological GVHD, however, was not totally prevented by MDSCs since lymphocyte infiltrations were still detectable in liver and intestine. MDSCs homed into lymphoid organs and GVHD target organs but did not interfere with the proliferation, phenotype or cytotoxicity of allogeneic T cells. However, in the presence of MDSCs, GVHD-associated cytokines TNF-α and IFN-γ were drastically decreased in the serum of transplanted mice. Most importantly, co-transplantation of MDSCs did not interfere with the GVL effect, since syngeneic thymoma cells were still efficiently eradicated by alloantigen-specific T cells.
Summary and Conclusions: Co-transplantation of *in vitro*-generated MDSCs efficiently prevented clinical and histological GVHD while preserving the T cell-mediated tumor cytotoxicity, indicating that MDSCs might represent a cellular treatment strategy after allogeneic BMT.

FUNCTIONAL CHARACTERISATION OF NOVEL REGULATORS OF HAEMATOPOIESIS: FROM GWAS TO FUNCTION

E Bielczyk-Maczyńska[1], N Soranzo[2], W Ouwehand[1], A Cvejic[1,*]
[1]Haematology, University of Cambridge, Cambridge, [2]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: Platelet count and volume are independent risk factors for heart attacks and ischaemic strokes. We therefore used meta-analyses studies (GWAS) to identify genes encoding novel regulators of megakaryopoiesis and platelet formation (HaemGen Consortium, Nature,2011:480,201). For about three-quarters of the 68 genetic signals associated with platelet count and volume credible gene candidates could be inferred. Two-third of these encode proteins hitherto unknown to be implicated in megakaryopoiesis and platelet formation. We hypothesise and have preliminary evidence that these new proteins are important rate-limiting factors of megakaryopoiesis and platelet formation, making them prime targets for further functional characterisation.
Aims: To delineate the function of genes identified by a platelet GWAS by gene knockdown in a relevant model organism.
Methods: To this end, we performed a high-throughput reverse genetic screen in zebrafish using morpholino (MO) knock down approach. This was followed by in-depth functional analysis of selected genes using a wide panel of different haematopoietic markers with the main aim to further our understanding of the function of the novel regulators of blood formation.
Results: We included 16 genes in the screen to identify novel pathways essential in thrombopoiesis and haematopoiesis in general. Knock down of all but four resulted in 50–90% reduction in the number of thrombocytes in a CD41-transgenic zebrafish. To further investigate lineage-specific effects of the candidate genes we assessed the status of definitive erythropoiesis, myelopoiesis and lymphopoiesis in MO injected embryos. The information gleaned from the initial knock-down/phenotyping was used to generate heat-map of gene expression profiles and to cluster genes with similar phenotypes. Consequently, we were able to hierarchically position candidate genes on the haematopoietic tree and to assign them a potential role during haematopoietic differentiation.
Summary and Conclusions: Using the from-GWA study-to-function strategy we have not only identified a series of genes that represent novel regulators of thrombopoiesis and haematopoiesis, but this work also represents, to our knowledge, the first example of a functional genetic screening strategy that is a critical step toward obtaining biologically relevant functional data from GWA study for blood cell traits. The results of these studies are now informing our next step in exploring the relationship between rare sequence variants in platelet GWAS-genes and the count and volume of platelets.

LOW/NEGATIVE EXPRESSION OF PDGFR-ALPHA IDENTIFIES THE CANDIDATE PRIMARY STROMA STEM/PROGENITOR CELLS IN ADULT HUMAN BONE MARROW.

H Li[1], R Ghazanfari[1], D Zacharaki[1], M Kassem[2], S Scheding[1,3,*]
[1]Stem Cell Center, University of Lund, Lund, Sweden, [2]Molecular Endocrinology Laboratory (KMEB), University of Southern Denmark, Odense, Denmark, [3]Dept. of Hematology, University Hospital Lund, Lund, Sweden

Background: Human bone marrow (BM) contains a rare population of non-hematopoietic mesenchymal stem cells (MSC) that are of central importance for the hematopoietic microenvironment. We and others have shown that primary BM-MSC were highly enriched in lin-/CD45-/CD271+ cells as reflected by high CFU-F frequencies up to ca. 1 in 20. However, a more precise phenotypical definition of these rare cells is required to be able to study the exact cellular properties of these putative stem/progenitor cell population.
Aims: This study therefore aimed to identify novel and potentially better markers for the isolation and characterization of primary human MSC.
Methods: Comparative gene expression profiling was performed on human lin-/CD45- BM cells sorted based on CD271 expression. Protein expression of candidate surface marker genes was evaluated by flow cytometry. Candidate primary MSC populations as defined by the novel markers were sorted by FACS, and assayed for MSC properties *in vitro* and *in vivo* at single cell and bulk level.
Results: In total, 215 genes including cytokine, growth factor and extracelluar matrix (ECM) genes such as latent transforming growth factor (TGF)-beta binding proteins (LTBP2), lumican (LUM), connective tissue growth factor (CTGF), fibulin-1 (FBLN1), and vascular endothelial growth factor (VEGF) were uP-regulated in the lin-/CD45-/CD271+ subset compared to CD271- cells. Twenty eight of the upregulated genes correlated to surface expressed molecules including previously described MSC markers such as CD140b and CD106. The majority of the genes identified by this approach, however, represented novel MSC marker candidates, such as CD151, CD81, and CD140a. FACS analysis of the expression of the potential novel markers on lin-/CD45-/CD271+ cells revealed two staining patterns, *i.e.* marker expression was either directly correlated with CD271 expression and did thus not enable to further enrich for CFU-F (*e.g.* CD151), or the novel marker was only expressed on a fraction of the lin-/CD45-/CD271+ cells, thus potentially allowing to identify a CFU-F and a non-CFU-F containing population within the CD271+ cells. In fact, sorting based on CD140a (PDGFR alpha) expression allowed to sort a population of lin-/CD45-/CD271+/CD140a low/- cells with a CFU-F frequency of 1 in 5 (24.15±4.51 CFU-Fs per 100 plated cells, n=6). Gene expression profiling of this close-to-pure population of CFU-F showed uP-regulation of cell cycle inhibitor genes such as CDKN1A, BTG3 and DUSP3, indicating a quiescent status of the cells, which was furthermore confirmed by cell cycle analysis (>98% in G_0). In accordance with the hematopoiesis maintenance function, expression of genes encoding ECM proteins such as laminin subunit alpha-4 (LAMA4), adrenomedullin (ADM) and collagen type I alpha 1 (COL1A1) were also highly higher in CD140a- cells compared to the CD140+ population. PCR analysis moreover demonstrated high expression of ALPL, PPARg, and ACAN as well as Oct4, Sox2 and Nanog in primary lin-/CD45-/CD271+/CD140a low/neg MSC. These cells furthermore gave rise to typical cultured MSC (expression of standard surface markers, in-vitro differentiation capacity), and they formed bone, adipocytes and hematopoietic stroma when transplanted s.c. into NOD-SCID mice.
Summary and Conclusions: Low/negative expression of CD140a on lin-/CD45-/CD271+ BM cells allows identify a close to pure population of candidate stroma stem/progenitor cells. These results will enable to better characterize this important cellular component of the hematopoietic microenvironment.

HIF-1ALPHA AND HIF-2APLPHA ARE NOT ESSENTIAL FOR STEADY-STATE HEMATOPOIETIC STEM CELL MAINTENANCE

A Guitart[1,2,*], P Pollard[3], T Holyoake[2], T Enver[4], P Ratcliffe[3], K Kranc[1,2]
[1]MRC Centre for Regenerative Medicine, Edinburgh, [2]Paul O'Gorman Leukaemia Research Centre, Glasgow, [3]Henry Wellcome Building for Molecular Physiology, Oxford, [4]UCL Cancer Institute, London, United Kingdom

Background: Lifelong adult hematopoiesis critically depends on rare multipotent hematopoietic stem cells (HSCs). These HSCs reside in niches within the bone marrow (BM) where they are subject to very low oxygen concentrations. Therefore hypoxia signalling is thought to play important roles in HSC maintenance. So far, the main characterised mediators of these pathways are the hypoxia-inducible factors (HIFs): HIF-1α and HIF-2α. These transcription factors have both common and different characteristics such as tissue expression, regulation/degradation mechanisms or target genes. HIF-1α is known to play a major role in the primary response to acute hypoxia whereas HIF-2α is thought to be involved in late or chronic hypoxic response. Whereas the role of HIF-1α in the maintenance of HSCs has been studied, the role of HIF-2α which could be more important due to its involvement in chronic response to hypoxia still remains to be investigated.
Aims: The aim of this study was to determine the cell-autonomous role of HIF-2α in HSC maintenance and the collective requirement for both HIF-1α and HIF-2α in HSC functions.
Methods: Tissue conditional deletion of the HIF genes in mice using a Cre-LoxP approach was used. HIF-2$\alpha^{fl/fl}$or HIF-1$\alpha^{fl/fl}$; HIF-2$\alpha^{fl/fl}$ mice were crossed to Vav1-Cre strain to entirely delete the gene(s) of interest strictly within the adult hematopoietic system. These mice were subsequently analysed phenotypically using flow cytometry. Briefly, extracted cells from BM, spleen and thymus were stained to identify HSCs, progenitors (CMP, GMP, MEP and CLP) and differentiated cells (B cells, T cells, and myeloid cells). The function of HSCs and progenitors lacking HIF-2α or both HIF-1α and HIF-2α were evaluated using standard methods such as colony-forming cell (CFC) assays and serial transplantation.
Results: The constitutive hematopoiesis-specific deletion of HIF-2α or both HIF-1α and HIF-2α in mice does not affect HSC numbers and does not perturb steady-state hematopoiesis. In addition, the ability of these cells to generate colonies remains comparable to the controls. Furthermore, using serial transplantation experiments we demonstrate that HIF-2α is dispensable for HSC maintenance. We also show that HSCs lacking both HIF-1α and HIF-2α efficiently repopulate primary recipients indicating that deletion of HIF-2α does not exacerbate the phenotype resulting from HIF-1α deficiency.
Summary and Conclusions: Therefore, we conclude that intrinsic HIF-dependent signalling is not essential for steady-state HSC functions and, unlike HIF-1α, HIF-2α is dispensable for post-transplantation HSC self-renewal. HIF-1α and HIF-2α have therefore fundamentally different functions in HSCs. Taking into consideration the role of HIF factors in some leukaemias and hematopoietic disorders, these results implicate HIFs as good targets for therapy.

S1189

REGULATION OF NORMAL AND LEUKEMIC ADULT HEMATOPOIETIC STEM CELLS BY ESTROGEN SIGNALING

A Sanchez-Aguilera[1,*], D Martin-Perez[1], L Arranz[1], A Garcia-Garcia[1], S Lama[1], V Stavropoulou[2], S Martin-Salamanca[1], A Martin[1], J Isern[1], J Schwaller[2], S Mendez-Ferrer[1,3]
[1]Department of Cardiovascular Development and Repair, Centro Nacional de

Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [2]Department of Biomedicine, University Hospital and Children's Hospital, Basel, Switzerland, [3]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Although estrogens may affect the hematopoietic microenvironment, *e.g.* through their anabolic effect on bone, little is known regarding their potential role in the regulation of hematopoietic stem cell (HSC) maintenance, proliferation and survival. A potential cause of resistance to chemotherapy in leukemia is the existence of a primitive, quiescent population of leukemia stem cells (LSC) insensitive to cytotoxic therapies; therefore, interfering with pathways that regulate HSC quiescence may represent a therapeutic advantage by sensitizing LSC to chemotherapy.
Aims: To investigate the role of estrogen signaling in the regulation of HSC, and the feasibility of targeting this pathway as anti-leukemia therapy, using a drug already approved in the clinic (tamoxifen).
Methods: We performed a detailed analysis of hematopoiesis both in adult, estrogen receptor- deficient (Esr1-/- and Esr2-/-) and in wild-type (WT) male mice treated with the synthetic selective estrogen receptor modulator (SERM) tamoxifen. For leukemogenesis experiments, we used a mouse model of acute myeloid leukemia (AML) induced by MLL-AF9, which accurately reproduces the human disease. Mice treated with tamoxifen and conventional chemotherapy (doxorubicin plus cytarabine) were compared to mice receiving chemotherapy alone.
Results: Estrogen receptors Esr1 (ERα) and Esr2 (ERβ) were detectable and differentially expressed at the protein level by distinct hematopoietic progenitors. Treatment of WT mice with tamoxifen rapidly caused apoptosis and reduced the numbers of immunophenotypically defined short-term HSC and multipotent progenitors in the bone marrow. This effect was direct as per *in vitro* experiments and was associated with impaired short-term competitive reconstitution capacity of Esr1-/- bone marrow cells. In contrast, tamoxifen treatment induced cell cycle entry and increased the numbers of immunophenotypically defined long-term HSC. This expansion, however, was not associated with increased repopulation ability in competitive transplant assays, suggesting a functional impairment of HSC. In fact, tamoxifen-treated mice showed defective hematopoietic recovery after 5-fluorouracil challenge or sublethal irradiation. Deep sequencing studies have confirmed cell cycle changes and revealed candidate genes responsible for the differential effects of tamoxifen on distinct HSC populations. Hence, SERM can decrease the number of multipotent progenitors and reduce the frequency and/or activity of a quiescent, primitive repopulating stem cell. Therefore, we studied whether SERM could be used to control leukemic HSC quiescence/survival. Tamoxifen induced apoptosis of MLL-AF9-positive leukemic blasts *in vitro* and enhanced the pro-apoptotic effect of low doses of cytarabine, suggesting that SERM might allow for reduced chemotherapy regimes. Combined tamoxifen and chemotherapy significantly attenuated leukemia relapse in a mouse model of MLL-AF9-induced AML. Although tamoxifen did not prolong overall survival in this model of aggressive, chemoresistant AML, preliminary data showed decreased peripheral infiltration in tamoxifen-treated mice.
Summary and Conclusions: Our data indicate differential roles of estrogen signaling in the regulation of primitive hematopoietic cells, particularly in the control of HSC survival and proliferation, and demonstrate that therapeutic targeting of this pathway with already available ligands could prove a useful strategy to sensitize chemotherapy-resistant leukemia to cytotoxic treatments.

S1190

THE ROLE OF OSTEOCLASTS IN THE DEVELOPING LEUKEMIC STEM CELL NICHE IN A MOUSE MODEL OF ADULT T-CELL LEUKEMIA

T Mizukami[1,*], K Takizawa[1], M Kuramitsu[1], W Kuribayashi[1], R Hiramatsu[1], H Momose[1], J Yamazaki[2], W Hall[3], H Hasegawa[4], K Yamaguchi[1], I Hamaguchi[1]
[1]Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, Tokyo, Japan, [2]Fels Institute For Cancer Research & Molecular Biology, Temple University, Philadelphia, United States, [3]Medical Microbiology, University College Dublin, Dublin, Ireland, [4]Department of Pathology, National Institute of Infectious Diseases, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a lymphoproliferative disorder caused by HTLV-I infection. Although various chemotherapies have shown significant complete remission rates, most of the treated patients undergo relapse. These data indicate the existence of leukemic stem cells (LSCs) and a specific niche that regulates stemness and protects LSCs from chemotherapy.
Aims: We previously reported that ATL-LSCs isolated from a Tax-transgenic (Tax-Tg) mouse are enriched in the $CD117^+/CD38^-/CD71^-$ fraction of the lymphoma, and LSCs have the potential to reproduce the original tumor when transplanted into a NOD/SCID mouse. However, the niche of ATL-LSCs is still unclear. This study aimed to identify the LSC niche in ATL and clarify its role as a potential therapeutic target.
Methods: To identify the ATL-LSC niche *in vivo*, we performed a homing assay. Lymphoma cells isolated from a Tax-Tg mouse were transduced with the GFP gene by a lentivirus, and then sorted GFP^+ cells (2×10^6) were transplanted intraperitoneally into a non-irradiated NOD/SCID mouse. Homing of GFP^+ cells to tissues was traced by flow cytometry (FCM) at 16 h, and3,7, 14 and 21 days post-transplantation. To assess the effect of an osteoclast inhibitor in ATL bone marrow (BM), mice were subcutaneously injected with zoledronic acid (ZOL; 0.2 mg/kg) twice weekly.
Results: GFP^+ lymphoma cells were first detected in the spleen and BM at 16 h post-transplantation. No GFP^+ lymphoma cells were detected in the thymus or lymph nodes. Interestingly, more than 60% of first colonized cells in the spleen and BM at 16 h post-transplantation were ATL-LSCs ($GFP^+/CD117^+$ cells). From day 3 to7, more than 40% of colonizing cells in the BM and spleen were ATL-LSCs. These data indicate that ATL-LSCs prefer to colonize and proliferate in the spleen and BM. To identify the specific niche of ATL-LSCs in the BM, we performed imaging analysis of ATL-LSCs. ATL-LSCs ($GFP^+/CD117^+$ and $CD38^-/CD71^-/CD117^+$ cells) were mainly localized near the BM endosteal region of the trabecular bone. ATL-LSCs were attached to reticular cells in the trabecular bone, and the number of osteoclasts was significantly increased at the trabecular region. The increased number of osteoclasts correlated with an increased serum calcium concentration and decreased trabecular bone mass. FCM analysis and an *in vitro* differentiation assay confirmed that the number of osteoclast precursors was increased in ATL BM.
To clarify the role of osteoclasts in ATL BM, we treated the ATL mouse model with ZOL. As a result, ZOL significantly reduced the number of GFP^+ ATL cells in the BM. When ZOL was coadministered with an anti-cancer drug, the number of GFP^+ ATL cells was dramatically reduced in the BM, which extended the mouse survival rate significantly, whereas the anti-cancer drug alone had no effect. These data suggest that osteoclasts may have a function in development of the LSC niche. To clarify the key signals that induce osteoclasts in ATL BM, we are now attempting to isolate ATL-LSCs, GFP^+ ATL cells, blood endothelial cells, and fibroblastic reticular cells from normal and ATL BM to compare the gene expression profiles of each niche cell type.
Summary and Conclusions: We found that the ATL-LSC niche is located at the trabecular bone region in the BM, and that osteoclasts have a role in supporting ATL cells and development of the LSC niche in a mouse model of ATL. Therefore, osteoclasts may be a potential therapeutic target of ATL.

OXIDATIVE STRESS INFLUENCE HYDROXYMETHYLATION STATUS IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS IN VITRO

A Gonçalves[1*] J Leite[2], M Ferreira[2], P Guarino[2], C Domingues[2], R Alves[2], A Sarmento-Ribeiro [1]

[1]Applied Molecular Biology/University Clinic of Hematology and CIMAGO – Center of Investigation on Environment Genetics and Oncobiology/FMUC – Faculty of Medicine, University of Coimbra/Coimbra,[2]Applied Molecular Biology and University Clinic of Hematology/FMUC – Faculty of Medicine, University of Coimbra/Coimbra, Coimbra, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) accounts for about 15% and 25% of ALL in pediatric and adult cohorts, respectively, and originates from the malignant transformation of lymphocyte progenitor cells. However, the biology of T-ALL is poorly understood. Reactive oxygen species (ROS) are known to play a dual role in biological system, since they may be either harmful or beneficial to living systems. Increasingly evidence shows that oxidative stress and ROS are involved in carcinogenesis. Moreover, it is now clear that epigenetic mechanisms are as important as genetic changes in the development of cancer. Same studies suggest that oxidative DNA damage can affect patterns of DNA methylation leading to aberrant gene expression and possibly contributing to the development of malignancy.
Aims: In this work, we study the effect of hydrogen peroxide (H_2O_2) and superoxide anion ($O_2^{\cdot -}$) in ALL cells, with special emphasis on the action of oxidative stress (OS) in cell death and methylation status.
Methods: CEM cells (T-ALL cell line) were treated in the absence and presence of hydrogen peroxide and menadione ($O_2^{\cdot -}$ donor) and cell viability and density were analyzed by trypan blue assay. Intracellular levels of H_2O_2, $O_2^{\cdot -}$, GSH and mitochondrial potential were determined by flow cytometry (FC), using the fluorescent probes. Cell death and were also evaluated by optical microscopy and FC using the Annexin V/Propidium Iodide staining. We also analyzed apoptotic proteins expression levels, namely BAX, BCL-2, FAS, FAS ligand and caspases, and cell cycle by FC. Global DNA methylation and hydroxymethylation were analyzed by ELISA using commercial kits.
Results: Our results show that H_2O_2 and menadione decrease cell viability in a dose and time dependent manner. In fact, we observe that IC_{50} of H_2O_2 and menadione in CEM cells is 25 mM and 7.5 mM, respectively, after 24 hours. These compounds induce cell death mainly by late apoptosis/necrosis, through the decrease in mitochondrial membrane potential and increase in caspases levels, BAX/BCL-2 and FAS/FAS ligand ratios. Besides that, these effects may also be mediated by an increase in ROS levels and a decrease in GSH. Furthermore, these compounds induce S phase arrest and an increase in 5-hydroxymethylcytosine (5hmC) levels when cells are treated with 25 μM H_2O_2. These results may be related with oxidation of 5-methylcytosine via oxidative damage, and consequently induction of global hipomethylation. In contrary, in cells treated with menadione 7.5 μM we observe a decrease in 5hmC levels.
Summary / Conclusion: In conclusion, our results suggest that besides cell death induced by higher OS levels, ROS could influence hydroxymethylation status and interfere with global DNA methylation status and gene expression levels in acute lymphoblastic leukemia cells in vitro.

B1192

EXPRESSION OF VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR-1, VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR-2 AND FMS-LIKE TYROSINE KINASE-3 RECEPTOR IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M Ibrahim[1*], R Hammad[2], M Alrayes[3], M And A El Baddiny[1]

[1]Clinical Pathology, National Cancer Institute, Cairo University, [2]Girls Faculty of Medicine, Azhar University, [3]Clinical Pathology, Girls Faculty of Medicine, Al Azhar University, Cairo, Egypt

Background: The Fms-like tyrosine kinase3, FLT3, has been a subject of several studies as a prognostic marker in both pediatric and adult acute leukaemia. The vascular endothelial growth factor family (VEGF) members are well established as key regulators of angiogenesis processes. Studies have shown that the expression of these mediators of angiogenesis in cancer patients is associated with an adverse prognosis in different leukemias.
Aims: This work was conducted to evaluate the expression of these molecules, their relation to clinical and laboratory parameters having prognostic significance as well as their relation to survival and response to chemotherapy in paediatric ALL patients.
Methods: This work was carried out on 55 newly diagnosed childhood ALL patients who presented to the National Cancer Institute (NCI), Cairo University during the period between July 2010 and June 2011, after having a written consent. Patients were followed up till January 2012. Their age ranged from 0.33 to 17 years and the male: female ratio was 1: 0.89. They included 41 patients (74.5%) B-lineage ALL and 14 (25.5%) T-lineage.
The studied markers were evaluated by flow cytometry and results are expressed as percent expression (%) and Mean Flouresence intensity (MFI).
Results: FLT-3% and MFI were significantly higher in B-lineage than in T-ALL (P=0.004 & 0.02 respectively) and within the B-ALL; both were significantly higher in pre-B-ALL as compared to c-ALL (P=0.002 & 0.017 respectively). No statistically significant difference in VEGFR-1% and MFI as well as in VEGFR-2 % and MFI in B-ALL as compared to T-ALL. In B-ALL, both VEGFR-1% and MFI (P=0.014 and 0.006 respectively) and VEGFR-2 % and MFI (P=0.009 and 0.006 respectively) were significantly lower in patients with splenomegaly than in those without. No statistically significant difference was found between the studied parameters (VEGFR-1 % and MFI, VEGFR-2 % and MFI and FLT-3 % and MFI) and gender, lymphadenopathy, and hepatomegaly in either B- or T-ALL. In B-ALL, there was a significant positive correlation between VEGFR-1% and haemoglobin level (P=0.008, r=0.415), between VEGFR-2 % and CD10 % (P=0.015, r=0.379) and between FLT3 % and BM blast % (P=0.009, r=0.405). In T-ALL, there were significant positive correlations between FLT-3 %, VEGFR-1%, and VEGFR-2 % on one hand and CD34 (%) on the other (P=0.001, 0.041, and 0.002 respectively, r=0.826, 0.596, and 0.798 respectively). In B-ALL, there was highly significant positive correlations between VEGFR-1% and VEGFR-2% (P=<0.001, r=0.704). In T-ALL, there was significant positive correlations between FLT3 % and both VEGFR-1% and VEGFR-2% (P=0.016 &0.011 respectively, r=0.627 & 0.654 respectively) as well as a significant positive correlation between VEGFR-1% and both VEGFR-2% (P=0.002, r=0.762). None of the studied parameters had any impact on either disease-free survival (DFS) or overall survival (OS).
Summary / Conclusion: FLT-3 was significantly higher in B-lineage ALL than in T-ALL, and in pre-B- as compared to c-ALL. In the B-ALL, both VEGFR-1 and VEGFR-2 were significantly lower in patients with splenomegaly. - In the B-ALL, there was a significant positive correlation between VEGFR-1% and haemoglobin level, between VEGFR-2 % and CD10 % and between FLT3 % and BM blast %. Also, there was a highly significant positive correlation between VEGFR-1 and VEGFR-2. Angiogenic receptors could play different roles in B cells and T cells as seen by the significant positive correlation between both VEGFR-1 & VEGFR-2 and the expression of the stem cell marker CD34 in childhood T–ALL but not in B-ALL.

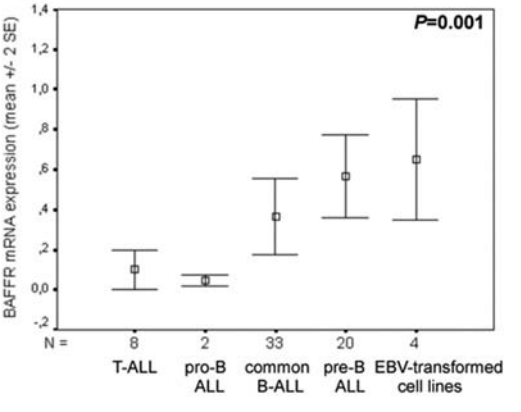
B1193

TNFRSF13B/TACI AND TNFRSF13C/BAFFR EXPRESSION IN ACUTE LYMPHOBLASTIC LEUKEMIA

M Speletas[1*], M Moschovi[2], N Argentou[1], E Kolokotsa[1], A Mamara[1], K Pieper[3], M Adamaki[2], H Eibel[3], A Germenis[1]

[1]Department of Immunology & Histocompatibility, University of Thessaly, Medical School, Larissa, [2]First Department of Pediatrics, Athens University Medical School, 'Aghia Sophia' General Children's Hospital, Athens, Greece, [3]Centre of Chronic Immunodeficiency, University Medical Centre Freiburg, Freiburg, Germany

Background: BAFF is a fundamental maturation and survival factor for mature normal and malignant B-cells, and among the three receptors that mediate BAFF signaling (BAFFR, TACI and BCMA), BAFFR seems to be the key molecule. Previous studies have shown that BAFF receptors are not expressed by normal progenitor B cells, while the contribution of BAFF signaling in ALL biology is still elusive.
Aims: The aim of this study was to investigate the expression of *TNFRSF13B/TACI* and *TNFRSF13C/BAFFR* receptors in ALL patients and their associations with clinico-laboratory characteristics of the disease.



Methods: Sixty-three ALL patients (male/female: 40/23, mean age: 8.2 years, range: 9 months - 72 years), including 55 with B-ALL (pro-B:2, common: 33, pre-B: 20) and 8 with T-ALL (pre-T:2, cortical:4, mature: 2) were enrolled. All patients were assessed with complete hematologic, flow cytometric and molecular

analyses (detection of BCR-ABL, E2A-PBX1, MLL-AF4 and TEL-AML1 rearrangements) and for the majority of them (52 out of 63 patients) data from cytogenetic and FISH analyses were also available. The mRNA expression of *TNFRSF13B/TACI* and *TNFRSF13C/BAFFR* was evaluated by qRT-PCR in all cases; the relative expression of each gene is presented as a multiple of the respective gene expression in isolated peripheral blood B cells of a healthy individual. The protein expression was confirmed by flow cytometry (TACI clone 1A1, BAFFR clone 11C1) in 8 B-ALL patients. Four EBV-transformed cell lines and Jurkat cells, with high and absent BAFFR and TACI expression respectively, were utilized as positive and negative controls in both molecular and flow cytometry studies.
Results: B-ALL patients displayed a remarkable mRNA expression of *TNFRSF13C/BAFFR*, ranging from absent in pro-B ALL to a higher expression in pre-B ALL (Figure 1). Consequently, we identified a positive correlation of *TNFSRF13C/BAFFR* expression with CD20, cIgM and the presence of E2A-PBX1 rearrangement. Moreover, the majority of ALL patients displayed very low to absent *TNFRSF13B/TACI* mRNA transcripts and only 3 patients with common-B and 2 with pre-B ALL exhibited a remarkable *TNFRSF13B/TACI* expression.
Summary / Conclusion: Anti-BAFF therapeutic approaches could be useful for the management of pre-B ALL patients, as well as in a proportion of other ALL patients with an aberrant expression of the abovementioned receptors.
This research has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program "Education and Lifelong Learning" of the National Strategic Reference Framework (NSRF) - Research Funding Program: Heracleitus II. B1194
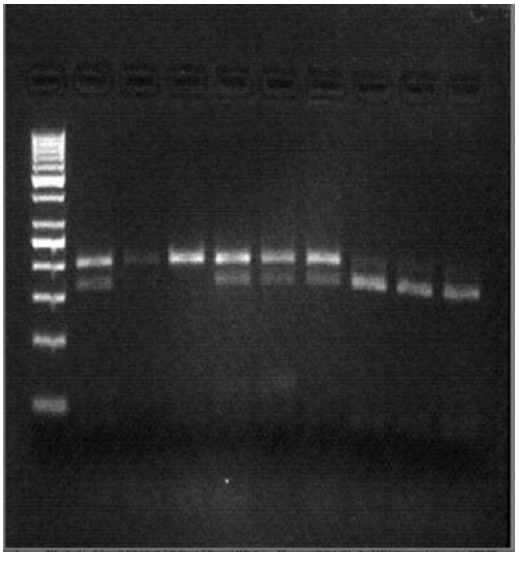
PAIRED IMMUNOPHENOTYPE COMPARISON OF DIAGNOSIS AND RELAPSE SAMPLES IN B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA
M Eveillard[1*], R Garand[1], N Robillard[1], S Wuillème[1], C Thomas[2], M Strullu[2], F Rialland[2], J Delaunay[3], P Chevallier[3], P Moreau[3], N Blin[2], M Béné[1]
[1]Hematology Laboratory, [2]department of Pediatrics, [3]department of Hematology, Centre Hospitalier Universitaire, Nantes , France

Background: Although great progress has been made in the treatment of acute lymphoblastic leukemia (ALL), relapse remains a major issue in the follow-up of these patients. Recent data about the emergence of subclones during haematological malignancies suggest that relapses could result from resistant cells initially in minority or from cells driven to resistance by previous treatments. Among the tools allowing for the characterization of leukemic cells, flow cytometry (FCM) is an essential approach. Increasingly used to evaluate minimal residual disease (MRD) based on the immunophenotypic features of the blasts at diagnosis, it can also allow to identify immunophenotypic shifts related to clonal evolution. Such an approach would be best studied by comparing follow-up samples from the same patients. In order to be thorough, this would however require that conditions as similar as possible are applied to both types of cells.
Aims: This work was designed to compare 1)the immunophenotypic features of B-ALL blast cells with those of normal hematogones and 2)potential immunophenotypic shifts at relapse.
Methods: FCM was performed simultaneously on thawed paired samples from 15 patients (9 children aged between 1 and 12 years old and 6 adults aged between 23 and 71 years old) with B-lineage ALL. With a three-tubes 8 colours panel comprising a backbone of CD45, CD34, CD22 and CD10, the expression of ten markers was examined and compared to that observed on normal hematogones contained in 29 bone marrow samples from healthy donors. These 10 markers were CD7, CD19, CD20, CD24, CD38, CD44, CD58, CD81, CD123 and CD304. Moreover, an additional four colours panel was used to examine the more recently described antigens CD200 and Her2Neu. The presence of leukemia associated immunophenotypes (LAIP) were defined as a difference in mean fluorescence intensity (MFI), between hematogones and blasts of at least 2 standard deviations.
Results: At diagnosis, the expression of each marker was at variance from that on hematogones for at least one patient. Antigens with the most aberrant expression were CD10, CD24 and CD81. Antigens with the least aberrant expression were Her2Neu, CD19, CD22, CD123 and CD20.
All patients retained at relapse the same global immunophenotype without any change in the EGIL classification (3 B-I, 8 B-II, 4 B-III). The expression of most markers was similar at diagnosis and relapse with at most 4 patients with modulation of a given antigen (CD10). There was no change at all for the expression of CD38 and only one patient each showed a change in the expression of CD44, CD58 or CD123. Immunophenotypic patterns associating variations of several antigens on a given population compared to hematogones, were globally stable. Only two patients showed major changes possibly associated with the emergence of a new clone.
Summary / Conclusion: This study confirms that B-ALL blast cells differ immunophenotypically from hematogones, although the latter have been reported to possibly be their normal counterpart. These data therefore comfort the interest of using LAIP in the detection of MRD in multiparameter FCM. Moreover, since molecular targets of therapeutic monoclonal antibodies do not shift sensibly, their use can also be considered at relapse.

B1195
GSTM1 GENOTYPE AS A RISK MODIFIER OF MDR1 C3435T - INDUCED RISK SUSCEPTIBILITY TO PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA
G Ebid[1*], S Kassem[2], A Kamel[1]
[1]Clinical Pathology, National Cancer Institute, Cairo University, [2]Biochemistry, Faculty of Physical Therapy,October 6 University, Cairo, Egypt

Background: *GSTM1* and *GSTT1* appear to be associated with a modest increase in the risk of acute lymphoblastic leukemia (ALL). *MDR1* C3435T polymorphism was also suggested as a risk factor for childhood ALL; individuals with TT allele have lower expression of P-gp than those with CC genotypes and hence less capable of extruding toxic substances and carcinogens.
Aims: To investigate the impact of *MDR1*gene C3435T polymorphism and both *GSTM1* and *GSTT1* polymorphisms, separately and in combination, on risk susceptibility to childhood ALL.
Methods: The study included 94 children with ALL and 314 apparently health control subjects. Multiplex-Polymerase chain reaction (PCR) was used to evaluate *GSTM1* and *GSTT1* status while PCR-restriction fragment length polymorphism (PCR-RFLP) was used for the detection of *MDR1* C3435T single nucleotide polymorphism.



Results: There was no significant effect of either *GSTM1* null or *GSTT1* null variant allele or both of them combined on susceptibility to ALL. On the other hand, *MDR1* CC, CT and TT genotype frequencies in childhood ALL patients were found to be 78.0%, 17.1% and 4.9 %, respectively vs. 91.2%, 8.8% and 0 % in the control group (P=0.016). *MDR1* gene C3435T homozygote and heterozygote have a 2.9 fold increased risk to develop ALL (OR = 2.918, 95%CI: 1.193-7.137,). There is a significant synergistic association between *GSTM1*-null allele and mutant *MDR* genotype homozygous TT or heterozygous allele CT on susceptibility to ALL with a 3.672 fold increased risk (p. value. 0.032 OR = 3.672, 95%CI: 1.059-12.733), however the presence of *GSTM1* abolished the effect of mutant *MDR1* allele on risk susceptibility to ALL (p. value. 0.193).
Summary / Conclusion: : the increased risk to develop pediatric ALL associated with *MDR1* gene C3435T homozygote and heterozygote is further potentiated by the presence of *GSTM1* null and abolished by the presence of *GSTM1*wild. Molecular genetic analysis is still required to understand genotype-genotype interaction and to clarify genotype-phenotype relation and their reflection on disease risk.

B1196
CAN WE KNOW MORE ABOUT ACUTE LEUKEMIA IN CHILDREN THROUGH EPIDEMIOLOGY?
T Maia[1*], M Benedito[2], A Ribeiro[3], M Ribeiro[1]
[1]Hematology, CHUC - Hospital geral, [2]Hematology, Hospital Pediátrico de Coimbra, [3]Hematology, CHUC- HUC, Coimbra, Portugal

Background: The Acute Leukemias (AL) are responsible for 30% of all pediatric cancers. They are biologically heterogeneous with distinct morphologic, cytogenetic and molecular characteristics. Recently, the knowledge of the AL epidemiology, molecular and cytological characteristics, has gained a crescent significance. Their high mortality rate makes the collection and systematic analysis of all biographic, geographic, clinical, cytogenetic and molecular data an important step as an attempt to contribute for a better knowledge of its etiology, physiology and pathogenesis.
Aims: To contribute for the knowledge of the epidemiologic and molecular pro-

file of AL in children.
Methods: Observational, retrospective and descriptive study, in children from the Center of Portugal, aged 0-13 years, diagnosed with AL in a central Pediatric Hospital, between 1st January 1999 and 31st December 2008. Several variables were searched: biographic, geographic, familiar, clinical and laboratory presentation, morphology, imunophenotype, cytogenetics, molecular genetics, and progression of the disease. All results were analysed with a statistical approach using SPSS® version 19.0.
Results: We diagnosed 95 new cases of AL: 19% myeloblastic and 81% lymphoblastic. The global incidence was 25,7% per million children, with a uneven distribution in the different districts of the Center of Portugal. There was a male predominance. Half the children had ages between 2-5 years. The majority was born from a first or second pregnancy, with a weight percentile between 25-50 (60.1%), being the median maternal age 34 years. Seven children had Down syndrome. Recurrent infections in the first year of life occurred in 26.3% of the 91 children aged over 1 year. At diagnosis, children with Acute Lymphoblastic Leukemias (ALL) presented more bone pain (31,2%), while the hemorrhagic manifestations were predominant in the Acute Myeloblastic group (AML) (50%). No significant differences were observed when comparing hematologic parameters, except for the leukocyte count, that is higher than expected in AML (27,8% higher than $100x10^9$/L), and for the platelet count, that is lower than expected in both groups (in ALL 24,7% with platelet counts less than $20x10^9$/L, while in AML 72% presents with counts inferior to $50x10^9$/L). In ALL 67/ 77 were from B cells, predominantly the subtype B common (n=47). Hyperdiploidy was the commonest genetic alteration (25,4%), followed by the translocation *t(12;21)(p12;q22)* (15,6%). In AML the M5 subtype was the most frequent and 15 children had acute promyelocytic leukemia. At the end of this study, 15/95 children were dead mostly due to disease progression. The ALL survival rate (SR) was 85% at 5 and 75% at 10 years while in AML was equal at 5 and 10 years (75%). The presence of the t(4;11)(q21;q23), was associated with a SR of 25% at 5 years.
Summary / Conclusion: This study constitutes the first report of the molecular and epidemiological profile of AL in Central Portugal, showing its incidence, and allowing the comparison of our sample with other studies. With this study we found some districts in Portugal with a much higher AL incidence, which could be related to the presence of some types of Industries and/or environment characteristics. Even though our numbers are short, the advanced maternal age, the low birth weight and being the first son appears to be risk factors for AL. Besides that, the presence of the MLL rearrangements was associated with a worst survival rate.

B1197
CHARACTERIZATION OF MDM2/P53 AXIS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)
A Ferrari [1*], I Iacobucci [1], C Papayannidis[1], C Venturi [1], M Abbenante[1], S Parisi[1], S Paolini[1], C Sartor[1], A Di Rora'[1], E Ottaviani [1], V Guadagnuolo[1], S Soverini[1], F Cattina[1], D Russo[2], M Baccarani [1], M Cavo[1], G Martinelli [1]
[1]University of Bologna, Institute of Hematology "L. e A. Seràgnoli", Bologna, [2]University of Brescia, Hematology and BMT Unit, Brescia, Italy

Background: MDM2/p53 pathway plays an important role in the control of apoptotic and proliferation mechanisms. MDM2 binds to the N-terminus of the p53 and negatively regulates its transcriptional activity. MDM2 is over expressed in many tumors and its expression levels may be affected by several factors, including single nucleotide polymorphisms (SNP), such as the SNP309T>G (rs2279744) in the MDM2 intronic promoter P2. Conflicting evidence has linked the G-allele to enhanced cancer risk as well as early cancer diagnosis across different tumor types.
Aims: New MDM2 antagonists are now available for Phase I/II clinical development and in order to efficiently treat ALL patients (pts) with MDM2 antagonists, is important to identify *TP53* lesions and MDM2 status.
Methods: 19 patients (17 B-ALL and 2 T-ALL) visited at the Institute Seragnoli (Bologna) were analyzed for TP53 mutation screening, MDM2 SNP309T>G and MDM2 transcript levels.
Deletions and uniparental disomy (UPD) involving *TP53* were assessed by Genome-Wide Human SNP 6.0 array (Affymetrix). No 17p UPD, deletions or amplification events were detected in short arm of chromosome 17, were *TP53* is located. *TP53* mutations were thereafter investigated in all 19 samples. Three overlapping shorter amplicons covering the entire coding cDNA sequence (GenBank NM_000546.4) and the untranslated exon 1 [amplicon 1 (491 bp): exons 1-5; amplicon 2 (482 bp): exons 5-8; amplicon 3 (498 bp): exons 8-11)] and a longer amplicon (1,317 bp) starting from exon 1 and ending to exon 11 were sequenced by Sanger method. No *TP53* mutations were detected suggesting that these alterations are very rare events in ALL. In humans, a common SNP involves the substitution of an Arginine for a Proline at codon position 72 of *TP53* (rs1042522).
Results: Many studies have investigated a genetic link between this variation and cancer susceptibility, however, the results have been controversial. SNP P72R (rs1042522) was investigated in all19 adult ALL samples and it was found heterozygous in 31.6% (6/19), homozygous in 57.9% (11/19) and wild-type in 5% (1/19) of cases. Several studies have examined the prognostic value of the TP53 SNP P72R and/or MDM2 SNP309 in multiple tumors. Combined effects of p53 and MDM2 polymorphisms, for example, were described to be associated with an increased risk of developing hepatocellular carcinoma. MDM2 SNP309 was also characterized in our cohort of adult pts: 31.6% (6/19) were wild-type, 57.9% (11/19) were heterozygous and 10.5% (2/19) of cases were homozygous. The MDM2 expression was quantified using BioMark System array (Fluidigm). At the time of writing, we analyzed 15 ALL samples. To stratify our pts we used the median of 10 leukemic samples in molecular remission. The cut-off was of 3.44. Seven samples (46.7%) were higher than controls.
Summary / Conclusion: In conclusion, we did not identify any *TP53* alterations in adult ALL patients but the TP53 rs1042522 was identified in 90% of pts. The MDM2 SNP309 was identified in about 70% of cases. Moreover the 47% of pts overexpress MDM2. These data provide the rationale for further clinical investigation on using of MDM2 inhibitors.

Supported by ELN, AIL, AIRC, Fondazione Del Monte Bologna e Ravenna, Ateneo RFO grants, PIO program, Programma di Ricerca Regione–Università 2007–2009, PRIN 2010-2011, FP7 NGS-PTL project.

B1198
DETERMINATION OF CYTOTOXIC AND APOPTOTIC EFFECTS OF CAFFEIC ACID PHENETHYL ESTER AND GOSSYPOL IN COMBINATION WITH FLUDARABINE AT A MOLECULAR LEVEL IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS
Y Baran[1*], G ISKENDER[1], O PISKIN[2], M OZCAN[2]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, [2]Department of Hematology, Dokuz Eylul University, , Izmir, Turkey

Background: Acute lymphoblastic leukemia (ALL) is a type of cancer of white blood cells which occurs as a result of an uncontrolled and excess production of lymphoblasts. ALL is the most common type of leukemia in the period of childhood and youth (80%), and makes up 20% of all adult blood cancers. While chemotherapy is the main approach for the treatment of ALL, but the most effective treatment method has not been specified, yet. Fludarabine is a chemotherapeutic agent used in hematological cancers. Caffeic acid phenethyl ester (CAPE), a natural phenolic chemical compound, is an active component of propolis found in honeybee hives, and was demonstrated to have anti-mitotic, anti-oxidative, anti-tumoral, anti-inflammatory and immunomodulatory activities. Gossypol (2,2-bis (8-formyl-1,6,7-trihydroxy-5-isopropyl-3-methylnaphthalene, $C_{30}H_{30}O_8$), a natural agent obtained from the seed and root parts of the cotton, was shown to have anti-cancer properties.
Aims: The aim of this study is to determine the potential cytotoxic and apoptotic effects of CAPE, gossypol and fludarabine separately, and the effects of CAPE and gossypol in combination with fludarabine (Fludarabine + CAPE and Fludarabine + Gossypol) on Jurkat ALL cells.
Methods: Jurkat cells were propagated in RPMI-1640 growth medium containing 10% FBS and 1% penicillin-streptomycin, and was grown at 37ºC cell culture incubator containing 5% CO_2. The antiproliferative and apoptotic effects of CAPE, gossypol and fludarabine separately, and the effects of CAPE and gossypol in combination with fludarabine (Fludarabine + CAPE and Fludarabine + Gossypol) on the Jurkat cells were detected by MTT cell proliferation assay and by the changes in caspase-3 activity, respectively. The IC50 values (drug concentration where cell proliferation is inhibited at a level of 50%) of the anticancer agents were determined by MTT cell proliferation test.
Results: According to analyses of the MTT assays, at 48 and 72 hour time points, CAPE, gossypol and fludarabine were shown to significantly inhibit the proliferation of Jurkat cells in a time- and dose-dependent manner as compared to untreated control group. At different time points, the proliferation of Jurkat cells incubated with fludarabine + CAPE or fludarabine + gossypol was decreased significantly in a dose-dependent manner as compared to untreated control group and the group of Jurkat cells incubated with CAPE, gossypol and fludarabine separately. Caspase-3 enzyme activity was identified to be elevated in the groups of Jurkat cells incubated with dual combinations of fludarabine when compared to the positive control group and the groups of Jurkat cells incubated with CAPE, gossypol, and fludarabine separately. This study has shown that gossypol alone or in combination with fludarabine increases the caspase-3 enzyme activity in Jurkat ALL cells.
Summary / Conclusion: The results demonstrated that CAPE, gossypol and fludarabine separately, or CAPE and gossypol in combination with fludarabine have anti-proliferative and apoptotic effects on Jurkat cells in a time- and dose-dependent manner. If these studies are supported by *in vivo* research, herbal and natural anti-cancer agents, CAPE and gossypol, could be considered to be used in the treatment of ALL.
This study was supported by Turkish Society of Hematology.

CLINICAL SIGNIFICANCE OF LOW SENSITIVITY PROBES IN MRD ANALYSIS OF ADULT ALL PATIENTS

O Spinelli[1*], M Tosi[1], B Peruta[1], M Montalvo[1], E Oldani[1], T Intermesoli[1], C Romani[2], E Di Bona[3], V Cassibba[4], E Borlenghi[5], E Pogliani[6], A Cortelezzi[7], R Bassan[8], A Rambaldi[1]

[1]Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, [2]Hematology, Ospedale Oncologico di Riferimento Regionale, Cagliari, [3]Hematology, Ospedale San Bortolo, Vicenza, [4]Hematology, Ospedale Civile, Bolzano, [5]Hematology, Spedali Civili, Brescia, [6]HSCT Adult Unit, Ospedale San Gerardo, Monza, [7]Hematology, IRCSS Cà Granda Ospedale Maggiore Policlinico ed Università degli Studi di Milano, Milano, [8]Hematology, Ospedale dell'Angelo, Mestre Venezia, Italy

Background: MRD analysis emerged as the most powerful indicator of the risk of relapse and is increasingly adopted in Acute Lymphoblastic Leukemia (ALL) patients for the risk-oriented administration of consolidation therapies. In most pediatric and adult clinical trial the required sensitivity of the probe is at least 10^{-4}. MRD evaluation is not performed with low sensitivity probes and patients are treated according to clinical risk stratification (high risk, HR or standard risk, SR).
Aims: To evaluate the ability of low sensitive probes in revealing high MRD levels and classify patients as high risk of relapse due to leukemia persistence.
Methods: The prospective Northern Italy Leukemia Group trial conducted between 2000 and 2006 enrolled a total of 280 consecutive unselected patients with Ph- ALL. In this study post-consolidation treatments were administered according to the MRD status. MRD was assessed by RQ-PCR methodology using one or two patient-specific molecular probes generated according to ESG-MRD-ALL study group guidelines. MRD was evaluated at weeks 10, 16 and 22 and results were used to categorize patients as MRD^{neg} (negative at w 22 and negative or positive $<10^{-4}$ at w16) or MRD^{pos}. SCT or intensified chemotherapy was prescribed to MRD^{pos} patients whether maintenance to MRD^{neg} patients, regardless of clinical risk class. Only probes reaching the sensitivity of 10^{-4} were used for treatment allocation; patients without a sensitive probes were treated according to clinical risk stratification .
Results: Of 280 registered patients 236 achieved complete remission (CR) and 142 completed consolidation phase. For these patients the MRD risk assignment was possible in 112 case: 58 resulted MRD^{neg} and 54 MRD^{pos} and treated accordingly. For 30 patients a molecular classification was not possible ($MRD^{u/k}$) due to lack of samples, no clonal identification or low sensitive probes (10^{-3}, 9 cases) and these patients were treated according to clinical risk class. In 8 out of 9 patients with low sensitivity probe MRD evaluation was performed on available sample collected during the consolidation phase. A positive MRD signal at 10^{-3} level or greater in at least one sample was found in 5 cases. Among these, one patient experienced an early relapse, one refused any treatment and relapsed 3 months later and one relapsed after stem cell transplantation (SCT). Interestingly, two of these patients had been previously assigned to the clinical standard risk class (one SR B and one SR T lineage ALL) while the transplanted patients was a HR B lineage ALL. Furthermore, the only two MRD positive surviving patients had been classified as clinical standard risk but received intensified chemotherapy courses, followed by SCT in one case.
Summary / Conclusion: Our analysis suggests the usefulness of MRD evaluation in acute lymphoblastic leukemia even with low sensitive probes to identify, especially in clinical standard risk group, patients with high residual disease in whom intensified treatments are needed to avoid impending relapse.

Acute lymphoblastic leukemia - Clinical

PROGNOSTIC VALUE OF DAY 15 BLAST COUNT IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH ALL-BFM 95 PROTOCOL

Z Kaya[1*], T Gürsel[1], Ü Koçak[1], I Yenicesu[1], M Albayrak[1], E Sal[1]

[1]The Pediatric Hematology Unit of the Department of Pediatrics, Medical School of Gazi University, Ankara, Turkey

Background: Children with acute lymphoblastic leukemia (ALL) treated with Berlin-Frankfurt-Münster (BFM)- 95 protocol have approximately 80% event free survival (EFS). However, 20% of patients develop relapse mainly due to poor chemotherapy response. Although respond to one week prednisone therapy has evolved as the strongest prognostic factor, recent studies suggest that blast count on Day 15 (D15) of BFM protocol may be another important prognostic factor.
Aims: The aim of this study was to evaluate the impact of blast count on D15 of ALL –BFM-95 protocol on survival.
Methods: D15 blast count in bone marrow (BM) aspirates were retrieved from patients files of 130 evaluable children treated with ALL-BFM 95 protocol at the Pediatric Hematology Unit of Gazi University Medical School. D15 BM examination was categorized based on residual blast count as M1 (<5%), M2 (5% to <25%), and M3 (≥25 %). Early death before Day 33 were excluded from analysis.
Results: Of the 130 children, 53 were girls and 77 were boys. Their age at diagnosis ranged from 6 months to 18 years (median 7 years). D15 BM was reported as M2 and M3 in 36 (27.7%) of them. Twenty-one children relapsed within a median 28 months after complete remission on day 33 of induction therapy. The relapse rates in 13 children with M2 and M3 (61.9%) on day 15 was significantly higher as compared to 8 children with M1 BM (38.1%) (P<0.05). The EFS rates for D15 M1, M2 and M3 BM were 89.4%, 66.7% and 50.0%, respectively. There was a significant differences for the probability of EFS in the 3 groups by the log rank tests (P<0.05).
Summary / Conclusion: High BM blast count (≥5%) on D15 is associated with poor survival in children treated with ALL-BFM 95 protocol. These data suggest that it can be used as a risk stratification criterion when assessment of minimal residual disease is not available.

B1201

ACUTE LYMPHOBLASTIC LEUKEMIA IN THE ELDERLY: A TOUGH ONE

F Folber[1*], M Hadrabova[1], S Hrabovsky[1], J Mayer[1], M Doubek[1]

[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: Elderly patients with acute lymphoblastic leukemia (ALL) or lymphoblastic lymphoma (LBL) form a special subgroup of patients with widely different outcomes.
Aims: As higher age is usually associated with an aggressive disease course and a higher susceptibility to treatment complications, the right choice of treatment approach (intensive or palliative) is sometimes difficult. Aim of the analysis was to compare results of elderly ALL therapy using intensive regimen (Czech Leukemia Study Group protocol for ALL/LBL patients over 50 years) or palliative approach (including palliative chemotherapy).
Methods: All patients aged over 50 years diagnosed with ALL or LBL at our centre between 2000 and 2012 were included into this retrospective analysis. We described the baseline features of these patients and treatment options used. The data were analysed for response and relapse rate, incidence of complications and risk factors affecting survival.
Results: A total number of 59 patients aged 50 to 83 years (median age 61 years) at the time of diagnosis were included into this analysis; forty-five (76%) patients with B-ALL, five (8%) with T-ALL, six (10%) with LBL, and three (5%) patients with acute undifferentiated or biphenotypic leukemia. Median baseline leukocyte count was 10.2G/L, range 0.4-334. Nearly half of the patients carried an adverse cytogenetic or molecular marker; BCR/ABL or Philadelphia chromosome in 23 (39%), MLL fusion gene in 2 (3%), complex karyotype in 1 (2%) and other abnormalities in 5 (11%) patients. Minimal residual disease analysis was performed repeatedly in 24 patients. Intensive treatment protocol was used in 37 (63%) cases, 22 (37%) patients received palliative treatment. Hematopoietic stem cell transplantation was performed in only 5 (8%) patients. Most of the patients developed treatment complications. These were mild or moderate in 11 (19%) patients, severe or life-threatening in 34 (58%) patients and fatal in 11 (19%) cases. Forty-four (88%) out of 50 evaluable patients achieved a complete hematologic remission (CR); 97% in the intensive arm vs. 70% in the palliative arm. Complete molecular remission was reached in 33% patients; 50% in the intensive arm vs. 17% in the palliative arm. Twenty-four (55%) patients in CR eventually relapsed. During the follow-up period with a median of 8.7 months (range 0.2 to 153 months) fourty (68%) patients died. Most common causes of death were disease progression (40%), infection (33%) and non-infectious treatment toxicity (18%). Five-year progression-free

(PFS) and overall survival (OS) in the whole cohort were 18% and 21%, respectively. The survival was significantly lower in patients over 65 years of age or treated using a palliative approach. In patients between the ages of 60-70 treated using our intensive protocol the survival was comparable to that observed in the age group 50-60 (5-year PFS 18% and 22%, respectively; 5-year OS 26% and 21%, respectively). The survival of patients over 70 years of age was poor, with 1-year PFS and OS of 18% and zero 2-year PFS and OS.
Summary / Conclusion: Elderly ALL patients in the age between 50 and 60 years clearly profit from intensive treatment. Outcome of patients over 70 years of age is still poor, with no signs of improvement over time. According to our analysis, some patients in the age between 60 and 70 can benefit from intensive therapy using less toxic protocols. These patients are candidates for further analysis.

B1202
NELARABINE FRONT-LINE THERAPY FOR ADULT T-LYMPHOBLASTIC LEUKAEMIA/LYMPHOMA (T-LBL/ALL): PRELIMINARY RESULTS OF A SINGLE CENTRE EXPERIENCE
C Sartor[1*], M Abbenante[1], C Papayannidis[1], I Iacobucci [1], S Paolini[1], E Ottaviani [1], LAnnalisa[1], S Parisi[1], A Ferrari[1], V Guadagnuolo[1], N Testoni [1], M Cavo[1], G Martinelli [1]
[1]Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy

Background: Precursor T cell LBL/ALL occurs most frequently in late childhood, adolescence, and young adulthood, with a 2:1 male predominance; it comprises 15 and 25 percent of childhood and adult ALL, respectively, and 2 percent of adult non-Hodgkin lymphoma. Nelarabine is an anticancer prodrug of arabinofuranosylguanine (ara-G); it inhibits DNA synthesis and leads to high molecular weight DNA fragmentation and cell death.
Aims: Nelarabine has showed relevant efficacy in phase II clinical trials, both in pediatric and in adult LBL/ALLpopulations.
Methods: We report clinical outcome results of 9 newly diagnosed and younger than 60 yearsT-ALL patients (median age 29 years, range 22-45 years, 3/6 M/F, 8 T-ALL, 1 T-LBL) treated according to pediatric-like adapted schedule. Cytogentics data and molecular biologic features will be provided on site. Induction cycle included Vincristine, daunoblastine, L-asparaginase and Prednisone. After induction, all the patients received consolidation therapy with cyclophosphamyde, L-asparaginase, Cytarabine and 6-Mercaptopurine. Subsequently all the patients receveid Nelarabine 1500 mg/sqm (days 1-3-5 every 21) for two cycles. All the patients shared the same strategy for intensification, which consisted in allogenic stem cell transplantation, if available, or additional courses of consolidation chemotherapy. Durations of complete remission (CR) and overall survival (OS) were estimated according to the Kaplan-Meier method. The CR duration was dated from start of CR to first evidence of disease recurrence.
Results: After a single induction course, 9/9 patients obtained a CR (100%). Eight patients underwent an allogenic bone marrow transplantation. Aftera median follow-up of 24 months, 7/9 patients (78%) are alive in CR. The median CR duration and OS were 13.4 and 24.4 months, respectively. Neurological toxicity of grade 3has not been reported. We did not observe grade 3-4 haematological toxicity.
Summary / Conclusion: Nelarabine is a promising drug, which induces a remarkable complete remission rate at the expense of a very low and manageable toxicity.

B1203
ACUTE MIXED LINEAGE LEUKEMIA TREATMENT OUTCOME: A 5 YEARS SINGLE INSTITUTE EXPERIENCE
M Fawzy[1*], H Sayed[1], N Eldeen[1]
[1]Pediatric Oncology, National Cancer Institute-Egypt, Cairo, Egypt

Background: Mixed-lineage acute leukemias (MLL) - or acute leukemias of ambiguous lineage- represent a heterogeneous category of rare, poorly differentiated acute leukemias that possess characteristics of both lymphoid and myeloid precursor cells.
Aims: To investigate treatment outcome of pediatric, Mixed-lineage acute leukemia's (MLL) patients diagnosed and treated at the National Cancer Institute, Cairo University during a 5 years period.
Methods: Retrospective review of patient charts with newly diagnosed histologically proven MLL, diagnosed and treated at the Pediatric Oncology Department, National cancer institute, Cairo University in the period from January 1st 2005 till end of December 2010 was performed. All patients were followed up till the end of June 2012. Clinical and laboratories data of these patients were retrospectively followed and evaluated.
Results: Twenty seven patients were included in our study. Age of patients ranged between 8 months - 17 years, median 9 years. They were 17 males and 9 females. Follow Up period ranged from 4-93 months, median of 12.3 months. Total leucocytic count (TLC) at diagnosis ranged between 1.5 to 546x$10^3/m^2$ with a median 21.4 x$10^3/m^2$. Bone marrow was suggestive of ALL in 9/27 patients (33.3%), AML in 5/27 patients (18.5%), and MLL in 13/27 patients (40.7 %). Immunophenotyping showed Myeloid+ T (M+T) cell in 37%, whereas M+B in 63%. Seven patients received ALL induction like therapy, while 20/27 patients received AML like treatment. Post induction CR rate was 63%. *Disease outcome*: 17/27 (63%) of patients died due to chemotherapy toxicity, mostly due to fungal chest infection. By the end of the study OS at 5 years was 20% with no statistical difference between the two subtypes.
Summary / Conclusion: Mixed-lineage acute leukemias carry an extremely poor prognosis in our institute. There is a strong need for implementing a standardized protocol of therapy offering an early bone marrow transplant as well as a better supportive care and further improving the infection control setup.

B1204
THE LONG TERM RESULTS OF CHILDHOOD ALL AT TWO CENTERS FROM TURKEY: 15 YEARS OF EXPERIENCE WITH ALL BFM 95 PROTOCOL
A Gunes[1*], H Oren[2], B Baytan[1], Ş Yılmaz[3], M Evim[1], Ö Tüfekçi[2], G İrken[2]
[1]Dpt. Ped. Hematology, Uludag University, Bursa, [2]Dpt. Ped. Hematology, Dokuz Eylül University , İzmir, [3]Dpt. Ped. Hematology, Dokuz Eylül University , Bursa, Turkey

Background: Dramatic progress in the treatment of childhood ALL has been achieved during the last two decades in western countries where the 5 year event free survival rate (EFS) has risen from 10% to 80%. However, this high cure rate has not been always occurred in every center in developing countries due to limited sources.
Aims: We evaluted the treatment results of ALL BFM 95 protocol used between 1995 and 2009 in pediatric hematology departments of Bursa Uludağ University and İzmir Dokuz Eylül University hospitals.
Methods: A retrospective analysis of 343 newly diagnosed children as ALL. M/F:200/143, mean age: 6.7±4.2;1-17.5 years) was performed. The overall (OS) and EFS according to age, sex, initial leucocyte count, chemotherapy responses on day 8th, 15th and 33rd and risk groups were analysed by Kaplan Meier survival analysis. MTX dose was not reduced and given as 5 g/m^2
Results: Median follow-up time was 6.4±4.02 years. Complete remission was achieved in 98.5% of children. The gender did not have a significant effect on EFS and OS (P>0.05). Children with good response to prednisolone on day 8th achieved significantly better OS and EFS (P=0.001). Children in the standart (95%)and the medium risk groups (83%) obtained higher EFS comparing to high risk group (56%)(P=0.001). EFS for B- and T-cell ALL were 81% and 66%, respectively. Adolescents achieved 65% of EFS. Five years EFS and OS were found 78% and 80%,respectively. Relaps rate was 15%. The median relapse time from diagnosis was 23.21±13.16 months. Death occured in 69 out of 343 patients (20%). The major causes of death were infection and relapse. None died of drug related toxicity.
Summary / Conclusion: ALL-BFM 95 protocol was applied successfully in these two centers. In developing countries in which MRD could not be performed, this protocol could be still used with high survival rates.

B1205
ZAP-70 EXPRESSION IN ACUTE LYMPHOBLASTIC LEUKEMIA:RELATION TO PATIENTS' PROGNOSIS AND CYTOGENETIC RISK GROUPS
G Mokhtar[1*], A Mohamed[2,3], A Abdelmaksoud[2], M Badawy[4], R Hagracy[5]
[1]Pediatric Hematology and Oncology, [2]Ain Shams University, Cairo, Egypt, [3]Clinical pathology, [4]Biomedical Department, Higher Technological Institute, [5]Internal medicine, Ain Shams University, Cairo, Egypt

Background: The Zeta-associated protein 70 (ZAP-70) is normally expressed in T and natural killer cells. Expression of ZAP-70 has been associated with poor prognosis in B-chronic lymphocytic leukemia.
Aims: To assess the expression of ZAP-70 in both B and T acute lymphoblastic leukemia (ALL) in pediatrics and adults and to correlate its expression to clinical, laboratory and cytogenetic characteristics as well as to evaluate its impact on patients' outcome and survival.
Methods: This study was conducted at Ain Shams University Hospitals. It included 50 patients with ALL; 32 adults and 18 children and adolescents. Regarding the phenotype; there were 33 patients with Pre-B-ALL, 10 with mature B-ALL and 7 with T-ALL. All patients were investigated for ZAP-70 expression by flowcytometry and cytogenetic abnormalities by conventional cytogenetics and Fluorescence in situ-hybridization (FISH) technique for t(9,22), t(12,21) and 14q11 rearrangements.
Results: ZAP-70 was expressed in 48/50 (96%) of patients, with no significant difference in its expression between childhood and adulthood ALL (P>0.05). Highest expression was recorded among T-ALL (48±6%) followed by mature B-ALL (37±8%) and Pre-BALL (35±7.5%); but this did not reach a statistical significance (P>0.05). High ZAP-70 expression ($\geq$51%) was associated with very high and high risk group of patients (P=0.001), poor response to chemotherapy (either death or early relapse in 82.4% of patients), as well as low platelet count (P=0.0), low hemoglobin (P=0.001), high LDH level (P=0.031), high peripheral blood blast (PBB) (P=0.022) and short disease free survival and overall survival.
Summary / Conclusion: ZAP-70 is highly expressed in both T and B-ALL in pediatrics and adults and its high expression was associated with the worse prognosis. Thus high ZAP-70 expression carries a bad prognostic impact in ALL and may be a new suitable therapeutic target.

B1206

SERUM LEVELS OF MULTIPLE CYTOKINES AND ADHESION MOLECULES IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LYMPHOBLASTIC LEUKEMIA AND IN HEALTHY SUBJECTS

J Horacek[1,2], T Kupsa[1,2*], M Vasatova[3], L Jebavy[1,2], M Jakl[1], P Zak[2]
[1]Internal Medicine, Faculty of Military Health Sciences, [2]Internal Medicine 4 - Hematology, [3]Institute of Clinical Biochemistry and Diagnostics, University Hospital, Hradec Kralove, Czech Republic

Background: Cytokines and adhesion molecules have been studied as markers of immune system activation in various diseases including hematological malignancies. Alterations in this network may have direct effect on the malignant cells or have indirect effect on leukemogenesis through altered functions of bone marrow stromal elements. The knowledge gained from multiple cytokine and adhesion molecule analysis should allow better diagnosis and disease management.
Aims: The aim of our study was to evaluate serum cytokine and adhesion molecule levels by biochip array technology in patients with acute lymphoblastic leukemia (ALL) and in healthy subjects.
Methods: Serum samples of 15 newly diagnosed ALL patients (median age 46, range 24 - 63 years, 11 males) and 15 healthy subjects (median age 41, range 25 - 58 years, 11 males) were analyzed. We evaluated serum levels of the following 22 cytokines and adhesion molecules: interleukins (IL-1 alpha, IL-1 beta, IL-2, IL-3, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-23), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-alpha), interferon-gamma (IFN-gamma), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1), E-selectin, L-selectin, P-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox). Probability values (p) < 0.01 were considered statistically significant.
Results: In newly diagnosed ALL patients, we found significant increase in serum VCAM-1 (1078.54±456.96 mcg/L vs. 328.31±88.66 mcg/L; P<0.000001), ICAM-1 (499.57±237.53 mcg/L vs. 196.69±36.06 mcg/L; P<0.0001), L-selectin (2366.33±1035.37 mcg/L vs. 1104.54±243.45 mcg/L; P<0.0001), IL-8 (34.07±28.52 ng/L vs. 4.87±3.09 ng/L; P<0.001), MCP-1 (433.99±328.59 ng/L vs. 153.25±53.60 ng/L; P<0.01). On the other hand, we found significant decrease in serum IL-3 (7.34±3.41 ng/L vs. 11.53±4.66 ng/L; P<0.01), IL-4 (1.10±1.08 ng/L vs. 3.27±2.21 ng/L; P<0.01). Serum levels of other evaluated cytokines and adhesion molecules were without significant differences.
Summary / Conclusion: Our results indicate that serum levels of some cytokines and adhesion molecules (VCAM-1, ICAM-1, L-selectin, IL-8, IL-3, IL-4, MCP-1) are significantly altered in patients with newly diagnosed ALL, reflecting activity of the disease. Whether these alterations could have a prognostic meaning for ALL is not known. Further studies in a larger number of patients and comparing cytokine and adhesion molecule levels with established prognostic markers will be essential to assess the potential role of these and additional markers in the stratification of risk in ALL patients.

The work was supported by a long-term organization development plan 1011 (FMHS).

B1207

MICRO-RNA PROFILE OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

B Antmen[1*], K Barbaros[1], I Sasmaz[1], K Tanriverdi[2], G Ucar[1], Y Kilinc[1]
[1]Pediatric Hematology, Cukurova University, Adana, Turkey, [2]Hematology, University of Massachusettes, Worcester, United States

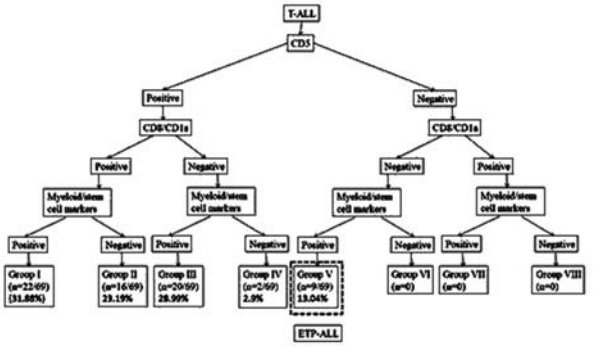
Background: Micro-RNAs are functional, non-protein coding RNA molecules and their transcriptions provided by intronor exon regions of the genome and non-protein coding regions of RNA genes. The role of micro-RNAs in acute leukemia has become the subject of research increasingly.
Aims: In this study we aimed to identify micro-RNA profiles in the childhood acute leukemia that one of hematologic malignancies.
Methods: Fourty nine patients who were diagnosed with acute leukemia and admitted to Cukurova University Faculty of Medicine Department of Pediatric Hematology between December 2010 and September 2011. Blood samples were taken twice in patient groups at diagnosis and during remission and plasma samples were stored. Blood samples were taken once in the healthy group and plasma were separated. The plasma samples were investigated by PCR analysis of micro-RNA. Acute leukemia was diagnosed by cytomorphological, immuno histochemical and flow cytometric studies. Thirtyone patients who were diagnosed with ALL and fortyseven healthy children as a control group were included to study.
Results: miR20a, miR25, miR92a, miR30c, miR106b, miR203, miR150, miR192, miR302c, miR184, miR218, miR320, miR342-3p, miR223, miR328, miR483-5p, miR376a, miR381, miR451, miR576-3p, miR548a levels were increased in newly diagnosed ALL patients when compared to healthy controls (p <0.05). The miR20b, miR342-3p and miR548a levels were found higher in healthy controls than the newly diagnosed ALL patients group (P<0.05) Healthy control groups when compared with pediatric ALL patients whose in remission; miR769-3p, miR20a, miR92a, miR16, miR27b, miR192, miR320, miR223, miR484, miR451 levels were found higher in healthy control groups than the patients. Newly diagnosed pediatric ALL patients compared with patients whose in remission; miR30c, miR106b, miR25, miR184, miR218, miR302c, miR483-5p levels were increased in newly diagnosed pediatric ALL patients than ALL patients whose in remission (P<0.05)
Summary / Conclusion: miRNAs are thought to be identified at a different level of expression in normal and pathological tissues can be determined between the miRNAs that are effective diagnosis and treatment of human cancers. We showed the microRNA profils that may play new roles treatment of acute leukemia in the futures.

B1208

IMMUNOPHENOTYPIC ANALYSIS OF T-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA. A CD5 PERSPECTIVE

R Kumar[1*], A Chopra[1], S Bakshi[2], S Gajendra[1], S Kumar[3], L Kumar[2], A Sharma[2], R Seth[4], A Gogia[2]
[1]Laboratory Oncology, [2]Medical Oncology, All India Institute of Medical Sciences, New Delhi, [3]Hematology, Command Hospital (Eastern Command), Kolkata, [4]Pediatrics, All India Institute of Medical Sciences, New Delhi, India

Background: T-cell markers CD5/CD1a/CD8 define early thymic precursor acute lymphoblastic leukemia (ETP-ALL). We reasoned that presence or absence of various combinations of these antigens could be used to divide non-ETP T-ALL into groups, in which to examine the expression of myeloid / stem cell (M/S) antigens and clinical features for comparison with ETP-ALL. This evaluation of non-ETP T-ALL from the perspective of ETP-ALL has not been done before may be relevant to an understanding of the spectrum of immature T-ALL of which ETP-ALL is part.
Aims: To examine expression of myeloid / stem cell (M/S) antigens and clinical features of subgroups of non-ETP T-ALL based on the defining T-cell antigens of ETP-ALL (CD5/CD1a/CD8), and compare these with ETP-ALL.
Methods: Records of 69 patients of T-ALL, immunophenotyped as part of routine diagnostic service were retrieved from the records of Laboratory Oncology, All India Institute of Medical Sciences, New Delhi. Clinical and immunophenotypic characteristics of all cases were noted. The immunophenotypic markers used were: CD3, CD45, CD5, CD8, CD1a, CD13, CD33, CD117, HLA-DR, CD34, CD65 and CD11b. The cases were classified based on expression of CD5 into two large groups: $CD5^+$ and $CD5^-$. These were further subdivided into $CD8^-/CD1a^-$ and $CD8^+/CD1a^+$ subgroups. In all these groups, presence of myeloid and/or stem cell markers were noted. Patients were thus divided into 8 groups, I to VIII, as shown in Figure 1. The different groups were compared for clinical features, remission rate, relapse rate and overall survival.
Results: $CD5^-$ was a homogenous $CD8^-/CD1a^-$, M/S antigen$^+$ ETP-ALL group (n = 9). $CD5^+$ cases were $CD8^-/CD1a^-$ pre-T ALL (n = 22) or $CD8^+/CD1a^+$ (n = 38) thymic/cortical T-ALL, with M/S antigens being significantly more frequent in the former (20/22; 90.91 %) than in the latter (22/38; 57.89%). Pro- and pre-T- ALL, which together constitute the immature T-ALL group of clinical and laboratory studies, were nearly always M/S+ (29/31; 89.9%) and had a significantly higher induction failure than cortical T-ALL. In multivariate analysis, ETP-ALL and female sex were significant predictors of event free survival (P=0.033, 0.016, respectively whereas only ETP-ALL was



Summary / Conclusion: Our results, (1) show that $CD1a^-/CD5$ pro-T ALL cases (EGIL) may all be ETP-ALL; (2) confirm pro-/ETP- and pre-T-ALL to belong to the wider spectrum of immature T-ALL on both immunophenotypic and clinical grounds; (3)indicate further studies on the T-ALL - AML interface and inclusion of CD1a and CD5 in the work-up of T-ALL; (4) confirm ETP-ALL has a poor prognosis.

B1209

ROLE OF ALLOGRAFTING IN ACUTE LYMPHOBLASTIC LEUKEMIA: A 12 YEAR EXPERIENCE

L Giaccone[1*], B Bruno[1], E Maffini[1], E Audisio[1], S D'Ardia[1], D Caracciolo[1], B Allione[1], A Busca[1], F Ferrando[1], F Testa[1], M Festuccia[1], L Brunello[1], M Boccadoro[1], U Vitolo[1], R Passera[1], M Falda[1], F Marmont[1]
[1]Divisions of Hematology, A.O. Città della Salute e della Scienza, Università di Torino, Torino, Italy

Background: Acute lymphoblastic leukemia (ALL) is a rare disease in adults. Despite the introduction of several novelties in this field in terms of prognostic factors and new therapies, clinical outcomes remain unsatisfactory.
Aims: To evaluate the experience on 84 consecutive patients diagnosed with ALL at the Divisions of Hematology, S. Giovanni Battista Hospital, Torino, between 1999-2011.
Methods: Patients, median age 49 years (18-73), were treated according to Center guidelines or on clinical trials active at the time of diagnosis. At diagnosis, patients who presented with leukocitosis, poor-prognosis cytogenetic abnormalities, or delayed response to induction therapy were defined as high risk. High risk patients younger than 60 were considered for allografting (SCT) as part of first-line treatment. Treatments for 80% (20/25) of patients with traslocation (9;22) also included tyrosine kinase inhibitors after 2002: in 14 as part of induction, in 4 as maintenance and in 2 as salvage treatment.
Results: Overall, 25% (21/84) presented with leukocytosis and 56% (38/68, not done in 16) had poor-prognosis cytogenetic abnormalities. Complete remission (CR) was achieved in 92% of patients (77/84). After a median follow-up of 5 years (3-143 months), 43% of patients are alive, with a median overall survival (OS) and event-free survival (EFS) of 2 and1,6 years, respectively. Forty patientsreceived an allograft in first (no.=32) or second (no.=7) complete remission, orin progression (no.=1), from a HLA identical sibling (no.=21), an unrelated (no.=17) or a related other than sibling (no.=2) donor. Cumulative incidences of acute and chronic graft-versus-host disease were 47% and 39%, respectively. Median OS and EFS in patients who received SCT were 60 months and not reached, respectively, whereas in those younger than 60 who did not undergo a SCT median OS and EFS were 16 and 13 months (P=0.024 and 0.026) respectively. Stratifying patients by year of diagnosis, a trend toward improved EFS in those diagnosed after 2008 as compared to those diagnosed before 2003 (2.3 years versus 1.3) was observed, whereas OS remained superimposable. By multivariate analysis, the prognostic role of leukocytosis at diagnosis was confirmed for both OS and EFS (HR 2.48, IC 95% 1.28-4.80, P=0.007, and HR 3.72, IC 95% 1.93-7.14, P<0.001, respectively). Furthermore, in younger patients, an advantage in those who received an allograft in terms of both OS (HR 0.11 CI 95% 0.03-0.44 P=0.002) and EFS (HR 0.12 CI 95% 0.03-0.47 P=0.002) was seen.
Summary / Conclusion: SCT played a significant role in improving survival in patients with ALL, though prognosis in patients with leukocytosis or older remained poor. The trend toward an improved outcome seen in more recent years may be due to less toxic transplant procedures and the introduction of "minimal residual disease-guided treatment" and the availability of tyrosin kinase inhibitors. The combination of allografting and tyrosin kinase inhibitors, or novel monoclonal antibodies such as blinatumomab, should be evaluated in prospective control trials.

B1210

FAVORABLE OUTCOME FOR ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH EORTC 58951

L Aissaoui[1*], Y Abdennebi[1], M Achour[1], H Neji[1], R Mansouri[1], M Zarrouk[1], K Kacem[1], R Jeddi[1], R Lakhal[1], H Abid[1], Z Ali[1], B Meddeb[1]
[1]Hematology, Aziza Othmana Hospital, Tunis, Tunisia

Aims: Retrospective studies have shown that adolescents and young adults with acute lymphoblastic leukemia(ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols. We examined results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.
Methods: From January 2006 to December 2010, 30 patients aged between 16 and 25 years (17 adolescents , 13 young adults) with newly diagnosed ALL were treated, in the department of clinical hematology of Aziza Othmana Hospital, according to the pediatric protocol EORTC 58951. The patients were 21 males (70%) and 9 females. 43.3% had a WBC> 50 Giga/l. Immunophenotyping was performed in all patients: 12 B-ALL (40%), 11 T-ALL (36.7%). All patients have had an AR2-VHR arm induction.
Results: Seven patients (23.3%) were corticoresistant. Twenty nine patients (96.7%) achieved CR. One patient failed to respond after 3 courses of chemotherapy and died as a result of disease (resistant). The MRD at D35 measured by CMF was<10^{-3} in 53.3% of cases. Twenty nine patients were evaluable. Only one patient was treated according AR1 arm, 8 patients according AR2 arm and 19 (65,5%) according VHR arm. Fifteen patients (51.7%) were eligible for allogeneic stem-cell transplantation (SCT) but, only 5 were allograft: 4 were alive and 1 died by GVH. Only one patient died by chemotherapy after the third bloc. Five patients (17.2%) relapsed during the first year of treatment. The median follow up was 50 months (4,2 years). The OS and the EFS at 5 years were 71%. Seven patients (23.3%) were corticoresistant. Twenty nine patients (96.7%) achieved CR. One patient failed to respond after 3 courses of chemotherapy and died as a result of disease (resistant). The MRD at D35 measured by CMF was<10^{-3} in 53.3% of cases. Twenty nine patients were evaluable. Only one patient was treated according AR1 arm, 8 patients according AR2 arm and 19 (65,5%) according VHR arm. Fifteen patients (51.7%) were eligible for allogeneic stem-cell transplantation (SCT) but, only 5 were allograft: 4 were alive and 1 died by GVH. Only one patient died by chemotherapy after the third bloc. Five patients (17.2%) relapsed during the first year of treatment. The median follow up was 50 months (4,2 years). The OS and the EFS at 5 years were 71%.
Summary / Conclusion: The results of this prospective pediatric based study show that response to therapy and prognostic in adolescent and young adults were better than those treated with adult protocols and tolerability of chemotherapy is acceptable. This experience of feasibility allowed us, since 2011 to treat adult aged up to 30 years with this pediatric regimen and the preliminary results of tolerability were good.

B1211

LONG-TERM RESULTS OF EORTC 58951 PROTOCOL FOR CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IN THE SOUTH OF TUNISIA

M Medhaffar[1*], I Frikha[1], S Hadiji[1], O Kassar[1], L Sfaihi[2], H Bellaj[1], F Turki[2], L Kammoun[1], I Chabchoub[2], M Ghorbel[1], L Gargouri[2], N Abdeljalil[3], M Hachicha[2], A Mahfoudh[2], T Othmen[3], M Elloumi[1]
[1]Clinical hematology, [2]Pediatric, Hedi chaker hospital, Sfax, [3]CNGMO, CNGMO, Tunis, Tunisia

Background: Childhood acute lymphoblastic leukemia (ALL) is one of rare malignant disease with high rate of cure.
Aims: We report the experience of the department of clinical hematology of Sfax for the treatment of childhood ALL with the EORTC 58951 protocol
Methods: We retrospectively studied the outcome of all childhood ALL treated with the EORTC 58951 pediatric protocol. For those patients we studied the leukemia characteristics (sex ratio, white blood cell counts WBC, blast's phenotype, cytogenetic abnormalities) and response to treatment: response to prophase, remission rate, risk group stratification, treatment related mortality (induction and post induction death) and survival (overall survival OS, event free survival EFS and disease free survival DFS).
Results: From January 2000 to December 2011, 138 children were treated with the EORTC 58951 protocol. Median age was 6 years (range: 13 months to 15 years). Sex ratio M/F was 1.55. WBC counts less than 10 G/l, from 10 to 100G/L and more than 100G/L were observed respectively in 41, 44 and 15% of cases. The blast's phenotype was B in 70% and T in 30%. Cytogenetic abnormalities were noted in 43% of cases. Response to prophase was noted in 86% and complete remission in 96% of cases. The EORTC risk group stratification was Low Risk (LR), Average Risk1 (AR1), Average Aisk2 (AR2) and Very High Risk (VHR) in 6.5, 43.5, 27 and 23% respectively. TRM was 12.5%: induction rate death was 8% and post-induction rate death was 4.5%. Three patients from VHR group with familial donor underwent allograft. The relapse rate was 25% of all patients in remission; it was 0, 25, 13 and 45% for LR, AR1, AR2 and VHR group respectively. At 5 years of follow up, OS, EFS and DFS were 65, 61 and 74% respectively.
Summary / Conclusion: Childhood ALL in our institut were characterized by a poor presentation at diagnosis: male sex, leucocytosis more than 100G/L, T phenotype and bad response to prophase are frequent compared to the occident reports. TRM is higher in our study than observed in the literature (12.5% vs 6 to 8%) especially the induction death rate. EFS are acceptable in our study but still less than observed in literature (85-90%). It can be improved by reducing TRM, detecting high risk patient with MRD study especially for AR1 risk group, and doing allograft for VHR patients.

B1212

ADOLESCENT AND YOUNG ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: TUNISIAN MONOCENTRIC EXPERIENCE

M Medhaffar[1*], I Frikha[1], S Hadiji[1], O Kassar[1], N Abdeljalil[2], H Bellaaj[1], L Kammoun[1], A Lakhal[2], M Ghorbel[1], T Othmen[2], M Elloumi[1]
[1]Clinical hematology, Hedi chaker hospital, Sfax, [2]CNGMO, CNGMO, Tunis, Tunisia

Background: Adolescent and young adult (AyA) with acute lymphoblastic leukemia (ALL) are currently treated like children with pediatric protocol allowing good results.
Aims: We report our monocentric experience of AyA ALL treated with the EORTC 58951 pediatric protocol
Methods: Between January 2000 and December 2011, AyA ALL aged from 16 to 29 years were treated with the pediatric EORTC 58951 protocol in the hematology department of Hedi Chaker Hospital Sfax Tunisia. Those patients were classified into two groups: G1; patients aged from 16 to 20 years and G2: patients aged from 21 to 29 years. Further leukemia characteristics (Sexe, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to prophase, risk group stratification (average: AR1 and AR2, very high: VHR), treatment related mortality (TRM), remission rate,

relapse rate and 5 years survivals (overall OS, event free EFS and relapse free survival RFS), then we compare the two groups results.
Results: Over twelve years, 51 AyA ALL were treated with the pediatric protocol. Thirty in the G1 group and twenty one in the G2 group. Sex ratio was1,7for all patients,1,2 for G1 and 3 for G3. WBC ≥ 100G/L was note respectively in 39, 35 and 45% of all patients, G1 and G2 group. A T blast phenotype was noted in 57% of cases, 53%for G1 and 63%for G2. Cytogenetic abnormalities were noted only in 53% of cases, 56% in G1 and 50% in G2. ALL were stratified into AR1, AR2 and VHR in respectively 18, 49 and 33%. G1 and G2 stratification risk group was respectively AR1: 26 and 5%, AR2: 42 and 60%, VHR: 32 and 35%. Cortico-sensitivity was noted in 71% of cases: 74% in G1 and 65% in G2. Induction death was noted in 10% of all patients (G1:10%, G2:10%). Remission rate was 98% (G1:96%, G2:100%). Consolidation death was noted in 18% (G1:22%, G2:11%). Relapse was observed in 26% (G1:19%, G2:35%). Five years OS, EFS and RFS were respectively 49, 48 and 68%. G1 and G2 OS, EFS and RFS were respectively 53, 52, 76% and 46, 45, 57%.
Summary / Conclusion: Our AyA ALL had a poor presentation: Male, leucocytosis more than 100 G/L, T phenotype and bad response to prophase were frequent particularly in G2 group. TRM is high 28% with more consolidation death in G1 group. Even good response rate, relapse still important particularly in G2 group. OS EFS and RFS are less than those observed in literature but still acceptable in our institution regarding ALL characteristics.

B1213
EVALUATION OF SURVIVAL RATES OF OUR PATIENTS WITH CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA:SINGLE CENTER EXPERIENCE
C Tımur[1*], A Ayhan[2], A Yoruk[2]
[1]Pediatric Hematology-Oncology, [2]Istanbul Medeniyet University, Istanbul, Turkey
Background: Improvements in treatment protocols result in longer expected survival rates in children diagnosed with acute lymphoblastic leukemia.
Aims: To evaluate survival rates of our patients diagnosed with childhood acute lymphoblastic leukemia
Methods: 250 children with newly diagnosed ALL in the Pediatric Hematology Department of Istanbul Goztepe Research and Education Hospital from January 2000 to January 2010 were evaluated. All of the patients included in this study were diagnosed at our institution and all were uniformly treated on a single tretment regimen, ALL–BFM (Acute Lymphoblastic Leukemia-Berlin-Frankfurt-Munster) portocole. Data were retreived from hospital records and were analyzed retrospectively.
Results: The age of patients at diagnosis ranged between 1 and 17 years (mean age6,37±4,17years). 116 (46,4%) patients were female, 134 (53,6%) were male. The follow up time ranged between 36-156 months. When patients were stratified into risk groups based on ALL-BFM protocole 83 (33,2%) patients were in standard risk group,127 (50,8%) patients were in median risk group and 40 (16%) in high risk group. 97% of patients achieved complete remission on the 33th day of induction therapy. During this 10-year follow-up period 38 (15%) patients relapsed. 24(9,6%) patients developed bone marrow relapse and 16 of these died because of the progression of the disease. 7 (2,8%) patients developed combined bone marrow and central nervous system relapse and 6 of these died. 2 (0,8%) patients developed combined bone marrow and testicular relapse. 1 patient died. 4 (1,6%) patients developed isolated testicular relapse and all of them are still in remission. 1 (0,4%) patientdeveloped retinal relapse and he's in remission. 10 (4%) patients died during induction therapy because of infections.56 events were recorded during the follow-up period. 5-year event-free survival was 75,5±3%, 10-year event-free survival was 73,1±3,4%.
Summary / Conclusion: Improvements in treatment protocols have been associated with increased survival rates in children with acute lymphoblastic leukemia.

B1214
IMPACT OF RISK FACTORS ON LONG-TERM OUTCOME IN 125 ADULT ACUTE LYMPHOBLASTIC
L Tukic[1*], D Stamatovic[2], O Tarabar[2], M Elez[2], Z Tatomirovic[2], B Zivanovic[2], B Cikota[2], M Strnad[2], O Radic[2], B Balint[2], A Zivanovic[2], M Malesevic[2]
[1]Clinic of hematology, [2]Military Medical Academy, Belgrade, Serbia

Background: Adult acute lymphoblastic leukemia (ALL) is often icurable despite intensive chemotherapy with or without hematopoietic stem cell transplantation (HSCT). Estimated overall long-term survival rate for adult ALL patients (pts) is about 20-50%.
Aims: To present our results of treatment adult ALL and impact high risk factors on overall survival (OS).
Methods: Since January 1989 till February 2013, 125 (male 87, female 38) pts with adult ALL were treated, average age was 30 years. Immunophenotype were determined in 93 (B-ALL 64, T-ALL 29) and cytogenetic/molecular analysis were succeeded in 62 pts. At the time of initial presentation: 34 pts were older then 35 years, 30 pts had high white blood cells (WBC), 5 pts had CNS involvement and 10 pts had Ph/bcr-abl+. Pts were treated with induction, consolidation and maintenance therapy under modified YU-ALL regimen for "high risk" (82), HyperCVAD (21), LALA 94 (8), etc. (14). High risk pts was defined by the presence of at least one of following factors: age > 35 years, WBC > $30x10^9$/l (B-ALL) or $100x10^9$/L (T-ALL), CNS involvement, more than 4 weeks to achieve complete remission, and finding Ph+/bcr-abl+, t(4;11)+ or t(1;19)+. Medicament prevention (without radiotherapy) of CNS disease was applied to every pts under 50 years.
Results: Complete remission (CR) was achieved in 114 pts (delayed CR in 24). Resistant to therapy were 5 pts (4.2%), 6 pts (4,8%) have died (2 early deaths, 2 before evaluation of remission, and 2 due to infective complications, 1 during II induction, 1 in CR during of intensification, respectively). Maintenance therapy (MT) was applied for 24-36 months in 69 pts. HSCT was done in 51 pts: allo in 34 pts (CR1 in 22, CR2 in8, and with partial response in 4 pts; 8/10 Ph/bcr-abl+ pts transplanted) and auto in 17 pts (CR1 11, CR2 5 and with molecular relapse 1 pts). Relapses have occurred in 75 pts (65,8%) with median time of 9 months. Frequency of relapses were in pts on MT 71% (45/63) and in HSCT pts 58,8% (30/51) or more exactly: in auto HSCT 76,5% (13/17) and allo HSCT 50,2% (17/34) respectively. The secondary allo HSCT was done in 6 pts (2 are still alive). Long.term survival without relapses had 31/114 (27.2%) pts; 10-years disease free survival in MT pts was 16.17±5%, auto HSCT pts 28.1±12%, and allo HSCT pts 33.1±11%. Uni- and multivariate analysis of impact high risk factors on OS showed significance with respect to CR achieved in 4 weeks (P=0.001), CNS involvement (P=0.01), and age (P=0.0176), while cytogenetics and WBCs were without impact on OS in this cohort of pts.
Summary / Conclusion: Results of our retrospective analysis are similar to the others and confirms that treatment of adult ALL is unsatisfactory. Further investigations of biology ALL, new targeting therapy and better control of minimal residual disease are necessary same as redefinition of traditional prognostic factors and according to them we can decide to use intensive chemotherapy with or without HSCT.

B1215
INFLUENCE OF SERUM CORTISOL LEVEL TO COLONY-FORMING EFFICIENCY OF BONE MARROW STROMAL FIBROBLASTS AT CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
V Bebeshko[1], K Bruslova[1*], L Panchenko[1], N Tsvietkova[1]
[1]SF "National Scientific Center for Radiation Medicine of NMSA of Ukraine", Kiev, Ukraine
Background: It is known that application of corticosteroids promotes violation of various origin fibroblasts function, including stromal fibroblasts. Our previous data suggesting that low serum cortisol level in debut (SCL-D)) of acute lymphoblastic leukemia (ALL) at children is accompanied by the worst prognosis in comparison with patients who had standard SCL in debut of acute leukemia.
Aims: To study the colony-forming efficiency of the bone marrow stromal fibroblasts (CFE -F) at children with ALL taking into account SCL in the debute of disease (before start of the treatment) for prognosis of leukemia course
Methods: 55 children with ALL were under investigation. Prior to executing ALL protocol treatment CFE of bone marrow stromal fibroblasts were studied in vitro by A.Y. Fridenstein's method in V.S. Astakhova's modification (2000). SCL before start of ALL treatment and overall survival (OS) of the patients were taken into account.
Results: Mean value of CFE-F in children ALL debut was 9,3±2,5 for 10^5 mononuclear cells, in control group this index was 52,3±3,2 for 10^5 mononuclear cells. On that time 14/55 children with ALL had SCL-D<200nmol/l , the others 41/55 had SCL-D>200nmol/l. Low CFE-F at children with ALL correlated with SCL-D lower than 200 nmol/l (Mann-Whitney U=10) and these children also demonstrated the excretion of calcium phosphates in urine raised by 2-2,5 times and bone densitometry decreased by 20-25% from the standard. Overall survival of ALL children with low SCL-D (<200nmol/ was 34,5±2,1 months, as at the standart value of SCL-D (483,4±11,5 nmol/l) OS of ALL children was 76,1±2,2 months.
Summary / Conclusion: Children with ALL who have SCL-D less than the 200 nmol/l also demonstrate lower CFE-F, shorter overall survival and osteoporosis phenomena as compared with patients who had standard SCL-D. The results give the chance to prognosticate ALL course at children taking into account SCL-D.

B1216
EARLY T CELL PRECURSOR LEUKEMIA: INMUNOPHENOTYPE AND CLINICAL CHARACTERISTICS OF A RARE AND AGGRESSIVE ALL-T SUBTYPE. EXPERIENCE IN ONE CENTER
L López[1,2*], B Boluda[2], C Ortiz[2], C Salazar[2], L Cordon[2], A Sempere[2], L Senent[2], F Gomis[2], M Perez[2], M Sanz[2]
[1]Hematology, Complejo Hospitalario Metropolitano Dr. Arnulfo Arias Madrid , Panama, Panama, [2]Hematology, Hospital Universitario y Politécnico La Fe, Valencia, Spain

Background: Currently there is special interest in the uncommon subtype of acute lymphoblastic leukemia T (ALL-T) known as early T-cell precursor leukemia (ETP). This has a particular inmunophenotype (CD1a-, CD5+dim, CD4-, CD8-,

and at least one myeloid or stem cell marker) that allows the distinction between other leukemias and confirms their intrathymic origin. However, their myeloid antigen expression could confuse them with biphenotypic leukemias. The main clinical characteristic is bad prognosis with poor response to treatment. Some genetic alterations have been related to ETP, but it is not yet identified a defined pattern; this has been analyzed mostly in children and there is few data available in adults.
Aims: Our goal is to identify ALL-T patients with ETP profile by inmunophenotype characteristics and correlate it with clinical course: overall survival (OS), event free survival (EFS), relapse free survival (RFS) and mortality rate (MR).
Methods: We reviewed data from 164 patients with ALL-T and biphenotypic leukemias diagnosis from Hospital La Fe Hospital in Valencia Spain from 1990 until January 2013. The clinical presentation was obtained from clinical records. The OS, EFS, MR were calculated using SPSS Statistic 17.0.
Results: There were identified 6 patients (3,6%) with ETP profile. Five cases expressed stem cell antigens and all of them at least one myeloid marker. Four patients (67%) met the EGIL (European Group for the Immunological Characterization of Leukemia) criteria for biphenotypic leukemia. The mean age was 24 years old (9 months to 63 years) and there was no gender predominance. Peripheral white blood count and bone marrow blast percentage average at diagnosis were $49.2x10^3$ cell/µL and 80% respectively. Two patients presented extramedular disease. No common genetic or molecular alterations were identified. The OS and EFS average were 11.8 months and 9.9 months respectively. In patients responding to induction therapy RFS was 3 months. Two patients had positive minimal residual disease >0.5% and they relapsed. All cases needed at least one reinduction and mortality rate was 83%.
Summary / Conclusion: ETP ALL-T is a rare subtype of ALL-T with specific characteristics. The outcomes are often unfavorable despite of aggressive treatment. The identification of this specific immunophenotype allow an accurate diagnosis. It would be necessary a multicenter study for the complete evaluation of the biological behavior of this entity to offer a targeted treatment.

B1217

CMV REACTIVATION IN ACUTE LYMPHOBLASTIC LEUKEMIA PH POSITIVE IN TREATMENT WITH DASATINIB

E Mazo[1]*, G Julio[1], M Callejas[1], M Rubio[1], M Calero[1], J Fernandez[1], F Carretero[1], T Pascual[1], N Curto[1], E Flores[1], C Casco[1] Carmen B De Ozalla[1]
[1]Hematology, Hospital Universitario Príncipe de Asturias, Alcala de Henares, Spain

Background: Dasatinib, a potent tirosine multikinase inhibitor targeting to a ABL and SCR ,among others, has transformed the treatment of chronic myeloid leukemia (CML) and Acute Lymphoblastic Leukemia Ph positive (Ph+ ALL). However, the information on infectious complications associated with its use is limited. Preliminary studies have reported 7% to mainly viral infections in patients with Ph + ALL who receive high doses of steroids.
Aims: To analyze the incidence of CMV reactivation during dasatinib treatment in Ph+ ALL patients
Methods: Between January 2012 and February 2013, we treated 3 Ph+ ALL patients with dasatinib and poli-chemotherapy according to PETHEMA LAL-070 protocol. In order to rule out CMV infection, we tested CMV antigenemia/PCR in patients with fever of unknown origin (FUO).
Results: We found one patient with CMV rectivation during dasatinib treatment in Ph+ ALL. An increased in number of LGL wasn´t observed. A56 year-old woman diagnosed with (Ph + ALL) started induction treatment as PETHEMA LAL-070 protocol, for over 55 years-old. The fifth day of treatment was confirmed positive by FISH (Bcr-Abl) and Imatinib therapy started at 200mg daily day (doses of imatinib were reduced to 50% for acute liver failure (ALF), DXM 10mg/m2 per 2 days a week, VCR 1mg/week, TIT weekly x 3 doses. As severe deterioration of liver function tests for probable liver infiltrative, we began polyQT with: Ciclofosfamide 20mg/m2/day for 5 days, prednisone 60 mg/m2/day for 21 days, VCR 1 mg weekly, Daunorubicine 15mg/m2 weekly. At day +8, for improvement of liver, the patient started imatinib 400mg daily, achievedat 3 weeks, Morphologic Complete Remission (MCR), Complete Cytogenetic Response (CCyR), absence of the transcript bcr/abl p210 and p 190 by real-time quantitative polymerase chain reaction análisis and persistent minimal residual disease (0.6%), which initiated maintenance therapy with mercaptopurine 50 mg/m2, methotrexate 20 mg/m^2/week and Dasatinib 70 mg/12h. In Day +21 of treatment, presented fever of 38° C, diarrhea, pancytopenia, cholestasis and cytolysis. The fever and diarrhea persisted with progressive worsening liver functions so we requested antigenemia and PCR CMV in blood, that resulted positive. The immunophenotype blood was normal without increase in number of LGL. As a result we started treatment with oral valganciclovir with clinical improvement, negativization antigenemia/PCR for CMV and progressive improvement of the Liver tests. As the diarrhea persist, we did a colonoscopy with biopsy result negative for CMV. Given the absence of fever, normalization of blood counts and improvement of Liver function, decided control consultation and increasing doses of imatinib.
Summary / Conclusion: Dasatinib presented *in vitro* Immunosuppression of T and NK cells. Some patients with leukemia treated with dasatinib, develop LGL cell expansion. Which is associated with a better therapeutic response, however, may be linked to a reactivation of CMV. The findings suggest that cytomegalovirus screening should be routinely in patients treated with dasatinib.

B1218

ACUTE LYMPHOBLASTIC LEUKEMIA OF HIGH AND INTERMEDIATE RISK. SINGLE CENTER EXPERIENCE SINCE 2000

J Loscertales[1]*, B Quereda[1], N Acedo[1], M Cuadrado[1], A Figuera[1], V de Soria[1], B Aguado[1], A Alegre[1]
[1]Hematology, Hospital Universitario de La Princesa, Madrid, Spain

Background: It is generally considered that adult patients with Acute Lymphoblastic Leukemia (ALL) reached only limited results after current BFM-based chemotherapy programs, especially those with age over 50.
Aims: We wanted to learn from our single center experience in the treatment of adult patients with ALL.
Methods: Between 2000 and 2012, 56 consecutive patients were diagnosed of ALL in our center. 46 cases were considered high risk, being the rest intermediate risk. Median age at diagnosis was 40 (range: 13-89). There were 29 women and 27 men. 7% were of T lineage, being the other 93% of B lineage. Among these, most frequent type was B common (41%), followed by preB (21.4%) and proB ALL (12.5%), with the rest being biphenotypic leukemias. Burkitt/Burkitt like ALL were excluded from this analysis. At diagnosis, 31% of cases had a white cell count over $30x10^9$/L. Protocols mainly used were PETHEMA versions of 1993 and 2003 (for high risk) and 1996 (for intermediate risk).
Results: Complete remission (CR) were reached in 94% of cases. 30 out of these 52 responding patients eventually relapsed. Progression free survival (PFS) was 58% at 1 year and 42% at 2 years. Median overall survival (OS) was 5 years. 37% and 12% had OS over 5 and over 10 years, respectively. 12 of the 30 relapsed patients had OS over 5 years, with a median OS of 4.7 years. OS for high-risk patients treated with PETHEMA 1993 protocol was over 10 years in 57% of cases, while 46% for the same population treated with 2003 protocol. Intermediate ALL cases had a median OS of 5 years.
Summary / Conclusion: Despite the small numbers, and a potential positive selection bias for a referral center, we found better results for ALL patients treated with conventional chemotherapy BFM-based programs, than the ones previously published for our global national group. Of note, quite elderly ALL patients can be long term survivors.

B1219

CYTOCHROME P450 3A4(CYP3A4) GENE POLYMORPHISM AMONG EGYPTIAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N Elbarbary[1]*, M Abo-El-Asrar [1], G Thabet [2], N Elrazik [1]
[1]Department of Pediatrics, Ain Shams University, [2]Department of Clinical Pathology, National Cancer Institute, Cairo, Egypt

Background: Acute lymphoblastic leukemia (ALL) is the most common pediatric cancer with a cure rate of approximately 80%.Relapse occurs despite treatment stratification based on clinical criteria **.** Cytochrome P450, family3, subfamily A, polypeptide 4(CYP3A4), a member of the cytochrome P450 mixed-function oxidase system, is the most abundant hepatic and intestinal P450 enzyme and is involved in the metabolism of more than 50% of all drugs used in humans including glucocorticoids such as dexamethasone, phenobarbital, and anticancer drugs . Interindividual variation in drug metabolism is a complicating factor in pharmacotherapy.
Aims: The aim of this study was to clarify the characteristic distribution patterns of the genotype of CYP3A4*1B in Egyptian children with ALL and in healthy control, and then explore whether the polymorphism of CYP3A4 is related to vulnerability to childhood leukemia and the development of relapse , secondary malignancy and chemotherapy induced toxicity.
Methods: Patients were subjected to full history taking with special stress on age, type of chemotherapy and their doses, then complete physical examination, laboratory assessment with adequate volume of venous blood was withdrawn from each patient and control for determination of liver, kidney functions, complete blood picture and bone marrow aspirate at day15,42 and 49.
PCR-RFLP and DNA sequencing was applied to assay genotypes of CYP3A4 in 67 Egyptian ALL children and 72 healthy children, then the difference of phenotypes and genotypes of CYP3A4 was compared between these two groups.
Results: In 72 healthy children, only two children were heterozygote genotype of *CYP3A4*1B*, others were all in wild type(n=70) and non in variant type,the percentages of genotypes were as follows: 2.8% for heterozygote, 97.2% for wild type and 0.0% for the variant type respectively. While in 67 children with acute lymphoblastic leukemia, eight children had (11.8%) heterozygotic genotype of *CYP3A4*1B*, one (1.5%) ALL child was homozygote genotype and 58 (86.6%) in wild type respectively. A significantly higher prevalence of the heterozygote polymorphic variant CYP3A4-A-290G (CYP3A4*1B) gene in ALL cases, when compared with controls (11.9% vs. 2.8%,P=0.000).Eight patients with heterozygote genotype developed complete remission at day 15 bone marrow aspirate while 56patints with wild genotype developed complete remission at day 15 bone marrow aspirate and two patients with wild type developed partial remission and one patient with variant type developed partial remission(P=0.000). In wild type group ; one patient developed relapse and another one developed secondary malignancy as biphenotypic leukemia(P=0.92). We could not find any association between CYP3A41*B polymorphism and other risk factors like age at diagnosis (P=0.500), initial total

leukocyte count (P=0.695), LDH (P=0.152),gender (P=0.468), clinical risk degree (P=0.238), immunophenotyping (P=0.746) and FAB classification (P=0.298).None of the patients developed symptoms or signs of toxicity from Vincristine, Adriamycin and VP16 .
Summary / Conclusion: Mutation frequency of CYP3A4*1B in children with ALL was higher than that of in healthy control, thus it could interfere with the leukemogenesis in Egyptian children but not the risk of relapse or secondary malignancy.

B1220
THE SERUM TRAIL AND TRAIL LIGAND ON THE APOPITOTIC PATHWAY IN CHILDHOOD ACUTE LEUKEMIAS
B Antmen[1], Z Haytoglu[1], I Sasmaz[1*], B Karagun[1], Y Kilinc[1]
[1]Pediatric Hematology, Cukurova University, Adana, Turkey

Background: In leukemias and malignant tumors the balance and interaction between apoptosis and cell proliferation is dysregulated. Many types of cancer cells have tumor necrosis factor related apoptosis inducing ligand (TRAIL) on their cell membran surfaces. Targeting the cell extrinsic pathway which triggers p-53 independent apoptosis offers a unique therapeutic stragety to induce apoptosis in only cancer cells thus prevents the damage of healthy cells. TRAIL induces apoptosis with its receptors TRAIL-R1, TRAIL-R2 however apoptosis can not be induceed by receptors TRAIL R-3 and TRAIL-R4. There are many trials to search the correlation between leukemia and apoptotic pathway disorders.
Aims: In this study we determined the seum levels of TRAIL and TRAIL receptors (TRAIL-R1, TRAIL-R2, TRAIL-R3, TRAIL-R4) in acute childhood leukemias at diagnose. We aimed to determine the relation between the levels of soluble TRAIL and TRAIL receptors and patient's survey, clinical parameters.
Methods: The study was performed in pediatric hematology and pediatric oncology department of Çukurova University Medical Faculty between October 2009 and July 2010. Twenty-three cases with ALL at the ages of 9 months-12 year 8 months and fourtteen cases with AML at the ages of 9 days-19 years are included in this study. The age distrubition of the control group varied 3 months-17 years consisted of twenty-one healty children with similar sex and age were included into the study. In this study we investigated serum TRAIL and TRAIL receptor levels a by using ELISA method and device elisa plate reader.
Results: The comparison of the average values of the TRAIL levels in acute leukemia patients and control group have shown that patients with leukemia have low soluble TRAIL levels (P=0.002) (P<0.05). The comparison of the average values of the TRAIL levels in ALL and AML patients have shown no difference (P>0.05). In patients with HRG of ALL have shown low soluble TRAIL levels (P=0.08) (P<0.05). In patients with CALLA- B ALL have shown low soluble TRAIL levels (P=0.04) (P<0.05). Children with acute leukemias (ALL, AML) who died during treatment have shown low levels of serum TRAIL (P=0.04) (P<0.05).The patients with AML who survived have shown high levels of serum TRAIL-R1 (P=0.03) (P<0.05). In ALL group we found high levels of TRAIL-R3 (P=0.04) (P<0.05).
Summary / Conclusion: This study indicate that children with leukemias (AML, ALL) have low levels of soluble TRAIL. In children with HRG ALL and CALLA-B ALL have low levels of soluble TRAIL. These results indicate that apoptosis may not be induced in this two groups which have poor prognosis. In ALL patients the receptor TRAIL-R3 levels were high. The low levels of sTRAIL and high levels of TRAIL-R3 decoy receeptors suggest that apoptosis can not be induced and this may be related in the pathogenesis of ALL. We found high serum TRAIL-R1 levels in AML patients who survived. As a result, soluble TRAIL and TRAIL receptors might play a role in leukomegenesis. However many investigations are needed involving determined inner cell mRNA levels and cell surface levels of TRAIL and TRAIL receptors to suggest soluble TRAIL's and TRAIL receptor's role in leukomegenesis.

B1221
LOW PLATELET COUNTS AS A PROGNOSTIC MARKER IN ALL TREATMENT IN PLACE OF MRD IN COUNTRIES WITH LIMITED FINANCIAL RESOURCES
T Celkan[1*], A Koka[1], N Ozdemir[1], G Tuysuz[1], H Apak[1], E Erginoz[1]
[1]Pediatric Hematology-Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: The evaluate children treated for their ALL by BFM protocols.
Aims: The aim of this study was to improve our therapeutic risk stratification in trials which no MRD analyses were done. For this purpose, we used peripheral blood counts being cheap and non-invasive.
Methods: There were 242 newly diagnosed non B-ALL patients enrolled into this retrospective study, during January 1995 to January 2012 and if they had enough data in their documentation.
Results: The median age was6,18y ±3,75years (8 month- 17 years). The 59,4'ü % of the group were boys. (boys /girls 1,46). The mean leucocyte count at admission was 37.000/mm^3 (200-285.000/mm^3). CNS involvement was positive in %7,7 at the time of the diagnosis. T-cell immunophenotype was shown in11,8% of patients. Genotypically t(12;21), t(9;22) and t(1,19) were positive in %8, %3 and %3 of patients, respectively. The overall survival of the B-ALL patients was %813,1, while that of the T-ALL patients was %62,2 12,4 (p:0.007). The EFS of the patients who had CNS involvement was %47,6 , lower than the ones who had not(p:0,0001). The OS and EFS of the whole group was 74,83,9 and 743,1 respectively, while EFS ratios for boys 72% and girls 80.5% (p:0.728).The OS and EFS were lower as the age increase (>10 years OS and EFS were 59,98,4 and 57,4 (p:0,001)) except <1 year (OS and EFS 37,5 28,6). Being a high risk patient was significantly associated with X3 relaps and X7 exitus (OS 22,7 9,1and EFS 27,6 (p:0,0001). Clinically having paleness corralated with improved prognosis (+ paleness 88 %4 , (p:0,026) . In our cohort bone involvement was a component of B cell leukemia. Having splenomegaly, hepatomegaly, t (9,22), CNS involvement (CNS leukemia increased exitus risk X4 times), higher Hb and WBC counts at diagnosis were related with poorer treatment results. (WBC >100.000 /mm^3 OS %53,7 12,8 (p:0.028); .Hb >8g/dl and T-ALL patients' OS 44,4 13,5 (p.0,01). Although the platelet counts at diagnosis had no prognostic value, the counts at 15 and 33th day of treatment significantly associated with treatment outcome. Patients whose platelet count at 15 and 33th days were <50.000/mm^3 had higher risk for exitus (respectively X3 and X7), and had lower OS p:0,008, p:0,0001). Thrombocytopenia usually goes parallel with neutropenia and monocytopenia. The blast count at 15 and 33 day were a reliable prognostic marker as if the blasts were >%5 OS 35,8 15,9 and 0 % while patients with blasts
Summary / Conclusion: Childhood ALL treatment results have reached great improvements in the MRD era. The potential benefit of simple methods such as full blood count and clinical findings, can predict us the outcome. The most striking and important finding of our study is probably the strong association of platelet counts with the prognosis. Having a platelet count less than 50.000/mm^3 at the 15 and 33th day of treatment, was associated with high mortality(p:0,0001)and this count would be easily used just for a marker in countries with limited financial resources where MRD is not avaliable.

B1222
TREATMENT EFFICACY IN PATIENTS WITH ALL UNDER 1 YEAR ENROLLED IN A CLINICAL TRIAL MLL-BABY IS STRONGLY ASSOCIATED WITH TREATING CLINIC EXPERIENCE IN INFANTS CARE
L Fechina[1*], E Shorikov[1], O Streneva[2], O Khlebnikova[1], G Tsaur[2], L Saveliev[3], A Popov[2], D Litvinov[4], N Myakova[4], K Kondratchik[5], D Peregudov[6], A Shamardina[7], E Boichenko[8], N Ponomareva [9], E Lapotentova [10], O Aleinikova[10], A Karachunsky[4], A Roumiantsev[4]

Novgorod, [8]Pediatric Oncology and Hematology, City Children's Hospital1, St. Petersburg, [9]Pediatric Oncology and Hematology, Russian State Children's Hospital, Moscow, Russian Federation, [10]Pediatric Oncology and Hematology, State Center of Pediatric Oncology and Hematology, Minsk, Belarus

Background: Prognosis in patients (pts.) under 1 year with acute lymphoblastic leukemia (ALL) is determined not only by the particular *MLL*-rearrangement, but by number of working together proven risk-factors. Quality of medical care provided by the experienced staff, also plays the important role in outcome of treating babies and might be taken into account with other factors influencing on the prognosis.
Aims: To estimate treatment related outcome in two groups of infants treated with ATRA containing MLL-Baby Protocol either in well-, or less experienced and/or small clinics of Russia and Belarus. To determine main cause of treatment failures in both cohorts.
Methods: MLL-Baby Protocol intended for infants' ALL treatment is widely applied chemotherapy regimen in Russia and Belarus. 20 clinics are participating in this trial nowaday. From July 2003 to November 2012–59(71%) out of 83 newly diagnosed pts. were treated in 5 well experienced oncological and hematological departments (Group 1), the rest 24(29%) pts.–in 15 small and/or less experienced clinical wards (Group 2). MLL-Baby Protocol design has been previously introduced at the EHA Meetings 2008-2012. The chemotherapy regimens and initial characteristics of pts.: age, gender, initial WBC, CNS status, proportion and type of *MLL*-rearrangements were equal in both groups, except immunophenotype – BI-46,5% in Group 1 vs. BI-75% in Group 2 (P=0.01).
Results: 4(6,7%) out of 59 and 4(16,6%) out of 24 pts. died during remission induction (P=0,16); 54(91%) and 20(83,3%) achieved CR (P=0,27); 14(25%) and 6(25%) relapsed (P=0,9) in Groups 1 and 2 respectively. Only 1(1,6%) infant from Group 1 with T-ALL and *Sil/Tal* microdel1p did not respond to the therapy. In contrast 2(3,3%) in Group 1vs. 6(25%) in Group 2 (P=0,002) died in complete remission due to the treatment related complications. Survival estimates differ significantly – EFS are 0,62±0,06 vs. 0,28±0,09 (P=0,007); DFS are 0,68±0,06 vs. 0,34±0,11 (P=0,01) and OS are 0,66±0,06 vs. 0,42±0,1 (P=0,02) in Groups 1 and 2 respectively; while RFS: 0,71±0,06 and 0,52±0,14

(P=0,37) and cumulative incidence of relapse (CIR): 0,47±0,02 and 0,28±0,04 (P=0,33) in Group 1 and Group 2 did not achieve the statistical significance. At present time 38(64,4%) from Group 1 and 8(33,3%) pts. from Group 2 are staying in CCR (P=0,009). In univariate analysis the following parameters influenced negatively on EFS: age of pts. <6 months (P=0,0002); *MLL*-status (P=0,001); Group of treatment (P=0,007) and Day8 response (P=0,01). Multivariate Cox-regression analysis confirmed the significant negative impact on EFS: age <6 months with $HR_{2,70}$ (95% $CI_{1,21-6,04}$) P=0,01 and Group (place of treatment) – $HR_{2,64}$ (95% $CI_{1,30-5,35}$) P=0,007 (Table 1)

Summary / Conclusion: Patients from Group1, treated by well experienced team have significantly better survival rates: EFS, DFS and OS, comparing to the patients from Group 2 treated in less experienced and/or small clinics, because of the different treatment related mortality rates in complete remission. Well experienced staff in infants care and clinic reliable infrastructure significantly improved patients' outcome. Place of treatment and quality of medical care should be considered as an addtional prognostic factor. Similar RFS and cumulative incidence of the relapses in both Groups demonstrate the efficacy of MLL-Baby Protocol in the relapse prevention, despite of the treating clinic experience in infants care.

	Univariate analysis				Cox regression	
	Pts	Events	EFS (SE)	p	HR (95% CI)	p
Age				0,0002

B1223

INFECTIONS DURING INDUCTION OF REMISSION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND LYMPHOBLASTIC LYMPHOMA- COMPARATIVE STUDY

K Martinova[1*], B Coneska[1], S Kocheva [1], A Jovanovska[1], E Bojadgieva[2]
[1]Hematology and Oncology, University Children's Hospital, Skopje, [2]Faculty of Medical Sciences, University Goce Delcev, Stip, Macedonia, The Former Yugoslav Republic Of

Background: Acute lymphoblastic leukemia (ALL) and lymphoblastic lymphoma (LL) are very similar diseases and in most treatments they are treated according to same or very similar protocols. Infection is an important complication and cause of death in children receiving highly myelosuppressive chemotherapy for treatment of ALL and LL. Many children experience one or more infectious complications during treatment.

Aims: To compare the characteristics of infective episodes in children with acute lymphoblastic leukemia and lymphoblastic lymphoma in primo induction treatment.

Methods: Objective of this study were 55 patients with ALL and 19 patients with LL aged1,1 to 15 years who were treated according to BFM-ALL-95 and BFM-NHL-95 protocol between January 2000 and December 2007 at the University Children's Hospital in Skopje. We explored the characteristics of infective episodes together with the causative pathogens, the episodes of febrile neutropenia (FN), the length of antibiotic treatments and treatments with G-CSF.

Results: Altogether during primoinduction treatment 132 and 35 infective episodes were detected in the patients with ALL and LL respectively. Regarding to the pathogens, 102 (77,30%) versus 32 (91,43%) were bacterial, 20 (15,15%) versus 1 (2,86%) were viral and 10 (7,58%) versus 2 (5,71%) were fungal in the two evaluated groups of patients. There is a slight predominance of Gram-positive bacteria in both groups: 42 (51,85%) gram (+) versus 34 (41,97%) gram(-) infective episodes in ALL group and 16 (55,17%) versus 13 (44,82%) in LL group of patients. Different microorganisms were isolated with Strept. pneumoniae, Staph. aureus, Hemoph. inf. and Klebsiella spp. accounting above 80% in both groups. Febrile neutropenia was observed in 16 (29,1%) patients in ALL group and in 8 (42,1%) in the LL group. The infections were treated with antibiotic treatment in average of 23,69±12,67 and 15,39±11,93 days in the patients with ALL and LL respectively. The number of treatments with G-CSF was 397 or about 7,22±4,79 for ALL patients and 172 or 9,56±7,66 for patients with LL.

Summary / Conclusion: Evaluation of the characteristics of infective episodes between two evaluated groups of patients with ALL and LL presented a difference just in the length of antibiotic treatment (longer in ALL patients). This difference is with statistical significance (P=0,0169). No difference in the number of infective episodes, neither in causative pathogens, the episodes of FN and the treatments with G-CSF was observed.

Acute myeloid leukemia - Biology

PROLIFERATION OF ACUTE MYELOGENOUS BLASTS AS EFFECT OF DIFFERENT CYTOKINES CAN BE USED TO IDENTIFIED PATIENT AND CYTOKINE SUBSETS ALSO BY GENE EXPRESSION PROFILES

H Reikvam[1*], A Margrete Øyan[2], K Kalland[2], R Hovland[3], K Hatfield[1], Ø Bruserud[1]
[1]Institute Of Medicine, University Of Bergen, [2]The Gade Institute, [3]Centre of Medical Genetics and Molecular Medicine, Bergen, Norway

Background: Acute myeloid leukemia (AML) is a heterogeneous group of hematopoietic disorders characterized by bone marrow accumulation of immature leukemic cells. Uncontrolled proliferation of blasts is a hallmark of AML. Several cytokines can function as growth factors for AML blasts, and abnormalities of cytokine and growth factor signalling pathways are characteristic for AML

Aims: We investigated proliferation features of two different groups of AML patients, to further use the findings for classification of patients and linked them to distinct gene expression profiles.

Methods: AML cells were cultured in standard *in vitro* condition in the absence or presence of seven given cytokines; stem cell factor (SCF), granulocyte-macrophage colony stimulating factor (GM-CSF), granulocyte colony stimulating factor (G-CSF), macrophage colony stimulating factor (M-CSF), FLT3-ligand (FLT3-L), interleukin 3 (IL-3) and interleukin 1β (IL-1β). The two groups contained 40 (group I cohort) and 54 (group II cohort) patients respectively. Proliferation rates were detected after seven days by ^{3}H-incorporation assay. Results were used to classify patients by clustering models. Results were compared with microarray experiments performed using the Illumina iScan Reader.

Results: All cytokines gave increased proliferation rates of AML blasts compared to blasts cultured in the absence of cytokines (P>0.001). By an unsupervised hierarchical cluster model we identified three main patient clusters based on cytokine dependent proliferation (i) high proliferation rates both in the presence and absence of cytokines, (ii) high proliferation rates in the presence of cytokines, but low proliferation without cytokines, (iii) lower proliferation rates with or without cytokines. The high proliferation clusters were characterized by high expression of CD34 and low frequency of the *NPM1* mutations combined with lack off the *FLT3* mutation. To further explore the differences between patients with high proliferation rates (i) and patients with low proliferation rates (ii and iii). Gene expression data were obtained for 32 patients belonging to the group I cohort. Of these 32 patients, 13 belonged to the high proliferation cluster (i) and 19 to low proliferation clusters (ii). ANOVA analysis was performed to identify genes to be differently expressed between the high proliferative group and the low proliferative group. Gene ontology allowed us to identified different terms/pathways which were differentially expressed between high and low proliferative AML cells. For group II cohort we examined genes differentially expressed between the high proliferative patients and the low proliferative patients only among patients harbouring the FLT3-ITD mutations. 16 patients were identified; ten in the high proliferative group and six in the low proliferative group. We identified 10 genes up-regulated in the high proliferative group and seven genes up-regulated in the low proliferative group. The genes were classified according to GO-annotations, and it is noteworthy that three genes belonged to the ubiquitin-proteasome pathway in addition to the cytokine stimulation factor EIF4E3.

Summary / Conclusion: *In vitro* proliferation varies considerably among AML blasts, and can be used to subclassify patients. Gene expression profiles can be used to identifying genes involved in AML cell proliferation.

B1225

DIFFERENTIAL EXPRESSION OF NEW METNASE (SETMAR) TRANSCRIPT VARIANTS IN HEMATOLOGICAL CANCERS- INCREASE IN AML PATIENTS

D Jeyaratnam[1*], M Hansen[1], J Jørgensen[1], H Ommen[1], P Hokland[1], C Nyvold[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark

Background: Evolutionary, the *Metnase* gene, also known as *SETMAR* and present in several transcript variants, is regarded as a unique fusion protein consisting of SET- and Transpose domains. While it functions as a human DNA repair protein it has previously also been shown to suppress experimentally induced chromosomal translocation in mice (Wray *et al*, CanGenCyt, 2010). In addition, high expression of *Metnase* leads to resistance to Topoisomerase IIα inhibitors, especially VP-16 generally used as a chemotherapeutic drug in cancers. By qPCR targeting all known transcript variants of *Metnase* we have shown that the gene is over-expressed in acute myeloid leukemia (AML).

Aims: We hypothesized that patients without a chromosomal translocation (AML^{TNeg}) had an increased level of *Metnase* mRNA expression compared to patients harboring a chromosomal translocation (AML^{TPos}). In addition, we wished to quantify the expression of the different *Metnase* transcript variants in AML^{TNeg}, in AML^{TPos}, in mantle cell lymphoma (MCL) harboring the t(11;14) translocation, and in healthy individuals.

Methods: PCR using primers located in exon 1 and exon 3 of *Metnase* targeted cDNA from peripheral blood (PB) of diagnostic AML samples. The PCR-products were cloned into a plasmid vector, in order to separate the different transcript variants, and subsequently Sanger sequenced. Specific qPCR assays spanning exon-exon junctions were designed for each of the identified variants. All samples were normalized to the cell line Granta-519, thereby defining the *Metnase* levels in Granta-519 as 1. *Beta-2-microglobulin* and *beta-glucuronidase* were used as reference genes. Samples with Cq > 40 were defined as negative.

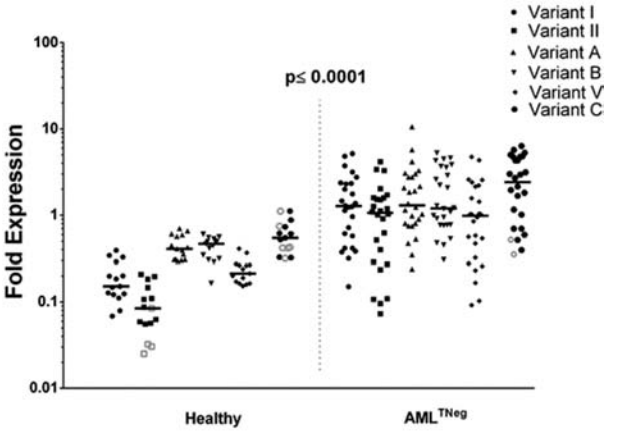

Figure 1: Expression of *Metnase* transcript variants.
Open symbols signify values with a Cq>40.

Results: Three already known (NM_006515, NM_001243723, and NR_075073, previously numbered I, II and V)) and three novel (here denominated A, B and C) transcript variants were identified. Variant I harbored the full length transcript, variant II had lacked the central part of exon2, variant A was found to have whole exon 2 spliced out, variant B harbored a deletion of the first part of exon2, variant V also had a deletion of the first part of exon 2 but was 20 base pair longer than variant B, and variant C encompassed a deletion internally in exon 2 but different from variant II. We observed a heterogeneous pattern of expression in healthy individuals and patients. Thus, while variants I, A, B and V were expressed in all selected subgroups of patients, variant II was only expressed in 11/15 healthy individuals, 26/26 AML^{TNeg}, 12/13 AML^{TPos} and 6/9 MCL patients. Finally, variant C was only expressed in 7/15 in healthy individuals, 24/26 AML^{Tneg}, 10/13 in AML^{TPos} and 2/9 MCL patients (see fig. 1 for AML^{TNeg} and AML^{TPos} comparison). All variants were significantly increased in the AML^{TNeg} group when compared to healthy individuals (P<0.0001, Figure 1), while only variant I, II, A and C were so in AML^{TPos} patients. When comparing the expression in the AML^{TNeg} and AML^{TPos} groups we found a significant higher expression in AML^{TNeg} for transcript variants A (P=0.0392) and B (P=0.0408). Interestingly, the expression pattern in MCL did not differ from that seen in healthy individuals.

Summary / Conclusion: We have identified three novel transcript variants of *Metnase* and designed specific qPCR assays targeting all six identified transcript variants of *Metnase*. All three new transcript variants can lead to non-functional proteins, if translated, and thereby non-functional as a DNA repair proteins. A significantly higher expression of *Metnase* in AML compared to healthy individuals was found. We propose that the determination of *Metnase* transcript variants expression could be of importance for the occurrence of chromosomal aberrations in AML. Further studies are needed to clarify the role of those transcript variants in hematological malignancies and to evaluate how patients with high expression of *Metnase* respond to treatment in particular Topoisomerase IIα inhibitors.

B1226

NEWLY DIAGNOSED ADULT AML AND MPAL PATIENTS FREQUENTLY SHOW CLONAL RESIDUAL HEMATOPOIESIS

C Fernandez-Gimenez[1*], M Santos-Silva[2], A López[1], S Matarraz[1], M Jara-Acevedo[1], L Gutierrez[1], M Sánchez[1], C Cervero[3], O Gutierrez[4], N González[5], C Salvador-Osuna[6], A Orfao[1]

[1]Department of Medicine and Service of Cytometry, IBSAL and Centro de Investigación del Cáncer (IBMCC USAL-CSIC), University Hospital of Salamanca and University of Salamanca, Salamanca, Spain, [2]Laboratório de Oncologia Experimental e Hemopatias do Departamento de Análises Clínicas, Universidade Federal de Santa Catarina, Santa Catarina, Brazil, [3]Hematology Department, , Hospital General Virgen de la Luz, Cuenca, [4]Hematology Department,, Hospital Rio Hortega, Valladolid, [5]Hematology Department,, Hospital Obispo Polanco, Teruel, [6]Hematology Department,, University Hospital Miguel Servet, Zaragoza, Spain

Background: The current WHO classification of myeloid neoplasms identifies three major subgroups of heterogeneous diseases, -acute myeloid leukemia (AML), myelodysplastic syndromes (MDS) and myeloproliferative neoplasms (MPN) - with a significant degree of overlap among them. Within AML, disease heterogeneity translates into six major subgroups each of which still contains several specific diagnostic entities, being of utmost clinical relevance because of their distinct prognosis. Among cases classified as *de novo* AML, a significant percentage of patients show AML with myelodysplasia related changes, representing a unique poor-prognosis WHO category of the disease, independently of the lineage and cytogenetic alterations of myeloid blast cells. Overall, these criteria confirm the clinical relevance of the presence of MDS-associated features in AML, for unequivocal differential diagnosis among *de novo* AML, secondary AML and AML with myelodysplastia related changes, that reflects the presence of an underlying clonal disorder of residual hematopoiesis, fact that at present, neither cytomorphology nor cytogenetics alone is sensitive enough to assess in every *de novo* AML patient.

Aims: To investigated the existence of an underlying clonal disorder of residual mature/maturing neutrophils, monocytes and NRC in the BM of *de novo* AML patients.To investigate the potential association between the molecular findings and both dysplastic features by cytomorphology and altered immunophenotypes by multiparameter flow cytometry.

Methods: iFISH studies, immunophenotypic studies, HUMARA assay (in female cases) and presence of *KIT* mutation was performed on FACS-purified cell populations from *newly-diagnosed* AML and MPAL patients

Results: The clonal nature of blast cells was demonstrated in all (59/59; 100%) *newly-diagnosed* AML and MPAL patients analyzed*,* meanwhile clonality of residual BM compartments of mature/maturing neutrophils and monocytic cells and/or NRBC was confirmed for at least one of these three cell compartments in most *newly-diagnosed* AML and MPAL cases (49/59; 83%).

No statistically significant differences were observed as regards the distribution of cases with clonal vs. non-clonal residual hematopoiesis among the different diagnostic subgroups of *newly-diagnosed* AML.

Residual BM mature/maturing granulomonocytic and NRBC showed aberrant phenotypes -similar to those recurrently described for MDS- in 52/58 cases (90%). Accordingly, immunophenotypically altered neutrophils, monocytes and NRBC were found in 51/58 (88%), 38/52 (73%) and 27/45 (60%) patients respectively.

Cases with "clonal residual hematopoiesis showed a significantly higher frequency of aberrant phenotypes among maturing neutrophils (98% vs. 50%; P<0.001), monocytic cells (83% vs. 30%; P=0.003) and NRBC (71% vs 13%; P=0.01) and a higher mean number of phenotypic alterations/case (6.9±3.0 vs. 3.7±4.2, P<0.001) as well as greater number of altered cell populations/case (2.4±0.8 vs. 1±1.2, P<0.03), than the other cases.

Summary / Conclusion: The vast majority of adults with *newly-diagnosed* AML and MPAL displays an underlying clonal hematopoiesis, residual mature/maturing granulomonocytic and/or erythroid cells displaying chromosomal alterations, which are frequently shared by the blast cells, in addition to multiple aberrant phenotypes that appears to involve most WHO 2008 diagnostic subtypes of AML and also MPAL. Whether the presence versus absence of clonal residual hematopoiesis contributes to a better prognostic stratification of *newly-diagnosed* adult AML and MPAL patients deserves further investigations.

B1227

MINIMAL RESIDUAL DISEASE AND CLEARANCE OF LEUKEMIC BLASTS IN ACUTE MYELOID LEUKEMIA: TIMING AND CUT-OFF VALUES BETWEEN MFC AND WT1

G Rossi[1*], M Minervini[1], L Melillo[1], F di Nardo[2], C de Waure[2], M Emanuela[1], M Greco[1], P Scalzulli[1], G Perla[1], D Valente[1], N Cascavilla[1]

[1]Hematology and Stem Cell Transplantation Unit, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, [2]Istitute of Hygiene, Catholic University of Sacred Heart, Rome, Italy

Background: The detection of leukemia –associated immunophenotypes (LAIPs) by multiparameter flow cytometry (MFC) and the quantification of WT1-RNA levels were widely used to monitor minimal residual disease (MRD) in acute myeloid leukemia (AML). Anyway an agreement between published studies on cut-off values and timing was missing. The clearance of blasts may represent an important solution to MRD cut-offs.

Aims: AML patients in complete remission (CR) were investigated in order to establish the most predictive time point and cut off value to monitor MRD by MFC and WT1. Timing, cut-off value and impact of clearance on the outcome of patients were further evaluated.

Methods: Fresh bone marrow samples from 88 AML patients were obtained at diagnosis between January 2010 and November 2012. CR was achieved from 45 patients evaluated by MFC and WT1 to study MRD and clearance at different time points: after induction therapy (T1), after consolidation therapy (T2) before transplant (T3) and after –transplant (T4). The immunophenotypic analysis was performed using a six-color combinations in order to correctly identify LAIPs. RQ- PCR to test WT1 expression was made according to the standardized and quality-controlled method . The obtained WT1 copy numbers were normalized with respect to the ABL transcripts. Clearance of blasts was expressed as the ratio, converted to logarithmic scale, between LAIP-positive blasts and WT1 copy number at diagnosis and each time point . ROC

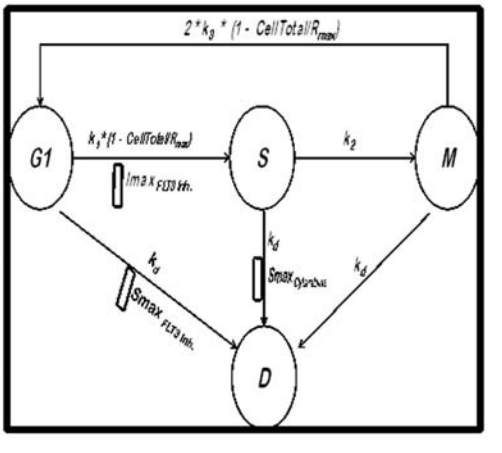
curves were studied to determine area under curve and optimal cut-off values at each time. A multivariate Cox regression was used to survival at different times.
Results: The assessment of MRD by MFC and WT1 at T4 predicted the recurrence better than the other time points. The more reliable cut-off values resulted 0.1% for MFC at T1, T2 and T3 and 0,055 % at T4. The cut-off values by WT1 were 90.0 at T1 and T3, 71.0 at T2 and 54.0 at T4. When the clearance was considered, the best prediction of relapse was evidenced at T4 with cut off values of 3.07 and 1.65 for MFC and WT1, respectively. Patients with values of MFC above 0.10% at T1 (n= 27 pts, 60%) had a significantly poorer expected disease free survival compared to those with lower levels (n= 18 pts, 40%; P<0.01; crude HR: 5.0; 95%CI: 1.4-17.5). This difference was preserved after adjusting for age, gender, Hb levels and stem cell transplant (P<0.01; adjusted HR: 7.7; 95%CI: 1.8-29.6). Results from MFC clearance showed that patients with log clearance at T1 equal to or below 2.81(28 pts, 62%) had a significantly poorer expected disease free survival compared to those with higher levels (17 pts, 38%; P<0.01; crude HR: 9.7; 95%CI: 2.2-43.2). This difference was preserved after adjusting for age, gender, Hb levels and stem cell transplant (P<0.01; adjusted HR: 22.6; 95%CI: 3.7-136.3). Patients undergone to stem cell transplantation showed a better disease free survival at the multivariate analysis (P=0.02; adjusted HR: 0.6; 95%CI: 0.1-0.7). At T1 no statistically significant correlations were observed between WT1 values , WT1 Log clearance values and DFS. No significant correlations between MRD and DFS were obtained at T2.
Summary / Conclusion: From our study, the most predictive evaluation of MRD was performed after the transplant while the post-induction evaluation stratified better high risk patients among pre-transplant times. Cut-off values needed to be lower after the transplant compared to previous times and the clearance of LAIP positive blasts makes an excellent prediction of the outcome.

B1228
FLOW CYTOMETRIC ASSESSMENT OF HUMAN EQUILIBRATIVE NUCLEOSIDE TRANSPORTER 1 (HENT1) EXPRESSION IN ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES
F Bellos[1*], B Davis[2], N Culp[2], B Booij[3], T Bergeland[3], S Schnittger[1], C Haferlach[1], T Haferlach[1], W Kern[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany, [2]Trillium Diagnostics, LLC, Brewer, Maine, United States, [3]Clavis Pharma, Oslo, Norway

Background: Transporters like human Equilibrative Nucleoside Transporter 1 (hENT1) transport nucleosides into cells. Nucleoside analogs depend on cellular hENT1 expression for entry into cells. Data on correlation of hENT1 levels with response to such chemotherapies in AML and MDS is scarce.
Aims: To examine hENT1 expression by multiparameter flow cytometry (MFC) in AML and MDS. To correlate results to morphology, cytogenetics (CG) and molecular genetics (MG).
Methods: We studied 130 AML and 94 MDS at diagnosis, 125/99 male/female, median age 66.5 (AML) and 73.3 years (MDS). CG was done in 115 AML and 84 MDS. hENT1 expression was quantified by a novel 4-color intracellular staining assay with monoclonal antibodies against hENT1, CD45, CD64 and myeloperoxidase. Median fluorescence intensities (MFI) of hENT1 were determined in myeloid progenitors (MP), granulocytes (Gra) and monocytic cells (Mo) and correlated to hENT1 MFI in lymphocytes to derive hENT1 index.
Results: Pt included 99 de novo AML, 4 t-AML, 27 s-AML; 7 FAB M0, 26 FAB M1, 43 FAB M2, 7 FAB M3, 19 FAB M4, 7 FAB M4eo, 7 FAB M5, 14 not classified; by CG (MRC): 18 favorable, 69 intermediate, 28 adverse [Grimwade, Blood 2010]. 89 were de novo MDS, 5 t-MDS; 1 RARS, 17 RCMD-RS, 37 RCMD, 3 5q- syndrome, 2 RAEB-1, 4 RAEB-2, 1 CMML, 24 not classified; by CG: 2 IPSS-R very low, 54 IPSS-R low, 7 IPSS-R intermediate, 8 IPSS-R high, 13 IPSS-R very high [Greenberg, Blood 2012]. Both in AML and MDS no correlation of index to age, gender, hemoglobin level or counts for blasts, WBC or platelets was seen. In MDS index in Mo and MP was lower than in AML (2.68 vs 3.01, P=0.008, 1.84 vs 2.65, P<0.001, respectively). AML FAB M3/t(15;17)/PML-RARA displayed higher index in MP than non-M3 AML (4.52 vs 2.55, P<0.001). FAB M2 vs M0 and M1 showed higher index in Gra (5.66 vs 3.2, P=0.035 and vs 4.46, P=0.033, respectively), in particular higher index in Mo and Gra in *RUNX1-RUNX1T1*$^+$ pt (4/69 pt, 1 M1, 3 M2; 4.32 vs 3.14, P=0.023; 8.16 vs 4.73, P=0.002, respectively) and lower index in Mo in *CBFB-MYH11*$^+$ AML (8/70 pt; 2.82 vs 3.25, P=0.007) was seen. A trend to higher index in MP in MRC favorable vs intermediate was detected (3.01 vs 2.60, P=0.076). In *FLT3*-ITD$^+$ AML index was higher in Mo and MP (18/98 pt; mean 3.64 vs 2.97, P=0.02; 3.21 vs 2.62, P=0.013, respectively), in *NPM1*mut AML higher in Mo (21/93 pt; 3.88 vs 2.88, P=0.015). MP showed lower index in *RUNX1*mut pt (10/57 pt; 2.03 vs 2.6, P<0.001). In MDS by IPSS-R, significance was reached for higher index in MP in very low risk pt compared to low, intermediate and high risk pt (4.07 vs: 1.77, P<0.001; 1.94, P=0.008; 1.76, P=0.002, respectively), and in MP and Gra in very low vs very high risk pt (4.07 vs 1.71, P=0.005; 5.86 vs 3.85, P=0.001, respectively). IPSS-R intermediate vs poor also showed higher index in Gra (5.56 vs 3.59, P=0.02). Lower index was found in Gra in both *ASXL1*mut (6/17 pt; 3.05 vs 5.72, P=0.048) and *RUNX1*mut pt (8/31 pt; 4.24 vs 5.86, P=0.056).
Summary / Conclusion: Assessment of hENT1 by MFC is feasible. In AML with good risk MG, higher hENT1 expression in MP, Gra and Mo was observed, suggesting a causal mechanism for better response to therapy and outcome. Coherently AML with poor risk MG displayed lower hENT1 in MP. Detection of higher hENT1 in *FLT3*-ITD$^+$ AML fits into the observation of their good responses to induction therapy while overall worse outcome is mostly due to early relapses. Higher index in AML than MDS may be considered causal for better response to nucleoside-based chemotherapies in AML.Data within MDS may be interpreted accordingly, low risk CG (IPSS-R1) showing higher index in MP and pt with poor risk MG presenting lower index in Gra, though the latter results have to be judged cautiously due to low pt numbers. Further analyses are warranted to explore hENT1 expression in AML and MDS more comprehensively and to correlate with outcome.

B1229
CELL CYCLE MODELING OFFERS A PLATFORM TO OPTIMIZE COMBINATION OF CYTARABINE AND FLT3 INHIBITORS IN ACUTE MYELOID LEUKEMIA
M Elmeliegy[1], J Haese[2,3], C Talati[2], W Jusko[1], M Wetzler[2*]
[1]School of Pharmacy and Pharmaceutical Sciences, State University of New York at Buffalo, Buffalo, NY, USA., [2]Leukemia Section, Department of Medicine, Roswell Park Cancer Institute, [3]Department of Math and Natural Sciences, D'Youville College, Buffalo, United States

Background: Acute myeloid leukemia (AML) patients with *FLT3* mutations have poor response to cytarabine-based therapy. FLT3 inhibitors may overcome cytarabine resistance and improve treatment outcome. Depending on the sequence of administration, combining FLT3 inhibitors and cytarabine can achieve synergistic or antagonistic effects.
Aims: The goal of our work was to develop a pharmacodynamic model that mechanistically describes the effects of cytarabine and FLT3 inhibitors on cell proliferation, cell cycle distribution, and optimize combination regimens.
Methods: Three AML cell lines were exposed to varying concentrations of cytarabine and a panel of FLT3 inhibitors (AC220, PKC-412, sorafenib, and JP11646) over 96 hours. The cell lines were: HEL (negligible expression of wild-type FLT3), EOL1 (wild-type FLT3 which depends on FLT ligand for activation), MV4-11 (FLT3 with internal tandem duplication resulting in constitutively active kinase). Cell proliferation kinetics and cell cycle analysis were assessed using trypan blue and propidium iodide staining. Model fitting was performed using Pharsight Modeling Language in Phoenix. Plasma concentration profiles for cytarabine and AC220 in humans were digitized [1, 2] using computer digitalizing program (Digitizer Version 1.9). One and two compartment models were fit to cytarabine and AC220, respectively. Estimated cell cycle, drug sensitivity, and pharmacokinetic parameters were used to simulate different combination regimens to predict synergism.



Results: Experimental data and model selection criteria showed that cytarabine induced apoptosis in S-phase. FLT3 inhibitors induced apoptosis and cell cycle arrest at G1 phase (Figure 1). MV411 was most resistant to cytarabine, followed by EOL-1, with HEL cells being most sensitive reflecting the role of FLT3 status in conferring resistance to cytarabine. AC220 showed highest sensitivity among tested FLT3 inhibitors (KC50 = 0.4 nM in MV411 cells). HEL cells lacking FLT3, were resistant to all FLT3 inhibitors ($KC50\text{-}_{HEL}$ >40 fold higher than $KC50\text{-}_{MV411}$). Simulations of candidate clinical regimens predict better cell kill upon adding FLT3 inhibitors simultaneously with or immediately after cytarabine exposure. In vitro combination experiments to validate the effects of administration sequence on cell kill are ongoing.
Summary / Conclusion: Patients with FLT3 perturbations are likely to benefit from combining FLT3 inhibitors to cytarabine. Simultaneous administration of cytarabine and FLT3 inhibitors is predicted to achieve highest cell kill. Our model presents a mechanistic interpretation for cytarabine and FLT3 inhibitors effects in AML cell lines and provides a useful tool to optimize combination regimens.

EXPRESSION OF PIM-2 GENE, BAD AND 4E-BP1 PROTEIN IS INCREASED IN PATIENTS WITH AML AND ALL AND CORRELATES WITH COMPLETE REMISSION RATE, OVERALL SURVIVAL AND APOPTOSIS RATE.
K Kapelko-Slowik[1*], T Owczarek[2], D Urbaniak-Kujda[1], K Grzymajło[2], B Jazwiec[1], J Jakubaszko[3], M Slowik[4], M Ugorski[2], K Kuliczkowski[1]
[1]Haematology, Wroclaw Medical University, [2]Biochemistry, Wroclaw University of Environmental and Life Sciencesl, [3]Cardiosurgery, [4]Ophtalmology, Wroclaw Medical University, Wroclaw, Poland

Background: Background. *PIM-2* is a proto-oncogene that encodes for serine/threonine kinase which interacts with various signalling molecules. PIM-2 kinase suppresses apoptosis and promotes cell survival. These events are a consequence of phosphorylation of pro-apoptotic factors: 4E-BP1 translation inhibitor and BAD protein belonging to BCL-2 family. *PIM-2* is highly expressed in neoplastic tissues and in leukaemic and lymphoma cell lines which is consistent with a its role during oncogenic transformation. In particular, *PIM-2* plays an important role in bone marrow cell growth, differentiation and survival.
Aims: The aim of this study was to investigate whether the *PIM-2* (both mRNA and protein level), BAD, 4E-BP1, p-BAD p-4E-BP1 expression is altered in acute myeloid leukaemia (AML) and acute lymphoblastic leukaemia (ALL). Patients and methods. One hundred twenty-six patients were included: 74 with AML and 52 with ALL aged 18-85 (median=48,1). Seventy-one patients reached complete remission (CR): 39 with AML and 32 with ALL. Bone marrow samples were collected at the time of diagnosis and in CR phase. Control samples were obtained from 24 healthy donors.
Methods: We analysed *PIM-2* expression by RQ-PCR analysis and proteins (PIM-2, BAD, 4E-BP1, p-BAD, p-4E-BP1) by Western blot. Moreover siRNA targeting human *PIM-2* in leukemic cell line HL-60 was used to examined influence on apoptosis rate.
Results: Median expression of *PIM-2,* both mRNA and protein level, BAD and 4E-BP1 in all leukaemic patients and in subgroups: AML and ALL was significantly higher than in controls. In AML group patients who reached CR expressed *PIM-2* at significantly lower levels than patients with primary resistance to chemotherapy (with no CR, NCR). Moreover in AML, we have found significant difference between survival in patients with *PIM-2* expression above and below median value. We revealed negative correlation between apoptosis rate of blastic cells and *PIM-2* expression in both AML and ALL patients. In leukemic cell line HL-60, the siRNA-mediated decrease of *PIM-2* expression induced the increase of cell apoptosis rate.
Summary / Conclusion: Our data indicate that *PIM-2*, BAD, 4E-BP1 expression is increased in patients with AML and ALL. In AML patients *PIM-2* expression correlates with CR, OS and apoptosis rate.

B1231
FLUVASTATIN CAN INCREASE APOPTOSIS INDUCED BY VALPROIC ACID AND ALL-TRANS-RETINOIC ACID IN FLT3-ITD-POSITIVE AML CELLS
E Zirm[1*], B Spies-Weißhart[1], U Schnetzke[1], A Hochhaus[1], S Scholl[1]
[1]Department of Haematology/Oncology, Jena University Hospital, Clinic for Internal Medicine II, Jena, Germany

Background: FLT3 internal tandem duplications (ITDs) represent the most frequent molecular aberration in acute myeloid leukemia (AML) associated with an impaired prognosis. The pattern of downstream activation by this constitutively activated receptor tyrosine kinase is influenced by the localization of mutated FLT3 depending on its glycosylation status. The important process of post-translational maturation can be inhibited by fluvastatin. Furthermore, overcoming of resistance to tyrosine kinase inhibitors (TKIs) reflects a current challenge in the treatment of FLT3-ITD-positive AML.
Aims: The objective of this study was to investigate whether fluvastatin has an impact on the induction of apoptosis or on differentiation of FLT3-ITD-positive AML cells in the presence of the histone deacetylase inhibitor valproic acid (VPA) or the differentiation-inducing compound all-*trans*-retinoic acid (ATRA).
Methods: The murine Ba/F3 leukemia cell line was stably transfected with a FLT3-ITD variant resulting in IL-3-independent growth. Signal transduction after exposing cells to fluvastatin, VPA, and/or ATRA was analysed by Western blotting. Apoptosis, cell cycle analyses, and differentiation were detected by flow cytometry.
Results: In FLT3-ITD expressing Ba/F3 cells, VPA or ATRA or the combination of both compounds were not able to induce apoptosis while fluvastatin alone resulted in a slight increase of apoptotic cells compared to the DMSO control. Co-treatment with fluvastatin, VPA, and ATRA, however, demonstrates additive effects and is associated with a significant increase of apoptosis in this cell model. Interestingly, acetylation of histone H3 is much more pronounced in the presence of fluvastatin as compared with VPA alone. Besides, phosphorylation of the anti-apoptotic protein AKT (Ser473) is strongly decreased in the triple combination while VPA plus ATRA results in the highest phosphorylation level of AKT. Surprisingly, these observations do not correlate with the phosphorylation status of the p70S6 kinase.
Summary / Conclusion: Co-treatment with fluvastatin can increase the susceptibility to VPA and ATRA. We suggest that compartmentalization of FLT3-ITD by statins might improve the effect of such a therapeutic approach and could represent a promising strategy to overcome TKI resistance in FLT3-ITD-positive AML.

B1232
OVEREXPRESSION OF WILMS TUMOR GENE 1 (WT1) IN ACUTE PROMYELOCYTIC LEUKEMIA.
A Candoni[1*], E Toffoletti[1], A Chiarvesio[1], E Simeone[1], F Zanini[1], M Zannier[1], G Ventura[1], C D'Odorico[1], R Fanin[1]
[1]Hematology and BMT, University Hospital, Udine, Italy

Background: *WT1* gene is known to be highly expressed in the majority of acute myeloid leukemia (AML), but remains unclear its role in the development of myeloid and leukemic cells. *WT1* gene is note to be expressed in highly proliferative cells (1) and recently, an anti-apoptotic effect of *WT1* has been demonstrated in acute promyelocytic leukemia (APL)-cell lines (2). However there are only few data regarding expression levels of *WT1* in APL.
Aims: Between January 2007 and June 2011 we evaluated the *WT1* expression in 169 AML patients at diagnosis. To assess the pattern of expression in different subtypes of AMLs, we performed a quantitative polymerase chain reaction (RQ-PCR) assay on bone marrow (BM) samples using the ELN ProfileQuant Kit (Ipsogen, Marseille, France) following the European Leukaemia Net protocol. As normal expression cut-off was established 250 *WT1* copies/10^4 copies Abelson (*ABL).* According to WHO classification of myeloid neoplasm we observed: 49 (29%) AMLs with myelodysplasia–related changes, 27 (16%) AMLs with minimal differentiation, 15 (9%) AMLs with maturation, 22 (13%) Acute Myelomonocytic leukemia, 35 (21%) Acute Monocytic leukemia and 21 (12%) APL. All the APL were PML-RARalpha and t(15;17)(q22;q12) positives.
Results: There were only 9 *WT1* normal expressing patients (5%), whereas 160 (95%) AML cases presented levels of *WT1* expression higher than the established cut-off, with a median value of 6776 copies *WT1*/10^4 copies ABL (range 235-62567). Inside each FAB subtypes, the median level of *WT1* in the overexpressing group at diagnosis was: 8669 *WT1* copies/10^4 copies ABL (range 1368-30529) in M0-M1 group, 4995 copies (1008-25585) in M2 group, 30110 copies (2069-62597) in M3 group, 8111 copies (235-41148) in M4 group, 6226 copies (416-15661) in M5 group, 4530 copies (353-24205) in secondary AML (Msec) group. The level of *WT1* expression in APL was significantly higher ($P<0.01$) than in all other subtypes (figure 1). All APL patients presented an overexpression of *WT1*, differently from M4, M5 and secondary AML groups. Moreover, the majority of APL patients (81%, 17/21 pts) had more than 20000 *WT1* copies at onset. Conversely, only 9 out of 139 (6%) Non APL cases demonstrated a number of *WT1* copies higher than 20000.
Summary / Conclusion: In our cohort of AML patients, Acute Promyelocytic Leukemia group showed highest levels of *WT1* expression. In particular, we observed that all APL patients overexpressed *WT1* gene at diagnosis and the transcript levels were significantly higher in APL cases than in other FAB subtypes. It is still unclear the role of *WT1* gene expression to promote or sustain proliferation of leukemic cells, but this observation could reinforce a possible relationship between the pathway stimulated by *PML-RARα* transcript and the *WT1* anti-apoptotic and pro-proliferative mechanisms(1;2).

ALU-REPEAT REGIONS ARE NOT HYPER- AND DEMETHYLATION TARGET POINTS .
D Marinitch[1*], Y Buryanov[2], O Dyachenko[2], T Shevchuk[2]
[1]Stem Cell Biology, Byelorussian Transfusion Center, Minsk, Belarus, [2]Branch of Institute of Bioorganic Chemistry, Pushtchino, Russian Federation

Background: Alu repeats contain nucleotide AGCT, a cleavage site for the Alu I restriction endonuclease. A high concentration of Alu elements in the chromosome regions which contain a lot of genes allows duplication or elimination of genome fragments located between two Alu copies, as well as chromosome rearrangements. Alu repeats can affect the composition, organization and expression of the genome. Owing to their own promoter or enhancer activity, Alu repeats may enhance transcription of the adjacent locus. Transcriptional suppression is also possible, as Alu elements may expedite nucleosome assembly on the adjacent region. In addition, Alu repeats seemed expedite methylation of neighboring loci, contributing to gene expression regulation. While methylation commonly suppresses transcription, cases are known when methylation of Alu repeats increases the transcriptional activity of the neighbor-

ing locus. Site-specific DNA methylation analysis of short-term granulocyte cultures of healthy volunteers and on the leukemic cells' DNA was performed.
Aims: Our aim was to investigate whether ALU-repeats are the targets of demethylation and hypermethylation process in acute myeloid leukemia.
Methods: The investigation was performed on the DNA of short-term ganulocyte cultures of healthy volunteers and on the DNA of leukemic cells of patients with acute myeloid leukemia (AML). Totally 22 DNA samples (12 AML and 10 of normal blood donors) obtained from mononuclear cells of peripheral blood or bone marrow were involved in the study. We used the DNA samples of untreated patients. Both peripheral blood and bone marrow samples were investigated. The methyl- sensitive (HpaII) and methyl-insensitive (MspI) restriction endonucleases were used for the digestion of the DNA-samples as well, as bisulfite sequencing, restriction analysis and gene trasfer methods were applied in the study. For the *in vivo* data confirmation the genetic construction based on pEGFP vector, containing eucariotic chromomethylase CMT3 gene, was created. It was designed under cytomegalovirus promoter. The abovementioned genetic construction was used to transform HEK293 kidney epithelium cells. After the selection analysis the stable cell lines expressing CMT3 gene were obtained.
Results: We have shown the morpho-physiological and biochemical difference of these CMT3-gene expressing cell lines. DNA restriction analysis showed hydrolysis protection from the methyl-sensitive CpHpG-endonucleases. This fact confirms transgen functional activity.
Summary / Conclusion: It was shown that the ALU-repeats are not demethylation and hypermethylation targets in acute myeloid leukemia.

B1234
CLINICAL AND BIOLOGICAL CHARACTERISTICS OF ACUTE MYELOID LEUKEMIA WITH ABERRANT EXPRESSION OF CD56+CD11B+
T Martin-Santos[1], J Raya[1*], A Sosa[2], M Brito[1], L Hernandez-Nieto[1]
[1]Hematology, [2]Statistical Research Unit, Hospital Universitario de Canarias, La Laguna, Spain

Background: Immunophenotyping is a widely used diagnostic tool which, together with cytology and cytogenetics, allows for a more accurate diagnosis of acute myeloid leukemia (AML). The literature describes a group of AML with a peculiar clinical and biological characteristics, such as monocytic/monoblastic AML, whose blasts coexpressed CD56 and CD11b (CD56+CD11b+). This subtype of leukemia has been associated most often with aberrant karyotypes (mainly 11q23/MLL gene rearrangement), as well as extramedullary disease and refractoriness to treatment and, ultimately, with a worse prognosis.
Aims: In our study we analyzed all cases of AML diagnosed at our institution in the years 2002-2012, and in particular those whose blasts coexpressed CD56+CD11b+ and its possible association with extramedullary involvement, abnormal karyotype and response to treatment.
Methods: We analyzed a total of 133 cases divided into three different groups according to WHO classification: Group 1 (n = 60), not otherwise specified AML; Group 2 (n = 44), AML with myelodysplasia-related changes; and Group 3 (n = 29), AML with recurrent genetic abnormalities. Among others, analyzed variables included age, sex, cytogenetics (karyotype and FISH), immunophenotyping, especially the coexpression CD56+CD11b+; blood count at diagnosis and LDH, number of blasts in the blood and bone marrow, extramedullary involvement at diagnosis (skin, liver, spleen, lymph nodes and other locations), treatment features (complete remission after induction, number of treatments to achieve complete remission), and data on survival (disease-free survival, overall survival and the mortality rate). Statistical analysis was performed using SPSS (Chicago, IL) and significance level (p value) was established at 0.05.
Results: Ten of the 133 studied cases (7.5%) had this phenotype. Extramedullary involvement at diagnosis was detected in 50% of patients with CD56+CD11b+ coexpression, while only in 19.4% of patients who had not (P=0.032). According to groups, extramedullary involvement incidence showed no significant differences between groups 1 and2, while in group 3 the combination CD56+CD11b+ was not observed. A statistical association between this phenotype and karyotypic alterations or FISH, was not found. MLL gene rearrangement only appeared in one of 96 AML available cases, and the blasts of this unique patient were not CD56+CD11b+. Concerning overall survival, we did not find differences in these patients when compared to double CD11b and CD56 negative (P=0.105). Cases of AML CD56+/CD11b+ more frequently corresponded to those with monocytic component, both monoblastic/monocytic and myelomonocytic, clearly different to the remaining AML subtypes (p <0.001). The frequency of this phenotype was similar in monocytic/monoblastic (62.5%) and myelomonocytic (66.7%) AML (P=0.898). Extramedullary involvement was also more common in those AML with monocytic component (52.4%) than in non-monocytic AML (18.5%) (P=0.001).
Summary / Conclusion: In our experience, AML with the CD56+CD11b+ coexpression present more frequently a monocytic component (monoblastic/monocytic and myelomonocytic subtypes of AML), and also show a clear tendency to present with extramedullary involvement. By contrast, in our study it was not possible to establish an association of this phenotype with 11q23/MLL gene disorders (which has been reported by other authors), and CD56+CD11b+ coexpression did not seem to correlate with overall survival in AML patients.

B1235
REDUCED EXPRESSION OF 90 KD HEAT SHOCK PROTEIN (HSP90) IS RELATED TO PU.1 AND PML-RARA COMPLEX IN ACUTE PROMYELOCYTIC LEUKEMIA
G Gaur[1,2*], N Noguera[1,2], F Lo-Coco[1,2]
[1]Department of Biomedicine and Prevention, University of Rome "Tor Vergata", [2]Laboratorio di Neuro-Oncoematologia, Fondazione Santa Lucia, Rome, Italy

Background: The 90 kD Heat Shock Protein (*HSP90*) is a dimeric molecular chaperone required for conformational maturation and stabilization of numerous client proteins involved in cell cycling, receptor function, signal transduction, and apoptosis. A high expression of *HSP90* has been reported in leukemic cell lines and in patients with acute myeloid leukemia (AML) where it has been associated with poor prognosis. In acute promyelocytic leukemia (APL), the disease-specific *PML-RARA* oncoprotein deregulates the expression of various genes involved in differentiation and apoptosis. Selective targeting of *PU.1*-regulated genes by *PML/RARA* is a critical mechanism for the pathogenesis in APL. To date, no studies have investigated the potential role of *HSP90* in APL pathogenesis.
Aims: Objective of this study was to comprehensively analyze the involvement of *HSP90* in pathogenesis of APL.
Methods: *HSP90* expression levels were analyzed using Western Blot and Real Time PCR in APL patient blasts and in NB4 cells both at baseline and after treatment with ATRA and ATO, as well as in the zinc inducible, *PML/RARA* transfected PR9 cells. ChIP was used to analyse the regulatory sequence of *HSP90* alfa and beta for the presence of Pu.1 and *RARE* half (*RAREh*) sites.
Results: A significantly lower *HSP90* expression was detected in blasts from APL patients, compared to those from non-APL leukemias at both transcriptional as well as translational levels. Furthermore, in vitro treatment of NB4 cells and APL primary blasts with ATRA and ATO restored the expression of *HSP90.* Moreover, treatment of PR9 cells with zinc reduced the expression of *HSP90*. Using ChIP, we found in-vivo binding of *Pu.1* and *PML-RARA* to the *HSP90* alfa and *HSP90* beta promoter regions. *PU.1* motifs coexisted with one or more *RAREh* sites in *HSP90* promoter regions.
Summary / Conclusion: The DNA binding domain, conserved in the *PML-RARA* fusion protein*,* displaces from the gene promoter sequence a *PU.1* containing complex necessary for the activation of *HSP90* transcription, thus suppressing the expression of the protein. We demonstrate here a new peculiar feature of APL which differentiates this subset from other tumors and leukemias, usually showing increased HSP90 level. Further studies are needed to define the significance of this finding.

B1236
ACUTE LEUKAEMIA WITH MULTILINEAL DYSPLASIA - CLINICAL AND IMMUNOPHENOTYPICAL FEATURES - 5 YEARS EXPERIENCE OF A SINGLE CENTER
H Bumbea[1*], S Nistor[2], C Enache[1], M Onisai[1], M Begu[1], O Cazaceanu[2], A Vladareanu[1]
[1]Hematology - Emergency University Hospital, [2]Carol Davila University of Medicine and Pharmacy Bucharest, Bucharest, Romania

Background: Non-lymphoblastic acute leukemia with multilineal dysplasia is a particular subset of acute leukemia, with a complex diagnostic and therapeutically approach.
Aims: Our study proposes to identify specific features in acute myeloid leukemia with dysplasia.
Methods: We analyzed 96 patients previously diagnosed with acute myeloid leukemia with myelodysplasia over a period of five years, compared to a control group of patients with acute myeloid leukemia without dysplastic features. Demographic characteristics (age, gender), hematological parameters, morphology and immunophenotype were assessed. Further analysis of dysplasia de novo and post myelodysplastic syndrome (MDS) was done.
Results: Dysplasia was observed more frequent in myelo-monocytic acute leukemia (53.5%), but without a statistical significance versus other FAB types. Age under 40 years was a protective factor (P=0.0005) for the development of AML with dysplasia, while age over 70 years seemed to be a risk factor, but less strong (P=0.35). Neither thrombocytopenia, nor leucopenia correlated significantly with the presence of dysplasia. In the control group, thrombocytopenia correlated significantly with low hemoglobin values at diagnosis (P=0.012), but not in the group of patients with dysplasia. This would suggest that thrombocytopenia and anemia were influenced simply by the degree of marrow infiltration in patients with leukemia, and not by the degree of dysplasia. The marrow blast number (controlled by CD34 expression) at diagnosis was lower in the group of patients with dysplasia versus control group (40.15% vs. 61.38%) (P=0.0001). This could be considered more as a hematopoiesis alteration in such patients with dysplasia. Regarding the correlations between peripheral and marrow parameters, we observed that, in patients with dysplasia, anemia (stratified by slight, medium and severe) was associated with a lower marrow blast count versus control group. This correlation enlightens that impaired erythropoiesis in patients with AML with dysplasia is more likely generated by erythrocyte dysplasia, rather than bone marrow infiltration. In the control group, throm-

bocytopenia was statistically significant associated (P=0.012) with a higher percentage of blasts. Concerning immunophenotype, we observed that expression of CD11b, known as a diferrentiation marker of myeloid precursors, was mostly associated with dysplastic AML, while expression of CD36, CD64, CD65w, was lower in patients with dysplasia, although without a strong statistical value (P>0.05). Antigens CD56, CD7, CD14 were not differently expressed in the two groups. Common antigens such as CD33, CD13, CD117, HLA-DR, CD15, have not been significantly different expressed in both patients groups. Kaplan-Meyer curves were used to compare survival in AML patients with or without dysplasia. 6 months survival was not different in the 2 groups. However, when AML developed after myelodysplastic syndrome, relative risk for death before 6 months was higher (odds ratio 2), valid only for 70% of the population studied, without statistical significance (P=0.3).
Summary / Conclusion: Dysplasia alters the clinical and immunophenotypic profile of AML, especially as an expression of hematopoiesis alteration and the prognosis is particularly worsened when AML develops after MDS.

B1237
ARE MUTATIONS IN THE IDH2 GENE SUITABLE MOLECULAR MARKERS FOR MRD MONITORING IN AML PATIENTS?
I Jeziskova[1*], F Razga[1], D Dvorakova[1,2], L Semerad[1], Z Sustkova[1], J Mayer[1,2], Z Racil[1,2]
[1]Department of Internal Medicine Hematology and Oncology , University Hospital Brno and Masaryk University, [2]CEITEC – Central European Institute of Technology, Masaryk University, Brno, Czech Republic

Background: Heterozygous missense mutations in isocitrate dehydrogenase 2 gene (IDH2) have been recently reported in pacients with acute myeloid leukemia (AML), notably in cytogenetically normal AML (incidence 12,1 %). These mutations affect mainly arginine codons p.R140 and/or p.R172, both localized in exon 4. The most frequently is c.G419A (p.R140Q). Potential of detected IDH2 gene mutations for monitoring of minimal residual disease (MRD) in AML patiens is unclear and is now under investigation.
Aims: i) to verify the use of most frequently detected mutation c.G419A (p.R140Q) for MRD monitoring in AML patients, and ii) to compare these results with those obtained from routine monitoring of NPM1 mutations in AML patients, who harbor IDH2 and NPM1 mutations simultaneously.
Methods: Method of DNA-based RQ-PCR with a specific set of primers and Locked Nucleid Acid (LNA) probe were used for quantification of IDH2 c.G419A (p.R140Q) mutation in a total of 73 samples (45 bone marrow and 28 peripheral blood samples) of 9 AML patients. These samples were obtained during AML treatment at the different time points. All patients signed an informed consent before the samples were collected. Six of nine (6/9) analyzed patients harbored parallel mutation in NPM1 gene. Quantification of NPM1 mutation was performed according to previously published work. The results were reported as the normalized copy numbers (NCN) defined as the number of mutated IDH2 or NPM1 gene copies for every 10^6 cell equivalents (CE).
Results: In our cohort, 7/9 AML patients revealed concordant results for the NCN of the IDH2 c.G419A mutation and disease status. Moreover, in 5/6 analysed patients, the kinetics of IDH2 mutations was nearly identical to the kinetics of NPM1 mutations. However, in the remaining two patients, IDH2 mutation status did not correspond to clinical course of AML. Both patients revealed persistent IDH2 c.G419A positivity (10^5 – 10^6 NCN) althougt they were in hematological remission. Moreover, one of them was also in molecular remission according to NPM1. In these discrepant cases (2/9) further analyses were performed and germinal origin of IDH2 mutation were excluded.
Summary / Conclusion: Our data indicate that, in the majority of AML patients, status of IDH2 mutation correlate with the clinical course of disease. Thus mutation c.G419A in IDH2 gene seems to be suitable marker for MRD monitoring in AML patients. However, we have shown that discrepant cases exist. Therefore further studies will be necessary to identify cases where the IDH2 mutation burden does not correlate with clinical course of AML.

ASSESSMENT OF WT1 TRANSCRIPT REDUCTION FOR PROGNOSTIC IMPLICATION IN ACUTE MYELOID LEUKEMIA PATIENTS
I Shmunk[1*], O Korobitsyna[2], M Lyubchenko[2], M Zakharova[2], A Korobkin[2], A Burmistrova[3]
[1]Chelyabinsk Regional Haemotransfusion Station, [2]Hematology, Chelyabinsk Regional Clinical Hospital, [3]biological, Chelyabinsk State University, Chelyabinsk, Russian Federation

Background: Wilms' tumor 1 (WT1) gene is over-expressed in most cases of acute myeloid leukemia (AML). It is one of proposed markers for minimal residual disease (MRD) monitoring.
Aims: Our study aims to estimate the utility of WT1 transcript reduction for prognostic implications in acute myeloid leukemia, including acute promyelocytic leukemia (APL).
Methods: Real time quantitative RT-PCR was made according to the ELN guidelines. WT1 transcript level was determined in BM samples of adult patients with AML and APL. We examined the samples of 122 patients with AML and 25 patients with APL at diagnosis. We also analyzed 384 specimens of AML and APL patients during follow-up. The obtained WT1 values were normalized with respect to the βGUS transcripts.
Results: The median value of WT1 levels at diagnosis was 755 (range 2.4-16283) in AML patients and 3528 (range 547-8103) in APL patients. The median value of WT1 levels of patients in complete remission was 8.5 (range 0.4-33) for AML and 11.3 (range 3.5-61) for APL . At diagnosis 89% of AML patients showed the expression of WT1 one log higher the median values in complete remission. WT1 transcript reduction after induction above 2 log showed 69% of patients in favorable subgroup with APL + AML with AML1/ETO, CBFb/MYH11, and only 25% of patients in subgroup of poor prognosis - AML with BCR/ABL, DEC/CAN, dupMLL; P=.042 (Fisher Exact test). In full group (all AML patients + APL) we assessed the correlation between the value of reduction in WT1 after induction and unfavorable event (relapse, failure in complete molecular remission after induction in APL patients) during 12 months: in subgroup with WT1 reduction above 2 log only 19% of patients had unfavorable event, whereas in subgroup with failure in WT1 reduction (under 2 log) 50% of patients had unfavorable event; P=.024 (Fisher Exact test).
Summary / Conclusion: Quantitative assessment of WT1 transcript reduction after the first cycle of chemotherapy can be used to assess treatment response. Failure in WT1 reduction is predictor of subsequent relapse risk.

B1239
ABERRANT EXPRESSION OF LYMPHOID-ASSOCIATED ANTIGENS IN ACUTE MYELOID LEUKEMIA: INCIDENCE AND CLINICOBIOLOGICAL IMPLICATIONS
A Marvaki[1*], V Douka[1], K Kotta[1], A Papalexandri[1], G Voutiadou[1], B Tachynopoulou[1], C Vadikolia[1], A Tsompanakou[1], A Athanasiadou[1], I Sakellari[1], R Saloum[1], K Stamatopoulos[1], A Anagnostopoulos[1]
[1]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: A variable proportion of patients with acute myeloid leukemia (AML) express lymphoid-associated antigens (LAA). The exact incidence and clinical significance of this phenomenon remains unclear due to inconsistencies between series, likely related to methodological aspects and/or case selection biases.
Aims: We aimed at obtaining insight into the prevalence and clinical impact of LAA expression in AML by retrospectively evaluating the expression of LAA in blast cells from 343 consecutive and unselected patients with AML diagnosed in our Department between 2002 and 2012.
Methods: The patient cohort included 203 males and 140 females with a median age of 61 years (range, 10-88); 183/343 (53%) cases were above the age of 60. Within this cohort, 235 cases (68%) had de novo AML, whereas the remaining 108 cases (32%) concerned secondary AML (sAML) to either hematologic (n=94) or other non-hematologic malignancies (n=14). Patients were treated uniformly according to age with Aracytin/Idarubicin induction regimens ("3+7" or "2+5" for ages <60 or ≥60, respectively). The immunophenotype was determined by flow cytometric analysis of bone marrow aspirate and/or peripheral blood samples utilizing a primary CD45/side scatter (SSC) gating procedure with antibodies against CD7, CD13, CD19, CD33, CD4, CD10, CD34, CD117, CD64, HLA-DR, CD20, CD2, CD15,CD56, CD14, CD8, MPO, CD3, CD79a, CD22, TdT and lysozyme; a cut-off value for positivity of 20% was adopted.
Results: Overall, 184/343 cases (54%) were found to express at least one LAA. The most commonly expressed LAAs were CD4 (outside AML with monocytic differentiation), CD56, CD7, CD2, CD10 and CD79a (in 47%, 31%, 30%, 11%, 10% and 7% of LAA+ AML cases, respectively); interestingly, all CD79a-positive cases co-expressed at least one more LAA. A significant association was identified between LAA expression and cytogenetic profiles. In particular, at least one LAA was detected in 39/57 cases (68.4%) with SWOG adverse cytogenetics (including monosomal karyotype, MK), compared to 123/232 (53%) in SWOG cytogenetically favorable and intermediate risk cases (P=0.036). No other statistically significant associations were found for LAA expression (positive vs. negative) in respect to age, de novo AML (128/235 cases, 54.4%) versus sAML (56/108, 52%), complete remission (CR) rate and overall survival (OS). Associations were sought for the six more frequent LAAs. This analysis revealed significant associations (P<0.05) between: (i) CD7 or CD10 expression and adverse cytogenetics; and (ii) CD4 expression and shorter disease-free survival (DFS) and OS. Cox-multivariate analysis identified CD4 expression in addition to sAML and adverse cytogenetic profile as negative prognostic indicators (P=0.05) for DFS. Regarding OS, only sAML, advanced age and adverse cytogenetic profile retained significance.
Summary / Conclusion: Expression of LAAs is frequent in AML, among both de novo AML and sAML, and significantly associated with adverse cytogenetics. However, the precise prognostic implications of this phenomenon require further evaluation, ideally in large prospective and well-controlled studies.

B1240

AML CELLS SENSITIVE TO THE NOVEL TYROSINE KINASE INHIBITOR AKN-028 SHOW A HIGHER OVERALL TYROSINE KINASE ACTIVITY THAN MORE RESISTANT SAMPLES

A Eriksson[1*], M Jarvius[1], R Hilhorst[2], R de Wijn[2], L Hovestad[2], M Fryknäs[1], R Larsson[1], V Parrow[3], M Höglund[1]

[1]Department of Medical Sciences, Uppsala University, Uppsala, Sweden, [2]PamGene International B.V., 's-Hertogenbosch, Netherlands, [3]Akinion Pharmaceuticals AB, Stockholm, Sweden

Background: AKN-028 is a novel tyrosine kinase (TK) inhibitor with preclinical activity in acute myeloid leukemia (AML), presently undergoing investigation in a phase I/II study. AKN-028 is a potent inhibitor of FMS-like kinase 3 (FLT3) and has shown in vitro activity in a wide range of AML samples, irrespective of FLT3 mutation status or quantitative FLT3 expression.
Aims: To further characterize the mechanism of actions involved in the AML cell response to treatment with AKN-028.
Methods: TK-activity profiles in AML cell lines HL60 and MV4-11 and three primary AML samples (UPN 1-3) were determined using the PamChip® tyrosine kinase peptide microarray system. For the primary AML samples, serine/threonine kinase (STK) activity profiles were generated on the PamChip® serine/threonine kinase array.
Results: Previous characterization regarding the cytotoxic properties of AKN-028 in vitro showed that the patient sample UPN1 and the cell line HL60 represent relatively resistant samples, UPN2 an intermediate variant and UPN3 and MV4-11 are relatively sensitive to AKN-028. The TK-activity profile between the cell lines resistant and sensitive to AKN-028 revealed a significant difference (p-value <0.05, Student's t-test) in basal phosphorylation level of 57 of the 141 peptide substrates tested. For primary AML samples, this pattern was even more pronounced with 73 out of the 141 peptides showing significantly higher peptide phosphorylation signals (p-value <0.05) in UPN3 as compared to the more resistant UPN1. The differences in STK-activity between the samples were in general less pronounced. The TK-activity in lysates from AML cell lines and from the three primary patients was also analyzed in the presence of AKN-028. In all samples tested, 10 µM of AKN-028 reduced peptide tyrosine phosphorylation to approximately the same level. Furthermore, the cell samples were tested against four different concentrations of AKN-028 (0-25 µM), showing a dose-dependent inhibition in all samples. STK-activity in UPN2 and UPN3 was not affected by 10 µM of AKN-028 whereas UPN1 showed slight inhibition on some peptides.
Summary / Conclusion: Cells sensitive to AKN-028 showed a higher overall TK-activity than more resistant ones. The TK-activity was inhibited by AKN-028 in a dose dependent manner in all samples tested, whereas the overall STK-activities were low in all cells. The results suggest that the difference in cytotoxic activity of AKN-028 may be due to the variation in basal overall TK-activity between cells. If confirmed in larger number of patient samples, this can indicate that TK-activity profiling could become a novel way of classifying AML, in order to predict good responders, i.e. serve as a predictive biomarker.

B1241

A NOVEL APPROACH IN THE DEFINITION OF "BLAST GATE" IN AML USING CD66 AND CD14 AS MATURATION INDICES

G Paterakis[1*], N Tsagarakis[1], A Taparkou[2], E Griva[3], P Vassileiou[4], D Koliouskas[2], G Paterakis[5]

[1]Flow Cytometry-Immunology, Georgios Gennhmatas General Hospital Of Athens, Athens, [2]Pediatric Oncology Department, Ippokration General Hospital, Thessaloniki, [3]Hematology Laboratory, Georgios Gennhmatas General Hospital Of Athens, [4]Flow Cytometry, Flowdiagnosis Laboratory, [5]Flow Cytometry, Georgios Gennhmatas General Hospital Of Athens, Athens, Greece

Background: CD45/side scatter (SS) gating is widely used for isolating blasts by flow cytometry (FC). However, mature cells contaminate the "blast gate" (BG) or blasts are located in "mature" monocytic and granulocytic regions CD45/SS gating is thus imprecise, particularly when there are few blasts as in myelodysplastic syndromes.
Aims: Aim of this study was the application of the maturation antibodies CD66abce and CD14 for the location of immature cells on CD45/SS gating acute myeloid leukemias (AML).
Methods: A multiparameter approach encompassing CD66abce, CD14, CD45, CD10, CD1c, CD33 and CD34 was applied in order to define myeloid and monocytic immature cells, which were CD66 and CD14 negative. Thus two blastic components were discriminated:1) CD34+/CD66-/CD14- 2) CD34-/CD33+/CD66-/CD14-. Normal counterparts were estimated in 25 control marrows, representing myeloid CD34+ stem cells and immature CD34- myelomonocytic precursors. From now on we will refer to them as stem cells and myelogones. The corresponding blastic components were defines in 146 marrow samples of de novo and secondary AML, in adults and children.
Results: We used the FAB nomenclature for the simplicity of data presentation. Specifically we analyzed 14 M0, 24 M1, 22 M2, 20 M3, 22 M4, 24 M5(a or b), 6 with M6 (myeloid erythroid) and 14 AML with myelodysplasia related changes. In each category we report the percentage of the two components (mean±SD),, stem blasts (SB) and myelogone blasts (MB). 1) M0: SB 30±7,5% and MB_{6},8±4,7% 2) M1:SB 51,3±8,3% and MB 14,5±6,6% 3) M2: SB 20,8±5,4% and MB 15,4±2,5% 4) M3:SB_{5},9±3,76% and MB 71,9±8,5% 5 M4:SB 11,7±4,1 and MB 28,5±7,9% 6) M5: SB_{1},5±1% and MB 43±7,4% 7) M6 SB 14,4±4,1% and MB_{2},6±1,4%, 8) AML-mrc SB14,3±2,6% and MB12,8±3,6%. There was statistical significance in the observed differences of the BG components (P<0.05) among the various leukemia subtypes. SB component as expected prevailed in M0 and M1, while MB in M3, M4 and M5. Reference range in control marrow samples were: stem cells 0.2-1.2% and myelogones 0.5-2.5%.
Summary / Conclusion: Leukemia subtypes presented specific SB/MB patterns. The above approach could be applied in the analysis of myelodysplastic syndromes and minimal residual disease.

B1242

GLOBAL GENE ARRAY ANALYSES TO IDENTIFY BIOMARKERS ASSOCIATED WITH CLINICAL OUTCOME IN ACUTE MYELOID LEUKEMIA

M Lindberg[1*], P Hååg[1], A Moshfegh[1], L Kanter[1], R Lewensohn[1], K Viktorsson[1], L Stenke[1]

[1]Dept of oncology/pathology, Karolinska Institutet, Stockholm, Sweden

Background: Among prognostic factors associated with outcome in acute myeloid leukemia (AML) cytogenetic aberrations, although detectable in only half of the patients, have long been recognized as clinically highly important. During recent year several distinct gene mutations, preferably detected by PCR, have also been linked to treatment response and long-term prognosis. Such mutations involve e.g. the FMS-like tyrosine kinase 3 (FLT3) and nucleophosmin 1 (NPM1) genes. There is, however, still a need to discover additional disease-related molecular signatures, including aberrant gene expression patterns that may serve as novel biomarkers and/or as targets of novel therapeutic regimens in AML.
Aims: Using global genomics to identify biomarkers at the molecular level, predictive of clinical response to chemotherapy, by comparing AML patients with a poor vs. those with a better clinical outcome.
Methods: We analysed mononuclear cells obtained from 42 patients at AML diagnosis, using Affymetrix U133 Plus 2.0 and the GeneSpring GX10 software. Subsequent pathway assessments were performed through IngenuityPathway-Analyses. Patient characteristics and clinical outcome were collected. All patients entered complete remission (CR) after high-dose chemotherapy, typically consisting of an anthracyclin and cytarabine. The median CR duration was 161 (range 12-3701) days. The patients were subdivided into two groups according to their CR duration: those with "short CR duration" (<180 days, n=24) and those with "long CR duration" (> 180 days, n=18). The groups were equivalent regarding age, gender, with blood cell count, cytogenetic status and presence of secondary leukemia.
Results: Gene array analysis revealed markedly differences with 383 genes to be up-regulated and 610 genes down-regulated more than 2 fold, in pooled samples from patients with short CR vs. those with long CR duration. Among the differentially most expressed genes we identified RUNX1T1 to be 116-fold up-regulated, while ANXA1 was 58-fold down-regulated in those with short CR. These gene expression data were confirmed using real time quantitative PCR (qPCR). Thus, a strikingly higher expression of RUNX1T1 was observed in individual patient samples with short CR duration (n=10) as compared to those with long CR duration (n=10); median relative expression 0.01 vs. 0.59 (P=0.0002). The transcription factor gene RUNX1T1 is a part of one of the well-known t(8;21)(q22;q22) cytogenetic aberration, creating the RUNX1-RUNX1T1 fusion gene that translates into a protein known to block normal hematopoietic differentiation. It is observed in 5-12% of adult AML patients and is associated with a favourable clinical prognosis. Our pathway analyses identified connections between RUNX1T1 and CD34 and TCF3, all found up-regulated in short CR duration patients. We are currently validating our results by making use of publicly available gene array data from two other, independent AML cohorts (a total of approx. 200 patients). Preliminary data reveal genes mutually up-regulated in all of the three patient cohorts with poor outcome, as compared to those with better outcome.
Summary / Conclusion: By using global gene array analysis to compare AML patients with short vs. those with long CR duration, we observed striking differences in gene expression. In our material RUNX1T1 had the highest differential expression, a finding confirmed by qPCR on individual patient samples. Further assessments of interacting signaling networks and *in silico* validation of independent patient cohorts are on-going, aiming at discovering additional biomarkers predictive for AML prognosis and, ultimately, collecting information that may lead to future novel targeted therapies.

B1243

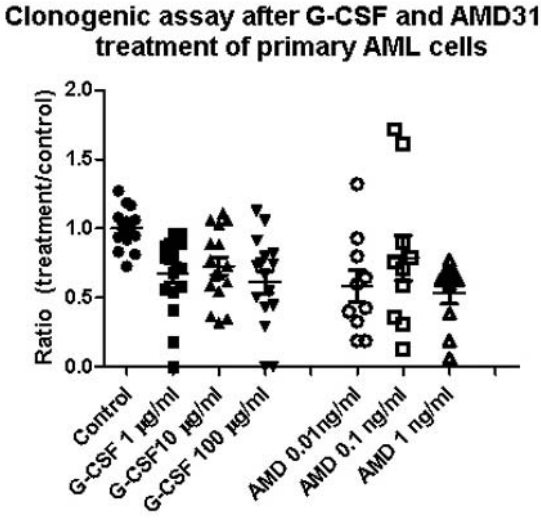
TREATMENT WITH G-CSF AND AMD3100 DIMINISH THE CLONOGENIC CAPACITY OF PRIMARY ACUTE MYELOID LEUKEMIA BLASTS IN VITRO

M Nomdedeu[1,2*], M Pratcorona[3], M Díaz-Beyá[1,2], X Calvo[4], M Rozman[4], J Esteve[1,5], R Risueño[2]

[1]Hematology, Hospital Clínic Barcelona, [2]Josep Carreras Leukemia Research Institute, [3]Fundació Clínic per a la Recerca Biomèdica, [4]Hematopathology,

Hospital Clínic Barcelona, [5]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: The simultaneous administration of G-CSF and chemotherapy as a priming strategy has resulted in a clinical benefit in determined subsets of patients diagnosed with acute myeloid leukemia (AML) (Lowenberg et al, NEJM 2003; Pabst T, et al, Blood 2012). On the other hand, the CXCR4 antagonist AMD3100 has shown to prolong survival in AML-bearing mice (Nervi Blood 2009). However, the mechanism responsible for these anti-leukemic effects is not fully characterized. We hypothesized that these observations could be explained based on a higher sensibility of leukemic stem cells (LSCs) to these priming agents.
Aims: The main goal of this project is to study the *in vitro* effect of G-CSF and AMD3100 on LSCs and the bulk leukemic population from primary AML samples.
Methods: Primary peripheral blood cells from 10 AML patients were treated with G-CSF or AMD3100 at different doses for 72 h. Cell viability was measured by 7-AAD (eBioscience) exclusion; cell surface phenotype and volumetric cell count were obtained by flow cytometry (FACSVerse, BD) and analyzed using the FlowJo software (TriStar). For the clonogenic assays, primary AML cells were treated for 18 h with G-CSF and AMD3100 at increasing doses and cultured on MethoCult H4034 Optimum (StemCell Technologies) for 14 days.



Results: Cell viability of the bulk blast population and the more immature CD34+ leukemic population remained unaffected in the presence of G-CSF or AMD3100. G-CSF treatment upregulated CXCR4 expression in a dose-dependent fashion. A 1.44-fold increased expression was observed at the highest G-CSF dose (100 µg/ml). However, the expression of VCAM-1 and VLA-4 did not change. On the contrary, AMD3100 treatment induced a 0.71-fold reduction of CXCR4 surface expression at the highest dose (1ng/ml) (P<0.0001). Additionally, AMD3100 also induced a significant downregulation of the VLA-4 and VCAM-1 surface expression (P=0.0004 and P=0.02 respectively). AML clonogenic capacity was significantly reduced in a dose-dependent manner after treatment with G-CSF and AMD3100 (Figure 1). At the highest concentration, G-CSF (100 mg/mL) and AMD3100 (1 ng/mL) decreased the clonogenic capacity by 41% (P=0.0004) and 44% (P=0.0002), respectively.
Summary / Conclusion: The addition of G-CSF or AMD3100 impairs remarkably the clonogenic capacity of primary AML cells. These results suggest that the use of these two molecules as priming agents may contribute to eradicate the LSC population. Our findings support the design of further studies aimed to explore a potential synergistic effect of these agents in combination with standard chemotherapy against LSCs.

B1244

CLINICAL AND BIOLOGICAL CHARACTERISTICS OF IDH1 AND 2 MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS WITH NORMAL KARYOTYPE (NC-AML) IN SERBIA

N Tosic[1*], T Karan-Djurasevic[1], I Glumac[1], V Spasovski[1], M Virijevic[2], I Djunic[2], N Suvajdzic[2,3], D Tomin[2,3], S Pavlovic[1]
[1]laboratory for Molecular Hematology, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, [2]Clinic of Hematology, Clinical Center of Serbia, [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Acquired mutations in exon 4 of both isocitrate dehydrogenase 1 and 2 genes (*IDH1* and *IDH2*) were recently reported in patients with acute myeloid leukemia (AML). Numerous studies have tried to reveale the association of these mutations with clinical features, prognosis and the outcome of the disease.
Aims: To evaluate the frequency and examine the impact of *IDH1/2* mutations on outcome, as well as their association with other molecular and clinical prognostic markers in adult *de novo* NC-AML patients.
Methods: Diagnostics bone marrow samples from 96 adult *de novo* NC-AML patients diagnosed between September 2009 and December 2012 were analyzed for *IDH1/2* mutations by DNA PCR amplification/sequencing. The patients (55 males/41 females; median age 54, range 19-78 years) were treated as follows: patients aged < 60 years- induction "3+7"; consolidation 3 cycles HIDAC; medically fit patients aged >60- 70 years-induction "3+7"/"2+5"; consolidation 3 cycles IDAC; patients aged >70 years- ara-C 20 mg s.c. 10-14 days/ 6 cycles or purinethol.
Results: *IDH* mutations were found in 21.9% of the patients. *IDH1* mutations were detected in 8 patients (7.9%, R132 (n=4), R132H (n=3), R132G (n=1)). *IDH2* mutations were detected in 13 patients (9.9%, R140Q (n=9), R140W (n=1), R140L (n=1) and R172K (n=2)). None of the patients exhibited simultaneously *IDH1* and *IDH2* mutations, and all of the mutations were in heterozygous form. They were predominantly detected among FAB M2 and M4 subgroups (M2, M4IDH mutations were not associated with *NPM1* and *FLT3* mutations or any other clinical characteristics except for the higher percentage of blasts in peripheral blood. *IDH* mutations impacted complete remission (CR) rate; only 13/21 *IDH* positive patients reached CR (P=0.044). Moreover, multivariate logistic regression analysis showed that the presence of *IDH* mutations is independent unfavorable factor for CR achievement (P=0.048). Similar finding was detected when we investigated the impact of *IDH* mutations on overall survivor (OS), i.e. IDH^+ patients exhibited shorter OS (median 4 months) compared to IDH^- patients (median 9 months)(P=0.058). The effect was more prominent in $IDH2^+$ patients (P=0.018). Nevertheless, the multivariate analysis showed that only $IDH2^+$ status was an independent prognostic factor for OS (P=0.015). *IDH+* patients were most numerous in the double negative *FLT3-ITD-/NPM1-* patients (10/21), and then in *FLT3-ITD-/NPM1+* patients (7/21). Double positive group *FLT3-ITD+/NPM1+* and single positive *FLT3-ITD+/NPM1-* group of patients had 2 *IDH+* patients each. The presence of *IDH* mutations in the half of patients (7/14) belonging to the molecular low-risk *FLT3-ITD-/NPM1+* group could explain the low OS in this group of patients of only 2 months compared to the other four groups (P=0.04).
Summary / Conclusion: This study shows that the presence of *IDH* mutations predicts both low CR rate and shorter OS in our cohort of patients. It also suggests that a caution should be addressed when assigning the patients to the molecularly low-risk $FLT3\text{-}ITD^-/NPM1^+$ group.

B1245

DOWNREGULATION OF PROGRAMMED CELL DEATH LIGAND-1 PROTEIN INHIBITS MIGRATION,ADHESION AND INVASION OF LEUKEMIA HL-60 CELLS

M Liu[1], P Zhou[2], Y Jiang[1*]
[1]Pediatrics, Renmin Hospital of Wuhan University, [2]Hubei Center for Medical Device Quality Supervision and Testing of State Drug Administration, wuhan, China

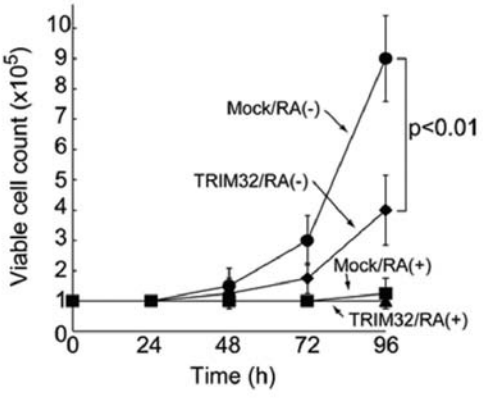
Background: Programmed cell deathligand-1(PD-L1) was a newly discovered apoptosis gene, which was highly expressed in children with leukemia ,and it was considered as a predictive marker for leukemia micrometastasis.
Aims: To investigate the impacts of programmed cell death ligand-1(PD-L1) downregulation on cell abilities of migration,adhesion and invasion of leukemia HL-60 cells.
Methods: PD-L1-siRNA,control-siRNA and blank-siRNA were transfected into leukemia HL-60 cells through liposome as experiment group,negative control group and blank control group,respectively.The transfection efficiency was observed by fluorescence microscope.Forty-eight hours after transfection,reverse transcription PCR and immunocytochemistry were employed to detect the expression of PD-L1 in three groups.Cell experiments were performed to assess cell migration,adhesion and invasion respectively,when PD-L1-siRNA was transfected into HL-60 cells for 48 hours.
Results: The transfection efficiency of HL-60 cells was 90%.PD-L1 mRNA and protein expression of PD-L1-siRNA group were 0.031±0.002 and 532.3±42.5,which were significantly lower than those of control-siRNA group and blank-siRNA group(t=3.452,t=2.905,P<0.05;t=3.167,t=3.792,P<0.05).The number of migrated cells in PD-L1-siRNA group was 23.17±2.06,fewer than those of control-siRNA group and blank-siRNA group(t=2.755, P<0.05;t=3.626,P<0.05).Compared with control-siRNA group,the adhesion rate at 30and 60min were decreased by(40.97±2.25)% and(51.26±3.07)% (t=2.787,P<0.05;t=3.965,P<0.05).Moreover,the number of invaded cells in PD-L1-siRNA group was 37.65±3.12,significantly fewer than those of control-siRNA group and blank-siRNA group(t=3.378,P<0.05;t=2.613,P<0.05).
Summary / Conclusion: Down-regulation of PD-L1 expression in HL-60 cells can inhibit the abilities of migration,adhesion and invasion,which suggests that PD-L1 plays an important role in the metastatic potency of leukemia cells.

B1246

THE TRIM FAMILY UBIQUITIN LIGASE TRIM32 PROMOTES CELL DIFFERENTIATION AND SUPPRESSES CELL PROLIFERATION OF HUMAN AN APL CELL LINE VIA RETINOIC ACID RECEPTOR ALPHA-MEDIATED TRANSCRIPTION

T Sato[1*], A Iguchi[1], S Hatakeyama[2], T Ariga[1]
[1]Pediatrics, [2]Biochemistry, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background: Retinoids are promising for cancer therapy due to their potential effects on cell differentiation and apoptosis. Initial treatment for acute promyelogenous leukemia (APL) is now carried out by using all-trans retinoic acid (ATRA). *In vitro* studies with human APL cell lines have shown that these leukemic cell lines provided clues for achieving satisfactory therapeutic results. However, the mechanisms by which ATRA functions have not been elucidated. We recently found that TRIM32, one of the ubiquitin ligase family proteins, is a positive regulator of transcriptional activity of retinoic acid receptor alpha (RARa) in differentiation of neural cancer cell lines.
Aims: With the aim of elucidating the molecular function of TRIM32 in APL cell differentiation, we checked the protein levels of TRIM32 by immunoblot analysis in various human leukemic cell lines and we investigated whether TRIM32 influences cellular proliferation of HL60 cells by facilitating transcriptional activity of RARa. We also tested whether exogenous overexpression of TRIM32 alone promotes APL cell differentiation without ATRA, suggesting that TRIM32



Methods: To clarify the expression profiles of TRIM32 in human leukemic cell lines, we compared the protein levels of TRIM32 by immunoblot analysis in various human leukemic cell lines. Next, to verify whether TRIM32 drives RARa-mediated transcription in human leukemia and cancer cell lines, we performed a luciferase assay using a RAR promoter-driven luciferase construct (RAR-Luc) and we performed immunoblot analysis to verify whether TRIM32 stabilizes the expression level of endogenous RARa in HL60 cells without ATRA. We also examined whether similar morphological features of granulocytic differentiation were observed even in some of the ATRA-untreated HL60 cells in which TRIM32 was transiently transfected. In addition, we calculated the percentage of CD11b-positive HL60 cells in which TRIM32 was induced without ATRA treatment.
Results: Expression of TRIM32 protein was observed in leukemic cell lines and its expression level of TRIM32 was various in blast cell lines. Immunoblot analysis showed that endogenous RARa was more highly expressed in HL60 cells in which TRIM32 had been expressed than in mock cells. We also found that similar morphological features of granulocytic differentiation were seen in some of the ATRA-untreated HL60 cells in which TRIM32 was induced. The percentage of CD11b-positive cells was significantly higher in HL60 cells in which TRIM32 was induced than in mock cells (1.4±1.0% for mock versus 21.9±5.1% for TRIM32 (P<0.01)). We performed cell proliferation assay using HL60 cells after induction of TRIM32 or empty expression vectors. The effect on HL60 cells after induction of TRIM32 was characterized by significant suppression of cellular proliferation compared with that of mock cells (Figure).
Summary / Conclusion: Results of cell proliferation assay suggest that TRIM32 induced granulocytic differentiation via RARa-mediated transcriptional activity in the absence of ATRA, and proliferation of HL60 cells after induction of TRIM32 showed slow proliferation because of their disappearance of self-division potential. In conclusion, it is important to analyze TRIM32 protein that has functions to regulate transcriptional activity of RARa. Our findings might provide clues for generating of new anti cancer agents. Detection of substrates of TRIM32 and pharmacologic enhancers of RAR-associated ubiquitin ligases would be helpful for patients suffering from malignant diseases, whose cancer cells are induced to differentiate by retinoic acid-dependent RARa-mediated transcriptional activity.

B1247

EXPRESSION LEVELS OF WT1 AND NPM1 AND NOVEL NONSPECIFIC MARKERS AS TOOLS FOR EVALUATING MINIMAL RESIDUAL DISEASE IN AML

R Petrbokova[1*], J Polák[1], H Hájková[1], C Haškovec[1], O Fuchs[1], A Kostečka[1], P Cetkovský[2], C Šálek[2]
[1]Dpt. of Molecular Genetics, [2]Clinical Division, IHBT, Prague2, Czech Republic

Background: Monitoring of minimal residual disease (MRD) is an important tool in the medical management of acute myeloid leukemia (AML). Of the specific molecular markers, mutations of the nucleophosmin 1 (*NPM1*) gene represent the most frequent aberration. This makes NPM1 a favorite gene for MRD detection. Approximately one half of AML patients do not have a suitable specific molecular marker for MRD monitoring. Therefore, development of sensitive assays for quantification of nonspecific leukemia-associated antigens (LAA) should be focused on, along with the search for rare specific mutations. The Wilm's tumor gene (*WT1*) has been suggested as a possible molecular marker of MRD in AML as it is overexpressed in 80% of AML patients at diagnosis. The LAAs that we focused on were *PRAME, MSLN, ST18, XAGE1, CSPG4, CA9* and *BAALC* in genes.
Aims: To examine selected LAAs as potential tools for MRD monitoring in AML.
Methods: Established IVD CE protocols of fluorescence-based quantitative reverse transcriptase-polymerase chain reaction (qRT-PCR) and protocols based on TaqMan Gene Expression Assays® were used for quantification of selected targets.
Results: Of the 475 patients treated at the Institute of Hematology and Blood Transfusion in Prague in 2002-2012, 113 (23.8%) had a mutation in the *NPM1* gene. Of the 45 patients with *NPM1* mutation and follow-uP>4 months, 7 never reached MRD negativity while sustaining hematological remission and 12 suffered hematological relapse. MRD positivity preceded hematological relapse by a median of 3.23 months. Overexpression of WT1 in peripheral blood was detected in 199 of 211 patients (94.3%) at diagnosis. Thirty-three experienced relapse. Median time from MRD positivity to hematological relapse was 1.8 months. MRD quantities monitored by *NPM1* on mRNA level were compared to *WT1* expression in 60 AML patients with a median follow-up of 12.3 months (range 1.32–110.4). Both methods for MRD detection correlated significantly (P<0.0001). Levels of selected LAAs (*MSLN, ST18, XAGE1, CSPG4, CA9*) were evaluated in 153 AML patients at diagnosis. Overexpression of *MSLN* was demonstrated in 22.5%. However, the high expression of *MSLN* in normal peripheral blood makes this marker unsuitable for MRD monitoring. This is not the case of *ST18, XAGE1, CSPG4* and *CA9*, which were overexpressed in 50.3%, 17.9%, 45.7% and 36.4% respectively. In 12 patients (7.8%) with high expression of a particular LAA at diagnosis, it was possible to trace MRD during the course of the disease. MRD data were in concordance with the disease status. Moreover, in seven of these patients, LAA was the only MRD marker because of the low expression of both *WT1* and *NPM1*. Levels of *BAALC* and *PRAME* were monitored in 373 AML patients at diagnosis. Overexpression of *BAALC* was demonstrated in 169 patients (45.3%). In 14 patients, MRD was monitored during the course of disease and, similarly, significant correlation of *BAALC* expression levels with those of *WT1* has been found (P<0.0001). The high expression of *PRAME* was detected in 91 patients (24.4%) at diagnosis. In 5 patients, MRD was monitored during the course of disease. Its expression rose in concordance with *PML/RARA* transcripts while *WT1* expression stayed below the upper normal limit.
Summary / Conclusion: By combining methods for detecting *NPM1* mutations and elevated LAA expression, a suitable MRD marker was found for every AML patient in our cohort. Median time from MRD positivity to hematological relapse was longer by 1.4 months in the *NPM1* group compared to *WT1*.

B1248

INCIDENCE AND CLINICAL FEATURES OF PATIENTS WITH AML1-ETO, CBFB-MYH11 AND PML-RARA TRANSCRIPTS IN THERAPY-RELATED COMPARED TO *DE NOVO* ACUTE MYELOID LEUKEMIAS IN A COHORT OF 449 BULGARIAN PATIENTS

G Balatzenko[1*], B Spassov[2], P Ganeva[2], V Hrischev[2], S Toshkov[1], G Myhailov[2], M Guenova[3]
[1]Laboratory of Cytogenetics & Molecular Biology, [2]Clinics of Hematology, [3]Laboratory of Hematopathology & Immunology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: *AML-ETO*, *CBFB-MYH11* and *PML-RARA* fusion transcripts (FT) are among the most frequent genetic abnormalities in de novo acute myeloid leukemia (dnAML) with geographic/ethnic-relatedvariationsinthe incidence. Generally, these FT are associated with a favorable prognosis. However data concerning the incidence of these aberrations in therapy-related AML (tAML) cases, and the association with clinical feature are contradictory.
Aims: To determine the incidence of *AML-ETO*, *CBFB-MYH11* and *PML-RARA* in tAML compared to dnAML and to define the main clinical and laboratory features of both groups of patients (pts).
Methods: In total 449 adult AML pts, including 403 (89.8%) dAML and 46

(10.2%) tAML, 222 males and 227 females, with a mean age of 54.3±16.9 years were diagnosed at the National Hematology Hospital – Sofia. All patients were screened for *AML1-ETO, CBFb-MYH11* and *PML-RARA* FT and *FLT3-ITD* by RT-PCR.
Results: In the whole cohort "favorable" FT were found in 74 pts (16.5%): 62 (15.4%) in dnAML and 12 (26.1%) in tAML (P=0.09). The overall incidence of the different markers was as follows: 4.9% for *AML1-ETO* (n=22), 4.9% for *CBFb-MYH11* (n=22), and 6.7% for *PML-RARA* (n=30), without significant differences in the frequency between dnAML and tAML (*AML1-ETO*: 3.7% vs. 8.7%; P=0.266; *CBFb-MYH11*: 3.7% vs. 8.7%; P=0.266, *PML-RARA*: 6.5% vs. 8.7%; P=0.53, respectively). Within the group of dnAML, pts with "favorable" FT were significantly younger compared to the remaining pts (55.9±16.2 years): *AML1-ETO*(+) 39.8±15.8 years (P=0.000); *CBFb-MYH11*(+) 44.1±15.9 years (P=0.003), *PML-RARA*(+) 44.3±18.9 years (P=0.001). In contrast, within the tAML group, only the *CBFb-MYH11*(+) pts were significantly younger (44.9±22.2 years, P=0.005) compared to negative cases (62.1±12.8 years), while a tendency for younger age was seen in *AML1-ETO*(+) pts (47.8±26.3 years; P=0.068), and no differences were detected in *PML-RARA*(+) pts (56.2±6.8 years; P=0.376). According to the FAB criteria, *AML1-ETO* were found in M1 (4); M2 (9); M2Eo (3); M4 (1); and not specified (1) in de novo AML, compared to only myeloid morphology M2 (3) and M2Eo (1) in tAML. *CBFb-MYH11* were found in M1Eo (1); M2 (2); M4 (8); and M4Eo (7) dnAML cases, vs. M2Eo (3) and M4 (1) in tAML. *PML-RARA* were found in M3 (22); and M3v (4) de novo cases, while in the tAML all pts had a classical M3 morphology. Furthermore, the molecular data revealed that within the *PML-RARA*(+) dnAML pts, 42.3% bared the Short form and 57.7% the Long form of the transcripts; while *FLT3*-ITD was detected in 7/15 (46.7%) patients. In contrast, all *PML-RARA*(+) tAML patients were positive for the Long form and only one was positive for *FLT3*-ITD. No differences in the mean age, gender, leukocyte and platelet counts, hemoglobin level, and blast cells/equivalents were observed between pts with different molecular abnormalities related to the origin of the disease (dnAML vs. trAML).
Summary / Conclusion: In this study we found a relatively high incidence of "favorable" fusion transcripts in patients with tAML similar to that, determined in dnAML. Our results further confirmed the heterogeneity of these entities, however most of the main characteristics did not differ significantly between de novo and therapy-related cases.

Studies were supported by the National Science Fund (grant D002-35/09). The authors express their gratitude to A.Stoimenov, V.Nikolova and the clinical team for their contribution to the patients diagnosis and management.

B1249
UNFAVORABLE PROGNOSTIC IMPACT OF WT1 MUTATIONS IN PEDIATRIC ACUTE MYELOID LEUKEMIA IN KOREA
D Han[1*], H Baek[1], H Jang[1], M Son[2], S Lee[2], K Yoo[2], K Sung[2], H Koo[2], J Park[1], T Hwang[1], H Kook[1]
[1]Pediatrics, Chonnam National University Hwasun Hospital, Hwasun, [2]Pediatrics, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Acute myeloid leukemia (AML) is a clinically and biologically heterogeneous disease. Recently, about 65% of pediatric AML patients show long-term survival. The relevance and prognostic value of mutations in *FLT3, NPM1, CEBPA*, and *WT1* for novel classification and risk-group stratification have been studied mainly in adult AML and to a lesser extent in patients with pediatric AML.
Aims: The aim of this study was to show the clinical implications of these genetic variants on childhood AML in Korea.
Methods: We have evaluated the frequency and prognostic significance for the mutation status of *FLT3-ITD/TKD, NPM1, KIT, CEBPA, WT1, NRAS, BAALC* and *IDH1/2* in childhood AML (n=104). Mutations were analyzed by PCR amplification of genomic DNA. *WT1* and *BAALC* expression levels were measured using real-time quantitative PCR. All patients were diagnosed with AML at Samsung Medical Center and Chonnam National University Hwasun Hospital.
Results: The incidences of these genetic alterations were as follows: *NPM1*, 20 (19%); *FLT3-ITD*, 14 (14%); *CEBPA*, 14 (14%); *WT1*, 11 (11%); *NRAS*, 5 (2%); *KIT*, 3 (3%); *IDH1*, 2 (2%); *IDH2*, 2 (2%); high *BAALC* expression, 6/15 (40%); high *WT1* expression, 6/15 (40%). The 5-year Kaplan-Meier EFS rate was 65%: standard risk karyotype, 67% vs. high risk karyotype, 60%; chemotherapy, 73% vs. SCT, 61%. The 5-year EFS rate was not significantly different according to *FLT3-ITD, NPM1, NRAS,* and *CEBPA* mutation status. *WT1* mutated patients showed a decreased EFS rate (68% vs. 44%, *P*=.064). The 5-year EFS rates were as follows according to the level of *BAALC* and *WT1* expression: high, 50% vs. low *BAALC*, 100% (*P*=.110); high, 42% vs. low *WT1*, 100% (*P*=.059). In 19 normal karyotype patients, EFS rates of *FLT3/ITD, CEBPA* and *NPM1* mutation status were not significantly different. *WT1* mutated patients of normal cytogenetic AML patients showed a poor prognosis (78% vs. 0%, *P*=.002).
Summary / Conclusion: The most common mutation was found in *NPM1*. The *KIT*, *IDH1/2* and *FLT3/TKD* mutations were very rare. Patients with High *BAALC* and *WT1* expression levels were associated with poor prognosis, but statistically not significant. *WT1* mutated patients with normal karyotype showed a poor prognosis. The result of this study was not consistent with previous published data because of small sample size, selection bias, high rate of SCTs, and ethnic differences. However, these data suggest that some clinical implications of molecular genetic alterations in Korean children with AML. Further retrospective and prospective multicenter studies are needed to unravel how these genetic abnormalities affect the leukemogenesis, treatment and prognosis in pediatric AML.

B1250
MANAGEMENT OF FIT OLDER PATIENTS WITH AML : MAJOR IMPACT OF CYTOGENETICS
J Nguyen[1*], T Vo[1], B Bailly[2], P Sidon[3], J Hotton[4], M Roos[5], M Maerevoet[1], P Lewalle[1], N Meuleman[1], M Paesmans[6], D Bron[1]
[1]Hematology, Institut Jules Bordet, [2]Hematology, Hôpital Erasme, [3]Pathological Anatomy, Institut Jules Bordet, [4]Hematology, Hôpital St Pierre, [5]ICSO, [6]Data Center, Institut Jules Bordet, Brussels, Belgium

Background: Median age of Acute Myeloid Leukemia (AML) patients at diagnosis is 67 years and represents a real clinical challenge. Major problems of olders AML remain co-morbidities, poor performance status and biological features increasing resistance to chemotherapy. However, some patients are cured with chemotherapy.
Aims: We studied prognostic factors in order to identify those patients deserving intensive treatment
Methods: We retrospectively reviewed 78 patients over 60 (60-86) years old referred to our centre for treatment. AML was classified according to WHO classification; cytogenetic data were obtained by routine karyotype, additional FISH analysis and molecular biology; fit patients (PS<2, reversible or controlled comorbidities and no geriatric syndromes) received intensive chemotherapy according to successive EORTC protocols. Several factors were assessed in univariate and multivariable analysis, in order to define their prognostic significance according to age subgroups. We also looked for factors predicting treatment related toxicity and/or death and disease related mortality. Kaplan-Meier curves were used to compare significant prognostic factors in terms of complete remission, overall survival and disease-free survival according to prognostic factors and complete remission.
Results: 64% of patients are male. 52% AML are secondary. 50% of all treated patients reached a complete remission post induction. Overall survival (OS) of patients over 60 years old is 48%; 31% and 17% at1, 2 and 5 years, with a median survival of 9 months. This is higher compared to other studies, since a majority of patients were "fit" enough to be referred to our centre. According to age, OS is significantly better (P<0.0001) for patients below 70 years than above (44% at 2y vs. 16%). In univariate analysis, whatever the age, favourable karyotype provides a better prognosis (2y OS 53% vs. 20%, P=0.007). Taking into account cytogenetic data and age, median survival of patients above 70 with favourable karyotype was very similar to population below 70 (38 and 44% at 2y).In multivariate analysis, OS in patients treated with curative intent is much better than supportive care (62% at 1y vs. 6%, P<0,0001). For patients who received intensive chemotherapy (77%), death due to uncontrolled disease remains a major concern compared to death induced by treatment related toxicity (10%). In multivariate analysis, levels of LDH (P=0.03), liver diseases and prior malignancy (P=0.01) come out as others majors significant prognostic factors.
Summary / Conclusion: In our single-centre experience of 'fit' olders AML patients, we confirm that cytogenetic data is the prognostic factor with the strongest predictive positive value in terms of outcome whatever the age in univariate analysis. Particularly for patients above 70, individual geriatric assessment combined with major prognostic factors should be refined in prospective studies to improve therapeutic decision making and limit treatment related toxicities. The survival of older AML patients remains poor, more likely due to disease resistance with aggressive biology, than because of treatment toxicity. New alternative treatment approaches using less toxic target therapies are urgently needed.

B1251
A RARE VARIANT TRANSLOCATION IN APL
E Grasso[1], C Consoli[1], P Fiumara[1], P La Cava[1], G Rizzo[1], G Avola[1], C Conticello[1], F Di Raimondo[1*]
[1]Divisione Clinicizzata di Ematologia con Trapianto di Midollo Osseo , Azienda Ospedaliero Universitaria "Policlinico-Vittorio Emanuele".P.O. Ferrarotto, Catania, Italy

Background: Acute Promyelocytic Leukemia (APL) is characterized by the t(15;17) patognomic translocation. Although almost all APL patients have the classical balanced translocation, a small proportion have complex or simple variant translocation , such as t(4;15;17) or t(5;17;15). Some of them , such as t(11;17)(q23;q21), show resistance to ATRA treatment whereas detection of classical t(15;17) or underlying PML-RARα rearrangement is highly predictive of response to ATRA in virtually 100% of cases.
Aims: The aim of this study was to describe a rare variant translocation in APL patient. A 21 year-old woman was admitted to our hospital because of fever and

hematomas. Coagulation test revealed that INR was 1.52, normal partial thromboplastin time (PTT) and there was a slight reduction of fibrinogen (94.8 mg/dL). Peripheral blood examination showed 127x10^3/mmc white blood cells and 10x10^3/mmc platelets. Bone marrow aspirate showed 100% infiltration by abnormal promyelocytes. At immunophenotypic analysis 91.1% cells were CD9, CD13, CD33,CD38, CD45RA, MPO, CD45 positive. PML/RARα transcript of the bcr3 subtype was detected by reverse transciptase polymerase chain reaction. A diagnosis of APL high risk was made according to the above data.
Methods: Chromosome analysis was based on G-banded metaphase and the karyotype was described according to the ISCN 2009. A whole chromosome painting (WCP) probe for chromosome 6 and a dual-color, dual-fusion probe for PML/RARα were used for fluorescence in situ hybridization (FISH).
Results: The karyothype of the patient was interpreted as 46,XX,t(6;17;15)(p23;q21;q22) by conventional cytogenetic and it was elucidated by fluorescence in situ hybridization. Patient started treatment with ATRA 45mg/m^2 die and idarubicina 12mg/m^2 every other day but she died at 3rd day because of a massive brain bleeding although platelets count was maintened above 40x10^3/mmc.
Summary / Conclusion: The t(6,17;15)(p23;q21;q22) translocation found is, to our knowledge, one of a few series in wich 6p arm is involved. This case is a contribution to the study of the infrequent variants APL translocation and could provide futher insigts into biologic and prognostic information provided by cytogenetics.

B1252

DNA METHYLTRANSFERASE FAMILY GENES MUTATIONAL STATUS IN CANIS FAMILIARIS AML: A POTENTIAL MODEL FOR THE DISEASE IN PEDIATRIC PATIENTS

I Bronzini[1*], M Paganin[1], M Gelain[2], L Aresu [2], F Cian [3], F Riondato[4], S Comazzi[5], G Basso [1], G te Kronnie [1]
[1]Department of Women's and Children's Health, [2]Department of Comparative Biomedicine and Food Science, University of Padova, Padova, [3]Department Veterinary Medicine, University of Cambridge, Cambridge, [4]Department Veterinary Science, University of Torino, Torino, [5]Department of animal pathology Hygiene and Veterinary Public Health, University of Milano, Milano, Italy

Background: Acute myeloid leukemia (AML) is the most widely occurring acute leukemia in adults with a high prevalence of relapses. Genetic aberrations are often found in AML specimens and recent whole genome sequencing studies identified somatic mutations with biological and clinical importance. In addition, several studies revealed that both global DNA hypomethylation and regional hypermethylation occur in tumorigenesis. In this respect, mutations of DNA methyltransferases gained particular interest. Indeed, several studies reported a high occurrence of somatic mutations at codon R882 of DNA methyltransferase3A in adult AML[1]. *DNMT3* family genes comprise two enzymes, *DNMT3A* and *DNMT3B*, that play a role in *de novo* CpG methylation and a functional accessory protein, *DNMT3L*, that activates the two enzymes by binding to their catalytic domain[2]. Functional studies performed *in vitro* on human cells line models or using murine models have associated mutations of *DNMT3A* with aberrant methyltransferase activity and altered whole genome expression profiles. However, a direct correlation between aberrant DNA methylation and mutated *DNMT3* remains elusive. We propose the dog as a model for functional studies of human AML providing the advantage that the disease occurs spontaneously in out bred dogs.
Aims: The purpose of this study is to explore canine AML as a model of human AML. Canine AML specimens were screened for *DNMT3A*, *DNMT3B* and *DNMT3L* to provide a view on the mutational status of all members of the family of DNA methyltransferase genes.
Methods: Sanger sequencing of the C-terminal domain of *DNMT3A*, *DNMT3B*, and *DNMT3L* was achieved in 16 samples of canine AML. The majority of canine patients were large breed in their middle age (mean age 6.9±2.7 years); the diagnosis of AML was based on clinical evaluation and immunophenotype. Primers were designed to obtain DNA sequences of the C-terminal domain of *DNMT3A*, *DNMT3B* and *DNMT3L* using ABI PRISM 310 Genetic Analyzer.
Results: Diagnosis of canine AML was confirmed by morphology with the major part of specimens classified as M2-M4 with some cases of M5[3], complete blood count profiles (CBC), white blood cell counts (WBC), and by the immunophenotype profile (CD34+, CD45+, MPO+, CD14+, CD11b). Specific sequences were obtained for exon 22 of *DNMT3A* and *DNMT3B* and exon 9 of *DNMT3L*. No mutations were found in canine AML specimens at positions homologous to sites of hot spot mutations in adult human patients with AML. Since the mutation detection limit of Sanger sequencing is 20% we will also use next generation amplicon deep sequencing to detect mutations down to 1% to more thoroughly analyze mutations including the analysis of all exons of the C-terminal domain of *DNMT3A*, *DNMT3B* and *DNMT3L*.
Summary / Conclusion: In this study we investigated the dog as a study model of human AML. Acute myeloid leukemia occurs spontaneously in out-bred dogs suggesting it to be a natural model for clinical and biological studies. Sanger sequencing failed to detect mutations in the terminal exons of *DNMT3A*, *DNMT3B*, and *DNMT3L*which may indicate that like childhood AML also canine AML has no mutations in the family of DNA-methyltransferase genes[4]. Along this line canine AML in spite of middle age of patients seems to resemble pediatric AML.

ANALYSIS OF ACTIVITY OF MATRIX METALLOPROTEINASES MMP-2 AND MMP9 IN BONE MARROW PLASMA OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

I Lesnichenko[1*], S Gritsaev[2], A Sergeev[2], I Kostroma[2]
[1]Biochemistry laboratory, [2]Hematology, Russian Institute of hematology and Transfusiology, St.Petersburg, Russian Federation

Background: Matrix metalloproteinases (MMPs) are of greit interest for oncohematologists because of their role in neoangiogenesis, including such processes as growing, invasion, metastazing of tumor cells. However the concept of clinical importance of MMP is still not stated.
Aims: To investigate the prognostic significance of MMPs in patients with acute myeloid leukemia (AML).
Methods: The MMP-2 and MMP-9 activities ratio (MMP-2/MMP-9) was investigated in BM plasma of 53 patients with de novo AML. During the collection of BM 33 patients were diagnosed with complete remission (CR) and 20 patients without CR. The method of zymografy in polyacrylamide gel containing gelatine as a substrate was used.
Results: MMP-2/MMP-9 ratio was approximately 1.00 (0.91+/- 0.06; from 0.42 to 1.77) in the BM samples of 30 patients in CR (91.0%) and 10 patients without CR (50.0%). The median overall survival (OS) of these patients was 27 months. At the same time the MMP-2/MMP-9 ratio was more than 3 times higher (3.34+/-0.34); from 1.80 to 5.50 (P<0.001) in 13 patients. In the group with high MMP-2/MMP-9 ratio, 10 patients had resistant variant of AML. Their median OS was only 7 months; P<0.001. Other 32 patients were in CR. The natural history of AML in 3 patients with CR and high MMP-2/MMP-9 ratio was poor. In 1 patient MMP-2/MMP-9 ratio was increased before relapse at 3 months and other 2 patients have got the sign of minimal redsidual desease.
Summary / Conclusion: The conclusion is that high MMP-2/MMP-9 ratio >/- 1.80 may be associated with unfavorable prognosis ii patients with AML./

B1254

CORRELATIONS AMONG CFU-GM GROWTH PATTERNS AND ACUTE LEUKEMIA WHO-2008 ENTITIES

P Lemez[1*], J Jelinek[2], Z Zemanova[3], J Galikova[1], K Michalova[4]
[1]Hematology - Blood Transfusion, Hospital Jihlava, Jihlava, Czech Republic, [2]Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States, [3]Center of Oncocytogenetics, First Medical Faculty, Charles University, [4]Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Acute leukemias (AL) represent a very heterogeneous and very large group of diseases that were divided into several subgroups (categories) defined by similar characteristics of their individual entities in the World Health Organization (WHO) Classification in 2008. Different growth patterns of granulocyte-macrophage colony forming cells (CFU-GM) from diagnostic bone marrows from patients with various types of AL have been described, especially depending on the stimulating factors used and the type of AL.
Aims: To correlate the CFU-GM growth patterns of diagnostic bone marrow (BM) cells from 103 patients with AL classified according to the WHO-AL categories, entities and prognosis.
Methods: CFU-GM were assayed in triplicate in 1 ml agar cultures containing 2x10^5 nucleated BM cells, Iscove's modified Dulbecco's medium, 20 % fetal calf serum, and 5 % of the human bladder carcinoma cell line 5637 conditioned medium as a source of cytokines. After 7 days of incubation the number of colonies (consisting of 40 or more cells) and clusters (3-39 cells) were counted. Informed consent was obtained from all patients.
Results: BM from 42 healthy BM donors produced 20-150 colonies and 20-150 clusters per 10e5 seeded BM nucleated cells. Low growth of colonies and high growth of clusters (L-H growth pattern) was found in 8/10 acute myeloid leukemia (AML) M3, 3/3 AML M2 with t(8;21) and 1/1 AML M4Eo case. Low growth of colonies and low growth of clusters (L-L growth pattern) exhibited BM cells of all 4 cases with near-tetraploid AML with myelodysplasia related changes (AML/MDRC). BM from other 36 AML/MDRC cases showed 13x L-L, 9x L-H, 5x L-N (low-normal), 1x N-H, and 8x H-H growth patterns of colonies and clusters. In 22 AML without MDRC the following growth patterns of CFU-GM colonies and clusters were found: 11x L-L, 6x L-H, 3x L-N, 3x N-H. All BM from 28 patients with various types of acute lymphoid leukemia (ALL) exhibited low growth of CFU-GM colonies and clusters (L-L growth pattern).
Summary / Conclusion: Several categories of AL seem to be associated with one type of CFU-GM growth pattern that is typical for each category. Diagnostic bone marrows from patients with AML M3 and AML M2 with t(8;21) exhibited the CFU-GM growth pattern with low growth of colonies and high growth of clusters (L-H). Diagnostic BM from patients with near-tetraploid AML/MDRC

exhibited the pattern with low growth of colonies and low growth of clusters (L-L). Low growth of CFU-GM colonies and clusters was found in diagnostic bone marrows from all patients with ALL studied. A special finding was a group of 8 patients with the CFU-GM growth pattern with high colonies and high clusters (H-H) who all were from the AML/MDRC WHO category only and had a very bad prognosis even in comparison to the other nonH-H AML/MDRC. Three of these 8 patients died early within 2-11 days since diagnosis, none of the 5 remaining cases reached complete remission after 3/7 induction treatment and none was a long-term survivor.

B1255

CLINICAL SIGNIFICANCE OF COMMON LEUKEMIA GENE MUTATIONS IN PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA

A Sun[1*], S Chen[1], J Yin[1]
[1]hematology, The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Key laboratory of Thrombosis and Hemostasis, Ministry of Health., Suzhou, China

Background: Acute promyelocytic leukemia (APL) is an extremely unique subtype of acute myeloid leukemia (AML). It is a more malignant form of acute leukemia with a severe bleeding tendency and high risk of DIC(Disseminated Intravascular Coagulation). Chemotherapy (retinoic acid , arsenic trioxide and anthracycline) was the front-line treatment of APL increasing the complete remission (CR) rate to 80%~90% in newly diagnosed APL patients. So far there has not been massive primary specimens of acute promyelocytic leukemia (APL) to verify leukemia-related gene mutation synergically involved in the pathogenesis of APL and research its relevance to clinical manifestations, prognosis and genetics.
Aims: Explore whether multiple common gene mutations of leukemia synergistically involved in acute promyelocytic leukemia (APL) pathogenesis, and to explore their relevance to clinical features, cytogenetic and molecular risk stratification.
Methods: 84 new diagnosed APL patients from February 2005 to Ocotber 2010 were collected, the gene mutations of bone marrow mononuclear cells and clinical features of mutation-positive patients were analyzed by genomic DNA-PCR and sequencing.
Results: Median age of our patients was 34 years (range, 8 to 79 years) and 44 patients (52.4%) were male and 40 (47.6%) were female. We demonstrate the presence of 66 cryptic genomic aberrations in 84 patients (78.6%) consisting of mutations (51 patients), in which the mutations with the highest incidence were found as *FLT3-ITD*, reaching 27.4%(23/84). Next, there were 12 cases *WT1* mutations, 9 for *FLT3-TKD*, 7 for *TET2*, 5 for *N-RAS*, 4 for *ASXL1*, 2 for *EZH2* mutation and 1 positive in *MLL-PTD*, *IDH1* and *CBL* respectively. No mutation was found in other *JAK1*, *DNMT3A*, *c-Kit*, *NPM1*, *IDH2*, *RUNX1* and *JAK2 (V617F)* common leukemia-related genes. Combined analysis with clinical data demonstrated that the patients with *FLT3-ITD* mutation compared to those without, had higher white blood cell counts(24.3×10^9/L vs 7.2×10^9/L;P=0.004); with the patients with *N-RAS* mutation showed lower platelet counts (21.5×10^9/L vs 70.0×10^9/L;P=0.012). Overall survival of these patients were obviously shorten with OS of wild-type. The difference between mutant and wild-type above all had statistical significance(for FLT3-ITD, 39.1 months vs 71.7 months; P=0.010; for N-RAS, 24.79 months vs 68.02 months; P=0.028). There were no significant correlations between age, sex, WBC and mutations in *WT1*, *FLT3-TKD*, *TET2*, *ASXL1*, *EZH2*, *MLL-PTD*, *IDH1* or *CBL*. The difference between APL with pure t(15;17) and additional abnormal karyotype did not show a significant different OS (28.94 months vs 67.10 months; P=0.576) or a mutation incidence of leukemia-related genes (6/13 vs 45/71; P=0.219)
Summary / Conclusion: The FLT3-ITD mutation is recurring genetic change in APL, together with N-RAS mutation indicates poor prognosis. Additional abnormal karyotype does not associate with prognosis and mutation incidence of APL.

Acute myeloid leukemia - Clinical

B1256

TREATMENT OF ACUTE PROMYELOCYTIC LEUKEMIA DURING PREGNANCY

V Troitskaya[1*], E Parovichnikova[1], A Kokhno[1], A Sokolov[1], T Konstantinova[2], A Korobkin[3], L Mazurok[4], G Galstyan[1], S Makhinya[1], O Latyshkevich[5], V Savchenko[1]
[1]Research Center of Hematology of Russian Ministry of Health, Moscow, [2]District Clinical Hospital, Ekatherinburg, [3]District Clinical Hospital, Chelyabinsk, [4]District Clinical Hospital, Kurgan, [5]Moscow Centre of Family Planning and Reproduction, Moscow, Russian Federation

Background: Acute promyelocytic leukemia (APL) is a favorable subtype of AML with 80-85% probability of 5-years survival on ATRA containing regimens.
Aims: Though APL in pregnant women is a very rare event we tried to evaluate the efficacy of treatment in this cohort of pts in the era of ATRA.
Methods: From Jan 1998 till Feb 2013 the Russian Acute Leukemia study group has treated 9 de novo and 1 relapsed APL in pregnant women. In all cases diagnosis was proved by cytogenetic and/or molecular approaches. The median age was 25 (19-37) years. According to the M. Sanz risk group stratification no one woman was in the favourable risk group, 5 were in the intermediate, and 4 - in the poor. APL was diagnosed in Ist trimester in 1 pt (8 weeks of gestation), in whom pregnancy finalised by spontaneous abortion, in IInd – in 4 pts (19, 20, 21, 24 weeks) and in IIIrd trimester - in 5 pts (28, 30, 32, 36, 38 weeks).
Results: Antenatal fetal mortality at 38th weeks of gestation was registered in 1 pt, followed by stimulated delivery before the APL diagnosis. The pt died within 7 days of ATRA plus chemotherapy (CT) due to septic shock and intracranial haemorrhage. 1 woman delivered by cesarean section after placental abruption and antenatal fetal mortality at the 24th week of pregnancy, complicated by uterine bleeding. She was diagnosed APL 2 months later. Now she is receiving AIDA-induction therapy. 1 woman delivered at 36 weeks of gestation before treatment. 2 pts (1- after delivery and 1 - after medical abortion at 1st trimester) were treated by 7+3 (Dauno=180mg/m^2) with ARTA. 6 pts were treated during pregnancy (5-AIDA, 1-7+3+ATRA). The CT was started at 19, 20, 21, 28 and 32nd weeks of gestation. Delivery was planned for all 6 pts at 34-35 weeks of gestation. 2 of 6 pts delivered by their own and 4 – by caesarean section. CT duration while pregnancy constituted 4-21 weeks (1-4 courses). CR was achieved after 1st course CT in all pts, in 5 of 6 – before delivery. In 1 pt the cesarean section was performed at 27 day of induction due to deterioration of hepatic function and fetus-damage symptoms. Differentiation syndrome was diagnosed in 2 of 10 pts. All pts had infectious complications during induction. CR was obtained in 8 of 9 pts (1 early death). 1 pt now is in neutropenia after induction. 1 pt died in CR after the 2nd consolidation due to Ps.aeruginosa sepsis and pulmonary aspergillosis. Late relapses occurred in 3 of 7 pts (in 2 - due to treatment refusal after induction/consolidation). 1 pt refused consolidation but is still in CR for 7 months. Only 5 pts are alive in CR now (1,5,7, 42 and 127 months). 3 y-OS and DFS constituted 30,5% and 34,3%. 3-y DFS in pts who did not refuse the treatment constituted 50%. 7 children were born at the median gestation`s time 36 weeks (34-40). All are alive (4 months -14 years) and healthy.
Summary / Conclusion: Our data demonstrate that APL in pregnant women is characterised by intermediate and high risk disease, most cases occurred in the 2nd and 3rd trimester, CR rate is high, but long term overall results are not so optimistic. We met with psychological problems resulted in 3 treatment refusals. All born children are well, without evidence of any abnormalities; cardiotoxicity in 5 treated with AIDA newborns is not registered so far. Pregnancy may be considered as an adverse prognostic factor in APL.

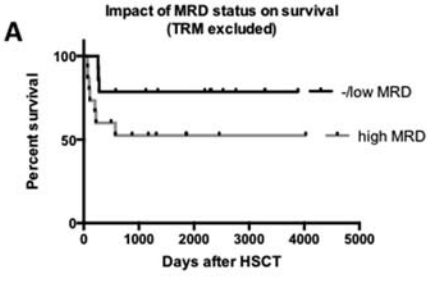
B1257

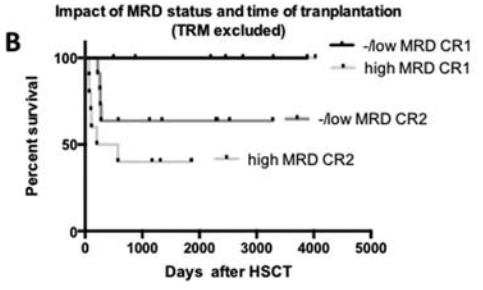
IMPACT OF MRD STATUS PRIOR TO HSCT IN PEDIATRIC AML

M Hansen[1*], C Nyvold[1], L Ebbesen[1], D Reinhardt[2], G Kaspers[3], J Stary[4], B De Moerloose[5], M Dworzak[6], C Zwaan[7], H Hasle [8]
[1]Hemodiagnostic Lab., Aarhus University Hospital, Aarhus, Denmark, [2]Department of Paediatric Haematology/Oncology, Medical School Hannover, Hannover, Germany, [3]Department of Peadiatric Oncology/Haematology, VU University Medical Centre, Amsterdam, Netherlands, [4]Department of Pediatric Hematology and Oncology, Charles University Prague, Prague, Czech Republic, [5]Department of Pediatric Hemato-Oncology and Bone Marrow Transplantation, Ghent University Hospital, Ghent, Belgium, [6]Department of Pediatrics, St Anna Children's Hospital and Children's Cancer Research Institute, Medical University of Vienna, Vienna, Austria, [7]Department of Pediatric Oncology/Hematology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, [8]Department of Paediatrics, Aarhus University Hospital Skejby, Aarhus, Denmark

Background: Despite great improvements in treatment protocols, relapse still occurs in 30-40% of all pediatric AML patients, being the leading cause of death with an overall survival (OS) of relapsed AML of only 35%. In an attempt to

improve the OS, attention has been focused on the concept of Minimal Residual Disease (MRD), the ability to detect and quantify small trace amount of residual leukemic cells in patients who have otherwise achieved morphologic clinical remission (CR). The hope is that MRD monitoring can guide preemptive interventions and thereby prevent progression from molecular to hematologic relapse and ultimately improve the course and outcome of childhood AML.
Aims: In this retrospective study we aimed to determine if there is a correlation between the MRD level prior to the allogeneic HSCT and the disease outcome in pediatric AML patients.
Methods: For the MRD assessment we used quantitative reverse transcriptase polymerase chain reaction (RT-qPCR).
The studied cohort consisted of 38 children with a confirmed AML diagnosis comprising one of the following aberrations: *t(8;21), inv(16), t(9;11), FLT3-ITD* or *NPM1* and who had undergone allogeneic HSCT transplantation. Exclusion criteria were Down syndrome and secondary AML. The median age at initial diagnosis was 9.1 years (range 0 – 18 years) and the female:male ratio 0.93.
Results: In the study cohort MRD levels directly prior to HSCT were undetectable in a third (32%, n=12) of the patients, five of these patients died, of which four were due to treatment related mortality (TRM). In the remaining 26 patients, MRD was detectable just before the transplantation. Among those, 18 patients (47% of the entire cohort) exhibited high levels, defined as MRD ≥0.01%. The group with high MRD had a death rate of 56% (4 due to TRM) while the group with low MRD had a mortality rate of 50% (4 of8, 1 caused by TRM). By grouping the non-detectable and low MRD level patients into one group (-/low MRD) and comparing them to the patients from the high group (+ MRD), a trend towards a favourable outcome of the -/low MRD patients in regards to OS was seen, albeit non-significant (P=0.08) (Figure 1A). Looking at the time of HSCT during the disease course we saw a clear superior outcome for patients transplanted in first remission (CR1) compared to second remission (CR2) (P=0.01). Likewise for the donor-type, matched sibling (MSD) vs. matched unrelated donors (MUD) showed a preference for MSD with P=0.009. When testing the timing of the transplantation in combination with the MRD status we again saw that patients transplanted in the first remission had an excellent outcome (fig. B). In cases where HSCT were performed in the second remission the OS considerably worsened, mostly for the patients with high MRD levels prior to HSCT (Figure 1B). We did not observe significant differences for overall survival in the favourable- (*t(8;21)*, *inv(16)*, *NPM1*) and poor-risk- (*FLT3-ITD*, *t(9;11)*) groups. This may be explained by the aberrations *FLT3-ITD* and t(8;21), as the latter exhibited a very poor prognosis with 9 death (4 due to TRM) out of 15 within the first 3 years after HSCT and a good profile for *FLT3-ITD* positive patients where only 1 out of 7 included in the analysis died. However, these data should be interpreted with some caution, as the cohort size is relatively small and the study is therefore with low statistic power. In addition, treatment of the patients has not been standardized within the study cohort.

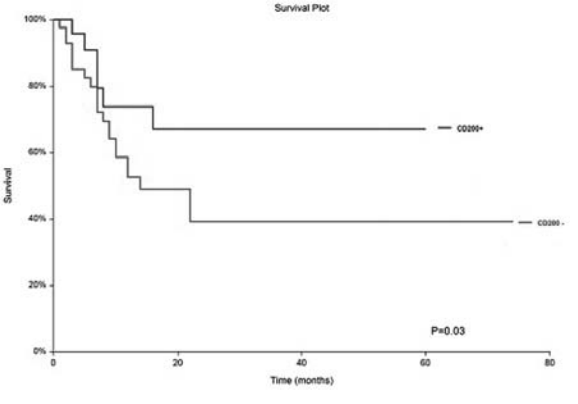




Summary / Conclusion: In this retrospective multinational study we have examined the impact of Minimal Residual Disease (MRD) levels just prior to hematopoietic stem cell transplantations and found that there seems to be some influence on the outcome when a certain MRD level is present at the time of HSCT. Whether additional therapy to reduce the tumor burden is beneficial before proceeding with HSCTs is still to be tested and verified in future clinical trials.

B1258
IMPACT OF CD200 EXPRESSION IN ACUTE MYELOID LEUKEMIA
M Tiribelli[1*], D Raspadori[2], A Michelutti[1], M Cavallin[1], A Meneghel[1], S Sirianni[2], E Toffoletti[1], E Simeone[1], R Fanin[1], M Bocchia[2], D Damiani[1]
[1]Division of Hematology and BMT, Azienda Ospredaliero-Universitaria di Udine, Udine, [2]Division of Hematology, University of Siena, Siena, Italy

Background: CD200 has been recently included among factors by which tumor cells can escape immune control. CD200 is a transmembrane protein structurally related to costimulatory molecules CD80 and CD86, widely expressed by thymocytes, activated T cells, B cells, dendritic cell, endothelial cells and neurons. The interaction of CD200 with its receptor inhibits immune system, thus facilitating tumor progression. An overexpression of CD200 has been associated with poor prognosis in many solid tumor, in CLL and in multiple myeloma. Moreover aberrant expression of the protein has been associated with negative outcome also in a small cohort of patients with acute myeloid leukemia (AML).
Aims: In the present work we retrospectively evaluated the incidence of expression and the impact on response to therapy in a series of 114 adults with AML.
Methods: One hundred fourteen patients with non-promyelocytic AML treated at our Institutions between 2007 and 2011 were included in this analysis. Blast cells immunophenotype and CD200 expression were evaluated by multiparametric flow cytometry.
Results: CD200 was expressed in 45/114 (39.5%) cases, with a median MFI of 11.8 (range: 3.8-88). No differences in CD200 expression rate were observed according to type of leukemia (de novo vs secondary), WBC count at diagnosis, or between cases with myeloid (M0-M2) or monocytic (M4-M5) morphology. However, higher incidence of CD200 expression was observed in CD34 positive patients compared to CD34 negative ones (35/44, 79% vs 23/69, 33%, P<0.0001). CD200 expression was strongly associated also to favorable cytogenetics (8/9, 89%) compared to patients with intermediate or unfavorable karyotype (29/87, 33%) (P=0.002). Moreover, a lower incidence of FLT3-ITD mutations was detected in CD200 positive cases (3/30, 10%) compared to those lacking CD200 expression (17/53, 32%) (P=0.032). One hundred and three patients received a three-drugs fludarabine-based induction course and was evaluable for response to therapy. Complete remission (CR) was achieved in 27/42 (64%) CD200 positive and in 45/61 (74%) CD200 negative patients (P=0.38), but a higher relapse rate was observed in the CD200 negative group (21/45 vs 6/27, P=0.046). Consequently, 3-years disease-free survival was 37% in CD200 negative patients and 67% in CD200 positive ones (P=0.03) [Figure 1].



Summary / Conclusion: Our data suggest a positive impact of CD200 expression on blasts of AML patients, in term of a lower incidence of relapse. This finding is in apparent contrast with what has been previously reported by Tonks et al. (Leukemia 2007). Reasons for this discrepancy could be the different way in detection of CD200 expression (gene expression and flow cytometry) and the high prevalence, in our CD200+ patients, of favorable features such as good-risk cytogenetics and FLT3 negativity. Moreover, we used an induction therapy based on fludarabine, that is known to significantly reduce the number of CD4+ lymphocytes, probably impacting also on the CD4+/CD25+ regulatory T cells, that suppress the anti-leukemia response, so neglecting the adverse effect of CD200 expression on AML blasts.

B1259
ANTI-TUMOR VACCINATION IN COMBINATION WITH MODIFIED DONOR LYMPHOCYTE INFUSION FOR AN AML RESISTANT PATIENT WITH EARLY EXTRAMEDULLAR RELAPSES
Y Finashutina[1*], T Akhlynina[2], E Zhelnova[3], N Lyzhko [2], T Gaponova[2], E Parovichnikova[3], A Misyurin[2], V Savchenko[2]
[1]Laboratory of molecular oncology and gene engineering, Federal Research Center for Pediatric Hematology, Oncology and Immunology, [2]Research Cen-

ter of Hematology of Russian Ministry of Health, Moscow, Russian Federation, [3]Chemotherapy of hemoblastoses and bone marrow transplantation, Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: Extramedullary relapse after allogeneic hematopoietic stem cell transplantation for AML is associated with poor prognosis as a contributor to post-transplant mortality. Due to the lack of efficacious treatment strategies, there is a need for novel approaches to manage extramedullary relapse after stem cell transplantation. PRAME is a tumor antigen that highly expressed in AML blasts and other malignancies but not in normal tissues. Moreover PRAME can elicit immune response in cancer patients.
Aims: To circumvent extramedullary relapse in AML patient by means of infusions of donor lymphocytes activated by autologous tumor cell lysate and recombinant PRAME protein as well as by consequent recombinant PRAME vaccination.
Methods: A 45 years-old male with AML M4-type had been treated with a cycle of chemotherapy following by allo-HSCT from sibling donor. 120 day after allo-HSCT the patient developed relapse with multiple extramedullary lesions in skin (leukemids) and viscera. The patient was treated with courses of chemotherapy and DLI. Subsequently 3 ordinary DLI were carry out (30, 45, 65 day after relapse) and molecular remission was achieved. The 2nd relapse was detected at 100 day after 1st relapse in developing multiple extramedullary lesions in skin (leukemids), viscera and central nervous system whereas bone marrow sample showed complete donor hematopoiesis. Chemo- and radiotherapy were carried out as well as surgical dissection of the lesions. After obtaining Informed Consent patient AML blasts were separated from leukemid-sampled cells and lysed by freezing-melting in liquid nitrogen. Donor lymphocytes ($8*10^6$/ml) were co-incubated *in vitro* in RPMI media with leukemid blasts lysate and recombinant PRAME protein (8 mcg/mL) in the presence IL-2 (100Uts) for 24h. Treated lymphocytes were used for donor lymphocyte infusion as well. Recombinant PRAME antigen was administered subcutaneously at the dose 100 mcg with 300 mcg aluminum hydroxide adjuvant twice with 3-weeks interval.
Results: RQ-PCR analysis of PRAME gene from skin biopsy-sampled cells revealed high level of expression. A bone marrow biopsy revealed complete morphological remission without evidence of minimal residual disease for all the time later. PRAME-injection was performed at the same day as DLI with stimulated lymphocytes (105 and 127 day after 1st relapse). Local inflammatory response at the injection site was observed. The extensive anti-relapse therapy was kept on. After first modified DLI the skin lesions disappeared. At parallel the stimulated donor lymphocytes were analyzed for cytotoxic effect *in vitro* in the presence auto-serum of the patient. Their ability to inhibit the growth of PRAME-expressing tumor cells (K562 line) was 2 to 5-fold better than non-stimulated donor lymphocytes. Overall survival at the time of writing is 14 months after immunotherapy.
Summary / Conclusion: Tumor specific immunotherapy in combination with allo-HSCT may be a potent curative method for AML patients with multiple extramedullary relapses.

B1260

MYELOID MORPHOLOGY AND THE NUMBER OF CO-EXPRESSED LYMPHOID-ASSOCIATED ANTIGENS CORRELATE WITH POORER CLINICAL BEHAVIOUR IN CBF-POSITIVE ACUTE MYELOID LEUKAEMIAS

M Guenova[1*], B Spassov[2], N Stoyanov[1], P Ganeva[2], V Nikolova[1], A Michova[1], E Hadjiev[3], N Yurukova[4], G Mihaylov[2], G Balatzenko[5]
[1]Laboratory of Haematopathology and Immunology, [2]Clinics of Haematology, National Hospital for Active Treatment of Hematological Diseases, [3]Clinics of Haematology, Alexandrovska University Hospital, [4]Clinics of Haematology, Specialised Childrens Hospital for Onco-Hematological Diseases, [5]Laboratory of Cytogenetics and Molecular Biology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Acute myeloid leukaemias (AML) with t(8;21) or inv(16)/t(16;16) are associated with rearrangements of the …core binding factor" (CBF) genes CBFA and CBFB, leading to disturbances in the transcription of genes involved in myeloid differentiation. Leukaemias defined as CBF-AML are recognized as nosological entities in the WHO classification and generally characterized by good prognosis after intensive therapy. However, heterogeneity in regard to blast cells features is still being reported.
Aims: To analyse the main morphological and immunophenotypic features of the blast cell population in AML patients (pts) with *AML1-ETO* and *CBFb-MYH11* fusion transcripts and to assess the clinical behavior in regard to overall survival (OS).
Methods: In total, 53 patients (32 male:21 female) were diagnosed with CBF-AML for a 10-years period, at a mean age of 37 years (range 6-79). *AML1-ETO* or *CBFb-MYH11* mRNA was detected by RT-PCR, complementing morphology and immunophenotyping by a panel of antibodies allowing for determining lineage affiliation, maturation and aberrant antigen expression. Follow up for a mean of 27 months (2-120) were available for 29 adult pts in whom induction therapy was completed at the National Haematology Hospital.
Results: The *AML1-ETO(+)* AML (n=26) showed variable morphology, corresponding to M1-M2-M2Eo-M4-M4Eo FAB subtypes. Characteristic morphology was observed in only part of the cases. In 23% of the pts pathological eosinophils (Eo) were increased (M2Eo, M4Eo). In addition to myeloid-associated markers, *AML1-ETO(+)* AMLs were characterized by a high incidence of CD34(91%), CD117(100%) and aberrant co-expression of CD56(69%) and/or CD19(53%) and CD4(23%). The morphological spectrum of *CBFb-MYH11(+)* AMLs (n=29) showed similar variations according to the FAB criteria. However, proliferation of Eo was found in 81% of the pts, bearing pathological basophilic granules in all cases. *CBFb-MYH11(+)* AMLs were also characterized by frequent CD34/CD117(100%) and aberrant CD56(31%) and/or CD2, CD4; CD7; CD19. Compared to *AML1-ETO*(+) p*ts, CBFb-MYH11(+)* AMLs had higher % of peripheral blood blasts (38% vs 46%, P=0,036), white blood cells (16G/L vs 32G/L, P=0,000) and platelets (18G/L vs 62G/L, P=0,036), while the analysis did not reveal any differences in terms of age, % bone marrow blasts, hemoglobin, LDH, DFS and OS. CR achievement was a major factor for better prognosis with 73% OS and a median not reached. Regardless of the type of transcripts the myeloid morphology was associated with a lower OS (22%, median - 8 mo) vs 77% with a median not reached in the M4 group (P=0.01) while abnormal Eo had no impact. The analysis confirmed the unfavorable value of CD56: median OS not reached in CD56(-) cases vs 17 mo in CD56(+) (P=0.02). Furthermore, the overall number of lymphoid-associated markers contributed to the poorer survival. Median OS was not reached for the time of the follow up in the negative cases, and was 31 mo in the presence of 1 marker and 8 mo if more than 1 marker was co-expressed.
Summary / Conclusion: The present study contributes to the heterogeneity of CBF-AML in regard to morphology and immunophenotype. Lymphoid-associated markers might provide additional prognostic information and are recommended in the diagnostic panel. An intergrated approach would allow for a risk-oriented therapies and optimized outcomes.
The present study was supported by the National Science Fund (grant D002-35/09).

B1261

DECREASED SERUM RETINOL-BINDING PROTEIN IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Gao[1], L Su[1*], W Li[1], Y Tan[1], Y Yang[1]
[1]Cancer center, The first hospital, Jilin University, Changchun, China

Background: Retinol-binding protein (RBP) is a single polypeptide chain protein that is classified under prototypical lipocalin due to its similarity to other lipid binding proteins. The ternary complex transthyretin-RBP-retinol thus serves to transport retinol from the storage site liver in the circulation and to deliver it to target tissues. The plasma membrane RBP receptor (STRA6) transports vitamin A from its blood carrier RBP into cells. RBP also maintains the free level of retinol in the plasma. Additionally, RBP secretion was positively regulated by retinol. In previous studies, RBP was evaluated as nutritional indice for children with acute myeloid leukemia (AML). However, there is no data available assessing the RBP level in adult and elderly patients with AML.
Aims: To assess the RBP level in AML patients of all age groups and to explore the potential relationships between serum RBP and clinical characteristics (*e.g.* white blood cell count, molecular markers) of AML patients.
Methods: In this study, 208 patients with *de novo* AML, 88 patients with benign hematological diseases, and 168 healthy subjects were enrolled. Peripheral blood sample of patients before treatment and healthy subjects were collected, and then were determined RBP and prealbumin concentrations by Automatic Chemistry Analyzer. Cytogenetics and molecular mutations were determined in patients with AML. Patients gave informed consent prior to enrolment in the study. Statistical analysis was performed with the software SPSS 17.0.
Results: AML patients (35.58±15.42 mg/L) had lower RBP concentration compared with benign hematopathy (42.69±15.62 mg/L) (u = -3.662, P<0.001) and healthy control (57.12±29.23 mg/L) (u = -10.187, P<0.001). AML patients of non-APL (32.62±12.94 mg/L) exhibited lower RBP concentration compared with APL patients (41.17±18.07 mg/L) (u = -3.161, P=0.002). A negative association could be observed between serum RBP level and peripheral white blood cell count (r = - 0.179, P=0.01), which was more evident in patients with M4 (r = - 0.499, P=0.036) and M5 (r = - 0.412, P=0.029). Elderly AML patients (≥ 60 years) had highest RBP level compared with children (< 16 years) (t = 2.284, P=0.049) and adult patients (16 ~ 59 years) (t = 2.572, P=0.011). Patients carry *FLT3-ITD* mutation [27.8 (21.35, 35.15) mg/L] exhibited lower RBP concentration than those without [35.75 (27.63, 43.55) mg/L] (u = -2.173, P=0.030).
Summary / Conclusion: These phenomena may suggest decreased level of retinol in patients with AML, which might be associated with excessive consumption of RBP in the proliferation of leukemic cells.

B1262

PERCENTAGE AND/OR ABSOLUTE LYMPHOCYTE COUNT AT DIAGNOSIS: PROGNOSTIC IMPACT IN ACUTE MYELOID LEUKEMIA (AML)

C Lalayanni[1*], V Douka[1], P Baliakas[1], K Karypidis[1], M Iskas[1], A Athanasiadou[1], R Saloum[1], A Anagnostopoulos[1]
[1]Hematology & HCT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: White blood cell (WBC) count at diagnosis is considered an

important prognostic factor for both acute lymphoblastic (ALL) and acute myeloid leukemia (AML). Absolute lymphocyte count (ALC) after induction treatment has been related to prognosis in acute leukemias, whereas it remains of importance after hematopoetic stem cell transplantation (HSCT) as a marker of immune reconstitution.

Aims: ALC at diagnosis has been studied as a predictor of survival for non-Hodgkin lymphoma and other cancers. There is little evidence regarding the prognostic significance of ALC and lymphocyte percentage (Ly%) at AML diagnosis.

Methods: We retrospectively studied ALC in 266 AML patients with median age 50 years (range: 14-75), male/female: 155/111, de novo/secondary: 197/69. Cytogenetic analysis was available in 250/266 cases and was favorable/intermediate/poor prognosis in 31/164/55 respectively. Complete remission (CR) was accomplished in 183/266 (68.8%). Median ALC at diagnosis was 3.515 x 10^9/μL. Low ALC (<1x10^3/μL) at diagnosis was observed in 44/266 (16.5%) patients. This patient group correlated with low CR rate (21/44, ie 47.7%, P=0.001), low WBC count, neutropenia and secondary AML, in comparison to patients with an ALC count >1x10^3/μL. A trend to shorter disease free survival (DFS) was observed only at the subgroup of intermediate risk cytogenetics (P=0.07). Patients with relative lymphopenia (Ly% ≤20%) were 125/266 (47%) and presented with elevated WBC count, LDH, blast count and neutrophil count at diagnosis and had the same trend for a shorter DFS (P=0.07) in comparison to patients with ≥ 20% lymphocytes at diagnosis.

Results: Combining the above findings, a group of 147 patients presenting with relative or absolute lymphopenia could be identified. These patients had a lower CR rate (64% vs 74.8%, P=0.05). Outcome was significantly worse in this group compared with non lymphopenic patients: 5-year DFS was 24% vs 41% (P=0.01) and 5-year OS was 31% vs 46% (P=0.015). Lymphopenia did not influence survival when studied seperately in the 3 cytogenetics risk groups. In multivariate analysis lymphopenia defined as ALC < 11x10^3/μL was an independent prognostic factor affecting OS (P=0.016) but not DFS. Other independent prognostic factors for OS were karyotype, age, CR achievement post induction therapy (P<0.001) as well as LDH levels at diagnosis (P=0.005).

Summary / Conclusion: In conclusion, patient's lymphocytes at diagnosis may have some assistive role in AML and the prognostic significance of lymphopenia in this setting needs further investigation.

B1263

CD56 EXPRESSION IN ACUTE PROMYELOCYTIC LEUKEMIA – A PREDICTIVE INDICATOR OF RELAPSE?

S Ramalheira[1*], C Moreira[1], C Ferreira[1], L Leite[1], D Pereira[1], M Nunes[1], M Brito[1], P Silva[1], R Silva[1], Â Martins[1], I Moreira[1], I Oliveira[1], L Viterbo[1], N Domingues[1], S Chacim[1], E Sousa[2], I Godinho[2], G Martins[2], C Mendes[3], ASanto[1], J Mariz[1]

[1]Onco-Hematologia, [2]Unidade de Citometria de fluxo, Serviço de Hematologia Laboratorial, [3]Serviço de Hematologia Laboratorial, Instituto Português de Oncologia do Porto, EPE, PORTO, Portugal

Background: Acute Promyelocytic Leukemia (APL, M3 in FAB classification) is a subtype of acute myeloid leukemia characterized by a unique chromosome translocation t(15;17). It is usually associated with a good prognosis despite coagulopathy often present at clinical presentation. Leukemic cell expression of CD56 at the time of diagnosis has been associated with a worse outcome, registering a shorter disease-free survival (DFS) as well as a lower overall survival (OS).

Aims: To characterize the adult patient population diagnosed with APL followed at our institution; assess the promyelocytic cell phenotype at diagnosis and verify if the presence of the CD56 antigen confers a worse prognosis. It is intended to compare the two groups (negative and positive CD56) with regard to the clinical presentation, response to therapy, relapse, DFS and OS.

Methods: We conducted a retrospective analysis of all APL cases diagnosed between 1999 and 2012. Thirty nine patients who had an evaluation for CD56 expression (> 20% positivity by flow cytometry) were selected and comparison of the two groups (negative and positive CD56) was made. Data analysis was performed using the SPSS v20.

Results: Median age of the thirty nine patients with APL was 42 years old (range 17-78 years), fifty-nine percent of the patients were women. CD56 expression was considered positive at diagnosis in twelve cases (30.8%); twenty-seven (69.2%) weren´t associated with the antigen presentation on blast cells. Those subgroups were similar in median age at diagnosis and gender (35.5 years and 58.3% female gender if CD56+, and 43 years and 59.3% female patients if CD56-). Comparing CD56+ patients with those who didn´t express that antigen, one can found (despite no statistical significance) that CD56+ patients have a more aggressive clinical and laboratorial presentation: hemorrhagic presentation (100% versus 81.5%); intravascular disseminated coagulation (33.3% versus 11.3%); median leukocyte count of 10.1x10^9/L (range, 1 to 102) versus 4.4x10^9/L (range, 0.4 to 40.8); 50% of all patients CD56+ had an hiperleukocytary presentation, only 16% in CD56- subgroup; and a median fibrinogen level of 120mg/dL (range, 62 to 209) versus 141,5 mg/dL (range, 36 to 372). CD56 expression is associated with a higher risk stratification (P=0,018) - 50% of the patient are at a high risk at diagnosis versus 14.8% in CD56- subgroup. Patients were treated with ATRA, idarrubicine, mitoxantrone and cytarabine with similar response in the two subgroups (complete remission 83.3% if CD56+ and 85.2% if CD56-). In the APL CD56+ subgroup there is a higher relapse rate 41.7% versus 7.4% in CD56- subgroup. Despite the difference in median time to relapse (16 months if CD56+ and 37 months if CD56-) we couldn't find statistical significance for disease free survival (Kaplan-Mayer). However, the relative risk for relapse is 5.63 (1.27-25.01, confidence interval 95%) in the CD56 positive population. In our population there were no differences in overall survival (median follow-up time subgroup CD56+ 39 months, range 10-115; subgroup CD56- 47 months, range 1-125).

Summary / Conclusion: Despite the limitations of our retrospective study we demonstrated a significant relative risk for relapse in patients with APL and positive CD56. This antigen is probably a prognostic marker that in association with other indicators can provide a stratification risk.

B1264

TREATMENT WITH AZACITIDINE INCREASES OVERALL SURVIVAL, REDUCES INFECTIONS AND HOSPITALIZATIONS IN ELDERLY PATIENTS WITH ACUTE LEUKEMIA COMPARED WITH INTENSIVE CHEMOTHERAPY: A MONOCENTRIC STUDY

C Buquicchio[1*], L ciuffreda[1], T Santeramo[1], G De Santis[1], D Diomede[1], M Santoro[1], R Miccolis[1], M Di Candia[1], G Tarantini[1]

[1]Ospedale San Nicola Pellegrino , Trani, SC Ematologia, Trani, Italy

Background: Survival in older patients(>65 years old) with acute leukemia is shorter than young patients.The inferior outcome reflects the major frequency of higher risk karyotypes,history of antecedent hematologic disorder, comorbidity that limit delivery /clearance chemotherapy

Aims: We reviewed the baseline characteristics and outcome after therapy of 40 consecutive patient aged 65 years and older with acute leukaemia admitted and treated in our institution from 2009 to 2013. 20 patients with performance status 2 or3, or some older patients that did not accepted intensive chemotherapy were treated with azacitidine(Aza group),while 20 patients with performance status 1 or 2 younger than 75 years were treated with intensive chemotherapy(IC group)

Methods: Azacitidine was administered subcutaneously (75mg/m2/d) for 7 days of every 28-day cycle until progression,while IC consisted of 1 induction course with mitoxantrone, cytarabine and etoposide followed by 2 course with idarubicine, cytarabine and etoposide (in patients in complete remission).In aza group(7 female and 13 male)the median age was 76.5(range 65-83),median white blood cells was 3.3 x 10^9(1.1-48),median hb was 7.85(6.2-12.2),median platelets 70 x 10^9(17-245),median bone marrow blasts counts was 47%(21-90%).Karyotype risk stratification was normal in 11(55%),intermediate in 2(10%) and high risk in 7 (30%).The median number of cycle was 10 (range 1-29).The fever infections that requiring IV antiobiotics were in 7 patients(35%),but only in 2(10%)were septic and 2(10%) bronchitis that needed hospitalization and 5/7(71%)of infected patients not reduced rate and time of next cycle,while 1(5%)patient presented an Early Death(ED,within two months after diagnosis).15 patients in Aza group achieved response to treatment in fact overall response rate (ORR) was 75%(complete remission 45%+ partial remission 30%)with a median duration of 9 months (range1-29),the median overall survival (OS) was 12 months (range 2-29).The transfusion independence was in 5(25%) patients, reduced in 9(45%) and stable in 6(30%).In IC group(10female and 10 male)the median age was 70.5(range 65-86),median white blood cell was 5.3 x 10^9 (1.0-450),median hb was 8.05g/dl(4.1-13.7),median platelets 33 x 10^9μl (7-148),median bone marrow blasts counts was 65% (range 35-90%).Karyotype risk stratification was normal in 15 (80%), and high risk in 5 (20%).The median number of cycle was 1.5 (range 1-3).The fever infections 3-4 grade that requiring IV antimicrobics were in 15 patients(75%) and in 9 (45%)were observed ED.9 patients in IC group achieved response to treatment:overall response rate (ORR) was 45%(complete remission 35%+ partial remission 10%)with a median duration of 3.5 months (range1-11),the median overall survival (OS) was 1.5 months(range 2days-19 months).

Results: Treatment with azacitidine in older patients with acute leukaemia prolongs overall survival compared to the chemotherapy group (P<0.01), expecially in patients with worse performance status(P<0.001),reduces ED (p.0.008) for lower toxicity and lower incidence/severity infections and improve overall response (p0.66)compared with intensive chemotherapy.In Aza group the platelet recovery (>100 x 10^9) after three months of therapy is predictive of complete response to the therapy (P<0.0005).

Summary / Conclusion: Older patients with AML and more comorbidities may benefit from less intensive approaches as azacitidine.Prospective and randomized clinical trials are necessary to confirm the effect of Azacitidine on larger number of elderly AML.

B1265

AMBULATORY CARE OF PATIENTS RECEIVING CONSOLIDATION CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA : A FEASIBLE AND SAFE OPTION FOR SELECTED PATIENTS

K Lang[1*], C Roughley[1], L Roberts[1], M Mohamed[1], V Ratnayake[2], K Saied[1], C Pocock[1], J Lindsay[1]

[1]Department of Haematology, East Kent Hospital Trust, Canterbury, [2]Depart-

ment of Haematology, East Kent Hospital Trust, Ashford, United Kingdom

Background: Conventional management of patients undergoing induction chemotherapy for acute myeloid leukaemia (AML) involves prolonged inpatient stays during treatment and the following myelosuppressive period. However whether consolidation chemotherapy for patients in remission requires a prolonged inpatient stay, is more contentious.
Aims: To prospectively assess the safety and suitabililty of the ambulatory care model for AML patients in remission after first induction undergoing consolidation chemotherapy.
Methods: We prospectively audited 23 patients deemed sufficiently fit to undergo consolidation chemotherapy as outpatients or to be monitored on an ambulatory basis following inpatient chemotherapy. All patients were in remission following induction chemotherapy and were managed through a single site BCSH Level 2b inpatient and day unit facility with 24-hr access to specialist nurse advice. All ambulatory patients received prophylactic levofloxacin and posaconazole as per local protocol.
Results: The median age was 51 years (range 20-78 years) and the mean distance of the patient's home from the unit was 14.2 miles (range 0.9 – 26.9). Twenty three patients received a total of 61 cycles of chemotherapy of which 16 were given purely on an outpatient basis. The average length of neutropenia during the first consolidation cycle was 13.7 days (range 0-48 days) and 10 patients required admission during the second course (average length of stay 3.7 days) for febrile neutropenia. No patients required organ support. Eleven patients received a third course, with 5 as inpatients. The mean duration of neutropenia was 17.8 days (range 4-46). There were 9 admissions during the third cycle (average LOS 8.7 days), and 2 required ITU admission. There were no fatalities. Four patients received a fourth cycle.
Summary / Conclusion: These data suggests that for AML patients in remission, the ambulatory care model for early discharge following chemotherapy and/or outpatient delivery of consolidation chemotherapy is safe. The second consolidation cycle was associated with more admissions and number of ITU stays, reflecting cumulative toxicity and myelosuppression. We had no deaths throughout the study period and the approach was well received by patients.

B1266
FLAG-IDA: A HIGHLY EFFECTIVE SALVAGE REGIMEN IN PRIMARY REFRACTORY ACUTE MYELOID LEUKEMIA
M Virijevic[1*], N Suvajdzic-Vukovic[1,2], I Djunic[1], A Novkovic[3], M Mitrovic[1], N Colovic[1,2], A Vidovic[1,2], D Tomin[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical Hospital Center Zemun, Belgrade, Serbia

Background: The prognosis for patients with primary refractory acute myeloid leukemia (AML) is poor. Achievement of complete remission (CR) in patients with this disease is a prerequisite for subsequent treatment with allogeneic stem cell transplantation. The FLAG-Ida protocol has shown the most success compared to other salvage therapy regimens preceding transplantation.
Aims: An investigation to find the most efficient salvage protocol for achieving CR of long duration and a high rate of overall survival (OS) in primary refractory AML.
Methods: The single-center study involved 53 patients with primary refractory AML who had failed to achieve CR after first-line standard-dose remission-induction therapy. During the period January 2008–December 2012, the subjects had received one cycle of the 3+7 protocol: ARA-C, days (D) 1–7 and daunorubicin D 1–3. After that FLAG-IDA (Fludarabin 30mg/m^2 D1-5; ARA-C 2000mg/m^2D1-5; Idarubicina 8mg/m^2 D1-3, G-CSF 300mg/m^2) or Mitoxantrone+Vepesid (Mitoxantron 10mg/m^2 D1-5 and Vepesid 100mg/ m^2 D1-5) or the HiDAC regimen (ARA-C 2x3g/m^2 D1,3,5) were given as salvage therapy. We determined the rate of achieving CR, duration of CR and OS.
Results: The median age of the patients was 53 years, range 19-70 years. Among them 16 (32.2%) received the FLAG-IDA regimen, 22 (41.5%) Mitoxantrone+Vepesid and 15 (28.3%) HiDAC. The rate of CR was 62.5% for patients treated with the FLAG-IDAregimen, which was significantly greater than for the other two protocols, (22.7% for Mitoxantrone+Vepesid and 13.3% for HiDAC;P=0.006). An age greater than 55 years was the only factor predictive for a significantly lower response rate (P=0.05). The duration of CR in subjects who receivedthe FLAG-IDA protocol was 4 months. This was significantly longer than for those given the other two regimens (2 months for both; P=0.022). Moreover, OS was significantly longer for patients treated by the Flag-Ida regimen (6 months) than for those receiving the other two regimens (4 months each; P=0.004). Three of the ten responders underwent successful bone marrow transplantations. The median remission duration for the remaining seven patients was 5 months, and the median survival time was 7 months.
Summary / Conclusion: The FLAG-IDA regimen showed significantly higher efficiency in comparison to the other two regimens in our group of patients with primary refractory AML. These data confirm that the FLAG-IDA regimen has high antileukemic activity in refractory AML.

B1267
TREATMENT OUTCOME OF PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA (APL) - A SINGLE CENTRE EXPERIENCE
S Tan[1*], T Ong [1], J Rajasuriar[1], J Tan [1], Z Zakaria[1], J Kuan[1], J Sathar[1], N Lau[1], P Liew[1], K Chang[1]
[1]Haematology, Hospital Ampang, Ampang, Malaysia

Background: Acute promyelocytic leukemia (APL) is a unique subtype of acute myeloid leukemia (AML) with distinct hematopathologic, cytogenetic, molecular and clinical features. The prognosis of APL has transformed from the worst among AML as it used to be, to currently the best ever since the emergence of all-trans-retinoic acid (ATRA). Patients in our centre have been routinely induced using ATRA in combination with anthracycline-based chemotherapy as first line regimen since 1994.
Aims: In this study, we evaluated the outcome of adult APL patients who received modified AIDA protocol in our institution from January 1994 till December 2012. The treatment protocol consisted of remission induction using co-administration of ATRA and Idarubicin followed by 3 courses of Idarubicin consolidation, and 18 months of maintenance treatment with 6-Mercatopurine/ Methotrexare/pulse of ATRA.
Methods: All records of the patients were analyzed in a non-randomized retrospective study on 1st January 2013. Overall survival was estimated by the Kaplan-Meier curve.
Results: A total of 114 patients were diagnosed as APL for the last 18 years which represented 12.98% of all AML cases. Most of the patients were young with the median age of diagnosis at 29 years (range 12 to 76) and predominantly female (male 39.47% and female 60.53%). The ethnic composition of our cohort was Malays 48.25 %, Chinese 35.96 %, Indian 10.53 % and others 5.26 %. Majority of our patients were at high risk of relapse on presentation as most of them fell into the high risk group 47.06% (intermediate risk group 44.78% and low risk group 8.95% respectively). Five patients died right after hospitalization before treatment initiated due to bleeding complication mainly CNS hemorrhage (60%). The remaining 109 patients proceeded with ATRA-Idarubicin chemotherapy with an induction death of 2.75% (2/3 of mortality due to intracranial hemorrhage and 1/3 attributed from sepsis) while during consolidation we observed a mortality rate of 1%. There was only 2 patients (1.8%) complicated with ATRA syndrome. Our patients achieved an overall complete remission (CR) rate of 90.48%. The cumulative relapse rate and mortality were 28.71% and 25.44% respectively over the 228 months observation period. 24 out of 29 relapsed patients managed to be salvaged with mainly Arsenic Trioxide (ATO)-based (66.67%) and achieved second CR of 75%. The event-free survival (EFS) and overall survival (OS) of the cohort will be presented later.
Summary / Conclusion: A modified AIDA protocol for adult APL leads to improved treatment outcomes, with limited ATRA syndrome-associated toxicity in our centre despite majority of our cohort are of high risk patients. Relapsed cases can be salvaged with ATO-based therapy. Early detection and active management of bleeding complications remained the most important measure that may help in reducing mortality.

B1268
TREATMENT OF MOLECULAR RELAPSE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
L Semerad[1*], M Palackova[1], I Jeziskova[1], D Dvorakova[1], F Razga[1], M Bajerova[1], J Prochazkova[1], J Mayer[2], Z Racil[2]
[1]Department of Internal Medicine, Hematology and Oncology, Masaryk University and University Hospital Brno, [2]CEITEC, Masaryk University, Brno, Czech Republic

Background: Evidence for beneficial effect of minimal residual disease (MRD) monitoring and early intervention (=pre-emptive therapy) in non-APL acute myeloid leukemia (AML) pts. are very limited.
Aims: To assess usefulness, efficacy and toxicity of various treatment regiments in the therapy of molecular relapse in non-APL AML patients.
Methods: We have performed a retrospective analysis of molecular relapses in AML pts. with molecular target and its treatments. RQ-PCR was used for the MRD monitoring. Molecular relapse was defined as confirmed reappearance of the fusion transcript or mutated gene detection or its 10-fold increase in pts. with persistent positivity and corresponding bone marrow cytology, immunophenotype and cytogenetic analysis remained negative.
Results: In the study period 1/1/2003 – 1/2/2013 we have treated 38 molecular relapses in 21 pts.. Median follow up was 35,5 months (range 12-121 months). The median time from the end of initial AML therapy to the first molecular relapse was 5 months (range1,0-29,0 months) –4,0 months (range1,0-14,0 months) for RUNX1/RUNXT1 positive pts.; 2,1 months (range2,0-14,0 months) for CBFB/MYH11 positive pts.; 13,5 months (range5,0-29,0 months) for patients with MLL fusion abnormalities;4,0 months (range2,0-4,0 months) for patients with NPM1 mutation. The frequency of treatment regimens and their efficacy in the first molecular relapse (n=21) was as follows: conventional chemotherapy ("5+2" like regimens) (CHT) – 19,0% (n=4), clofarabine (CLO) – 42,8% (n=9), gentuzumab ozogamicine (GO) – 14,3% (n=3), immunomodulation after allogeneic hematopoietic stem cell transplantation (IMMUNO) – 19,0% (n=4), and low dose ARA-C (LD-ARAC) –4,8% (n=1). The overall response rate (RR = CMoR + PMoR) to pre-emptive therapy of the first molecular relapses was

66,6 % (14/21) (47,6% CMoR+ 19,0% PMoR) - CLO – 77,8%RR (55,6% CMoR + 22,2% PMoR); CHT – 100% RR (50% CMoR + 50% PMoR); IMMUNO – 50% RR (CMoR); GO - 33.3% RR (CMoR); LD-ARAC - 0% RR.
In the follow up period 69,2% (n=9) of responding pts. revealed the second molecular relapse with median7,0 months (range1,0-19,0 months). Moreover, in 15,9% (n=2) hematological relapse occurred without foregoing molecular relapse with median3,5 months (range3,0-4,0 months). The second molecular relapse was pre-emptively treated in 9 patient with RR 66,6% (n=6) (CR+PR). However, again in 4/6 (66,6%) of successfully treated pts. with the second molecular relapse, subsequent molecular relapses occurred with median 9,5 months (range4,0 – 16 months) and were again treated with RR 25% (n=1).
At any time during treatment 61,9% of patients underwent allogeneic HSCT.
Overall, only 3 pre-emptively treated patients did not revealed any further hematological or molecular relapse during the observational period (2/3 pts. underwent allogeneic HSCT)
6/21 (28,6%) of patients with molecular relapse survived during the study period (all with initial or subsequent molecular response) with OS 68 months, compare to OS of 17 months in 15/21 (71,4%) of pts that expired during the follow up period.
Summary / Conclusion: Our study has shown feasibility of MRD monitoring and pre-emptive strategy using molecular targets in non-APL AML pts. Different pre-emptive treatment strategies led to response in 66,6% of molecular relapses with the highest frequency of CMoR when CLO was used. Even pre-emptive therapy enables us to obtain time for preparing allogeneic HSCT (performed in 2/3 of patients), majority of patients relapsed again in follow up period. However, our data showed that this approach (even in limited number of patients with initial or subsequent response) could provide prolongation of overall survival.

B1269

CYTARABINE PLUS IDARUBICIN AS INDUCTION THERAPY FOR UNTREATED ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA. A SINGLE CENTER RETROSPECTIVE ANALYSIS OF 141 PATIENTS.

L Leite[1*], M Nunes[1], S Chacim[1], I Ferreira[1], C Moreira[1], D Pereira[1], M Brito[1], L Viterbo[1], Â Martins[1], I Moreira[1], N Domingues[1], A Espírito-Santo[1], I Oliveira[1], J Mariz[1]
[1]Serviço de Onco-Hematologia, Instituto Português de Oncologia do Porto, Porto, Portugal

Background: The chemotherapy regimens containing cytarabine and an atracycline, traditionally known as "7+3", remain the most effective induction therapy for untreated adult patients with non-promyelocytic acute myeloid leukaemia (AML).
Aims: Present the response rates, overall survival (OS) and relapse free survival (RFS) of adult patients with non-promyelocytic AML, diagnosed and treated at single haematology center.
Methods: We performed a retrospective analysis of the clinical data of patients with non-promyelocytic AML, diagnosed between January 1995 and December 2010 and treated with the "7+3" induction containing cytarabine (200mg/m2/d as a 7-days continuous infusion) plus idarrubicin (12mg/m2/d on the first 3 days).
Results: We identified 141 patients with a median age at diagnosis of 46 years (interval 15 to 67), including 43 (31%) with more than 55 years. According to de World Health Organization (WHO) classification, 73 patients (52%) had AML NOS, 33 (23%) AML with recurrent cytogenetic abnormalities, 31 (22%) AML with myelodisplasia-related changes, 3 (2%) therapy-related AML and 1 (1%) myeloid sarcoma. The SWOG/ECOG cytogenetic risk was accessed in 135 patients. Sixty-nine (51%) were classified as intermediate risk, 25 (19%) as favorable risk, 22 (16%) as adverse risk and 13 (14%) as unknown risk cytogenetic abnormalities. After induction, 101 patients (71.6%) achieved a complete remission (CR), 5 (3.5%) a complete remission with incomplete hematological recovery (RCi) and 35 (24,8%) were resistant. Ninety-eight of the 101 patients who achieved a CR were consolidated with cycles of high dose cytarabine, followed in 15 patients by allogeneic hematopoietic stem cell transplantation (AlloHSCT) in first CR. A 28 months OS was registered, with a minimum of 18 days and a maximum of 141 months, associated with a 5 and 10 years survival probability of 43 and 34%, respectively. Fifty-two (49%) of the patients that respond to the induction treatment registered disease relapse, with a median time to relapse of 48 months, interval between 18 days to 141 months, with a 5 and 10 years RFS probability of 60 and 32%, respectively. For the group of patients with an age at diagnosis inferior to 55 years, the OS was 51 months, which was significantly higher when compared to the group with more than 55 years that registered an OS of 16 months (P=0.034). The stratification of patients by cytogenetic risk also provided an OS significantly different between favourable, intermediate and adverse risk groups, 91, 37 and 10 months, respectively, P=0.013.
Summary / Conclusion: In accordance to results published by other groups, in our department AML remains a disease associated with a poor OS, which is worse in patients with more than 55 years of age and with cytogenetic abnormalities associated with an adverse outcome.

B1270

EARLY DETECTION OF SERUM GALACTOMANNAN ANTIGEN IN HEMATOLOGIC MALIGNANCIES: IMPACT OF A LABORATORY ASSAY IN ASPERGILLUS INFECTION MORTALITY RATE

O Pérez-López[1*], I Montero-Cuadrado[1], M Gómez-Rosa[1], M Aguilar-Guisado[1], J González-Campos[1], J Falantes-González[1], M Martino-Galiana[1], R Parody-Porras[1], I Espigado-Tocino[1], J Pérez-Simón[1]
[1]Virgen del Rocío University Hospital, Sevilla, Spain

Background:
The incidence of deep fungal infections in patients with malignancies has increased dramatically over the past decades**.** Aspergillus spp. represent the main cause of these infections. The serum galactomannan(GM) antigen detection is a relatively recent test and it is recognized as an indirect mycological criteria for diagnosis of invasive aspergillosis. Mortality rates of up to 60% have been reported with invasive *Aspergillus*infections in high-risk hematology patients,which makes early diagnosis of said infection an important challenge.
Aims: 1.-Evaluate the diagnostic potential of the determination of GMinserumin patients with hematological malignancies and fever and /or respiratory symptoms. 2.- Set mortality group diagnosed with invasive aspergillosis as EORTC criteria.
Methods: We have evaluated 70 patients between 2008 and 2012, supplying 89 episodes of fever syndrome, 39 in men and 50 in women, with an average age of 49 (range 14-83 years). Hematologic malignancies in these patients were: 42 acute myeloid leukemia, 11 acute lymphoid leukemia, 7 Hodgkin lymphoma, 7 non Hodgkin lymphoma, 5 chronic lymphocytic leukemia, 4 multiple myeloma, 3 aplastic anemia, 3 acute mixed leukemia, 6 myelodysplastic syndrome and 1 chronic myeloid leukemia. An early GM determination (ELISA)was performed for persistent fever syndrome, despite antibiotic treatment, mainly with an initial respiratory focus (56 episodes). After a positive result, a chest high resolution CT was requested followed by fibrobronchoscopy depending on real clinical suspicion and the results. The diagnosis of invasive aspergillosis was made using EORTC criteria (possible, probable and proved).
Results: The patients suffering from fever and respiratory symptoms were 58 (65%), presenting a positive GM rate of 67% (39 cases). In these cases, a probable or proved aspergillosis diagnosis was confirmed in 25 cases (64%). In the group of patients with fever without respiratory symptoms (31 episodes), 18 positive GM were detected (58%), corresponding with suggestive aspergillosis CT in 7 cases (39%). The test was more sensitive when patients have respiratory symptoms with stadistically significance (P=0,05). Amongst the probable or proved aspergillosis diagnostics (32), we find 9 related deaths, which indicates a related mortality rate of 28%.
Summary / Conclusion: An early GM determination is a profitable test in patients with hematological malignancies and persistent fever, especially if they present respiratory associated symptoms. The implementation of this diagnostic test has enabled us to set up an early treatment, reducing the associated mortality rate compared with previous published results.

B1271

SECONDARY ACUTE MYELOID LEUKEMIA – FIRST LINE TREATMENT WITH CYTARABINE, DAUNORUBICIN AND CYCLOSPORINE, A PORTUGUESE HOSPITAL'S EXPERIENCE

M Nunes[1*], L Leite[1], S Chacim[1], C Ferreira[1], C Moreira[1], D Pereira[1], M Brito[1], M Marques[1], L Viterbo[1], A Martins[1], N Domingues[1], I Moreira[1], A Espírito-Santo[1], I Oliveira[1], J Mariz[1]
[1]Onco-hematology, Portuguese Oncology Institute, PORTO, Portugal

Background: Secondary acute myeloid leukemia (s-AML) includes AML with myelodysplasia-related changes and therapy-related AML, whenever AML occurs after a preceding disease treated with chemotherapy, irradiation, or both. In the last years, the incidence of s-AML has been increasing, accounting for 10-30% of AML cases**.** The incidence is age-dependent, with s-AML constituting a larger part of AML in the elderly than in the young. The first line treatment offered to these patients is not consensual, and the combination ofan antraciclinwithcytarabineand cyclosporine isone of the optionsto consider.
Aims: To characterize the group of patients treated with cytarabine, daunorubicin and cyclosporine (SWOG 9126 Protocol) as first line treatment of patients diagnosed with s-AML. To present the results referents to the overall survival (OS), disease free survival (DFS) and response rates of this goup.
Methods: We analyzed the clinical data of all patients admitted in an Onco-hematology center, diagnosed with s-AML in the period of January1, 1998, to December 31, 2010, treated with SWOG 9126 Protocol as first line induction scheme. Survival curveswere obtainedbyKaplan-Meier methodand differences wereassessedby thelog-rank testconsideringsignificantdifferenceswithP<0,05.
Results: In the considered period of time, we identified 46 patients diagnosed with s-AML. The median age was 56 years (24-76), 52,2% of which were men. Around 80% of all patients had an ECOG performance status of 0 or 1. According to the World Health Organization (WHO) 2008 classification, 26 patients (56,5%) had multilineage dysplasia AML, 16 patients (34,8%) had therapy-related AML and 4 patients (8,7%) were classified as having AML not otherwise specified. Regarding SWOG's cytogenetic risk classification, patients were divided as follows: 52,2% in the intermediate group, 32,6% in the unfavorable group and4,3% in the favorable group (10,8% unknown). After treatment 32

patients (69,6%) achieved complete remission (CR). Treatment toxicity with this regimen was acceptable in all patients. Eleven patients underwent allogeneic bone marrow transplantation as postremission therapy, 9 of related donor and 2 of an unrelated donor. The median OSwas 12,1 months (0,5-81,2) and the median DFS was 24,9 months (3,2-81,2). We obtained a 3 year's survival rate of 20%. The analysis of OS according to the cytogenetic risk classification did not show statistically significant differences.
Summary / Conclusion: The use of SWOG 9126 protocol as first line treatment of patients with s-AML led to similar CR rates as those reported in current literature. Although the majority achieved CR after induction therapy, the high recurrence rate of this disease reflects on the poor prognosis of these patients.

B1272
CD117 EXPRESSION IS ASSOCIATED WITH IMPROVED EVENT AND OVERALL SURVIVAL IN PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA TREATED WITH AIDA BASED REGIMEN
H Ghédira[1*], H Stambouli[2], R Mansouri[2], H Néji[2], M Zarrouk[2], S Abdennebi[2], K Kacem[2], L Aissaoui[2], R Lakhal[2], Z Ali[2], H Abid[2], E Gouider[2], R Jeddi[2], B Meddeb[2]
[1]Clinical hematology department, Military Hospital, [2]Clinical hematology department, Aziza othmana hospital, Tunis, Tunisia

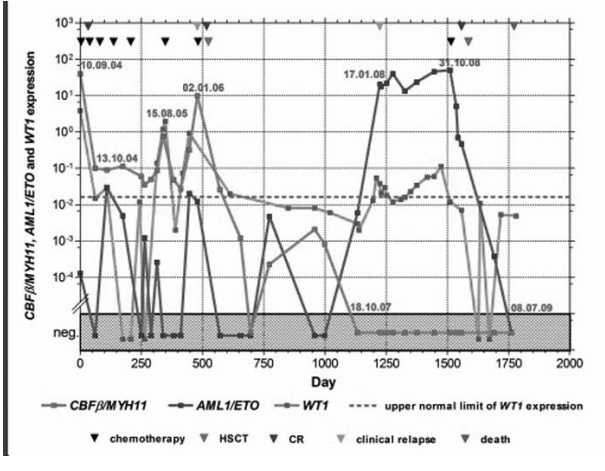
Background: Flow Cytometry immunophenotyping is important tool for the diagnosis of APL. The antibodies in our routine panel included CD34, CD117, HLA-DR, CD2, CD11b, CD11c, CD13, CD14, CD16, CD33 and CD56.
Aims: Our purpose to analyze the prognostic impact of immunophenotyping in patients with APL treated with an AIDA based regimen.
Results: We have prospectively analyzed the prognostic impact of antigenic markers, assessed by flow cytometry, in a series of 51 newly consecutive genetically confirmed APL between August 2004 and December 2010 treated with the Spanish PETHEMA LPA99 trial in the Department of Hematology of Aziza Othmana University Hospital, Tunis, Tunisia. One patient died from CNS bleeding before treatment and 50 patients received induction therapy according to the PETHEMA LPA99 trial. Median age was 30 yr (range 4-71), M/F was 0.64, median WBC was $4.4x10^9$/L (range 0.6 - 123). Additional cytogenetic abnormalities were seen in 17 patients (39.5%). Median body mass index (BMI) was 23.5 kg/m^2 (range 13- 40). The immunophenotyping profile of our patients is summarized in the table below:

Immunophenotyping	n (%)
CD33+	48 (94.1)
CD13+	49 (96)
CD117+	29 (67.8)
CD34-	45 (80.3)
HLADR-	47 (92.1)
CD2+	9 (17.6)
CD56+	4 (7.8)

We found a significant correlation between the expression of CD117 and BMI<30 kg/m^2 (P=0.045). The expression of CD2 was signifigantly more frequent in microgranular (61.5% vs 3%, P<0.0001) than in hypergranular form, and it is notably correlated with leukocytosis (P=0.037). Expression of CD117 was noted as an independent factor of OS (89.3% vs 61.9%) P=0.033 and EFS (89.3 % vs 52.4%) P=0.008.
Summary / Conclusion: We found the expression of CD117 to be significantly associated with better EFS and OS in patients with APL.

B1273
THREE CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIAS (CBF-AML) IN A SINGLE PATIENT
J Marková[1*], J Polák[1], C Haškovec[1], J Maaloufová[1], M Marková[1], P Soukup[1], C Šálek[1], M Vraná[1], M Dobrovolná[1], A Vítek[1], P Cetkovský[1], J Schwarz[1]
[1]Institute Hematology and Blood Transfusion, Prague2, Czech Republic

Background: CBF-AMLs carrying fusion genes *AML1/ETO* or *CBFβ/MYH11* predict a relatively favourable outcome and are classified as a low risk AML group. Hardly ever these two aberrations appear simultaneously in a single patient.
Aims: To report a male patient with AML carrying both the *AML1/ETO* and *CBFβ/MYH11* fusion genes at diagnosis, who developed a donor-derived AML with *AML1/ETO* translocation following hematopoietic stem cell transplant (HSCT).
Methods: At diagnosis, bone marrow expression of *AML1/ETO* and *CBFβ/MYH11* fusion genes was screened by qualitative RT-PCR. Quantitative real-time RT-PCR was performed to monitor MRD (the two given fusions in bone marrow and *WT1* gene expression in peripheral blood). To determine the origin of the *AML1/ETO*+ clone after the HSCT, real-time allelic discrimination assay for an HLA polymorphism was employed.
Results: Case Report: In a 30-year-old male with WBC 256.1 G/l, AML FAB M1 type of AML was diagnosed on 10.09.04, CNS infiltration was also suspected. *CBFβ/MYH11* fusion associated with an exon 8 *C-KIT* frameshift mutation was detected. Screening for *FLT3*/ITD, *FLT3*/TKD, *K-RAS*, *N-RAS* and *JAK2* mutations was negative. After the classical "3+7" idarubicin + cytarabine induction therapy (+ intrathecal methotrexate), the patient reached complete remission (CR) with a nearly 3 logdecrease of *CBFβ/MYH11* transcript and *WT1* on the borderline of normal expression on 13.10.04 (Figure 1). Consecutively, he received 4 consolidation cycles of high-dose cytarabine, which was followed by another slight decrease (but not negativity) of *CBFβ/MYH11* expression. *WT1* expression was within normal levels (01.06.05). However, both *CBFβ/MYH11* and *WT1* positivity grew again considerably and on 15.08.05 another "3+7" therapy was given.Despite it,the patient faced overt clinical relapse (with CNS infiltration on top of it) on 02.01.06. He was rescued by the "HAM" protocol (mitoxanthrone + high dose cytarabine, with additional intrathecal methotrexate). He achieved second CR and underwent myeloablative HSCT from a 7 out of 10 HLA-matched unrelated donor on 16.02.06. Only on 18.10.07 he reached stable molecular remission as judged by *CBFβ/MYH11* expression. Nevertheless, during the next two months, the *WT1* expression grew above normal and the patient relapsed again on 17.01.08,while *CBFβ/MYH11* expression remained negative. A new molecular screening was performed and the *AML1/ETO* transcript was detected (Fig. 1). Therefore, all previously taken samples were tested for the presence of *AML1/ETO* and a very low expression was found in the diagnostic sample using real-time RT-PCR. The following samples oscillated around the sensitivity threshold of the RQ-PCR method (10^{-6}). Although *AML1/ETO* was present already at diagnosis, donor-derived *AML1/ETO* clone was confirmed by allelic discrimination of the donor/recipient HLA polymorphisms, as well as by the chimerism analysis. The patient received induction treatment by "3+7" and underwent second HSCT from another donor with 3 mismatches on 13.01.09 after a non-myeloablative conditioning. On 08.07.09 he reached molecular remission of *AML1/ETO* as well as *WT1*. However, this time he suffered grade II acute GvHD and succumbed due to CMV pneumonia and acute respiratory distress syndrome on 18.07.09.



Summary / Conclusion: We deem this is the first report of multiple CBF-AMLs in a single patient. The patient may have had some unrecognized predisposition in his environment or in his hematopoietic milieu. Developing of the donor cell leukemia is a quite rare but serious complication of the HSCT.

B1274
HDAC AND AMSACRINE FOR TREATMENT OF REFRACTORY AND RELAPSE ACUTE MYELOID LEUKEMIA: A SINGLE CENTRE RETROSPECTIVE STUDY
C Calmettes[1*], A Pigneux[1,2], T Leguay[1], E Lippert[1], A Lascaux[1], C Duclos[1], S Dimicoli-Salazar[1], M Dilhuydy[1], K Boubdallah[1], G Marit[1,2], S Vigouroux[1], R Tabrizi[1], N Milpied[1,2], P Dumas[1]
[1]Hematologie, CHU Bordeaux, [2]Université Bordeaux 2 Segalen, BORDEAUX, France

Background: Patients with relapse and refractory acute myeloid leukemia (AML) had poor prognosis and there is a lack of data supporting an established standard chemotherapy. The end point of a salvage treatment is to induce high remission rate without severe toxicity to allow secondary allogeneic stem cell transplantation.
Aims: We performed a retrospective study in 56 patients treated in our center from October 2010 to January 2012 with the aim to investigate: overall response rate (ORR) defined by complete response (CR) and complete response with

incomplete blood count recovery (CRi), toxicity, and outcomes of the combination of HDAC and amsacrine.
Methods: This salvage chemotherapy consisted on the association of HDAC 3 g/m²/12h (5-8 infusions) and amsacrine 150 mg/m2/day for 5 days or 100 mg/m2/day for 3 days.
Results: Median age was 57 years (range 25-69), with 23 patients (41%) ≥ 60 years. Among the 56 patients, 27 (48%) were in primary induction failure (PIF) and 29 (52%) were in first relapse (16 patient with duration of CR1 < 12 months). Among the whole cohort, one patient had a favourable cytogenetic risk, 35 (62%) had an intermediate cytogenetic risk and 20 (35%) an adverse cytogenetic risk. Among the 27 PIF and the 29 relapse, cytogenetic risk was favourable, intermediate and adverse for respectively 0/15/12 and 1/20/8 patients. Twelve patients had secondary AML. Among the whole cohort, ORR was 43% (24 patients), respectively 52% (13 CR and 1 CRi) and 34% (6 CR and 4 CRi) for PIF and relapse AML. None of tested variables: age < 60 years, good/intermediate cytogenetic risk, relapse AML and *de novo* AML was associated with improved ORR. Eighteen patients underwent an allogeneic stem cell transplant in ORR. After a median follow-up of 17 months (range 2-96), median overall survival (OS) at three years was 11.5±6%. Leukemia free survival (LFS) at 1 year for the 24 patients in ORR was 51%, with a 59% 1 year-LFS for the 18 patients allografted and 25% 1 year-LFS for the 6 patients exclusively treated by chemotherapy. Median duration of neutropenia after HDAC-amsacrine was 17 days (6-25), 44/56 patients had febrile neutropenia, with 27 bacterial bloodstream infections, one disseminated fusariosis and 6 possible pulmonary aspergillosis.
Summary / Conclusion: Our results suggest that HDAC-amsacrine regimen is an efficient salvage combination for patients with refractory or relapse AML. This regimen could represent a bridge to allogeneic transplant, which remains the only curative option in this setting.

B1275
CD96 AS A LEUKEMIA STEM CELL-SPECIFIC MARKER AND A FACTOR FOR PROGNOSIS EVALUATION IN LEUKEMIA
J Zheng[1], Y Hu[1], W Du[1], Y He[1], C Lu[1], W Liu[1], P Wang[1], C Cheng[1], S Huang[1*]
[1]Center for Stem cell Research and Application, Union Hospital, Tongji Medical College, Huazhong University of science and Technology, Wuhan, China

Background: The cancer stem cell hypothesis holds that cancers are composed of a subset of cells that the unique ability to transplant disease as well as self- renew. Hematopoietic stem cell (HSC) has the ability of self-renewal, therefore, the clonal progression of preleukemias likely occurs in a succession of HSC subclones until augmented or poorly regulated self-renewal pathways are activated, leading to the emergence of final stage leukemic stem cells (LSCs) usually at the level of a downstream progenitor.Acute leukemia by chemotherapy remains elusive for most patients because of the leukemia stem cells (LSCs), the self-renewing component of the leukemia.
Aims: Find the relationship between CD96 and leukemia, especially for acute myeloid leukemia.

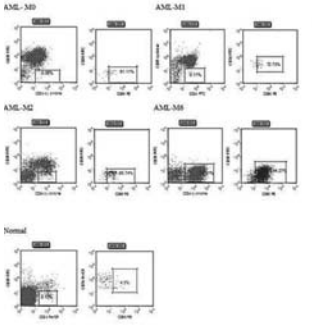


Table1. Compare the mean of $CD34^+CD38^-$ and CD96 between leukemia patients and control

Group	N (134)	Mean of $CD34^+CD38^-$%	p-value	Mean of $CD96^+$ in $CD34^+CD38^-$%	p-value
Control	15	0.10±0.16		7.77±13.86	0.644
AML	87	---	---	---	---
M0	7	3.03±4.93	0.028	44.21±31.58	0.001
M1	10	4.45±8.83	0.066	46.36±40.80	0.002
M2	47	8.39±15.55	0.045	26.07±34.47	0.051
M3	4	6.70±10.15	0.014	22.79±44.38	0.252
M4	10	7.15±10.84	0.018	20.04±22.20	0.101
M5	5	4.65±8.54	0.042	20.52±36.93	0.241
M6	3	2.77±4.30	0.014	53.70±22.77	0.000
M7	1	11.14	0.000	0.59	0.624
ALL	15	24.48±20.14	0.000	11.34±26.13	0.644
MAL	3	0.04±0.05	0.504	58.98±51.33	0.002
MDS	14	1.13±1.93	0.050	17.02±24.47	0.217

Methods: We investigated CD96 expression in 119 leukemia patients by flow cytometry, which were obtained after informed consent at diagnosis and after chemotherapeutic treatment.
Results: It was found that CD96 expressed highly in the group of CD34+CD38- cells in AML, especially in M0, M1, M2and M6 non complete remission cases. At the same time, we also observed that CD96 was high in the group of CD34+CD38- cells in MAL.
Summary / Conclusion: The results showed that CD96 was frequently expressed in LSC population, which could be as a marker of AML-LSC and a candidate therapeutic target. In addition, CD96 was related to the prognosis of AML patients, which might suggest CD96 to be an important factor to evaluate the prognosis of leukemia patients.

B1276
STUDY OF THE GM-CSF GENE EXPRESSION AND ANTI GM-CSF AUTOANTIBODIES IN RELATION TO DISEASE BEHAVIOR AND OUTCOME IN AML/MDS CASES
D Eldemerdash[1*], M Mattar[1], N el Husseiny [1], A el Aziz [1], N Kassem[2]
[1]internal medicine, clinical hematology unit, faculty of medicine, cairo university, [2]clinical pathology unit of oncology department, faculty of medicine, Cairo university, Cairo, Egypt

Background: Blood cells under a variety of conditions produce cytokines which regulate their proliferation, communication and functioning. While, Growth and progression of many of malignant cells are mediated by alterations in the microenvironment often caused by an aberrant expression of growth factors and receptors. Granulocyte macrophage-colony stimulating factor (GM-CSF) is an autocrine and a paracrine cytokine. It stimulates growth, differentiation and function of normal and leukemic myeloid progenitors. Antibodies to GM-CSF, while uncommon and of unknown significance are implicated in the pathogenesis of few diseases. e.g.; idiopathic pulmonary alveolar proteinosis (PAP) where they inhibit GM-CSF mediated endocytosis of surfactant in alveoli. also, they have been detected in 0.3% of healthy donors (HD), Neonatal cord blood, Patients with autoimmune diseases and Exogenous recombinant human GM-CSF.
Aims: We aimed to Study of GM-CSF *mRNA* gene expression, its protein and anti GM-CSF autoantibodies in Acute Myeloid leukemia/Myelodysplastic syndromes AML/MDS patients and their correlation to disease behavior and therapy outcome.
Methods: We examined GM-CSF *mRNA* gene expression by real time PCR (RT-PCR) and GM-CSF protein by ELISA methods in sera of 50 AML/MDS. Also, we examined anti GM-CSF antibodies by ELISA methods in sera of 42 cases out of the 50 AML/MDS cases. all results were compared to 20 healthy blood donors (HD). also, we correlated results with disease behavior and response to therapy. All cases were of Egyptian origin.
Results: There was significant decrease in GM-CSF *mRNA* gene expression (P value 0.008), Increase in GM-CSF concentration (P value 0.001) and increase in anti GM-CSF antibody titer (P value 0.003) in AML/MDS patients in comparison to HD, significant negative correlation between titer of GM-CSF and initial PB blast count (P value 0.011) and significant negative correlation between GM-CSF concentration and response to therapy (P value 0.016). we found no segnificant correlation between GM-CSF mRNA gene expression and other variables especially anti GM-CSF antibodies.
Summary / Conclusion: Any alteration in GM-CSF gene expression Could have an implication in leukemiogenesis. Also anti GM-CSF could have the same role. GM-CSF concentration could be used to predict outcome of therapy, but anti GM-CSF couldn't be used to predict the outcome. Normal GM-CSF gene expression & GM-CSF is necessary for normal hematopoiesis & cellular maturation. The origin of the immunity to GM-CSF and the consequences of this immunity in leukemia patients are not clear.

B1277
NO MODIFIED ANTI-INFLAMMATORY AND ANTIVIRAL COMPOUNDS AGAINST ACUTE MYELOIDE LEUKEMIA; FROM CELL LINE TO PATIENT BLOOD
M Radojkovic[1*], M Mojic[2], H Obradovic[2], M Bulatovic[2], D Maksimovic-Ivanic[2], D Miljkovic[2], S Stosic-Grujicic[2], M Zocca[3], Y Al-Abed[4], F Nicoletti[5], S Mijatovic[2]
[1]Clinical Center Dr Dragisa Misovic, University of Belgrade, [2]Department of Immunology, Institute for Biological Research "Sinisa Stankovic", Belgrade University, Belgrade, Serbia, [3]Onconox Aps, Copenhagen, Denmark, [4]Laboratory of Medicinal Chemistry, North Shore Long Island Jewish Health System, New York, United States, [5]Department of Biomedical Science, University of Catania, Catania, Italy

Background: Antiinflamatory compound VGX1027 acquired antitumoral features after the addition of NO (GIT27-NO) while anticancer potential of antiviral drug Saqunavir became stronger and highly selective against transformed cells (Saq-NO). Despite the basically same approach in chemical intervention, first mention compound acts as NO donating drug with specific feature to release NO in contact with the cell membrane while the last is qualitatively novel drug with essentially different intracellular response in comparison to original compound.
Aims: This study is created with an idea to explore the effects of both compounds on HL60 cell line as a model of acute myeloid leukemia and define the reproducibility of their efficiency on peripheral mononuclear cells isolated from blood samples of untreated AML patients.
Methods: Cell viability was assessed by acid phosphatase test while the cell cycle distribution was analyzed by cytofluorimetric analysis of on propidium-iodide (PI) stained cells. Apoptosis was detected using Annexin-FITC / PI double staining while the activity of caspases was confirmed by Apostat staining. For detection of intracellular nitric oxide (NO) DAF-FM diacetate was used. Reactive oxygen (ROS) and nitrogen (RNS) species were determined with DHR 123 staining.
Results: Both drugs modified by NO exaggerated strong cytotoxic activity

against HL60 cells. Reduced viability was accompanied with enhanced apoptosis confirmed in early and late phase of this process. Mechanistically, the dying signal involved the activation of caspases upon the treatment with both, GIT27-NO and Saq-NO. However, cytocidal activity of GIT27-NO correlated with intensive oxidative stress confirmed by specific staining of reactive oxygen and nitrogen species. In parallel, treatment with Saq-NO didn't promote significant enhancement of free radical production, indicating more sophisticated intracellular pattern of its action. Effects of GIT27-NO after 48h of exposure of PMC isolated from patients with AML remarkably varying from good to completely inefficient. Oppositely, sensitivity of the same cultures to Saq-NO was comparable with HL60 and independent from the blood source.
Summary / Conclusion: Both NO modified drugs exerted strong anticancer potential against HL-60 cells. Low reproducibility of patients MNC response to GIT 27-NO is possibly related to different capacity of individual clones to fight with oxidative stress triggered by this drug. On the contrary, the ROS independent cytocidal signal delivered by Saq-NO probably targeted important pathway involved in malignant cell proliferation, independent from individual variation.

B1278

RESULTS OF >60 AML UNTREATED PATIENTS THERAPY IN DEPENDENCY OF QUALIFICATION TO RISK AND INDUCTION INTENSITY GROUPS. RETROSPECTIVE STUDY.

S Grosicki[1*], E Bodzenta[1], M Kriegler[1], M Twardosz[1], I Szypuła[1], M Fejklowicz[1], T Kurzawa[2], Aleksandra Melisz[1], A Barchnicka[1]
[1]Department of Hematology, [2]Laboratorium Centralne, SPZOZ ZSM w Chorzowie, Chorzow, Poland

Background: The aim of this study was assessment of therapy results In acute myeloid leukemia (AML) patients in age >60 treated according to PALG stratification for AML >60 patients.
Aims:
The primary aims were comparison of overall survival (OS) and complete remission rate (CR) in whole group of AML >60 patients in dependency of qualification to risk group and a way of treatment. The secondary aims were comparison of OS and CR rates in younger older (61 – 70) AML patients.
Methods: Patients with AML >60 after diagnosis were qualified into the risk groups according to PALG stratification for AML >60. In group I patients were receiving induction chemotherapy DAC (daunorubicin, cytarabine, cladribine) or DA (daunorubicin, cytarabine), in group II patients were receiving induction chemotherapy cytarabine/thioguanine, and in group III they were receiving chemotherapy with low doses of cytarabine. Patients with group I, who reached CR after first or second induction course were receiving consolidation with mitoxantrone and cytarabine, and next they were qualified to alloHSCT or autoHSCT, or maintenance phase. Patients with group II and III independently of results were receiving successive cycles of chemotherapy like in first course every 4 weeks to 2 years. W period 02.2009-12.2012 123 untreated patients with AML, age 73 (61-89), men 50% were included to this study. Thirty three patients were qualified to group1, 47 to II and 43 to III. After preliminary analysis, because of similar early and late outcomes of the therapy in group II and III, those groups of patients were joint for next analysis.
Results: In comparison of therapy outcomes in group I and in joint group II and III of patients with AML >60 significantly higher CR rate in group I vs. II/III 47% vs. 2% (P<0,001) was confirmed. And significantly better OS after 2 years 11% vs. 7% (P=0,006) was noted
However, in comparison of those parameters In subgroup of age 61-70 despite of significantly higher CR in group I vs. group II/III 46% vs. 7% (P=0,01) we did not obtain a benefit in OS after 2 years 12% vs. 17% (P=NS) respectively.
Summary / Conclusion: In conclusion we must state, that in AML >60 proper qualification to favorable risk group (group I) and as a consequence more intensive induction chemotherapy is a main predictor of better early outcomes (CR rate), but overall survival do not depend of risk group and kind of induction therapy, but only it depends of age of patients, what can be cause by too low intensive postremission approach in younger and fit patients, who reached CR after induction chemotherapy

B1279

TRANSFUSION IRON INTAKE IN TRANSPLANT ELIGIBLE PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA: RETROSPECTIVE ANALYSIS OF IRON LOAD AT THE END OF CHEMOTHERAPY PROGRAM AND BEFORE TRANSPLANTATION

A Belotti[1*], E DONI[1], L BORIN[1], M FUMAGALLI[1], M PARMA[1], E POGLIANI[1]
[1]Division of Hematology, Ospedale San Gerardo, MONZA – Università degli Studi Milano Bicocca, MONZA, Italy

Background: Iron overload is an important adverse prognostic factor for patients (pts) undergoing hematopoietic stem cell transplantation (HSCT): it increases the risk of infections, veno-occlusive disease and hepatic dysfunction. Elevated pretransplant ferritin levels have been reported to increase the risk of non relapse mortality following HSCT and might influence the risk of acute and chronic GVHD. The majority of data derives from studies regarding pts with thalassemia and myelodysplastic syndromes, with established iron chelation strategies in these diseases. On the contrary, the extent of transfusion iron overload in transplant eligible *de novo* acute myeloid leukemia (AML) and the need of iron chelation therapy (ICT) remains debated.
Aims: To evaluate transfusional iron intake in potentially transplant eligible pts with *de novo* AML treated with conventional chemotherapy regimens, focusing on pts who underwent HSCT or completed consolidation chemotherapy courses.
Methods: We retrospectively analysed 44 potentially transplant eligible AML pts (20 males, 22 females) from March 2009 to February 2013. All pts completed their treatment program: 23 of them were treated with induction and consolidation chemotherapy followed by HSCT, while 21 pts received only chemotherapy. Iron intake until HSCT or until the end of consolidation chemotherapy, expressed in mg of iron, was calculated as total amount of red blood cells (RBCs) transfused X 1.08. Ferritin levels at the end of the treatment was also evaluated.
Results: Standard induction treatment (cytarabine 100 mg/sqm twice daily for 7 days and idarubicin 12 mg/sqm daily for 3 days) was administred in 40 pts, while 4 pts received high dose induction chemotherapy with cytarabine 2g/sqm twice daily (day1,2,8, 9) and idarubicin 18mg/sqm daily (day3, 10). 11 of the 23 pts underwent transplantation in second complete remission after reinduction chemotherapy. Mean transfusional iron intake was 0.65 mg/kg per day, among a mean treatment period of 6.6 months. Mean ferritin level at the end of the treatment or before transplant conditioning regimen was 2951 µg/L (median 2123 µg/L).
Summary / Conclusion: This retrospective evaluation confirms a relevant transfusion iron load in *de novo* AML in a short time interval; of note, patients with β-thalassemia major or other refractory anemias receiving 2-4 units of blood per month have a transfusion iron intake of 0.3-0.6 mg/kg per day. It is known that serum ferritin is sensitive but not specific for iron overload and is a poor predictor of body iron burden, and maybe it is even less specific in AML as a reliable marker in monitoring iron loading. Moreover, the optimal ICT in this setting of pts is still to be defined: subcutaneous deferoxamine infusion is inconvenient and troublesome due to thrombocytopenia and neutropenia, while oral deferasirox administred in proven iron overloaded pts may not be sufficiently rapid in his action if we consider the short time available before transplantation. Considering our data regarding daily iron intake, it could be interesting to investigate the role of early low dose deferasirox administration at the beginning of chemotherapy treatment program, in order to prevent transfusion overload and his prognostic impact at transplantation.

B1280

RED BLOOD CELL ENCAPSULATING ASPARAGINASE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA UNFIT FOR INTENSIVE CHEMOTHERAPY: A PROSPECTIVE PHASE IIB STUDY

X Thomas[1], W Berlier[2], C Bonin[2], K Aguera[2], C Plisson[3], Y Godfrin[2*]
[1]69495, Hospices civils de Lyon, [2]69008, ERYTECH Pharma, Lyon, [3] 92058, Orphan Europe, Paris, France

Background: L-asparaginase (ASNase) holds a key role in chemotherapy for Acute Lymphoblastic Leukemia (ALL) in children and young adults. In elderly patients, its efficacy is counterbalanced by its toxicity, which impairs its use and creates an unmet need. To reduce toxicity, a new product, GRASPA, encapsulates L-asparaginase in Red Blood Cells (RBC). A current study in ALL patients (GRASPALL-GRAAL SA2 2008) shows an improved therapeutic index for elderly patients.
In adults, Capizzi (1988) reported a significant benefit of ASNase associated with high-dose cytarabine treatment (HiDAC) in Acute Myeloid Leukemia (AML). Indeed, there was an overall statistically superior complete remission rate for HiDAC/ASNase (40%) vs HiDAC (24%) and an overall survival benefit for patients treated with HiDAC/ASNase (19.6 weeks vs 15.9 weeks). The benefit of ASNase in different AML was also reported by Petti (1989), Horikoshi (2009) and Rubnitz, (2009). Furthermore our preclinical results also showed that an AML cell line (HL-60) and blast cells from the bone marrow of AML patients were sensitive to ASNase in vitro.
The main issue is that, up to now, the toxicity of ASNase for elderly had prevented its use in this fragile population that represents the majority of AML patients.
Aims: Considering the promising results of ASNase for AML treatment and the better safety profile offered by RBC encapsulating ASNase (GRASPA®), a multicenter, randomized, controlled IIb trial is evaluating the answer to the fragile patients unmet need Efficacy and tolerability of GRASPA® plus low-dose cytarabine will be evaluated versus low-dose cytarabine alone in treatment of AML patients over 65 year-old, unfit for intensive chemotherapy.
Methods: One hundred and twenty-three patients (65-85 year-old) newly diagnosed for AML or diagnosed for post myelodysplastic syndrome in the 6 months before enrollment are planned for inclusion in the study. Included patients must be unfit for intensive chemotherapy, with WHO performance status ≤2 an estimated life expectancy ≥3 months. Patients with M3 AML or with AML involving chromosome 16 abnormalities are not eligible for inclusion. Written informed consent will be obtained for included patients.
A 2:1 randomization will be respected (82 patients treated with GRASPA® plus low-dose cytarabine and 41 patients treated with low-dose cytarabine alone). In the experimental group, every 28 days, patients will receive one intravenous

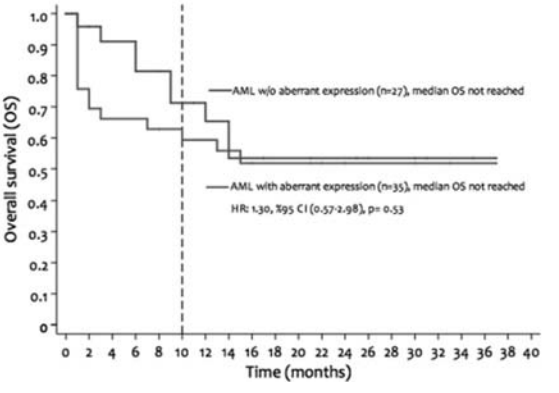
infusion of GRASPA® (100 IU/kg) after 10 consecutive days of subcutaneous low-dose cytarabine (20mg twice daily) versus low-dose cytarabine alone in the control group.
Each patient will be followed for 24 months. Progression-free survival (PFS, time elapsed between treatment initiation and disease progression/death) will be evaluated as a primary endpoint. A 75% improvement in the median FPS is assumed in the experimental group vs control group. Percentages of remission (complete and partial), survival (event-free and overall), patient quality of life, general safety, pharmacodynamic/pharmacokinetic and immunogenicity of GRASPA® will be also evaluated.
Results: The HL-60 AML cell line was found equally sensitive to ASNase than the MOLT-4 ALL cell line in vitro. Blasts isolated from the bone marrow of 5/6 AML patients were highly sensitivity to ASNase. The only subject tested with no leukemia was resistant.
Summary / Conclusion: Given its efficacy/tolerability profile, L asparaginase encapsulated in red blood cell, GRASPA® should be the solution for elderly patients in AML. Final results of this clinical study are expected mid 2017.

B1281
MAINTENANCE THERAPY WITH CEPLENE® (HISTAMINE DIHYDROCHLORIDE) AND PROLEUKIN S® (IL-2) LEADS TO ACTIVATION OF NK CELLS BUT ALSO EXPANSION OF T REGULATORY CELLS IN AML
T Altmann[1*], F Lichtenegger[1], B Beck[2], C Krupka[2], F Schnorfeil[2], W Hiddemann[1], M Fiegl[1], M Subklewe[1]
[1]Department of Internal Medicine III, Klinikum der Universität München, [2]Clinical Cooperation Group Immunotherapy, Helmholtz Zentrum München, Munich, Germany

Background: The prognosis of acute myeloid leukemia (AML), particularly when associated with adverse chromosomal or molecular aberrations, is poor due to a high relapse rate after induction chemotherapy. Postremission therapy for elimination of minimal residual disease (MRD) remains a major challenge in AML. For patients that are not eligible for allogeneic stem cell transplantation, there is no approved cytotoxic maintenance therapy after consolidation. Novel therapeutic strategies to prevent relapse are therefore intensively investigated.
Aims: In 2008, the EMA approved an alternative immunomodulating maintenance treatment consisting of repetitive administrations of Interleukin-2 (IL-2) and histamine dihydrochloride (HDC). However, limited data is available about the immunological effects of this therapy in AML patients.
Methods: We analyzed peripheral blood from AML patients receiving Ceplene / IL-2 for changes in inflammatory markers including C-reactive protein (CRP), IL-6, soluble IL-2 receptor and leukocyte counts. Immune cell subsets were monitored by flow cytometry. Changes in activation and function of NK cells were determined by upregulation of CD69 expression and IFN-gamma production. In addition, we surveyed the MRD level during the course of the treatment by molecular markers and immunophenotyping.
Results: We found that the inflammatory markers temporarily increased during the course of treatment. On a cellular level, different NK cell subsets were expanded and activated during the treatment. Besides, the immunotherapy resulted in a slight increase in T regulatory (Treg) numbers, consistent with recent studies showing Treg expansion by low-dose IL-2 application. Noticeably, one of the patients achieved an MRD conversion with no detection of the CBFb-MYH11 transcript after two cycles of Ceplene / IL-2.
Summary / Conclusion: Ongoing studies in a larger patient cohort will help to better understand the immunological effect of IL-2/HDC in the setting of AML maintenance therapy.

B1282
THE PROGNOSTIC IMPACT OF ABERRANT ANTIGEN EXPRESSION IN ACUTE LEUKEMIAS
O Yucel[1*], O Salim[1], M Ulubahsi[1], A Timuragaoglu[1]
[1]Hematology, Akdeniz University School of Medicine, Antalya, Turkey

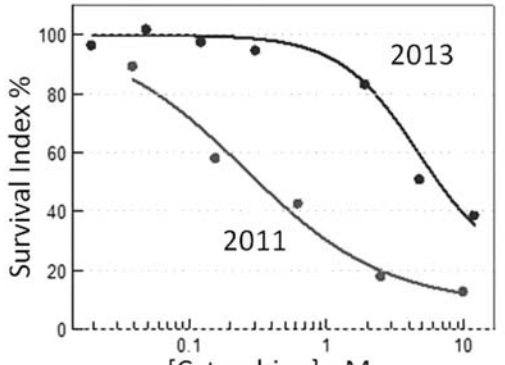
Background: Multiparametric immunophenotyping analysis allows the identification of aberrant antigen expression in acute leukemias.The clinical and prognostic impact of this phenomenon remains controversial.
Aims: This retrospective study was designed to investigate the impact of aberrant antigen expression on the response to remission induction therapy and overall survival in patients with acute leukemia.
Methods: We have analyzed the multiparametric flow cytometric (Becton Dikinson, San Jose, Calif., USA) data of 90 de novo acute leukemia adult patients (M/F:56/34, age(min-max):18-90 year) between 2008 and 2011. Aberrant phenotypes was considered to be positive when the percentage of positive blast cells was equal or greater than 20% for surface antigens and equal or greater than 10% for cytoplasmic antigens.
Results: In this study 62 (69%), 18 (20%), 5 (5,5%), and 5 (5,5%) out of all patients diagnosed with AML, ALL (16 B-ALL, 2 T-ALL), AUL, and BAL, retrospectively. The patients with AUL and BAL were not included into the analysis. Aberrant phenotype was observed in 35/62 (%56) out of AML (Ly + AML) and 8/18 (%44) out of ALL (My + ALL) patients. There were no difference between ALL patients with (My + ALL) and without aberrant phenotype (My – ALL) regarding to response to the remission induction therapy and overall survival. The most common myeloid antigen in ALL was CD33 (%29). There were no differences between CD33+ ALL patients and CD33 – ALL in terms of response to the remission induction therapy and overall survival. There were also no differences between AML patients with (Ly + AML) and without aberrant phenotype (Ly – AML) in response to the remission induction therapy and overall survival. Ly + AML and Ly – AML groups were comparable in terms of risk status based on cytogenetics (better-intermediate-poor). There was also no difference between My + ALL and My – ALL in terms of cytogenetic risk status (standart vs high). The most common lymphoid antigens in ALL were CD7 (%27), CD10 (%16), and Tdt (%15). CD7 + AML and CD7 – AML, Tdt+ AML and Tdt – AML, CD10 + AML and CD10 – AML groups had similar response rates to the remission induction therapy and overall survival.
Summary / Conclusion: In our study aberrant antigen expression did not have an impact on response to the remission induction therapy and overall survival of patients with acute leukemia. Although there is, recently, growing evidence about the prognostic importance of aberrant antigenic expression in acute leukemias during the diagnosis and monitorization of the disease, cytogenetic and molecular analyses remain to be main prognostic determinants. Studies combining cytogenetic and molecular features and aberrant antigenic expression profiles are needed.



B1283
PREDICTION OF CLONAL EVOLUTION UNRESPONSIVENESS TO THERAPY BY *ex vivo* CHEMOSENSITIVITY ASSAY IN A CASE OF ACUTE MYELOID LEUKEMIA
M Bonillas[1*], A Heiniger[1], M Barrios[1], C Bethancourt[1], P Montesinos[2], F Moscardó [2], D Cuadrón[2], M Sanz[2], J López[3], D Primo[4], P Hernández-Campo[4], J Gorrochategui[4], B Liébana[4], T Bennett[4], J Nobell[4]
[1]Haematology, Hospital Regional Universitario Carlos Haya, Málaga, [2]Haematology, Hospital Universitari i Politecnic La Fe, Valencia, [3]Haematology, Hospital Universitario Doce de Octubre, [4]Vivia Biotech, Madrid, Spain

Background: Patient was part of a multicenter, prospective, non-interventional study of the PETHEMA group conducted by Vivia Biotech to determine the validity of an *ex vivo* personalized drug sensitivity test to predict clinical response based on the analysis of leukemic cell death *ex vivo*. Case study: A 23-year-old female patient was diagnosed with AML, M1 FAB type, in Aug-2011. She presented severe anemia, thrombocytopenia and leukocytoses with 80% blast cells in peripheral blood. BM aspirate showed 80% blast cells with myeloid phenotype and hyperploid kariotype. The molecular study was negative for PML-RARa, BCR-ABL, AML1-ETO, inv (cr16) translocations and FLT3-ITD, NPM1 and CEBPA mutations. The patient was classified at the intermediate risk group and received treatment according to PETHEMA-2010 protocol for patients <65 year-old with AML. After the induction course (idarubicin (Ida) plus cytarabine (Cyt), 3+7), she achieved complete remission with negative minimal residual disease (MRD) by immunophenotype, receiving then 2 consolidation courses followed by an autologous peripheral blood stem cell transplantation. First relapse was detected 6 months later; a rescue course of chemotherapy was started with FLAG-Ida schedule (fludarabine (Flu), Cyt, Ida). Still with MRD after recovery, treatment with clofarabine (Clo) and Cyt followed; however 10% of blast cells remained in BM. The patient did not have HLA compatible donor, so a reduced-intensity haploidentical transplantation was performed, with positive MRD (0.5%). After 2 months, patient progressed again. Chemotherapy with an IDICE course (Ida, Cyt and etoposide (Eto)) was then administered, with no further response.
Aims: For the patient presented here, a bone marrow (BM) sample was obtained at diagnosis in August 2011, and again in February 2013, allowing for the chance to examine the *ex vivo* patient response at two time points during the disease process.
Methods: BM samples were processed in Vivia'a lab according to protocol. The samples were diluted in its entirety and plated with the pharmacological agents, each at 8 concentrations. The plates were incubated for 48-hours, then ana-

lyzed by our automated flow cytometry-based ExviTech© platform. Malignant cell death was determined via labeling with appropriate monoclonal antibodies and AnnexinV-FITC. Dose-response curves for 9 drugs (including Cyt, Ida, Flu, Clo and Eto) were generated for both extractions. Key parameters are the efficacy of the drug to deplete cells, and potency measured as the concentration at which 50% of the cells are eliminated (EC50). The survival index calculates the percentage of malignant cells remaining. The Effective Maximum (Emax) is the maximum possible effect for the drug, thus an Emax of 0% indicates no surviving malignant cells.
Results: The patient's *ex vivo* response to 8 of the drugs was similar at both time points. However there was a marked change in the response to Cyt. Seen in figure1, the green line represents the data collected in 2011, where the sample was sensitive to Cyt with a high level of effectiveness. However the sample collected in 2013 displayed a marked change in response, with the drug losing both potency and effectiveness, with over 20% of the cells being resistant to the drug even at concentration that are not reached in the body.
Summary / Conclusion: Vivia's *ex vivo* results for Cyt mirror the clinical response in this patient. Upon diagnosis both the *ex vivo* sample and patient were sensitive to Cyt treatment, and then later displaying resistance.



Cyt	EMAX	EC50
2011	8.46%	0.26µM
2013	19.24%	4.74µM

B1284
THE COMPARISON OF TOXICITY AND OUTCOMES OF THE INDUCTION CHEMOTHERAPY DAC (DNR, ARAC, 2CDA) AND IAC (DNR REPLACED BY IDARUBICINE) IN THE ACUTE MYELOID LEUKAEMIA (AML) PATIENTS. RETROSPECTIVE STUDY
S Grosicki[1*], E Bodzenta[1], M Kriegler[1], M Twardosz[1], I Szypuła[1], M Fejklowicz[1], O Haus[2,3], A Jaskowiec[2], A Barchnicka[1]
[1]Department of Hematology, SPZOZ ZSM w Chorzowie, Chorzow, [2]Klinika Hematologii, Nowotworów Krwi I Transplantacji Szpiku , Medical University, Wroclaw, [3]Katedra Genetyki Klinicznej Collegium Medicum , University of Kopernik, Bydgoszcz, Poland

Background: This study is a continuation of the previous studies concerning optimization of induction chemotherapy using purine analogues. (Hołowiecki J., Grosicki S., Robak T. et al. Leukemia 2004, Holowiecki J, Grosicki S, Giebel S. et al. J Clin Oncol. 2012).
Aims: The aim of this study was assessment of the toxicity and outcomes of the induction chemotherapy DAC (DNR, cytarabine, cladribine) and IAC (DNR was replaced by idarubicine) in the acute myeloid leukaemia (AML) patients. The primary aims were complete remisson rate (CR) and toxicity of the treatment, secondary was leukaemia free survival (LFS) and overall survival (OS).
Methods: DAC induction chemotherapy program is a standard in younger patients with AML. IAC program was used in those cases, when daunorubicin was not attainable in our center. Between 03.2009 and 03.2012 52 untreated AML patients in age 57 (20-72), women 54% and assessed as fit to intensive chemotherapy and alloHSCT, treated in Hematology Unit in Chorzow/Poland were included to this study. AML PML/RAR alfa positive patients were excluded.
Results: Materials and results

	DAC (n = 30)	IAC (n = 22)	p
Age (median)	20-72 (55)	38-70 (59)	NS
Sex (%)	W-53, M-47	W-55, M-45	NS
WBC at dgn. x10^3/L median (range)	27,7 (2,3 -257)	11,0 (0,9 – 210)	NS
Cytogenetic risk (%) low	0	0	NS
intermediate	50	64	NS
high	7	5	NS
CR	70	59	NS
2 years OS	31	12	NS
2 years LFS	43	22	NS

Study groups were well balanced according to age, sex, WBC at diagnosis and cytogenetics. CR rates in both groups were no differ and was similar to previous published after DAC induction. Whole patients reached deep thrombocytopenia and neutropenia WHO grade IV. The frequency and intensification of infection, mucositis, vomiting, diarrhea, alopecia, polineuropaty, as well as cardiologic, hepatic, or kidney failure were comparable in both arms, Statistically confirmed differences in LFS amd OS after 2 years were not reached. Number of alloHSCT in both groups was similar.
Summary / Conclusion: In conclusion, we must state, that results of this study authorize to alternative use of idarubicine and daunorubicine In induction chemotherapy based on antracycline, cytarabine and cladribine in fit AML patients without higher risk of additional toxicity.

B1285
SALVAGE WITH VERY HIGH DOSE CYTARABINE FOR RELAPSED/REFRACTORY AML IN THE SETTING OF INTENSIFIED ANTHRACYCLINE INDUCTION AND POST STEM-CELL TRANSPLANTATION – CLINICAL EFFICACY WITH ACCEPTABLE TOXICITY
O Wolach[1*], M Bar-Natan[1], G Itchaki[1], M Yeshurun[1], R Ram[1], C Herscovici[1], D Douer[2], M Tallman[2], O Shpilberg[1], P Raanani[1]
[1]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, Petah Tikwa, Israel, [2]Leukemia Service, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, New York, United States

Background: Primary refractoriness to induction therapy as well as relapse of AML are associated with poor outcome. Cytarabine is considered one of the most potent anti-leukemic drugs and a cornerstone in most induction, consolidation and salvage regimens. The dose-response relationship of cytarabine in AML is complex and the question which is the most efficient and yet safe regimen is still open. Herzig et al. (Blood, 1983) demonstrated that a total dose of 36 g/m^2 delivered over six days achieves a high efficacy/toxicity ratio in patients with relapsed/refractory AML. Very high dose cytarabine (VHDAC) salvage may be of special relevance in the era of higher induction anthracycline dose. Safety and efficacy of VHDAC for AML patients refractory to intensified anthracycline induction regimen (with 90mg/m^2 daunorubicin [DNR]) and for those relapsing after hematopoietic stem cell transplantation (HSCT) has not yet been described.
Aims: We describe our experience on the efficacy and toxicity profile of VHDAC as salvage therapy for relapsed and refractory AML.

Outcome and major toxicities (n=8)	
Patient outcome n (%)	CR\CRp – 7 (87.5) Resistant disease – 1 (12.5)
Hematological toxicity	
Median duration of grade IV neutropenia (days, range)	20 (15-24)
Median duration of grade III-IV thrombocytopenia (days, range)	26 (12-48)
Non hematological toxicity (grade III-IV) n (%)	
Pulmonary	2 (25)
Severe infections	3 (37.5)
Ophthalmic	2 (25)
GI tract	1 (12.5) attributed to GVHD

Methods: Medical charts of patients treated in our institution with VHDAC as salvage for relapsed/refractory AML between January 2012 and January 2013 were reviewed. Treatment was administered according to Herzig et al. and was comprised of 12 doses of cytarabine 3g/m^2 administered over 1 hour every 12 hours for 6 days for a total of 36 g/m^2.
Results: Eight patients were eligible for the analysis. Median patient age at diagnosis was 54.5 years (40-56); 7 patients were males; 6 patients had unfavorable AML (by the ELN classification) and 2 patients were diagnosed with acute leukemia of ambiguous lineage. Five patients had primary refractory disease. Three patients relapsed after HSCT. Five patients received induction treatment with intensified anthracycline regimen with 90mg/m^2 DNR and 3 patients received induction with 60mg/m^2 DNR. Seven (87.5%) of the patients responded (CR-6 and CRp-1). This included 4 patients with primary refractory disease and all 3 patients following HSCT. One patient developed high fever and grade IV pulmonary toxicity and therapy was withheld after 8 out of the 12 scheduled doses. His day 24 BM demonstrated resistant disease, and he died on day 26 of treatment of multi-organ failure. In the 4 refractory patients that responded the toxicities were manageable. Serious infections (possible invasive fungal pulmonary infection and severe sepsis) developed in 2 patients

with refractory disease, both treated with intensified anthracycline induction before salvage. These 2 patients also developed grade III eye dryness (decreased visual acuity limiting self care) one of which also demonstrated superficial punctuate keratitis and subconjunctival hemorrhage. Of note, all patients were treated with prophylactic eye drops. A characteristic rash of grade II severity developed in 2 patients: palmar erythema in 1 and desquamation of the palms and soles in the other. One patient treated post HSCT developed grade IV diarrhea and hyperbilirubinemia on day 31 of therapy, attributed to GVHD and died on day 107 of treatment with no evidence for leukemia in BM. No CNS manifestations were noted in the cohort. Median duration of grade IV neutropenia and grade III-IV thrombocytopenia in patients who achieved CR/CRp were 20 days (15-24) (7 patients) and 26 days (12-48) (6 patients), respectively.

Summary / Conclusion: Salvage therapy with 36g/m^2 of cytarabine appears to be effective with acceptable toxicity in patients with AML refractory to intensified anthracycline induction treatment and in those relapsing after HSCT.

B1286

EFFECT OF HIGH DOSE CYTOSINA ARABINOSIDE I.V. ON EEG BACKGROUND ACTIVITY AND ON NEUROPSYCHOLOGICAL FUNCTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A Mengarelli[1*], M Maschio[2], L Dinapoli[2], S Dispenza[2], F Sperati[3], G Petreri[2], A Romeo[1], M D'Andrea[1], M Dessanti[1], S Mastroianni[2], T Cantelmi[2]
[1]Hematology, [2]Center for Brain tumor Epilepsy - Area of Supporting Care, [3]Biostatistical Department, Regina Elena National Cancer Institute, Rome, Italy

Background: Citosina arabinoside (Ara-C) is a nucleoside analog used in the treatment of hematologic malignancies. However, high doses of Ara-C i.v. (>2 g/m2) have been noted to produce a number of Central Nervous System (CNS) toxicities. A number of studies have evaluated CNS toxicity of others pharmacological treatments in patients suffering from leukemia, using either standard EEG or neuropsychological tests. To date, no reports have been published on the effect of Ara-C on the CNS, using both computerized EEG and neuropsychological tests in this patient population.
Aims: An open study to evaluate if high dose of Ara-C i.v can induce CNS side effects in adult patients affected by acute myeloid leukemia (AML), using computerized EEG analysis and neuropsychological tests.
Methods: 9 patients affected by AML (4 male, and 5 female, mean age 49.4 range 38-64 year); 5 treated with high dose of Ara-C i.v (≥ 2 g/m²die), and 4 treated with standard dose Ara-C i.v. (100g/m²die). We recorded EEG at rest with eyes closed (REST) and during hyperventilation (HP), mental arithmetic task (MA) and blocking reaction (BR). We used the following tests: Karnofsky Performance Status, Mini Mental State Examination, Rey Auditory Verbal Learning Test, Trail Making Test , Verbal Fluency Test, EORTC QLQ C30. We compared the EEG background activity and neuropsychological tests, at baseline and after six months of therapy, between the two groups.
Results: At baseline and at final follow-up, the comparison between the two groups revealed no significant differences, for the mean relative power for all frequency bands (delta, theta, alpha, beta), at REST and during BR, HP, MA, and for the Neuropsychological tests.
Summary / Conclusion: This is the first report indicating that high doses Ara-C do not induce CNS side effects, as revealed by EEG background activity and neuropsychological tests.

B1287

CLINICAL COURSE OF ACUTE PROMYELOCYTIC LEUKEMIA: SINGLE-CENTER REPORT FROM A DEVELOPING COUNTRY

E Gürkan[1*], P Aytan[1], D İskender[1], F Başlamışlı[1]
[1]Dept of Hematology, Çukurova University Medical School, Adana, Turkey

Background: Since the introduction of all-trans retinoic acid (ATRA) in 1980's acute promyelocytic leukemia (APL) has been the most curable variant of acute myeloid leukemias. However, recently International Consortium on APL and some other reports pointed out that the treatment outcomes of APL patients in developing countries are inferior compared to those of Western countries.
Aims: In this report we have retrospectively evaluated the clinical course and treatment outcomes of APL patients referred to our center between 2004 and 2012.
Methods: Molecular remission and bone marrow response was evaluated after completion of first consolidation chemotherapy. Overall survival and disease free survival were calculated with Kaplan-Meier analysis using SPSS 13.0 version.
Results: The prevalance of APL among all our acute myeloid leukemia patients was 2.8%. There were 22 patients, all of whom were treated according to AIDA protocol consisting of remission induction regimen with oral ATRA (45 mg/m^2 per day), divided into 2 daily doses and maintained until complete hematologic remission, and idarubicin (12 mg/m^2 per day) given on days2,4,6, and 8. After achievement of complete remission(CR), three cycles of consolidation chemotherapy with ATRA, idarubicin and cytarabine and then maintenance therapy with intermittent ATRA, 6-mercaptopurine and methotrexate for two years followed. Median age was 41.5 (range, 20-64) and 10 of the patients were male. Approximately 13.6 % (3) of patients had more than 10 x 10^9/L leukocytes at diagnosis and thus were classified as high risk for relapse; whereas only 6 (27.3%) patients presented with less than or equal to 10 x 10^9/L leukocytes and more than 40 x 10^9 /L platelets and were considered low risk. Thus, the majority (45.5%) of patients were classified as intermediate risk. The median time from the onset of symptoms until hospitalization was 7 days (range, 2-30). Coagulopathy was present in 32% of the patients at diagnosis. The median plasma level of fibrinogen was 226.9 mg/dL (range: 114-1083). Three of the patients relapsed at 24, 36 and 48 months after achievement of CR. There were 4 (18.2%) early deaths which occurred during induction therapy. At a median of 22 months overall survival and disease free survival rates were 68.9% and 59%, respectively. Among all patients differentiation syndrome, thromboembolic events and Sweet syndrome was seen in3, 4 and one patient, respectively during induction period.
Summary / Conclusion: In summary, when compared to reports from developed countries long-term disease-free survival was inferior (85% vs 59%) in our center. This analysis suggested that the delays in referral of these medically emergent patients to our tertiary medical center might explain the early deaths since hemorrhagic complications were the most common reason for the losses. It is clear that it is a must to improve early diagnosis and prompt medical intervention. Additionally, shortage of better anthracyclines such as daunorubicin and reimbursement issues for frontline usage of highly effective arsenic trioxide might have been likely contributed to somewhat worser outcomes.

B1288

THE EXPRESSION AND SIGNIFICANCE OF PD-L1 AND BCL-2 IN CHILDREN WITH ACUTE LEUKEMIA

M Liu[1], P Zhou[2], Y Jiang[1*]
[1]Pediatrics, Renmin Hospital of Wuhan University, [2]Hubei Center for Medical Device Quality Supervision and Testing of State Drug Administration, wuhan, China

Background: Programmed cell deathligand-1(PD-L1) is a newly discovered apoptosis gene, and it plays an important role in children with leukemia development along with Bcl-2 gene.
Aims: To examine the expressions of PD-L1 and Bcl-2 in bone marrow cells in children with acute leukemia (AL) and to detect a relationship with the classification, clinical features, therapeutic effects and prognosis of AL.
Methods: Using the SABC method of immunohistochemical staining, expressions of PD-L1 and Bcl-2 in the bone marrow cells of 67 cases with AL were detected.
Results: The expressions of PD-L1 and Bcl-2 in the initial treatment, refractory relapse and relief groups were obviously higher than that in the control group (P<0.05). There was no significant difference in the expression of PD-L1 and Bcl-2 between the acute lymphoblastic leukemia ALL and acute nonlymphoblastic leukemia ANLL groups (t=1.015,t=1.032;P>0.05) . The expressions of PD-L1 and Bcl-2 in the complete remission(CR) group were lower than that in the initial treatment group(t=3.452,t=3.864;P<0.05). The expression of PD-L1 in the refractory relapse group was higher than that in the initial treatment group(t=2.885,P<0.05). However,high expression of Bcl-2 occurred both in the initial treatment group and the refractory relapse group, and there was no significant difference (t=0.932,P>0.05). Pearson rank correlation analysis indicated that there was a positive correlation between the expression of PD-L1 and Bcl-2 (r=0.617,P<0.05). Statistical analysis showed that the CR rates in patients with negative expression of PD-L1 and Bcl-2 were remarkably higher than that with positive PD-L1 and Bcl-2 expression(P<0.05).
Summary / Conclusion: Expressions of both PD-L1 and Bcl-2 play a role in onset, progression and prognosis of AL, and the two may act synergistically in the onset and development of AL.

B1289

PROGNOSTIC VALUE OF MICRO RNA92A IN ACUTE MYEOID LEUKAEMIA

M Aldefrawy[1*], N Elhalawani[1], N Hamed[1], Z Morad[2], A Sorour[2], D Elneily[2], O Ghallab[1], M Morsy[3]
[1]Internal Medicine (Haematology), [2]Clinical Pathology, Faculty of Medicine Alexandria University Egypt, [3]Internal Medicine (Haematology), Ministry of Health, Alexandria, Egypt

Background: The search for non invasive tools for diagnosis and management of cancer is extremely important for reducing the world wide health burden of cancer. MiRNAs show potential as biomarkers. MiR-92 is present in healthy individuals in the serum. qRT-PCR is superior to other methods of detection due to its high sensitivity, specificity and reproducibility. It requires less RNA input, as little as a single cell can be used for profiling. Since the expression levels of circulating miRNAs are very low, qRT-PCR is well adapted for analyzing circulating miRNAs profiles because of its sensitivity. Evidence implicating miRNA deregulation in the initiation and progression of cancer exposes opportunities for exploiting the miRNA system for therapeutic manipulations and development of novel therapies. Consequently oncogenic miRNAs can be targeted for down-regulation using anti-sense miRNA oligonucleotides to their precursor or mature

forms, and tumor suppressive miRNAs may be directly upregulated for an anticancer effect. the impact of some drugs such as DNA demethylating agents on miRNAs expression is also another therapeutic approach to modulate miRNAs expression.
Aims: To assess plasma level of micro-RNA 92a in acute myeloid leukemia patients and to correlate it with prognostic factors and therapeutic response
Methods: This study was carried out on fifty AML patients admitted to Hematology unit in Alexandria Main University Hospital as patients group as well as thirty five healthy subjects of matched age and sex as a control group. FLT3/ITD gene mutation using PCR were done to patients group. Measurement of plasma level of miR-92a using TaqMan quantitative RT-PCR and miR-638 as standardization was done to both groups. Cytogenetic study was done. Therapeutic response was assessed in patients group by doing bone marrow aspirate at day 28 of standard induction chemotherapy (3+7 protocol).
Results: The ratio (RQ) of plasma miR-92a to miR-638 in AML patients had a mean of 0.31±0.41 while in control group it had a mean value of 0.99±0.57 that confirmed statistical significance (p <0.001). Also there was negative correlation between RQ of miR-92a and bone marrow blast percentage on admission in patient group (r_s = -0.086). Patients who achieved complete response after induction chemotherapy had a median RQ higher than non-responder (0.36 versus 0.06 respectively) with statistical significance (P=0.001). There was no significant correlation between RQ of miR-92a and FLT3/ITD.

Correlation between plasma level micro RNA 92 and different parameters

	Number Of subjects	Plasma level micro RNA	r (p)
Age (patient) 42.90 ± 17.47	50		r_s = 0.165 0.251
Age (control) 35.09 ± 13.60	35		r_s = -0.063 0.762
FLT3			
-ve	32	0.12 (0.0 – 1.83)	0.693
+ve	18	0.15 (0.0 – 1.91)	
Response to therapy			
Non responder	16	0.06 (0.0 – 0.18)	
Partial remission	5	0.14 (0.01 – 0.50)	0.001*
Complete remission	29	0.36 (0.0 – 1.90)	
FAB			
M0	4	0.06 (0.0 – 1.91)	
M1	7	0.09 (0.2 – 0.24)	
M2	18	0.14 (0.01 – 1.83)	
M3	4	0.39 (0.0 – 1.08)	0.943
M4	8	0.23 (0.0 – 0.50)	
M5	5	0.08 (0.07 – 0.48)	
M5a	?	0.10 (0.13 – 0.10)	
M6	?	0.49 (0.18 – 0.79)	
Blast %			r_s = -0.086 0.554

r_s: Spearman coefficient

Summary / Conclusion: plasma level of miR-92a is decreased in newly diagnosed AML patients than normal subjects, and it was related to bone marrow blast percentage. This may be attributed to the package of microRNAs inside exosomes that are secreted from cells to be delivered to other cells and function in a new location. Thus, it might be possible that blast cells specifically take the exosomes that contain miR-92a and, as a result, miR-92a decreases from the plasma. Also resistance to induction chemotherapy is significantly related to lower RQ of plasma miR-92a. This may justify the possibility of its usage as a predictive to response to chemotherapy in newly diagnosed AML patients. Our data suggest the potential importance of microRNAs as noninvasive cancer biomarkers helping in diagnosis, clinical prediction of therapeutic response.

B1290
CONSOLIDATION CHEMOTERAPY WITH HIGH DOSE CYTARABINE FOLLOWED BY ALLOGENEIC HSCT IN *DE NOVO* ACUTE MYELOID LEUKEMIA PATIENTS: RESULTS FROM A SINGLE CENTRE EXPERIENCE ACCORDING TO DIFFERENCE RISK CLASSES
E Doni[1*], A Belotti[1], M Fumagalli[1], I Casaroli[1], L Borin[1], M Parma[1], ACastelli[1], E Pogliani[1]
[1]Division of Hematology, Ospedale San Gerardo – Università degli Studi Milano Bicocca, Monza, Italy, Monza, Italy

Background: High-dose cytarabine applied during remission induction or as consolidation after attainment of a complete remission (CR) has become an established element in the treatment of adults with acute myeloid leukemia (AML). Recent evidences have challenged the need for these exceptionally high-dose levels of cytarabine. There is no direct evidence either to suggest that any particular genetically defined subset of AML would benefit from high-dose levels of the drug.
Aims: We report the outcome of 41 adult patients (pts) diagnosed as having AML between January 2009 and January 2013 and treated with high dose cytarabine (18 g/m2) for 2 or 3 courses as consolidation therapy followed by allogeneic hematopoietic stem cell transplantation (HSCT) and investigate the impact of this approach among different risk classes.
Methods: We consider 41 adults patients (mean age 54 years) with AML between January 2009 and January 2013. They were divided at diagnosis into low (LR, 15 pts), intermediate (IR, 17 pts) and high risk classes (HR, 9 pts) according to European Leukemia Net classification. Among LR pts, 4 were diagnosed as CBF leukemias (2 inv(16) positive, 2 t(8,21) positive, all of them c-KIT wild type) and 11 were NPM1 mutated/FLT3-ITD-. Patients allocated in HR class had complex karyotype (4 pts) or carried del(7q) (1 pt); we included in HR class also FLT3-ITD+/NPM1 wild type pts (4 pts). All other pts were defined as IR patients. All pts underwent induction therapy with cytarabine 100 mg/sqm twice daily (7 days) and idarubicin 12 m/sqm (3 days). 36 patients obtained complete remission (CR) after induction therapy and they underwent 2 or 3 cycles with high dose cytarabine (18 g/sqm per cycle, cumulative dose 36 g/sqm or 54 g/sqm). 12 pts underwent allogeneic HSCT in first or second CR (5 HR pts, 6 IR pts). Log-rank (Mantel-Cox) test applied to Kaplan-Meyer method was employed to estimate progression free survival (PFS) and overall survival (OS). OS, PFS and relapse rate were defined by the standard criteria.
Results: At 2 years 11 pts relapsed, 1 after HSCT and 10 without receiving HSCT: of them, 3 relapsed pts were not candidate to HSCT because they had a LR disease; they were all NPM1 mutated/FLT3-ITD-. Cumulative incidence of relapse at 2 years was 35.8%, 43.2% and 58.3% in LR, IR and HR pts respectively, with no statistical difference among risk classes. Overall, 12 pts underwent allogeneic HSCT in first (CR1) or second CR (CR2) No difference was found among different risk classes for PFS and OS: 2 year PFS was 64%, 42%, 57% for LR, HR and IR pts respectively (p 0.77) and 2 year OS was 65%, 50% and 53% for LR, HR and IR pts (p 0.83).
Summary / Conclusion: In our experience high dose cytarabine based consolidation regimen (36 g/mq or 54 g/mq) followed by HSCT in selected pts (IR pts in CR2 or in CR1 with a sibling donor and HR pts) seems to give an equal OS e PFS among different risk classes. Thus, in our experience this kind of approach seems to reduce the poor impact of adverse cytogenetic abnormalities and molecular markers such as FLT3 mutation in AML, without a significant difference in outcome among risk classes.

B1291
INFLUENCE OF FLT3/ITD MUTATION ON OUTCOME OF PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA: A SINGLE CENTRE EXPERIENCE
E Doni[1*], A Belotti[1], M Fumagalli[1], I Casaroli[1], L Borin[1], M Parma[1], E Pogliani[1]
[1]Division of Hematology, Ospedale San Gerardo – Università degli Studi Milano Bicocca, Monza, Italy, Monza, Italy

Background: Survival of *de novo* acute myeloid leukemia (AML), particularly in younger patients (pts), has improved in recent years. Relapse continues to remain an important obstacle to successful outcome. This is particularly true in AML patients with FMS-like tyrosine kinase 3/internal tandem duplication (FLT3/ITD) molecular mutations. The FLT3/ITD mutations occur in about 30% of AML pts; when compared with their FLT3 wild type counterparts, FLT3/ITD+ pts are at particularly high risk of relapse when treated with chemotherapy alone. These pts are often referred for allo-SCT in first complete remission (CR1), which is becoming the preferred therapeutic option. However, there is no clear evidence that hematopoietic stem cell transplantation (HSCT) in CR1 decreases the relapse rate or improves overall survival (OS).
Aims: We retrospectively analyzed the impact of FLT3/ITD on outcome of citogenetically normal AML under 65 year-old pts treated at our institution between 2009 and 2013 in terms of progression free survival (PFS) and overall survival (OS).
Methods: We retrospectively considered 41 adults pts (median age 54 years) with *de novo* AML between January 2009 and January 2013. 39 pts who had FLT3/ITD mutation status available were included in the final analysis. The FLT3/ITD and NPM1 mutation assay was performed using fluorescent PCR with primers and amplification conditions. All pts received standard AML induction chemotherapy with cytarabine 100 mg/sqm twice daily (7 days) and idarubicin 12 mg/sqm (3 days) followed by consolidation chemotherapy with high dose cytarabine for 1–3 courses (18 g/sqm each course); among these pts, 11 underwent allogeneic HSCT. 8 pts were FLT3/ITD + (5 pts NPM1 mutated, 3 pts NPM1 wild type), 31 were FLT3/ITD- (12 pts NPM1 mutated, 19 pts NPM1 wild type). Log-rank (Mantel-Cox) test applied to Kaplan-Meyer method was employed to estimate PFS and OS. OS, PFS and relapse rate were defined by the standard criteria.
Results: At 2 years we observed a relapse after consolidation chemotherapy in 4 of 8 pts FLT3/ITD+ pts and in 5 of 31 FLT3/ITD- pts. Among FLT3/ITD+ and FLT/ITD- pts, 5 pts and 6 pts were transplanted in first or second remission, respectively. 2 years PFS was 16.7% for FLT3/ITD+ and 68.7% FLT3/ITD- pts (p 0.041); 2 years OS was 18.7% for FLT3/ITD+ pts and 72.2% for FLT3/ITD- pts (p 0.048).
Summary / Conclusion: We observed a significant difference in 2 years OS and PFS among FLT3/ITD+ and FLT3/ITD- pts, indipendently by NPM1 mutational status. In our experience FLT3/ITD mutation has a poor impact on AML patients, although most of FLT3/ITD+ pts underwent HSCT. It is debated from literature the role of HSCT in overcoming the poor impact of FLT3/ITD mutation; in different studies FLT3/ITD mutation seems to have an adverse effect on outcome of HSCT in the same direction it does after chemotherapy. Our data seem to confirm this hypothesis.

B1292

THE EFFECTIVENESS OF INTENSIVE CHEMOTHERAPY TO THE ELDERLY ACUTE MYELOGENOUS LEUKEMIA PATIENTS

D Kim[1*], C Choi[1], Y Park[1], S Lee[1], H Sung[1], B Kim[1]
[1]Hematology, Korea University Medical Hospital, Seoul, Korea, Republic Of

Background: Despite of advances in the treatment for acute myelogenous leukemia (AML), the response of chemotherapy for the elderly is still poor and there is no definite guideline for the elderly AML patients.
Aims: This study was conducted to verify the effectiveness of intensive chemotherapy in elderly AML patients, and to determine which sub-group of patients is more effective to the therapy.
Methods: The retrospective analysis with medical chart review was taken to the 82 patients over 65 years old and treated with AML from January 2003 to April 2012 at the Korea University Medical Center. The efficacy of chemotherapy for the elderly patients was evaluated and sub-group analysis was taken to determine which conditions are more effective to the chemotherapy.
Results: Median overall survival period of 82 patients were 3.9 months. 52 patients were treated with chemotherapy (33 patients were intensive chemotherapy with idarubicin plus cytarabine, 19 patients were low dose cytarabine) and 30 patients received best supportive care only. Among the intensive chemotherapy group, there were 16 cases of remission (48.5%) after induction chemotherapy. The treatment related mortality was 24.2% and the most common cause was pneumonia sepsis. Median overall survival period of intensive chemotherapy group was 7.9 months. In a multivariate analysis, significant factors for longer overall survival were performance status, no underlying heart disease, no fever at diagnosis, high platelet count, low blast count and type of induction chemotherapy. In the sub-group analysis, the efficacy of chemotherapy was observed in the relatively younger patients group (HR 0.437, *P*=.022), De novo AML group(HR 0.421, *P*=.025), no underlying heart disease group (HR 0.421, *P*=.031), high WBC count group (HR 0.306, *P*=.026), Low platelet count group (HR 0.12, *P*<.001), high blast counts group (HR 0.233, *P*=.005), high LDH group (HR 0.21, *P*=.001).
Summary / Conclusion: The result of chemotherapy in the elderly AML patients is poor. However the results of the chemotherapy will be better if the patients are selected appropriately through sub-group analysis.

B1293

IMMUNOPHENOTYPE DISTINCTION BETWEEN ACUTE PROMYELOCITIC LEUKEMIA AND HLA-DR-CD34 NEGATIVE ACUTE MYELOD LEUKEMIA: SINGLE CENTER EXPERIENCE

D Dukovski[1,2*], L Cevreska[1,2], S Trajkova[1,2], M Ivanovski[1], M Popova-Simjanovska[1], S Stankovik[3], I Panovska-Stavridis[1,2]
[1]Hematology, University Clinic for Hematology, [2]Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of, [3]Hematology, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The availability of genotype-specific therapy for PML/RAR alpha positive acute promyelocytic leukemia (APL) requires exact diagnosis of this acute myeloid leukemia (AML) entity. The lineage assignment of the AML blasts cells guides to implementation of specific molecular analyses in those subtypes of acute leukemia and facilitate their further definition. APL blast cells usually do not expressed HLA-DR and CD34 antigens, but also a proportion of non-APL-AML sustain the same immunophenotypic characteristics.
Aims: In order to define more precise immunophenotypic criteria that delineate APL from non –APL-AML that are HLA-DR and CD34 negative we conduct retrospective study aimed to establish a surrogate marker profile for APL. We further evaluate antigenic and clinical features of confirmed APL by using Real time quantitative polymerase chain reaction (RQ-PCR) in comparison with the non-APL–AML cases.
Methods: We analyzed a series of 30 APL and 32 of non-APL-AML patients who were diagnosed in the last three years at the University Clinic for Hematology in Skopje, Macedonia. The diagnosis of acute leukemia was made by standard morphological examination and cyto-chemical analyses of bone marrow smears according to the criteria established by FAB Cooperative Study Group and confirmed by immunophenotyping of bone marrow aspirates and/or peripheral blood samples following the criteria of the European group for the immunological Classification of acute leukemia (EGIL). Flowcytometry analyses were performed by using the FAXS Canto II BD flow cytometer analyzer. Acquired data were analyzed with the software FACSDiva version 6.1.2 by using CD45 gating strategy. Slightly modified panel of monoclonal antibodies (McAb) against myeloid- and lymphoid-associated antigens as suggested by the EGIL was utilized.
Results: Our results showed significant differences between APL and non-APL patients in CD2, CD13, CD33 reactivity. Aberrant CD2 expression was absent in all non- APL AML. Moreover, all cases from non-APL-AML group did not expressed CD15. Mean florescence intensity of CD33, CD13 showed differences between the two groups. Regarding the clinical characteristic, non-APL-AML patients had higher leukocyte and platelets counts in comparison with APL cases.
Summary / Conclusion: Our results showed that expression of CD2, CD13, CD33 may be useful for initial delineation of APL from non-APL-AML patients that are HLA-DR and CD34 negative. However, cytogenetic and molecular characterizations are ultimate for to establishing the diagnosis of APL. Immunophenotypic characteristic could lead us prompt implementation of the specific molecular analysis in APL patients but implementation of multimodal diagnostic approach is essential for APL diagnosis and allows individual tailoring of the treatment of those patients.

B1294

HYDROXYUREA (HU) ASSOCIATED TO SUPPORTIVE THERAPY AS CONSERVATIVE APPROACH IS STILL A VALID OPTION FOR TREATING ELDERLY PATIENT WITH ACUTE MYELOID LEUKEMIA (AML)

S Ferraro[1*], F Marchesi[1], N Cenfra[2], E Cerchiara[1], A Rago[2], M De Muro[1], S Mecarocci[2], O Olimpieri[1], G Cimino[2], G Avvisati[1]
[1]Hematology Unit, Campus Bio-Medico University Hospital, Rome, [2]Hematology, Sapienza University, Polo Pontino, Latina, Italy

Background: In elderly, Acute Myeloid Leukemia (AML) is characterized by a poor prognosis, due to the presence of several negative prognostic factors as performance status (PS), comorbidities and high incidence of adverse cytogenetic abnormalities. Therefore the better treatment in this category of patients remains still controversial. During last years several studies have been performed in order to compare different therapeutic regimens, including intensive chemotherapy, low-dose of Citarabine, Hydroxyurea (HU) and other novel innovative drugs.
Aims: The aims of the present study were to evaluate clinical outcome of elderly AML patients considered "unfit" for intensive treatment and treated with conservative approach and to establish the clinical prognostic factors affecting survival in these patients.
Methods: From 10/2008 to 4/2012, 38 elderly patients with a median age of 78 years (range 63-87 years) were analyzed by a retrospective *"real life"* study. All patient were considered "unfit" to receive intensive chemotherapy and were treated with HU 30-50 mg/Kg daily and transfusions (n=21) or only whit transfusions (n=17). At diagnosis, 33 patients (86.8%) presented at least one severe comorbidity: cardiovascular disease (n=19), metabolic alteration (n=9), neurological diseases (n=6), respiratory disease (n=7) and active infection (n=8). Nineteen patients (50%) presented at diagnosis a poor PS (≥2), whereas the remaining patients had a PS of 0-1. Median value of White Blood Cells (WBC) at diagnosis was 10.150/µl (range 510-213.330). Out of 38 patients, 5 presented at diagnosis a WBC count higher than 50.000/µl, 13 between 10.000-50.000/µl and the remaining 20 lower than 10.000/µl. Median value of Platelets (PLTs) count was 55.000/µl (range: 9.000-511.000), whereas the median percentage of bone marrow blasts was 59% (range 20-100%).
Results: After a median of follow-up of 600 days (range 487-699), 4 of 38 patients are still alive. The global Overall Survival (OS) are 10.5% with a median of survival of 161 days (range 5-699) from the diagnosis. The 1-years survival rate is 21%. Poor PS (P<0.001), high WBC count (P=0.021), high percentage of bone marrow blasts (P=0.017) and older age (P=0.05) were negative prognostic factors for OS in univariate analysis. Multivariate analysis was not performed because of the low patients number. The median of hospitalization was 14 days (range 0-86) and treatment with HU was well tolerated without specific adverse effects and treatment discontinuation.
Summary / Conclusion: A conservative approach with HU and supportive therapy is still a valid option for treatment of elderly patients with AML. Our data suggest that this approach is well tolerated and it is able to obtain a fairly clinical outcome with a reduced hospitalization time in a non-selected cohort of elderly patients. Survival rate and median survival time were similar to that reported in the most important studies in which low-dose of Cytarabine and other novel innovative drugs have been investigated.

B1295

EVALUATION OF FEBRILE NEUTROPENIC EPISODES IN ACUTE MYELOID LEUKEMIA PATIENTS

M Comert[1*], I Aydogdu[2], E Kaya[3], F Yetkin[4], M Erkurt[3], I Kuku[3]
[1]Hemathology, Ege University, School of Medicine, [2]Hemathology, Kent Hospital, Izmir, [3]Hemathology, [4]Infection Disease, Inonu University, School of Medicine, Malatya, Turkey

Background: The most important cause of mortality in febrile neutropenic episodes (FNEs) which mature after chemotherapy is infections. Therefore fewer in neutropenic patients must be accepted as an infection until the contrary is proved and broad-spectrum empric antibiotherapy must be started immediately as a standard approach.
Aims: To evaluate febrile neutropenia episodes of AML patients to develop empiric antibiotic treatment policies.
Methods: Eighty-seven patients who have been treated because of acute myeloid leukemia in İnönü University Turgut Özal Medicine Center Adult Hematology Clinic between 2002 and 2010 was evaluated. The infection categories, isolated pathogen microorganisms, mortality ratios and antibiotherapy regimens in 236 febril neutropenic episodes which mature after chemotherapy were examined retrospectively in this study.
Results: Fifty-three (61.0%) of the patients were males and 34 (39.0%) were

females. The median age of the patients was 52.4. The median follow-up period was 9.5 months. In FNEs, fewer was evaluated as microbiologic defined infection (MDI) in 73 (30.9%) episodes, as clinical defined infection (CDI) in 95 (40.3%) episodes and as fewer of unknown origin (FUO) in 68 (28.8%) episodes. In forty-seven (19.9%) episodes efficient pathogen microorganism was isolated from blood cultures. 91.5% of the pathogens which isolated from blood cultures were bacteries and 8.5% was fungal agents. 55.8% of the pathogen bacteries were gram-positive and 44.2% were gram-negative. The predominant isolated gram-positive bacteria was *KNS*, gram-negative bacteria was *E. coli.* Pneumonia was the most clinical infection seen in CDI. The mean neutropenia duration was 13.3 days in all episodes, 16.7 days in MDI, 13.1 days in CDI and 10.0 days in FUO. The mortality rate was 8.5% in all episodes, 9.6% in MDI, 11.6% in CDI and 2.9% in FUO. The mean neutropenia duration in exitus patients were 21.6 days and 12.6 days in living patients. This difference was statistically significant.

Summary / Conclusion: Prolonged fever and neutropenia was more often accompanied with MDI and the lenght of the duration of neutropenia was found to be a risk factor for mortality in this study. For a better febrile neutropenia management process, medical centers must follow their infection agents closely and modify their empiric antibiotic treatment policies.

B1296

PROGNOSTIC IMPLICATIONS OF BIOLOGICAL PARAMETERS IN THE DIAGNOSIS OF ACUTE MYELOGENOUS LEUKEMIA. SINGLE INSTITUTION EXPERIENCE.

F Torres[1], P Sierra[1*], M Arance[1], M Quesada[1], J López[1], S Nieto[1], A Muñoz[1]
[1]Hematology, University Hospital of Jaen, Jaen, Spain

Background: Acute Myelogenous Leukemia (AML) is a heterogeneous group of diseases, who is characterized by acquired genetic alterations in hematopoietic progenitor cell. Throughout the history it has been evaluated how different biomarkers, biochemical, cytogenetic and molecular correlate to the prognosis of the disease, survival and risk of relapse. The complete response after induction is an important goal in the prognostic of these patients.

Characteristics to diagnostic. (Table 1)

Age (years) Median (range)	Bimodal (32 y 70 years) 60 (0.23-88)
Sex (Men / Women)	57.5% / 42.5%
Subtypes FAB (%)	
- MO	4 (10)
- M1	3 (7.5)
- M2	10 (25)
- M4	13 (32.5)
- M5	8 (20)
- M6	2 (5)
- M7	0 (0)
Leukocytes	20760/mm³ (1070-296000)
- > 20.000/mm3	52.5%
- < 50.000/mm3	27.5%
Hemoglobin (g/dl) Median (range)	9.7 (5.4-14-9)
Platelets (/mm3) Median (range)	59.500 (13000-254000)
LDH (U/L) Median (range)	825 (276-13239)
Uric Acid (mg/dl) Median (range)	5.7 (1.7-12.5)
Infiltration MO % median (range)	25-98

Aims: Evaluating different diagnostic variables as potential predictors of response to induction.

Methods: We evaluated the diagnostic of AML non promyelocytic retrospectively; these were diagnosed from November 2006 to November 2011. We took the diagnosis data and specifically did a hematologic, biochemical and medular rating. We also wrote data in diagnosing bone marrow infiltration and the FAB classification; cytogenetic, immunophenotype, response rates after induction, complications and deaths. The patients chosen for chemotherapy received scheme 3+7 (idarrubicin plus cytarabine)treatment of the protocols PETHEMA (99 y 2007). In patients over 65 years it was opted for schemes 2+5 and in patients no eligible, supportive treatment and cytoreductive therapy with low dose thioguanine and/ or cytarabine.

Results: Data, related to the characteristics of the study population studied, is shown in the Table 1. We performed a comparison of variables about diagnosis to assess their impact on the response to induction therapy in candidates. We have seen significant association between the age on diagnosis and the survival at the end of the induction, as described in the literature. Superior hyperleukocitosis to 20000/mm^{3}leukocytes indicated a trend to significance for the estimation of survival to induction therapy (P=0.07). When the range was extended to 50000/mm^3, we observed statistically significant differences between groups (P<0.05). In evaluating others parameters showed no differences in the groups when considering the hemoglobin, plateletscountor uric acid to diagnosis. In the statistical analysis of LDH, there were values near to significance, as all patients, who died during induction, showed higher values of LDH. There were no statistically significant differences in the response rate in patients with different cytogenetic and molecular alterations. When phenotypes associated with leukemia measured by flow cytometry were described, the positivity or negativity of markers CD34 or CD117 did not have impact in the rates of response after induction treatment.

Summary / Conclusion: 1. Knowledge of cytogenetic and molecular alterations that influence in the development of acute leukemia allows the study of a higher number of factors in the survival. 2. Leucocytes levels to diagnostic LDH and uric acid are related, indicating an estimation of tumoral mass, replicative data y cellular turn-over. 3. In our study we have tried to identify predictors of response to induction. It does seem that citogenetic and molecular alterations to the diagnosis have not involved significant differences in obtaining response or not after induction. In conclusion, its effect on survival appears to be determinated in the medium term for possible selections of resistant clones. 4. The only factor clear induction response and survival is leukocytes level and age. 5. We are trying correlating phenotypes associated to leukemia with the success to treatment and survival. Relationship has not been established, although their range is limited in number. However, if it is clear that the depth in the characterization of the phenotype associated with leukemia is crucial for monitoring and accurate assessment of treatment response.

B1297

TUMOR FORMING PLASMACYTOID DENDRITIC CELLS ASSOCIATED WITH MYELOID NEOPLASM OR BLASTIC PLASMOCYTOID DENDRITIC NEOPLASM? A DIAGNOSTIC CHALLENGE: LITERATURE REVIEW AND CASE REPORT

F Jimenez[1*], R Tamayo[1], P Massare[2], F Osuna[3], M Gamiz[3], R del Moral[2], A Aguilar[1], J de Pablos Gallego[1], M Chacon[1]
[1]Hematology, [2]Pathological anatomy, [3]Immunology, Virgen de las Nieves University Hospital, GRANADA, Spain

Background: Tumor forming plasmacytoid dendritic cells (TFPDC) associated with myeloid neoplasms is a clonal proliferation of mature plasmacytoid dendritic cells (PDC) associated with myeloid malignancies, normally chronic myelomonocytic leukemia and acute myeloid leukemia (AML) that can occur in lymph nodes, skin, spleen, or bone. Blastic plasmacytoid dendritic cells neoplasm (BPDCN) is derived from precursors of a specialized subset of dendritic cells, plasmacytoid dendritic cells, and hence is a myeloid-related neoplasm. It is a clinically aggressive neoplasm that is usually characterized at its onset by solitary or multiple skin lesions, often with associated regional lymphadenopathy. Case series of BPCN lacking cutaneous involvement was reported by Michael J Rauh et al in Leukemia Research 36 (2012) 81– 86. Although these two entities can mimic both show defining immunophenotypic characteristics described by Jegalian AG et al. in Adv. Anat. Pathol. Vol.16 Nº6 2009.Proliferation index Ki-67 <10% and CD56- are key data to differentiate TFPDC from a BPDCN.

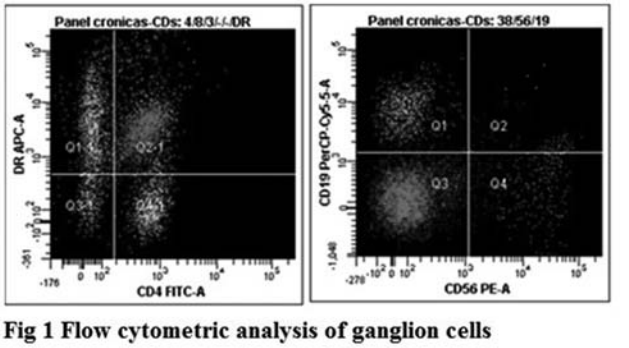


Fig 1 Flow cytometric analysis of ganglion cells

Aims: Present a case of tumor forming plasmacytoid dendritic cells associated with acute myeloid leukemia diagnosed in our institution this year.

Methods: A 68 years old woman with a history of cervical tumor and CT images compatible with multiple lymphadenopathy and splenomegaly of 14 cm was referred to hematology department for suspected lymphoma.

Results: Laboratory basal findings: normocytic anemia. Flow cytometric analy-

sis of peripheral blood was normal. Cervical node biopsy: plasmacytoid neoplasm with parafollicular and sinus distribution, immunohistochemical techniques reveal: CD68 +,CD123 +,CD4 +,CD74 +, CD43 +, CD31 + and CD56 - and granzyme B-. Flow cytometric analysis of ganglion cells: CD4 +, CD123 +,CD56-,CD11b- (Fig. 1). A TFPDC was diagnosed. Bone marrow aspiration: hypercellular bone marrow with 86% of blast cells, esterase and peroxidase were negatives. Flow cytometric analysis of bone marrow: 74% of myeloid blast cells, CD13 +,CD33 +,CD117 +,CD34 +,DR +. Bone marrow trephine : blast cells accumulations with immunohistochemical technical positivity for CD 34, CD 117, myeloperoxidase focally, CD31,CD7,negativity for CD38, CD4, CD123, CD TLE 1 and 56, compatible with AML with minimal differentiation . According to these findings, a diagnosis of TFPDC associated with acute myeloid leukemia was made. At that time there was no periphery expression of leukemia. The patient was admitted for start treatment and a new blood count and peripheral blood immunophenotype were made. The results were the following: hemoglobin: 8.9 g/dL; WBC: 24.0 10^9/L (3% neutrophils, 40% lymphocytes),LUC 3.63 10^9/L. Flow cytometric analysis of peripheral blood: 17% myeloblasts with two subtypes: one CD34+, DR+, CD13+, CD33+, CD117+, CD15-,MPO- and other CD34-, CD117+, CD13-, CD33, DR+, CD15- and 4.6% of cells with phenotype similar to ganglion cells CD4+, CD123+, CD56-, CD11b- . Standard chemotherapy induction cycle according to the PETHEMA LAM99 65 and older protocol: cytarabine and idarubicin based was started. The patient is still in hospital.

Summary / Conclusion: Although these two entities can mimic both show defining immunophenotypic characteristics. A panel of stains including CD56, TdT, and Ki-67, are recommended in cases of diffuse PDC proliferations that are clinically indistinguishable of BPDCN. Treatment and prognosis of these two entities is different so it is very important to reach the correct diagnosis.

B1298

ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS NOT CONSIDERED FIT FOR INTENSIVE TREATMENT; AZACITIDINE, LOW DOSE CYTARABINE AND ETOPOSID COMBINATION EXPERIENCE FROM A SINGLE CENTER

H Okutan[1*], B Öneç[1], M Albayrak[1], V Aslan[1], E Can[1], Ö Kösemehmetoğlu[1], B Koluman[1], A Albayrak[2]

[1]hematology, [2]pathology, dıskapi yildirim beyazit education and research hospital, ankara, Turkey

Background: Acute myeloid leukemia (AML) is associated with poor prognosis in elderly patients with median survival estimated to be 2 months and a 2-year survival rate of 6%. Most of the patients cannot be treated with intensive chemotherapy (IC) because of comorbidities or poor performance status. For patients who are deemed unfit for standard induction or intermediate intensity therapy, low intensity treatments subcutaneous low dose ara-c (LDAC,), azacitidine, decitabine or best supportive care (BSC) can be chosen.

Aims: Despite marked activity in myeloid malignancy, monotherapy with azacitidine is limited by low response rates and median response durations. As with classical cytotoxic therapy, outcomes may be improved using a combination of agents azacitidine with LDAC and etoposid , which have been used to improve response rates and duration in our center.

Methods: We reviewed through medical records of 24 elderly AML patient diagnosed between 2010-13 who could not receive IC and treated with low intensity regimes including this combination or BSC. We reviewed medical records for response rates and overall survival.

Means and Medians for Survival Time

	Mean[a]				Median			
			95% Confidence Interval				95% Confidence Interval	
TREATMENT	Estimate	Std. Error	Lower Bound	Upper Bound	Estimate	Std. Error	Lower Bound	Upper Bound
AZACITIDINE	4,000	1,780	,512	7,488	2,000	1,500	,000	4,940
AZACITIDINE + ETOPOSIDE+ ARA-C	12,495	4,202	4,260	20,730	9,000	3,247	2,636	15,364
HYDROXYUREA	1,167	,441	,302	2,031	1,000	,408	,200	1,800
BEST SUPPORTİVE CARE	,867	,410	,064	1,669	1,000	,735	,000	2,440
ETOPOSIDE + ARA-C	,100	,000	,100	,100	,100			
LOW DOSE ARA-C	1,867	1,073	,000	3,970	1,000	,327	,360	1,640
Overall	6,051	1,900	2,328	9,774	2,000	1,220	,000	4,392

Results: Of the 24 elderly patients (age 61-84, mean age71,3)8 were female and 16 were male. All of them had poor performance status (ECOG ≥2), and mean ECOG was2,71. Patients' bone marrow blast ratios (BMBR) were between 20 and 93 (median 62). Four of them (16,6%) had azacitidine 75 mg/m^2/day for 7 days of every 28-day cycle, for 4 cycles. Ten of patients (41,7%) were treated azacitidine 75 mg/m^2/day for 7 days combined with cytarabine 40 mg/m^2/day for 7 days and etoposide 50 mg/m^2/day for 3 days and 1 patient (4.2%) treated etoposid and cytarabine in the same schedule. After a BMBR evaluation either continued same therapy or switched another one. Hydroxyurea alone, LDAC (20 mg twice day for 10 days) and BSC alone were each used at 3 patients (each 12,5%) BMBR was evaluated only at 8 patients that peripheral blast clearence observed, after 4 cycles in groups containing azacitidine. Complete and partial remission were only seen at combination group (44.5% and 11,1%), one patient from combinated and 2 from azacitidine alone group had progresive disease after fourth cycle and all other patients died before evaluation. Mean overall survival was 12,5 months (95% CI:4,26-20,7)at azacitidine combined with ARA-C and etoposide group and 4 months (95% CI: 0,51-7,49) at azacitide alone group. Men survivals were significantly lower in other groups (LDAC: 1.87, hydroxyurea: 1.17, BSC: 0,87, Etoposide + ARA-C:0.1 months).

Summary / Conclusion: Retrospective evaluation of elderly and medically unfit AML patients showed interesting complete remission rates of %44.4 and mean OS of 12.5 months of combination therapy of azacitidine, etoposide and LDAC but results were not from a randomized study. Azacitidine has better CR and median OS results (18% and24,5 months respectively) reported in elderly but with low (20-30%) BMBR AML before and new studies on combination of azacitidine and cytarabine reports its safety. We think additional trials about combinations ofazacitidine should be designed based on our experiences.

B1299

POSSIBILITY OF MOLECULAR REMISSION OBTAINING WITH NK AND T-CELLS RESTORATION USING AUTOLOGOUS LYMPHOCYTES INFUSIONS AND IL2 IN RELAPSED ACUTE MYELOID LEUKEMIA PATIENTS

A Sokolov[1*], E Parovichnikova[1], M Pashenkov[2], B Pinegin[2], A Misurin[3], V Savchenko[4]

[1]Chemotherapy of hemoblastoses and bone marrow transplantation, Research Center of Hematology of Russian Ministry of Health, [2]Institute of immunology, [3]Molecular biology laboratory, [4]Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: Chemotherapy together with the antitumor action leads to depletion of the lymphoid population which possesses a probable antileukemic potential. Recovery of lymphoid population takes a long period of time. More rapid lymphoid recovery after chemotherapy associated with good long term prognosis.

Aims: To assess antileukemic potential and recovery of the autologous lymphoid population in adult acute myeloid leukemia (AML) we initiated the pilot study performing multiple harvesting, storing and reinfusing of autologous lymphocytes in relapsed AML patients during second morphological remission in period of consolidating chemotherapy (CT) followed by interleukin-2 (IL-2) continuous infusions.

Subpopulations	Before lymphocytapheresis		After all autologous limphocytes infusions	
	M2 Pt	M4 Pt	M2Pt	M4Pt
T-cells	x10^9/L			
CD3+	0,36	1,082	0,739	0,147
CD4+CD8-	0,0827	0,26	0,236	0,054
CD4-CD8+	0,229	0,822	0,389	0,09
CD4+ T-cells subpopulations				
CD4+CD28+CD45RA+	0,0212	0,0439	0,055	0,00221
CD4+CD57+	0,00678	0,0078	0,0104	0,00448
CD4+CD25high	0,00132	0,0148	0,0046	0,0081
CD8+ T-cells subpopulations				
CD8+CD28+CD45RA+	0,0137	0,0518	0,0202	0,0099
CD8+CD57+	0,103	0,192	0,158	0,0519
NK subpopulations				
CD56+CD3-	0,0391	0,162	0,17	0,245
CD56highCD16-	0,0046	0,0225	0,0272	0,0108
CD56lowCD16+	0,0289	0,0951	0,107	0,211
CD56lowCD16-	0,00375	0,0433	0,025	0,0173

Methods: We treated two relapsed AML patients (pts): M2 t(8;21) and M4 inv(16). The second morphological remission in both pts was obtained after CT consisted of 7+3 Ida (conventional dose AraC + idarubicin) and HAI (high dose AraC + idarubicin) in M2 pt and two 7+3 Ida blocks in M4 pt. The consolidation CT consisted of 7+3 Ida two blocks in both pts and 5+2 Ida one block in M4 pt. The 1-3 lymphocytaphereses (LA) were performed straight before every consolidation CT block. The cells were stored frozen in liquid nitrogen. Unfrozen lymphocytes were transfused on 10th day after every consolidation CT block in profound cytopenia period. IL-2 started on lymphocytes reinfusion day and continued for 5 consecutive days 2-6 mln U per day as continuous i.v. infusion.

Results: In M2 pt 9,2x10^9 lymphocytes before 1st CT block and7,4x10^9 lymphocytes before 2nd CT block were harvested. In M4 pt 15,9x10^9 lymphocytes before 1st CT block, 17,1x10^9 lymphocytes before 2nd CT block and7,7x10^9 lymphocytes before 3rd CT block were harvested. After completion of consolidation CT with autologous lymphocytes infusions and hematological recovery

in both pts we observed increase of NK count in peripheral blood (see table), especially CD56lowCD16+ subpopulation (mature cytotoxic NK). The other NK subpopulations were changing in different ways. CD56highCD16- cells (immature NK) and CD56lowCD16- cells (mature NK) increased in M2 pt but decreased in M4 pt. In M2 pt CD3+ T-cells increased including CD4+CD8- (presumably) and CD4-CD8+ (to a small degree) together with their subpopulations: CD4+CD28+CD45RA+ (naive CD4+), CD4+CD57+ (terminally differentiated CD4+), CD4+CD25high (regulatory T-cells), CD8+CD28+CD45RA+ (presumably naive CD8+), CD8+CD57+ (terminally differentiated CD8+). In M4 pt all those CD3+ cell subpopulations decreased. In M2 pt relative amount of both T-cells and NK increased from 25,8% to 91%, NK compartment increased from2,5% to 17%. In M4 pt relative amount of both T-cells and NK decreased from 92% to 80%, but NK compartment increased from 12% to 50%. As a result of consolidation CT with autologous lymphocytes infusions in M2 pt, but not in M4 pt, molecular remission (mCR) was obtained.
Summary / Conclusion: The data of the study point out that in AML pts repetitive autologous lymphocytes harvesting before and reinfusion after consolidating CT blocks together with IL-2 stimulation could lead to significant increase of circulating NK cells, particularly mature cytotoxic NK subpopulations. T-cell subpopulations restoring correlated with mCR achievement. The lack of mCR was associated with all T-cell subpopulations decrease (especially naive CD4+, naive CD8+ and regulatory T-cells).

B1300
THE CLINICAL AND THERAPEUTIC FEATURES OF ACTUE PROMYELOCYTIC LEUKEMIA IN CHILDREN.
N Sayed[1], K Zahra[1*], N Amri[1], A Bechir[1], Z Monia[1], R Haifa[1], Y Youssef[1], A Khelif[1]
[1]hematology, Hopital Farhat Hached, SOUSSE, Tunisia

Background: Acute myeloblastic leukemia (AML) is a heterogeneous group of malign diseases characterized by uncontrolled proliferation of myeloid progenitor cells in the bone marrow. It accounts for 15-25% of all childhood acute leukemia. Acute promyelocytic leukemia (APL) is an uncommon form of acute myeloid leukemia (AML). APL in children has constituted only 6-10% of AML. Molecularly, the disease is characterized by a fusion protein, PML/RARa that results from a balanced reciprocal translocation between the PML gene on chromosome 15 and the retinoic acid receptor alpha gene on chromosome 17. A major advance in the treatment of APL has been the use of all-trans-retinoic acid (ATRA). ATRA differentiates leukemic promyelocytes into mature granulocytes. Concurrent chemotherapy and ATRA have resulted in superior remission and survival rates so does the Arsenic in relapsed ones's.The aim of our study is to report the epidemiological, clinical and therapeutic features of APL in children.
Aims: The aim of our study is to report the epidemiological, clinical and therapeutic features of APL in children.
Methods: We report 9 cases of newly diagnosed APL in children patients. These patients were followed in the clinical hematology department at Farhat Hached university hospital (Sousse -Tunisia) over a period of 10 years.
Results: The median age was 13 years (3- 18 years). 44% of the patients were male with female/male ratio of 1.25. The motif of consultation was hemorrhagic syndrome of varying intensity in 8 cases and splenomegaly in one patient. One patient presented a left exophthalmia with homolateral facial paralysis. The blood cell count showed no leukocytosis in all patients and low levels of platelets so a high tendency for severe bleeding. The diagnosis is made after cytology, cytogenetic and molecular analysis (made in 5 patients). The t (15; 17) was detected in all patients. The research of PML/RARA mutation done in 5 patients was positive in 4 cases. All patients were treated with chemotherapy (induction + 3 consolidations courses) and ATRA according to AIDA protocol. Only one patient did not receive the ATRA due to its unavailability. 7 patients have completed the treatment and the other 2 patients refused to continue treatment (lost sight after the third cure of chemotherapy). The cytology, cytogenetic and molecular remission was achieved in 8 patients (89% of cases). The relapse was observed only in one patient (14 years old) 2 years after end of treatment. The patient received the same initial treatment due to the unavailability of arsenic with obtaining a complete remission. The bone marrow transplant was performed in this patient after the second course of consolidation with good results. Medium global survival rate was 43 months (24-84).
Summary / Conclusion: Since the introduction of ATRA, there have been remarkable advances at the laboratory and clinical level in treatment of APL. APL is the most curable disease and is a paradigm for successful targeted treatment. However, the treatment of APL in children is challenging because of the risks of early death and potential long-term cardiac toxicity resulting from the need to use high doses of anthracyclines. Prospective, randomized large clinical trials are needed to address several issues in APL and to possibly minimize and eliminate chemotherapy by combining ATRA and Arsenic.

B1301
ACUTE MYELOID LEUKEMIA WITH FLT3-ITD AND COMPLETE ANDROGEN INSENSITIVITY SYNDROME (MORRIS SYNDROME) –A CASE REPORT
G Tsvetkova[1*], T Nikolova[1], E Hadjiev[1], E Vikentieva[2], R Vazharova[3]
[1]Department of Internal Diseases- Clinic of Hematology, [2]Central laboratory of clnical immunology, [3]National genetic laboratory, Medical University - Sofia, Faculty of Medicine, Sofia, Bulgaria
Background: In the classification of disorders of sex development Morris syndrome is included in the group of 46,XY disorders. It is a rare X-linked recessive condition, due to a complete or partial insensitivity to androgens, resulting in a failure of normal masculinization of the external genitalia in chromosomally male individuals.
Aims: We report a rare case of a patient with Morris syndrome, proven during late childhood, associated with acute myeloid leukemia. The described combination has not been previously reported in the literature.
Methods: A 41 year old phenotypically female patient was diagnosed in our department with acute myeloid leukemia with maturation, according to the WHO classification 2008. The diagnosis was established on the base of 56% blasts detected in peripheral blood and 74% blast population in the bone marrow samples. Cytochemical reaction for myeloperoxidase was positive. Multi color flow cytometric analysis of the bone marrow and peripheral blood blasts showed positivity for CD45, CD71, CD117; cyCD13 and cyMPO, while CD34 and CD15 were negative. Conventional cytogenetic analysis showed a male karyotype (46 XY), while molecular genetic tests revealed FLT3-ITD.
Results: A complete remission was achieved after a standard induction regimen, followed by consolidation and intensification therapy. Six months after the diagnosis the patient underwent a successful peripheral blood stem cell transplantation from a male sibling donor.
Summary / Conclusion: The described case is interesting on account of the combination between a rare genetic disorder and acute leukemia with molecular aberration.

B1302
CLINICAL RELEVANCE OF THROMBOSPONDIN RECEPTOR (CD36) EXPRESSION IN EGYPTIAN DE NOVO ADULT ACUTE MYELOID LEUKEMIA
M Salah-Eldin[1*], S El-Aziza[2], D Salem[2]
[1]Medical Oncology, Oncology Center, Mansoura University, [2]Department of Clinical Pathology, Faculty of Medicine, Mansoura, Egypt

Background: Acute myeloid leukemias (AMLs) are a heterogeneous group of disorders that often present with different morphological, immunophenotypic, and cytogenetic patterns. Identification of these characteristics may be useful for a better prognostic evaluation and for a more appropriate therapeutic approach. CD36 is a transmembrane, highly glycosylated, glycoprotein commonly expressed on blasts in acute monocytic leukemia, megakaryoblastic leukemia, and erythroleukemia.
Aims: We evaluated CD36 surface expression in 97 newly diagnosed AML patients, and the results were correlated with the morphology, immunophenotype, cytogenetic pattern, and clinical outcome.
Results: CD36 antigen was recorded in 48 of 97 patients (49.5%) and particularly in those with M5 and M6 FAB subtypes. Moreover, CD36 expression was significantly associated with the expression of CD11b (P=0.001) and CD14 (P=0.0001), unfavorable cytogenetic abnormalities (P=0.001), shorter overall survival (P> 0.0001), and leukemia-free survival (P=0.03).
Summary / Conclusion: On the basis of the results of the study, it can be concluded that CD36 expression in AML patients may identify a subgroup with a poor prognosis, and may thus be a valuable adjunct to be added to the current prognostic factors.

B1303
LEUKEMIC TRANSFORMATION OF MULTIPOTENT HEMATOPOIETIC PROGENITOR CELL WITH T(4;11)(Q21:Q23) , MLL-AF9 FUSION PRODUCT AND LINEAGE SWITCH FROM B ACUTE LYMPHOBLASTIC TO ACUTE MONOBLASTIC LEUKEMIA (AML
N Colovic[1*], A Vidovic[1], V Djordjevic[2], N Tosic[3], N Kraguljac[4], N Suvajdzic[1], I Djunic[4], M Virijevic[4], S Pavlovic[3], D Tomin[1]
[1]Medical Faculty University Belgrade, [2]Cytogenetic laboratory, Clinic of Hematology Clinical Center Serbia, [3]Institute of molecular genetics, [4]Clinic of Hematology Clinical Center Serbia, Belgrade, Serbia

Background: Aim of the study. A chromosomal translocation t(4;11)(q21:q23) is associated with an aggressive mixed-lineage leukemia. We present a patient with B acute lymphoblastic leukemia and t(4;11)(q21:q23) az the diagnosis who during evolution of the disease changed immunophenotype to acute monoblastic leukemia, AML M5.
Aims: We have analysed the clinical course and responses to treatment of this so called mixed lineage leukemias which are mostly associated with a poor prognosis and obviously urges the search for better treatment modalities.
Methods: The diagnosis of the disease was based on cytology, cytochemistry

and immunophenotypic analyses with flow cytometry and . Cytogenetic analysis.
Results: A 37-year-old male presented in April 2012. with thrombophlebitis of deep veins on both legs, malaise and loss in weight. Laboratory data: Hb 118 g/l, WBC 254x109/l (with 91% blasts in differential leukocyte formula), platelets 60x109/l. In bone marrow aspirate hypercellularity was found with 90% blasts , which were myeloperoxidase negative. Flowcytometry of the blast cells detected the following immunophenotype: (HLA-DR, CD38,Tdt,CD19, CD22,cCD79a,cIgM, CD15)+ and (CD10,CD24-). Cytogenetic analysis: 46,XY, t(4;11)(q21:q23)[2]/62-82,XY,t(4;11)[18]. Molecular analysis showed MLL-AF4 rearrangment. The patient was on LMWH and chemotherapy according to protocol hyperCVAD. On day 11 a myocardial infarction was diagnosed with AV block II range. After recovering and achiving myocardial ejection fraction above 60% bone marrow aspirate showed presence of 63% blasts but with cytomorphologic monocytoid appearance which on repeated flowcytometry expressed the following immunophenotype (CD33, Lysozime, CD11b, CD64, CD24, CD56)+. Minor population of B lymphoblasts(CD19, CD79a, CD64, cLizozim, CD56)+ was detected. The cytogenetic evolution was also found: 46XYt(4;11)(q21;q23)[19],/47XY,t(4;11)(q21;q23),+C[1]. Chemotherapy with HiDAC+Daunoblastin (Ara-C 2 x 6 g days1,3,5,7 and DA 100 mg day2,4,6)-was given. The bone marrow aplasia lasted 20 days during which developed febrility, hepatosplenomegaly with huge abssces in the upper pole of the spleen, bronchopneumonia, anuria, hypotension. Control bone marrow aspirate showed hypocelullarity without blasts but again 2 weeks later bone marrow aspirate contained 17% of blasts of monocytopid morphology. He was treated with purinethol, mitoxantrone and vepesid. At this time cutaneous leukemic nodular infiltrates appeared. Again after period of aplasia 24% of blasts remained in bone marrow. Very soon the number of WBC rose to 45x109/l and in spite of the therapy with purinetol he died 8.10.2012 , 4 months after clinical presentation.
Summary / Conclusion: Conclusion.Analysis of cytoplasmatic and surface cell markers of leukemic cells permitt classification most of the leukemias depending on lineage belonging and maturation stage. Lineage switch is a phenomenon when acute leukemia express markers for one lineage at the diagnosis and meets the opposite phenotypic criteria upon relapse. The fusion MLL-AF9 is associated more commonly with acute myeloid leukemia. Lineage switch is nowadays considered as mixed lineage leukemia which occurs in 6-9% of cases at relapse. This phenomenon may occur due to clonal selection because chemotherapy eradicates the dominant clone present at diagnosis and enabling the expansion of lineage different clone at relapse.

B1304
PROGNOSTIC SIGNIFICANCE RBC TRANSFUSIONS' VOLUME INFUSED DURING THE FIRST INDUCTION CHEMOTHERAPY TO PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA (AML)
B Davaasambuu[1*], S Gritsaev[1]
[1]Hematology, Russian Institute of hematology and Transfusiology, St.Petersburg, Russian Federation

Background: Long-term survival of patients with AML is dependent from different factors. R. Comrokji and co-authors [ASH 2011, Abstr. 3600] demonstrated the prognostic significance of 10 RBC transfusions during induction period on overall survival (OS).
Aims: The aim was to verify whether RBC transfusions are a potential predictor of OS.
Methods: A retrospective analysis of 38 patients' data treated with 7+3 scheme during the first induction chemotherapy was done.
Results: Median age of patients was 40.5 y. (17 – 61). Complete remission was verified in 24 patients (63.2%). The number of RBC transfusions was 3 – 20, median 7.5. There was no correlation between number of RBC transfusions and age of patients, and between number of RBC transfusions and variant of response to chemotherapy. The difference of OS was not statistical significance between the groups of patients received ≤7 RBC doses (n=21) and >7 RBC doses (n=17): 25.8 mo versus 9 mo; P=.334. But the difference of OS was significant when the borderline of RBC transfusions have been chosen like 10: 26.6 mo (n=27) versus 7.3 mo (n=11). The composition of 11 patients with the worst OS was very different. There were 4 patients with complete remission and 7 patients with no any kind of response after the first induction course of chemotherapy. According to ELN criteria there were 3 patients with good karyotype, 7 with intermediate karyotype, and 1 patient with poor karyotype.
Summary / Conclusion: The reason of poor outcome of patients with de novo AML received high number of RBC transfusions during the first induction course is not clear. We suppose 2 reasons at least. The first one is the biological phenotype of leukemic cells and its negative influence on recovery of hematopoesis in postinduction period. The second one is the injury of microenvironment that takes the active role in the progression of AML. Nevertheless we conclude that the patients transfused with more than 10 RBC doses during the first induction chemotherapy have to consider like potential candidates aggressive consolidation including to stem cell transplantation.

B1305
CONCOMITANT OCCURRENCE OF BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM AND ACUTE MYELOID LEUKAEMIA AFTER LENALIDOMIDE TREATMENT FOR DEL (5Q) MYELODYSPLASTIC SYNDROME: A COINCIDENCE OR MORE?
N Fracchiolla[1*], S Artuso[1], V Ferla[1], D Vincenti[1], A Iurlo[1], A Freyrie[1], M Colombi[1], A Cortelezzi[1]
[1]U.O.C. Ematologia/CTMO, IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milano, Italy

Background: Lenalidomide, a thalidomide analogue with multiple mechanisms of action implicated in cancer, including inhibition of angiogenesis, modulation of cytokines, induction of apoptosis, inhibition of growth and cell adhesion, increase of T cells and NK cells *via* stimulation of dendritic cells, has been approved in 2005 by FDA specifically for the treatment of 5q- syndrome, a subtype of myelodysplastic syndrome (MDS) characterized by a specific hematologic phenotype and low rate of progression into acute myeloid leukemia in comparison to other subtypes of MDS.
Aims: Describe the concomitant occurrence of blastic plasmacytoid dendritic cell neoplasm (BPDCN), a rare and highly aggressive lymphoma deriving from the clonal proliferation of precursors of plasmacytoid dendritic cells (pDC), and of acute myeloid leukaemia observed in a MDS 5q- patient who had been previously treated with lenalidomide.
Methods: Literature search for: mechanisms of action of lenalidomide and of resistance to it; mechanism of MDS transformation; AML and BPDCN pathogenesis.
Results: The main findings are the following: 1) Up to 20% of BPDCN are associated with or subsequently develop myeloid disorders: this fact could be explained by the hypothesis that malignant pDC cells and myeloid blast might have a common origin at an early stage of differentiation. 2) Lenalidomide increases the expression of the ARPC1B gene, that is both an activator and a substrate of aurora A: its depletion inhibits aurora A, which impairs the ability of mammalian cells to enter mitosis. Moreover, ARPC1B regulates the centrosome integrity and has been described as a regulator of cell cycle. Because overexpression of aurora A leads to polyploidy and chromosomal instability, the augmented expression of ARPC1B induced by lenalidomide may have a negative impact on the stability of 5q- patients remission. 3) The mechanism of MDS transformation is thought to be due to clonal expansion of an abnormal pluripotent stem cell. In fact, most of the patients, including ours, acquired new chromosomal aberrations in addition to the 5q-. In the specific case of 5q- MDS it has been speculated that lenalidomide, while suppressing an indolent clone, prolonging the disease free survival period, can potentially favour the selection of a more aggressive clone, subsequently evolving to acute leukaemia. 4) It has been shown that there is persistence of rare but distinct stem cells harbouring the 5q- in patients even in complete remission after lenalidomide treatment. These cells provide a reasonable explanation both for relapses and clinical and cytogenetic progression. Actually, both the propensity toward clonal evolution and transformation of these persistent MDS stem cells and the role of lenalidomide in this process (inhibiting or accelerating it), are unknown.
Summary / Conclusion: It is possible that our patient presented cells resistant to lenalidomide that continued to expand slowly during treatment with lenalidomide, even when the patient appeared to be in complete cytogenetic remission, and that constituted the basis for AML progression. Lenalidomide, through induction of ARPC1B gene, may have contributed to this process; moreover, for its known stimulatory effects on dendritic cells, it may have triggered the expansion of malignant pDC from the common clone they share with myeloid blasts.

B1306
THE USE OF AZACITIDINE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA UNFIT FOR INTENSIVE TREATMENT OR RESISTANT TO CHEMOTHERAPY
M Alpoim[1*], R Pinto[1], P Gomes[1], M Amorim[1], A Carneiro[1], F Príncipe[1], J Guimarães[1]
[1]Serviço de Hematologia Clinica, Centro Hospitalar de São João, Porto, Portugal

Background: The effectiveness of hypomethylating agents for treatment of high risk myelodysplastic syndromes has raised the question of its potential use in acute myeloid leukemia (AML) patients unfit to receive intensive chemotherapy or with relapsed/refractory disease.
Aims: To analyse the use of azacitidine in patients with acute myeloid leukemia unfit for intensive treatment or resistant to chemotherapy
Methods: Herein, we retrospectively analyzed the outcomes of a series of 15 AML patients treated with 5-Azacitidine in a single centre, between 2009 and 2012.
Results: The median age was 64 (range, 45-76). Five patients (33.3%) received 5-Azacitidine as first-line treatment. Seven (46.7%) medically unfit for intensive chemotherapy or 8 (53.3%) relapsed/refractory patients were given a 7-day regimen of 5-Azacitidine every 28 days. A median of 4 (range 1-15) Azacitidine cycles were given to each patient. Cytogenetic risk was intermediate in 7 (46.7%) and poor in 8 (53.3%) patients. Of 10 patients with evaluable

FLT3 and NPM1 mutations, 1 (6.7%) patient had isolated FLT3-ITD, 1 (6.7%) patient had isolated NPM1 mutation, and 8 (53.3%) patients had no FLT3 and/or NPM1 mutations. Six (40%) patients presented with more than 30% of blasts before initiating treatment. The median overall survival (OS) of this cohort was 12 months. The overall response rate was 40% (6 of 15 patients), and included 2 (13.3%) complete remissions, 2 (13.3%) partial responses (less than 20% blasts) and 2 (13.3%) patients had any kind of hematological improvement. The best cumulative response was seen at a median of 4 cycles (range, 2-8). The median number of blasts at diagnosis and post-treatment was 50% (range: 30-90) and 17.5% (range: 2-60), respectively. The median OS for patients who achieved a response was 18 months versus 4 months for non-responders (P=.029). Of note, it was observed a response in two (13.3%) patients with pre-treatment relapsed/refractory AML: one patient achieved complete remission (< 5% blasts) and other patient showed a reduction in the number of blasts to 12% (evaluated at the 4th cycle of 5-Azacitidine). No significant differences were found for OS with regard to age, cytogenetics, number of pre-treatment blasts and "de novo" versus relapsed/refractory AML. During treatment, five patients (33.3%) presented adverse events: the most common was febrile neutropenia, observed in 3 (20%) patients. Two (13.3%) of these patients required hospitalization due to febrile neutropenia. None of the remaining 13 (86.7%) patients needed to be admitted in hospital throughout 5-Azacitidine treatment.

Summary / Conclusion: In conclusion, our analysis demonstrates that 5-Azacitidine is generally well tolerated by patients unfit for intensive chemotherapy. Although our series is small, it was possible to observe an anti-leukemic activity of 5-Azacitidine in a significant number of poor prognosis patients.

B1307

MULTIPLE INVOLVED SITES OF EXTRAMEDULLARY MEGAKARYOBLASTIC LEUKEMIA IN A CHILD

S Aytac[1*], B Tavil[1], D Orhan[2,2], F Gumruk[1], M Cetin[1]
[1]Pediatric Hematology, Hacettepe University , Ankara, [2]pediatric pathology, Hacettepe University , ankara, Turkey

Background: Extramedullary acute megakaryoblastic leukemia is a rare entity. To our knowledge there are 10 pediatric case report in the literature.These patients tend to be younger than 2 years of age and accompanying lytic bone lesions can be seen. Bone marrow involvement was noted at the time of diagnosis in all these case reports except one. Literature review revealed multiple sites of bone infiltration and bone + skin involvement however here we report a patient with multiple sites of infiltration (iris,orbita,gingiva, maxilla, skin, testis) without a prominent bone lesion and bone marrow involvement.

Aims: Diagnosis of the extramedullary presentation of acute megakaryoblastic leukemia is somehow challenging. Atypic morphology of megakaryoblasts outside the bone marrow and sometimes similar morphological features with small blue cell tumors may cause confusion. However, immunohistochemical analysis(CD41, CD61) detection of t(1:22) which is characteristic among infants with AML-M7 may help in diagnosis.We aimed to present our unique case.

Results: Case: A 8- month- old boy was admitted to our hospital for a swollen, red left eye. His symptoms began 2 days prior and his mother recognised painless nodularity on his forehead and eyebrow beginning with an erythematous papul 6 days ago. He was treated with an antibiotic treatment with the initial diagnosis of preseptal cellulitis. An orbital MRI was not compatible with preseptal cellulitis however a mass with a 1x2x1 cm in diameter exhibit homogeneous contrast enhancement and another mass with a 3x2x2 cm in diameter which was invaded the right maxillary sinus and obliterated right pterygopalatine fossa were detected. His past medical history revealed intermittently appearing skin lesions localised on the lower extremities for 4 months and a skin biopsy detect atypical T lymphocyte infiltration at the local hospital. Physical examination showed mild gingival hypertrophy, multiple painless nodules on his extremities, skulp, left eyebrow and forehead. Laboratory examination revealed Hb:12.9 g/dl, Htc:39.3 %, MCV:71.6 fl, WBC: $9x10^{-9}$/l Plt: $594x10^{-9}$/l peripheral smear showed 65% lymphocyte, 25% PMNL, 10% inmature lymphocyte with an hypochromic microcytic erythrocyte morphology. Orbital examination under general anestesia showed a stromal infiltration of the iris which may suggest a leukemic infiltration.Bone marow aspiration, biopsy and flowcytometry did not confirm leukemic infiltration. Incisional biopsy of the maxillary mass was suggestive of neoplastic infiltration of megakaryoblasts with different maturation stages and stromal fibrosis(immunohistochemically CD61, CD68, CD31, CD43 and Factor 8 were positive , MPO, Tdt, CD20, CD3 and CD117 were negative).Cytogenetic studies and FISH were normal. During his follow up scrotal enlargement and nodularity was detected and excision of these nodules again showed a megakaryoblastic infiltration. AML-BFM 2004 protocol was given and after receiving chemotherapy skin and testicular lesions disappear.

Summary / Conclusion: Our previous experince with the extramedullary infiltration showed that 40% of pediatric AML had EMI at the time of diagnosis and 27% demonstrated multiple involved sites wheras 73% had single site involvement and EMI was detected in children with all subtypes of AML except in patients with AML-M7. Therefore, this patient is unique for us who had the unusual presentation of multiple involved sites with no peripheral and bone marrow abnormalities.

Chronic lymphocytic leukemia and related disorders – Biology

STUDY OF ANGIOGENESIS ON LYMPH NODES OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

S Sachanas[1*], G Levidou[2], M Angelopoulou[3], M Moschogiannis[4], X Yiakoumis[1], T Vassilakopoulos[3], C Calpadakis[5], M Kyrtsonis[3], F Kontopidou[3], A Dimitrakopoulou[2], P Tsirkinidis[1], S Kokoris[3], H Papadaki[5], P Panayiotidis[3], K Nikolaos[2], E Patsouris[2], K Pinelopi[2], G Pangalis[3]
[1]Hematology, Athens Medical Center, Phychikon Branch, [2]Pathology, [3]Hematology, University of Athens, [4]Hematology, Athens Medical Center, Athens, [5]Hematology, University of Crete, Iraklion, Greece

Background: An increasing body of evidence support the hypothesis that angiogenesis plays an important role in the leukemogenic process in CLL. Among angiogenic factors VEGF has a key-role in promoting tumor angiogenesis.There are only a few reports with small series of patients on the evaluation of angiogenesis on lymph nodes of CLL patients.

Aims: To evaluate the angiogenic status including the measurement of microvessel characteristics and VEGF expression in lymph nodes and other tissues apart from bone marrow specimen of Chronic Lymphocytic Leukemia (CLL) patients and correlate it with clinical and laboratory parameters as well as with patients' survival.

Methods: Sixty-two patients fulfilling the diagnostic criteria of CLL-SLL were enrolled in this study. The specimen analysed was lymph node in 57 cases and spleen in 5 . This analysis was performed in formalin-fixed, paraffin-embedded tissue. Microvessel characteristics were evaluated using CD31 staining and parameters regarding microvessel caliber (area, perimeter, Feret diameter and major and minor axis length), microvessel shape (shape factor and compactness) and the extent of microvascular network [total vascular area (TVA) and microvascular density (MVD)] were assessed in the region of most intense vascularization using image analysis software. VEGF assessment was obtained separately in the proliferation centers (PCs) and in the non proliferation areas (nPC) using proper antibody. A Histo-score (H-score) based on the percentage of stained neoplastic cells multiplied by staining intensity was calculated. Moreover, the extent of vascularization within and outside the PCs was assessed manually.

Results: Median patients' age was 58 years (36-78) with male predominance. Thirty-seven (60%) had disease stage A while 17(27%) and 8(13%) had B and C respectively. Seventeen patients presented with splenomegaly, 7(11%) with bulky lymphadenopathy and 6 (10%) with B-symptoms. Eighteen patients had elevated LDH. 29 and 25 out of 50 patients presented with CD38 and ZAP-70 positivity respectively. VEGF expression in the PCs ranged from 0,5 to 70% (H-score 0,75-285)with a median value of 25% (H-score 30) and was significantly higher from that observed in the non-PC areas (range 0-90%, median 20%, H-score 20-200, p value <0.0001). Non-PC areas showed higher extent of vascularisation compared to PCs in 55,6% of the examined cases, which also displayed higher major and minor axis length (P=0.0128 and P=0.0253), as well as higher vascular area(P=0.0119) and perimeter (P=0.0383).Those cases that displayed higher VEGF in the PCs showed also lower MVD (P=0.0345), TVA (P=0.0257) and vascular shape factor (P=0.0431). Moreover, VEGF expression in the PCs was negatively correlated with TVA and MVD (r=-0.03536, P=0.0344 and r=-0.02992 and P=0.0762 respectively). VEGF expression within and outside the PCs was not correlated with any of the patients' clinical parameters. Finally, higher VEGF H-score in the PCs (>90) was correlated with increased time to relapse (median time 100.3 months) when compared to decreased VEGF H-score (median time 39.3 months).

Summary / Conclusion: This is the largest study concerning the assessment of angiogenesis in lymph node of CLL patients. VEGF expression is higher in the PCs compared to the non-PC areas CLL lymph nodes are not uniformly vascularized Lower VEGF expression in the PCs associated with shorter time to relapse.

B1309

UBLITUXIMAB (TG-1101), A NOVEL ANTI-CD20 MONOCLONAL ANTIBODY, DISPLAYS MARKED IN VITRO ACTIVITY IN LOW-CD20 EXPRESSING TUMORS

H Miskin[1*], P Sportelli[1], A Bellon[2], F Brune[2], A Sadoun[2], O O'Connor[3]
[1]TG Therapeutics, Inc., New York, United States, [2]LFB Biotechnologies, Les Ulis, France, [3]Columbia University Medical Center, New York, United States

Background: In contrast to normal B-lymphocytes, malignant B cells in CLL patients (pts) generally express low CD20 levels on their cell surface. Rituximab (RTX) has shown limited activity in CLL pts as a single agent, often attributed to low CD20 expression. Importantly, RTX exposed pts have also exhibited B cells with decreased CD20 levels. Ublituximab (UTX) is a novel, chimeric mAb targeting a unique epitope on the CD20 antigen. UTX has been glycoengineered to enhance affinity for all variants of FcγRIIIa receptors, demonstrating

greater ADCC activity against NHL/CLL cell lines compared to RTX and ofatumumab (OFA), an anti-CD20 mAb optimized for high CDC activity. UTX has displayed single agent activity in a Phase I trial in Rel/Ref CLL pts (ORR=45%).
Aims: Herein, we analyzed the CDC and ADCC activity of UTX vs. OFA and RTX in cell lines exhibiting varying levels of CD20.
Methods: CD20 expression/binding were quantified in MEC-1, SUDHL-8, Raji, JY E5.1 and patient CLL cells by flow cytometry. C1q-dependent-CDC triggered by OFA, RTX and UTX was determined. ADCC in various cell lines was observed after incubation with mAbs at various concentrations in the presence of PBMCs.
Results: Higher CDC activity was observed for OFA vs. UTX and RTX on several cell lines expressing high CD20 levels (MEC-1 cells: 90% cell-lysis by OFA vs 60% by UTX). In contrast, CDC activity against low CD20 cells was significantly lower and almost identical with all three mAbs (≤5%). UTX was shown to mediate higher ADCC than OFA and RTX against all cell lines (MEC-1 cells: 55% UTX lysis vs <30% RTX or OFA lysis; Raji cells: UTX EC_{50}= 0.93 ng/ml vs RTX EC_{50}=14.20 ng/ml). Importantly, UTX consistently mediated potent ADCC against low CD20 cells, whereas OFA and RTX ADCC activity was diminished (SUDHL-8 cells: 20% UTX lysis vs <10% RTX or OFA lysis; B-CLL cells: UTX EC_{50}= 5.0 ng/ml vs RTX EC_{50}=125.0 ng/ml).
Summary / Conclusion: While CDC activity of OFA was diminished in low-CD20 cells, ADCC activity of UTX was robust in cells with low and high CD20 expression. Results support the potential therapeutic use of UTX in hematologic malignancies with low CD20 expression such as CLL, Marginal Zone lymphoma, and other lymphoma subtypes in addition to RTX or OFA Rel/Ref pts.

PHOSPHORYLATION OF ROR1 RECEPTOR TYROSINE KINASE AT TYROSINE 641, 646 AND SERINE 652 RESIDUES: THE IMPACT ON THE SURVIVAL OF LEUKEMIC CELLS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Hojjat-Farsangi[1*], A Daneshmanesh[1], M Norin[2], A Khan[1], A Moshfegh[1], A Osterborg[1], H Mellstedt[1]
[1]Oncology-Pathology, Karolinska Institute, [2]Kancera AB, Karolinska Institute Sciences park, Stockholm, Sweden

Background: Receptor tyrosine kinases (RTK) are important for different cellular processes as cell proliferation and survival, as well as for the malignant transformation of many types of cancer. ROR1, as a member of RTK families, has shown to be overexpressed in chronic lymphocytic leukemia (CLL), mantle cell lymphoma and other hematological malignancies. ROR1 inhibition in CLL leukemic cells induced apoptosis of the cells. In this study, we studied the effects of an anti-ROR1 mAb for specific dephosphorylation at the tyrosine kinase domain of ROR1 in CLL cells.
Aims: To investigate phosphorylation of tyrosine and serine residues, within the kinase domain of ROR1, of importance for survival of CLL cells.
Methods: Bioinformatic analysis of the ROR1 structure revealed that three amino acid residues in the tyrosine kinase domain might be critically phosphorylated. Based on this prediction, a 19 amino acid long peptide, phosphorylated at two tyrosine (tyrosine $_{641, 646}$) and one serine (serine $_{652}$) residues was designed and used for immunization of rabbits. An anti-phospho-ROR1 (pROR1) polyclonal antibody (pAb) was purified, using phospho-peptide affinity chromatography. The specificity of anti-pROR1 pAb was determined by ELISA, immunoprecipitation (IP) and western blot experiments. An anti-ROR1 mAb (IgG) (CRD 1D8 clone) was used to investigate the effects on ROR1 phosphorylation in CLL cells at tyrosine $_{641, 646}$ and serine $_{652}$ residues preceding apoptosis. ROR1 phosphorylation was investigated by western blot and IP of ROR1 probed with anti-pROR1 pAb, from untreated and CLL cells treated with the anti-CRD 1D8 mAb. Quantitative intracellular staining of ROR1 by flowcytometry in time kinetics experiment after treatment with anti-CRD 1D8 mAb was also used to check phosphorylation of ROR1. Annexin V/PI staining (flowcytometry), MTT assay, PARP and caspase 8 cleavage as well as MCL-1 protein (western blot) were used for detection of apoptosis. To investigate phosphorylation and localization of 64-130 kDa ROR1 isoforms in various compartments of CLL cells, lysates were prepared from the nucleus and cytoplasmic proteins of CLL cells.
Results: Two tyrosine (641, 646) residues and one serine (652) residue of the tyrosine kinase domain were phosphorylated in CLL cells. As previously described (Mellstedt et al, Abstract No: 1771, 53th ASH annals meeting, 2011), the 64, 105 and 130 kDa ROR1 isoforms were shown to be constitutively phosphorylated at tyrosine and serine residues in CLL leukemic cells. Treatment of CLL cells with an anti-ROR1 mAb against the CRD domain induced rapid dephosphorylation of ROR1 at tyrosine $_{641, 646}$ and serine $_{652}$ residues within 20 min and gradually increased up to 4 hours. The phosphorylated 64 kDa ROR1 isoform was localized to the nucleus of CLL cells and probably represents an intracellular part of ROR1, while the ROR1 130 kDa isoform was presented both in cytoplasm and nucleus of CLL cells.
Summary / Conclusion: Our data show that the ROR1 molecule is phosphorylated at tyrosine $_{641, 646}$ and serine $_{652}$ residues. The presence of 64 and 130 kDa ROR1 isoforms in the nucleus of CLL cells may suggest a role of these isoforms as transcription factors. Collectively, the data might suggest that phosphorylated ROR1 may be an important protein for the growth of CLL cells as well as an interesting structure to target in a therapeutic intervention.

B1311

THE REPERTOIRE OF HEAVY CHAIN IMMUNOGLOBULIN GENES IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA IN UKRAINE AND RUSSIA

B Biderman[1*], N Bilous[2], I Abramenko[2], A Chumak[2], E Nikitin[3], A Sudarikov[1]
[1]Department of Molecular Hematology, National Hematology Center, Moscow, Russian Federation, [2]Clinical Immunology Department, National Research Center for Radiation Medicine, Kiev, Ukraine, [3]Outpatient department, National Hematology Center, Moscow, Russian Federation

Background: Mutation status of the heavy chain variable region genes (IgVH) is known as an important factor in long-term prognosis in B-cell chronic lymphocytic leukemia (B-CLL). A more detailed study of IgVH genes led to the discovery of stereotyped antigen receptors (SARs) which carry highly similar or almost identical amino acid sequences. Narrowing of the repertoire of IgVH genes in CLL and SARs indicate that influence of antigen (at least in some cases) occurs during the development of the disease. SARs have been reported previously to represent 20 to 30% of all B-CLL cases in different regions. Here we present the data concerning SARs repertoires in CLL patients from eastern slavic countries.
Aims: To measure and compare repertoire of IgVH genes in representative sample of B-CLL cases from Ukraine and Russia.
Methods: DNAs were PCR amplified in 6 separated reactions using primers specific for VH-families, and a consensus JH primer [Campbell et al. 1992] or primer sets recommended by the BIOMED-2 [van Dongen et al. 2003]. PCR products were sequenced using family-specific primers and Big Dye Terminator v3.1 kit (Applied Biosystems). Sequences were analyzed with IMGT/V-QUEST (http://www.imgt.org/IMGT_vquest/vquest). 98% homology cut-off was used to discriminate between mutated and unmutated cases.
Results: Study included 564 Russian and 390 Ukrainian patients with B-CLL. Among Russian patients 350 (62%) were without mutations and 214 (38%) with mutations. In the Ukrainian cohort 260 (66.7%) patients were with unmutated VH-genes and 130 (33.3%) with mutated. There is almost identical VH-, D-, JH-gene usage in B-CLL patients from Russia and Ukraine. Stereotyped receptors found in 20% and 27% of Russian and Ukrainian B-CLL cases respectively. Most prevalent in both countries were$_{7,6}$, 3 and 1 subsets according to published classification [Tobin et al. 2004, Stamatopoulos et al.2007]. VH1-69 gene is found in 19-21% of all cases of B-CLL, and almost always (95%) in unmutated cases. This may explain the predominance of$_{7}$, 6 and 3 SARs subsets compared with European countries. VH3-21 typical for Nordic countries occurs in Russia and Ukraine less frequently (about 5%). Accordingly, SARs subset 2 is also infrequent.
Summary / Conclusion: The main features of the repertoire of the immunoglobulin heavy chain genes in the Russian and Ukrainian patients are almost the same. Compared to western Europe higher occurrence of VH1-69 and SARs subsets$_{7}$, 6 and 3 has been detected.

B1312

THE HDAC INHIBITOR TRICHOSTATIN A INDUCES EFFECTIVE CELL KILL IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL).

L Peiffer[1*], H Flamme[1], S Poll-Wolbeck[1], M Hallek[1], K Kreuzer[1]
[1]Department I of Internal Medicine | University at Cologne, 50937 Cologne, Germany

Background: Chronic lymphocytic leukemia is characterized by an accumulation of mature, functionally incompetent B cells. In CLL B cells the WNT pathway is constitutionally active with upregulated levels of LEF 1. Proteins bind to the frizzled receptor, the pathway is activated, β-catenin can translocate to the nucleus and start the transcription of effector proteins by activation of the transcription factor LEF 1. For the inactive state of the WNT pathway, a multiprotein complex is formed to phosphorylate β-catenin, which is further ubiquitinated and degraded. This multiprotein complex is formed by APC, AXIN 1 (acting as a scaffold protein), GSK3β (a kinase) and the pre-kinase CK Iα.
Aims: The aim of this study is to find and discribe WNT modifying drugs for experimental CLL therapy.
Methods: In order to examine the functionality of the WNT cascade we tested a compound library containing 75 substances. Divided in activators and inhibitors the substances have different targets along the pathway. Testing of the library was performed via ATP assay on CLL cells, PBMCs and healthy B cells extracted from human peripheral blood. Survival analysis on effective substances was performed via FACS analysis with Annexin/PI staining.
Results: The ATP assay revealed several substances that selectively affect CLL cells. A positive survival effect was seen for QS 11, an inhibitor targeting ARF-GAP1, which showed a survival advantage of up to 150% at 10 µM. The most selective effects on CLL cell viability were achieved by the NO-donators NO-ASA, JS-K and the HDAC inhibitor Trichostatin A. The NO-donator NO-ASA resulted in an IC50 of$_{6}$,7 µM (n=17) on CLL cells and 47,25 µM (n=9) on healthy PBMCs after 24h. Via FACS survival analysis the NO-donator JS-K leaded to CLL cell death with an IC50 of$_{3}$,58 µM (n=5) after 24h and$_{2}$,87 µM (n=5) after 48h compared to healthy PBMCs with an IC50 of 18,03 µM (n=3) after 24h and$_{8}$,1 µM (n=3) after 48h. The HDAC inhibitor Trichostatin A showed a stronger effect compared to JS-K. Whereas JS-K showed a high potency after 24h, Trichostatin had its maximum after 48h. Here we saw via FACS analysis an IC50 of 166,7 µM (n=4) after 24h and 157,4 nM (n=5) after 48h on CLL cells compared to an IC50 of$_{4}$,21

mM (n=3) on PBMCs after 24h and 145 μM (n=3) after 48h.
Summary / Conclusion: Besides the know targets of the WNT pathway three substances with a slight link to the WNT pathway showed interesting results. As we saw NO donators show a potent effect on CLL. But comparing results of CLL cells and PBMCs Trichostatin A showed the most selective effect on CLL cells while not harming the healthy PBMCs or B cells.

B1313

REDUCED EXPRESSION OF TOLL-LIKE RECEPTOR 4 IN B-CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH AUTOIMMUNE COMPLICATIONS

W Barcellini[1*], B Fattizzo[1], F Imperiali[1], A Zaninoni[1], S Lonati[2], G Reda[1], A Cortelezzi[2]
[1]U.O. Ematologia e Centro Trapianti di Midollo, [2]U.O. Ematologia e Centro Trapianti di Midollo e Università degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: B-chronic lymphocytic leukemia (B-CLL) is characterized by the accumulation of mature-like monoclonal B lymphocytes, defective apoptosis, progressive hypogammaglobulinemia with immunodeficiency, and high prevalence of autoimmune phenomena.Toll-like receptors (TLRs) are a pattern of type I integral membrane glycoproteins expressed on cells of the immune system and represent major agents of innate immunity and initiators of adaptive immunity.
Aims: To evaluate TLR4 and TLR9 genes and protein expression in B-lymphocytes from B-CLL patients, and its relationship with stage, therapy, and known prognostic markers (IgVH region mutational status, cytogenetic alterations, CD38 and ZAP70). Further aim was to correlate TLR4 and 9 expression with infections, autoimmunity and disease progression.

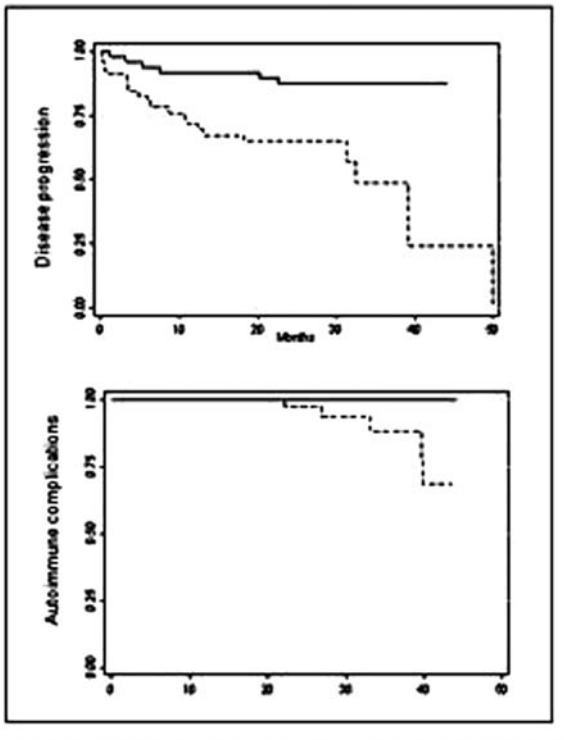

Figure 1 - Disease progression (upper panel) and occurrence of autoimmune complications (lower panel) in patients with TLR4 gene expression higher/equal (continuous line) and lower (dotted line) than the median value, estimated by Kaplan-Meier method.

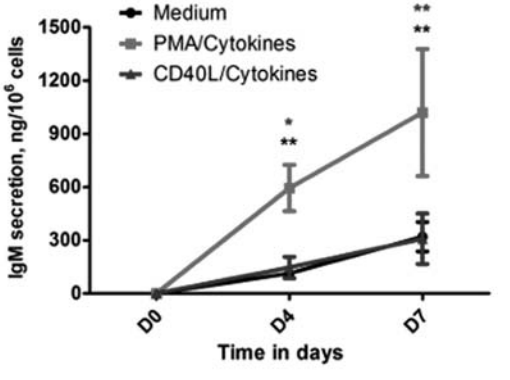
Methods: TLR4 and TLR9 gene expression was evaluated in total RNA of B cell from 95 B-CLL patients and controls (pool of 10 healthy donors) by TaqMan® Gene Expression Assays on the model 7300 real-time PCR system (Applied BioSystems-Life Technology, Foster City, CA, USA). The results of relative quantitation (RQ) assays were analyzed using SDS Software (Applied BioSystems-Life Technology). Surface TLR4 and TLR9 expression on B-lyphocytes was determined by standard flow cytometry. TLR4 expression was evaluated in cultured B cells, obtained with RosetteSep (purity >97%) either unstimulated or stimulated with 1mg/mL lypopolysaccharide (LPS). Culture supernatants were assayed for IL-10 and TGF-β production using commercially available ELISA kits.
Results: Patients (41 females and 56 males, median age 74 years, range 41-89) were 78.9% in Binet stage A, 11.6% in B, and 9.5% in C and were followed for a median of 27.6 months, range 19-44. Quantitative real-time PCR revealed that TLR4 gene expression was decreased (RQ=16.1±1.56) and TLR9 increased (RQ=2725±165) in all B-CLL patients versus controls (RQ=100). Consistently, the percentage of CD19+ cells expressing TLR4 by cytofluorimetric analysis was lower (1.70±0.2% versus 3.93±0.68%, P=0.004) and TLR9 greater (5.5±0.6% versus 1.39±0.31%, P=0.04) in patients compared to controls. TLR4 reduction was more pronounced in advanced and multi-treated disease, and in patients with unmutated IgVH status and unfavorable cytogenetic abnormalities. Univariate Cox regression model showed that patients with reduced TLR4 gene expression had an increased risk of disease progression (HR 4.6, 95% CI 1.8-11.6; P=0.001) (Figure1, upper panel), suggesting that an impaired innate immunity identifies a subset of B-CLL patients with poor prognosis. Interestingly, patients with reduced TLR4 gene expression had an increased risk to develop autoimmune complications (P=0.02) (Figure1, lower panel). Finally, TGF-β production by B cells was increased in patients who thereafter developed autoimmune complications, compared with those that did not (1092±158 versus 793±18 pg/mL, mean±SE, P=0.07).
Summary / Conclusion: Reduced expression of TLR4 in B-CLL patients correlates with an advanced and multi-treated disease and is a risk factor for disease progression and development of autoimmune complications. Moreover, B-lymphocytes from patients with autoimmunity produced high levels of TGF-β. These findings suggest that interactions between the B cell receptor and TLRs signaling, and an abnormal cytokine pattern play a critical role in the maintenance of self-tolerance.

B1314

IMMUNE CO-STIMULATION (BY CD40L) IS NOT SUFFICIENT TO INDUCE DIFFERENTIATION OF CLL B-CELLS INTO IMMUNOGLOBULIN SECRETING CELLS

H GHAMLOUCH[1*], H OULED-HADDOU[1], A GUYART[1], A REGNIER[1], S TRUDEL[2], B ROYER[3], B GUBLER[2], J MAROLLEAU[3]
[1]Immunology, [2]Molecular oncobiology, [3]Hematology and Cell Therapy, CHU Amiens - EA4666, Amiens, France

Background: B cell chronic lymphocytic leukemia (B-CLL) is a monoclonal proliferation of CD5+ B lymphocytes blocked at a stage of differentiation. However, the normal counterpart from which these cells evolve is still not identified. Gene expression profiling and IGVH genes mutation status relate B-CLL cells to memory B cells or to pre-germinal center B cells. In vitro, memory B cells differentiate into plasma cell in CD40L differentiation system. Efficiency of this system has not been studied on CLL B-cells. Previous study has shown that phorbol myristate acetate (PMA) induces activation and differentiation of CLL B-cells into Immunoglobulin secreting cells (ISC), however this differentiation is not well characterized.
Aims: Thereby, in this study we have tried to answer three questions, the first, how CLL B-cells behave following CD40L differentiation model? The second, is antigenic stimulation necessary for the differentiation of CLL B-cells into ISC? And the third, what can behaviour of differentiated CLL B-cells teach us about their normal counterpart?
Methods: Therefore, CD19+ CD5+ CD38- B lymphocytes of 13 patients with A-stage CLL were purified with a purity >98%, and then activated in vitro with PMA or CD40L in the presence of a mixture of cytokines for four days. Cells were washed and incubate in the presence of a second combination of cytokines for three days. Morphological, phenotypic and molecular changes were examined after 7 days of culture.



Results: Both stimulations resulted in dramatic phenotypic and molecular changes in CLL B-cells. Surface expression of CD19, CD20, CD5, CD27 and CD45 decreased whereas the expression of IgM, HLA-DR and CD25 increased. Unexpectedly, CD38 surface expression and mRNA was induced in only 40% of cases. We also observed that the expression of CD138 mRNA was induced in some cases. Transcriptions factors studied by quantitative RT-PCR showed that immunophenotypical changes involved a decrease in the expression of B cell transcription factor PAX5, LEF1, BACH2, IRF8 and an increase

in the expression of plasma cell markers BLIMP1, IRF4, XBP1s and ERN1. Changes in transcription factor profile were confirmed by western blot. Importantly, Gas6, BATF and AID transcriptional expression were induced. Furthermore, we also observed that stimulated cells displayed proliferation and prolonged survival in culture. However, the difference between PMA and CD40L stimuli was more evident at two levels, cell morphology and IgM secretion. Our data show that only CLL B-cells stimulated by PMA can differentiate into ISC. IgM secretion levels were highly significant in PMA differentiated cells while IgM levels in CD40L treated cells were comparable to control condition. Morphologically, PMA differentiated cells developed plasmacytoid/plasma cell morphology with an eccentric nucleus and a developed cytoplasm whereas CD40L treated cells resembled to that of activated lymphocytes.

Summary / Conclusion: All these results strongly suggest that CLL B-cells can be driven to a more mature stage and that antigenic signals are critical for ISC differentiation of these cells. Describing events and behaviour of malignant B cells differentiation may be relevant for understanding the biology of B-cell malignancies. Based on our data we speculate that memory B-cells cannot be a normal counterpart of B-CLL.

B1315

IMMUNOGLOBULIN GENE REARRANGEMENTS IN ASIAN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Marinelli[1*], I Del Giudice[1], C Ilari[1], I Della Starza[1], S Bonina[1], Y Kwong[2], T Chan[2], K Wong[3], A Guarini[1], E Tse[2], R Foà[1]

[1]Department of Cellular Biothecnology and Hematology, Sapienza University, Rome, Italy, [2]Department of Medicine, Queen Mary Hospital, Hong Kong University, [3]Department of Pathology, Queen Elizabeth Hospital, Hong Kong, Hong Kong

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in the Western world, with 4 new cases x 100,000 individuals per year. In Asia this figure is 5-10 times lower and does not change in Asian residents in the US and their descendants. The underlying environmental and genetic bases remain obscure. Limited data on Asian CLL seem to confirm the prognostic impact of conventional biologic markers, while suggesting a different distribution of immunoglobulin heavy chain variable (IGHV) gene families in comparison with Western CLL.

Aims: To characterize IGHV-D-J rearrangements of a series of Asian CLL and compare them with those in Caucasian CLL, focusing on gene family usage and stereotype of the HCDR3 region.

Methods: A cohort of 77 untreated CLL patients fromHong Kong has been analyzed. There were 57 men and 20 women, with a median age of63 years (range: 43–94). Forty-five cases were in Binet stage A (58.4%), 17 in stage B (22.1%) and 15 in stage C (19.5%). IGHV-D-J gene rearrangements were sequenced and analyzed by the IMGT database (http://imgt.cines.fr). We evaluated: IGHV mutational status; IGHV-D-J gene usage; HCDR3 length and composition analyzed by the Clustal X software (http://www.clustal.org). The published series by Agathangelidis A. et al (Blood 2012) on Caucasian CLL was used as control.

Results: Of 77 Asian CLL patients, 32.5% and 67.5% harbored unmutated and mutated IGHV genes, respectively. The most frequent IGHV families were: IGHV3 (53.2%), IGHV4 (22.1%), IGHV1 (14.3%), IGHV5 (6.5%), IGHV2, IGHV6, and IGHV7 (1.3% each). The most frequent IGHV genes were V3-7 (15.6%), V1-69 (7.8%), V5-51 (6.5%), V4-34 (6.5%), V3-74 (6.5%), V4-39 (5.2%), whilst V3-21 was very low (2.6%). Compared with Caucasian CLL the frequency of V3-7 (P=0.0015), V3-74 (P=0.013), V5-51 (P=0.019) appeared to be significantly higher. This different distribution does not seem related to the higher proportion of mutated cases among Asians, as shown by a dedicated analysis (V3-7, P=0.022; V5-51, P=0.001). Overall, the most frequent IGHV genes employed by Caucasian CLL (V1-69, V4-34, V3-23, V3-33, V3-7, V4-39, V3-30, V1-2, V3-48, V3-21), accounting for 62% of the total, are significantly less represented (37/77, 48%, P=0.01) in Asian CLL. IGHD genes were identified in 76/77 sequences. Among them, the IGHD3 (42.1%) was the most frequent followed by IGHD6 (19.7%), IGHD2 (11.8%), IGHD1 (11.8%), IGHD4 (9.2%), IGHD5 and IGHD7 (2.6% each), at variance from the frequency shown by Caucasian CLL i.e. IGHD3>IGHD2>IGHD6>IGHD5>IGHD1>IGHD4>IGHD7. Among IGHD genes, D3-10 (13.0%) and D3-22 (13.0%) were the most recurrent. D5-18, displayed by 3/77 (4%) Asian CLL, was never found among Caucasian cases (P=0.0001). No difference was found in IGHJ families. Only 2.6% of Asian CLL carried known stereotyped receptors (subset #59, subset #77) and no new subset has been identified so far.

Summary / Conclusion: Our data suggest a different frequency in IGHV and IGHD gene usage in Asian CLL: IGHV4 genes were more represented than IGHV1, although the frequency of V1-69 was similar.In addition, the frequenciesof V3-7, V3-74, V5-51 genes werehigher than in Caucasian CLL. By extending this study to other collaborators in China, it will be possible to corroborate this distinctive pattern, evaluate the frequency of known subsets and identify potential new subsets among Asian CLL. Overall, these results may ultimately translate into pathogenetic hypotheses on Asian CLL.

B1316

ABERRANT EXPRESSION OF TOLL-LIKE RECEPTORS HIGHLIGHTS IMMUNE DEREGULATION WITH SERIOUS CLINICAL CONSEQUENCES IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

K Giannopoulos[1,2*], M Zajac[1], P Wlasiuk[1], W Tomczak[2], K Skorka[1], M Osiak[3], N Pajak[3], A Piechnik[1], J Zaleska[1], M Grzywnowicz[1]

[1]Experimental Hematooncology Department, [2]Hematooncology and BMT Unit, [3]Medical University of Lublin, Lublin, Poland

Background: In CLL patients who suffer from recurrent infections the nonspecific immune response could be continuously stimulated. The response of the innate immune system could eliminate infectious agents and is crucial for developing pathogen-specific adaptive immunity mediated by B and T cells. Toll-like receptors (TLRs) are responsible for host defense against pathogens by recognizing a wide variety of pathogen-associated molecular patterns. These receptors regulate innate immunity and determine the polarization and function of adaptive immunity. Triggering TLRs results in increased expression of inflammatory genes, which then play a protective role against various infections. Functional TLRs are expressed in a most of tumors and suggest that activation of tumoral TLRs induces the releasing of proinflammatory as well as immunosuppressive factors. This process increases the resistance of tumor cells to cytotoxic lymphocyte assault and further results their escape from immune surveillance. However, it has been suggested that the stimulation of TLRs expressed on CLL cells could increase immunogenicity of tumor cells and thus potentially contribute to the induction of tumor-specific immune response.

Aims: In the current study we performed comprehensive characterization of expression pattern of *TLR2, TLR7, TLR9* as well as splicing variants expression of *TLR4 (TLR4(1), TLR4(3), TLR4(4)*) in peripheral blood and bone marrow compartments/samples. Additionally, we assessed the protein expression level of TLR 9 in independent group of 41 patients and evaluated its impact on the treatment-free survival (TFS).

Methods: For 94 CLL patients samples qRT-PCR was performed. Expression levels of *TLR2, TLR7, TLR9, TLR4(1), TLR4(3)* and *TLR4(4)* were assessed and normalized against housekeeping gene *GAPDH*. The protein expression of TLR9 was assessed using flow cytometry.

Results: We found that the expression of *TLR7* and *TLR9* were significantly higher in CLL patients compared to healthy volunteers (HVs) and correlated with prognostic factors such as CD38 and ZAP-70 expressions or *IGVH* mutational status. In contrast, expression levels of *TLR2, TLR4(1), TLR4(3), TLR4(4)* were decreased compared to HVs. *TLR2*, *TLR7* and *TLR9* possessed higher expression in III and IV stages according to Rai classification. Moreover, protein expression of TLR9 strongly categorized patients for good and bad prognosis. Patients with higher expression of intracellular expression of TLR9 have significantly longer TFS than patients with lower expression of TLR9 (P=0.004). While TFS in group with lower expression of TLR9 (below median expression of 84.5%) was 8 months, in group with higher expression of TLR9 (above median expression of 84.5%) was 57 months.

Summary / Conclusion: The mRNA expressions of *TLR7* and *TLR9* were significantly higher in CLL patients compared to HVs, while the expressions of *TLR2, TLR4(1), TLR4(3)* and *TLR4(4)* were decreased. The protein expression level of TLR-9 was found to be associated with clinical outcome. Obtained data suggest that TLR-9 might provide a prognostic value in CLL. Furthermore, higher expression of certain TLRs may manifest deregulation of immune system in advanced stages of CLL.

B1317

***IN VITRO* EFFICACY OF PARA-NITRIC OXIDE DONATING ACETYLIC SALICYLIC ACID TOWARDS LYMPHOMA CELL LINES AND PRIMARY CHRONIC LYMPHOCYTIC LEUKEMIA CELLS HARBORING TP53 MUTATIONS OR DELETION 17P.**

S Krallmann[1*], A Liakos[1], H Flamme[1], S Poll-Wolbeck[1], M Krüger[2], A Berkessel[2], M Hallek[1], K Kreuzer[1]

[1]Department I of Internal Medicine | University at Cologne, [2]Department of Chemistry | University at Cologne, 50937 Cologne, Germany

Background: Chronic lymphocytic leukemia (CLL) is characterized by a remarkable heterogeneity in the clinical course among patient subgroups with distinct genetic characteristics. Some patients have a rapidly fatal disease despite therapy, which is accompanied by the incidence of deletion of chromosome 17p and mutation of TP53. Non-steroidal anti-inflammatory drugs (NSAIDs) possess anti-neoplastic activity in CLL. Moreover, nitric oxide donating derivatives of NSAIDs, most notably para-nitric oxide acetylic salicylic acid (NO-ASA), show superior anti-neoplastic efficacy compared to their parent compounds. The mechanism of the anti-neoplastic action is still not clarified.

Aims: Our main objectives were to determine whether NO-ASA is a specific therapeutic substance in high risk CLL and to illuminate the mechanism of its cytotoxic effect.

Methods: p-NO-ASA was synthesized by standard organic chemistry procedures. Primary cells were isolated from peripheral blood of CLL patients or healthy individuals. Further, the human B-cell lymphoma cell lines HT (B-cell non-Hodgkin lymphoma, TP53 mutated), U2932 (treatment resistant B-cell lymphoma), GRANTA-519 (relapsed high-grade B-non Hodgkin lymphoma, Cyclin D1 activation),

JVM3 (B-prolymphocytic leukemia, expresses proto-oncogene Bcl2) and MEC-1 (chronic B-cell leukemia, del17p) were used. Primary CLL cells with or without TP53 mutation, selected cell-lines as well as PBMCs and B-cells of healthy volunteers were tested in a luminometric assay (ATP content) after 24 h incubation with p-NO-ASA. Caspase-dependency on the cytotoxic effect on CLL cells was determined in a luminometric assay after 6 h drug-incubation as well as in immunoblot analysis after 24 h drug-incubation. Impact on NFκB-pathway was investigated via immunoblot analysis after 3 h drug-incubation.
Results: p-NO-ASA effectively reduced ATP content in the cell lines HT (LD50 9.20 μM), U2932 (LD50 4.81 μM) and JVM3 (LD50 3.33 μM). LD50 values were comparable with those achieved for CLL cells from a mixed patient population (LD50 4.34 μM). Primary CLL cells from TP53 mutated patients (n=5) showed a slightly increased LD50 of 25.56 μM, which was still significantly lower than that for healthy PBMCs (n=5) (LD50 63.72 μM). GRANTA-519 and MEC-1 were less sensitive (LD50 53.44 μM and 22.21 μM, respectively). In addition a concentration-dependent activation of the caspase cascade could be shown via luminometric assay as well as an apoptosis induction via western blot analysis. Phosphorylation of the NFκB p65 subunit at Ser 536 was reduced by NO-ASA around 58% (n=3), which implies an inhibition of NFκB pathway and a reactivation of apoptosis protein p53.
Summary / Conclusion: p-NO-ASA shows potent reduction of ATP content in cell-lines derived from treatment resistant cell lines featuring several bad prognosis markers such as TP53 mutation or Bcl2 overexpression. Further, TP53 mutated patients are about three fold more sensitive towards p-NO-ASA treatment as PBMCs derived from healthy individuals. The cytotoxic effect depends on caspase-activation and might be influenced by inhibition of NFkB-pathway. Hence, p-NO-ASA is worth further evaluation as a treatment for poor prognosis patients unresponsive to conventional CLL treatment regimens.

B1318
INCIDENCE AND PROGNOSTIC SIGNIFICANCE OF TCL-1 ONCOGENE IN CHRONIC LYMPHOCYTIC LEUKEMIA
S Sachanas[1*], D Rontogianni[2], T Vassilakopoulos[3], M Moschogiannis[4], C Calpadakis[5], X Yiakoumis[1], M Kyrtsonis[3], F Kontopidou[3], A Dimitrakopoulou[6], G Levidou[6], K Pinelopi[6], PTsirkinidis[1], H Papadaki[5], P Panayiotidis[3], M Angelopoulou[3], G Pangalis[3]
[1]Hematology, Athens Medical Center, Phychikon Branch, [2]Pathology, Evangalismos Hospital, [3]Hematology, University of Athens, [4]Hematology, Athens Medical Center, Athens, [5]Hematology, University of Crete, Iraklion, [6]Pathology, University of Athens, Athens, Greece

Background: TCL1 oncogene has been shown to be highly expressed in most B-cell tumors including CLL and contributes to the pathogenesis of CLL as a regulator of signaling of B-cell receptor, directly involved in activation of kinase cascade. Deregulation of this oncogene has implicated in the pathogenesis of the aggressive form of B CLL.
Aims: To evaluate TCL1 expression in a series of CLL patients (pts) and correlate its activity with patients' clinical and laboratory findings as well as other prognostic factors and survival.
Methods: 97 pts diagnosed with CLL based on standard criteria were included in this study. Baseline clinical and laboratory features were recorded. All pts underwent bone marrow aspiration and biopsy at diagnosis. Analysis of the IgVH mutational status as well as FISH for the detection of 11qdel and 17pdel were performed also at diagnosis. TCL1 as well as ZAP70 expression were evaluated by immunohistochemistry (IHC) using standard techniques in bone marrow paraffin embedded sections in all pts.
Results: Patients' median age was 60 years (30-85) with male predominance(56). According to Binet staging system, 79 pts (81%) had disease stage A, 12 (12%) B, and 6(6%) C 12 pts (12%) presented with splenomegaly and 4 had B-symptoms. Increased LDH values had 15/93 pts, abnormal $\beta_2$microglobuline 18/45, while 15 presented with rapid lymphocyte duplication time. Thirty-two (33%) had nodulal pattern of bone marrow infiltration while 32 (33%), 10(10%) and 24(25%) interstitial, diffuse and mixed pattern respectively. IgVH mutational analysis was performed in 55(57%) pts and 23/55 were unmutated. FISH analysis for 11q del and 17p del were evaluated in 44 and 48 pts respectively. In 3 pts 11q del was detected while 4 pts were positive for 17p del and 45 pts were ZAP70 (+). Fifty-nine pts (61%) were TCL1 positive. Male patients tended to present with higher TCL1 positivity compared to female ones [38 out of 56 (68%) male disclosed TCL-1 positivity against 21/41 females (51%) (p:0.097)]. TCL-1 expression was higher in ZAP-70(+) pts compared to ZAP-70(-) and this difference was statistically significant [39/45 (87%) ZAP70 (+) pts were TCL1(+) against 20/52 (39%) ZAP(-) (P<0.001)]. Further on, unmutated CLL patients presented with higher TCL-1 expression. Analytically, 19/23 (83%) unmutated pts expressed TCL1 against 14/32 (44%) mutated pts (P=0.004). TCL1 expression was more frequent in pts with non nodular pattern of bone marrow infiltration. Median Treatment Free Interval (TFI) was132 months, 7-year TFI was 51% and 10-year overall survival was 71% (median not reached). TCL-1(+) patients had marginally lower 7-year TFI(45% vs. 65%, P=0.09). No differences in overall survival were observed between TCL1 (+) and TCL1(-) patients (P=0.38).
Summary / Conclusion: TCL1 expression correlates with adverse prognostic factors in CLL such as ZAP70 and IgVH unmutation status and could be an additional easily applicable, reliable and reproducible marker for the disease. TCL-1(+) patients tend to have shorter TFI compared to TCL-1(-) patients

B1319
COMBINED PATTERNS OF IGHV REPERTOIRE AND CYTOGENETIC/MOLECULAR ALTERATIONS IN MONOCLONAL B LYMPHOCYTOSIS VERSUS CHRONIC LYMPHOCYTIC LEUKEMIA
A Henriques[1], A Rodriguez-Caballero[2], W Nieto[2], A Langerak[3], I Criado[2], Q Lécrevisse[2], M González[4], M Pais[1], A Paiva[1], J Almeida[2], A Orfao[2*]
[1]Blood and Transplantation Center of Coimbra, Coimbra, Portugal, [2]Cancer Research Center, Salamanca, Spain, [3]Erasmus Medical Center, Rotterdam, Netherlands, [4]University Hospital of Salamanca, Salamanca, Spain

Background: Chronic lymphocytic leukemia (CLL)-like monoclonal B lymphocytosis (MBL) with (MBL^{hi}) or without (MBL^{lo}) absolute B-lymphocytosis precedes most CLL cases, the specific determinants for malignant progression remaining unknown.
Aims: To investigate the potential existence of unique cytogenetic/molecular profiles associated with specific IGHV repertoires which could confer an increased risk of progression from MBL to CLL.
Methods: Simultaneous analysis of well-known abnormalities of chromosomes 11, 12, 13, 14 and 17 in CLL-like cells by iFISH and molecular pattern of rearrangements of IGHV genes of both MBL and CLL cases.
Results: Our results based on 78 CLL-like MBL and 117 CLL clones from 166 subjects living in the same geographical area and whose written informed consents were obtained; show the existence of three major groups of clones with distinct but partially overlapping patterns of IGHV gene usage, IGHV mutational status and cytogenetic alterations. These included a group enriched in MBL^{lo} clones expressing specific IGHV subgroups (e.g. VH3-23) with no or isolated good-prognosis cytogenetic alterations, a second group which mainly consisted of clinical MBL^{hi} and advanced stage CLL with a skewed but different CLL-associated IGHV gene repertoire (e.g. VH1-69), frequently associated with complex karyotypes and poor-prognosis cytogenetic alterations, and a third group of clones with intermediate features.
Summary / Conclusion: These findings suggest that the specific IGHV repertoire and IGHV mutational status of CLL-like B-cell clones may modulate the type of cytogenetic alterations acquired, their rate of acquisition and/or potentially also their clinical consequences.
Further studies investigating the IGHV gene repertoire of MBL^{lo} clones in distinct geographic areas and microenvironments, may shed light on the role of some antigen-binding BCR specificities contributing to clonal evolution.

B1320
VEGF AND BFGF SINGLE-NUCLEOTIDE POLYMORPHISMS IN CHRONIC LYMPHOCYTIC LEUKEMIA: IMPACT ON SUSCEPTIBILITY
S Garcia[1*], B Pineda[1], E Tormo[1], P Rodrigues[1], A Teruel[2], B Navarro[2], M Terol[2], P Eroles[1]
[1]Institute of Health Research INCLIVA, [2]Hematology-Oncology, Clinical Hospital, VALENCIA, Spain

Background: B-cell chronic lymphocytic leukemia (B-CLL) is a heterogeneous disease with a highly variable clinical outcome. Recent studies have identified a number of different molecular prognostic markers (including mutational status of the *IgVH* gene, ZAP70 and CD38 expression) that allow to discriminate patients in prognostic subgroups. However, different expression patterns of angiogenic factors as *VEGF*, *VEGFR1* and *bFGF* have been related with B-CLL susceptibility and treatment requirements.
Aims: We have analyzed the polymorphisms: -710 C/T in *VEGFR1,* rs1109324, rs1547651, rs3025039 (936C/T) and rs833052 in *VEGF* and rs1449683 (223 C/T) in *bFGF* in order to determine the possible association with susceptibility in B-CLL.
Methods: Peripheral blood samples from 224 B-CLL patients and 476 healthy controls were genotyped using probes TaqMan SNP Genotyping Assays. Samples were providing from the Hospital Clinic of Valencia. Four SNPs in the *VEGF* gene, one SNP in the *bFGF* gene and one SNP in the *VEGFR1* gene were evaluated. Statistical analysis was performed using SNPStats program (Catalan Institute of Oncology) and Fisher's exact test was applied to evaluate the significance.
Results: We have observed an increased frequency of the T allele in the rs1449683 SNP [OR 1.62 (95% CI: 0.98-2.66) p-value =0.063] and in the rs1547651 SNP [OR 0.72 (95% CI: 0.51-1.03), p-value=0.072] in our B-LLC patients when compared to control subjects. Moreover we observed that T allele carriers of rs3025039 (*VEGF)* have a significant protective effect concerning this disease [OR 0.59 (95% CI: 0.39-0.89) p-value=0.009].
Summary / Conclusion: Our data indicate an increased frequency of the T allele in polymorphisms rs1449683 (*bFGF)* and rs1547651 (*VEGF)* in the group of patients, which possibly account for the individual susceptibility to develop B-CLL. On the other hand the data provided suggest that the T allele of *VEGF* rs3025039 is likely important genetic marker of susceptibility to B-CLL.
Further studies regarding the role of pro-angiogenic markers in B-CLL would be beneficial to help elucidate pathogenic pathways in this disease.

B1321

ASSOCIATION BETWEEN THE MDM2 SNP309 POLYMORPHISM AND CLINICAL OUTCOME IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH UNMUTATED IGHV GENES

N Bilous[1*], I Abramenko[1], AChumak[1], Z Martina[2], I Kryachok[3], I Filonenko[4], J Gusachenko[4]

[1]Clinical Immunology, [2]Hematology, National Research Center for Radiation Medicine, [3]Chemotherapy, National Cancer Institute, Kiev, [4]Hematology, Poltava Regional Hospital, Poltava, Ukraine

Background: Data concerning prognostic significance in chronic lymphocytic leukemia (CLL) of the single nucleotide polymorphism 309T>G polymorphism in the promoter region of the MDM2 gene (SNP309) are still controversial (Willander et al., 2010; Asslaber et al., 2010; Kaderi et al., 2010; Zenz et al., 2010).
Aims: To evalute impact of the MDM2 SNP309 polymorphism in CLL prognosis.
Methods: The study of the MDM2 SNP309 polymorphism was performed in 231 CLL patients (178 males and 53 females). Median duration of follow-up period was 62.4 months. The following patient characteristics were analyzed: clinical data at diagnosis, time-to-treatment period (TTT), progression-free survival (PFS), overall survival (OS), immunoglobulin heavy chain variable (IGHV) gene mutation status. Polymerase chain reaction with restriction of product reaction by MspAI was used. Statistical analyses were performed using SPSS 13.0 for Windows.
Results: The distribution of the SNP309 genotype in observed patients was as follows: T/T carriers, n = 110 (47.6%); T/G carriers, n = 96 (41.6%); and G/G carriers, n = 25 (10.8%), that was comparable with other CLL cohorts (Gryshchenko et al., 2008). CLL patients with G/G genotype vs T/T+T/G genes were more likely to have an advanced stages (B or C according to the Binet classification) at the moment of diagnosis 72% vs 49%; P=0.03), shorter TTT period (medians 5 and 14 months correspondingly; P=0.035) and PFS (medians 30 and 50 months correspondingly; P=0.024), and a tendency to shorter OS (medians 61 and 98 months correspondingly; P=0.099) regardless the IGHV gene mutation status. Any significant differences in these parameters were found in CLL patients with mutated IGHV genes. Impact of the SNP309 genotype was found in CLL patients with unmutated IGHV genes only. Namely, 18.8% of CLL patients, carriers of G/G genotype, had A stage at the moment of diagnosis comparing with 43.4% patients among carriers of T/T+T/G genotypes (P=0.024). Medians of survival parameters in CLL patients with unmutated IGHV genes were as follows: TTT period 3 months in G/G carriers vs 10 months in T/T+T/G carriers (P=0.04); PFS 24 months in G/G carriers vs 45 months in T/T+T/G carriers (P=0.002); and OS 43 months in G/G carriers vs 86 months in T/T+T/G carriers (P=0.005).
Summary / Conclusion: The MDM2 SNP309 polymorphism may be an additional unfavorable prognostic marker for CLL patients with unmutated IGHV genes.

B1322

COMPARISON OF DIFFERENT RQ-PCR DESIGN STRATEGIES FOR MINIMAL RESIDUAL DISEASE EVALUATION IN LYMPHOPROLIFERATIVE DISORDERS: CORRELATION BETWEEN IMMUNOGLOBULIN GENE MUTATION LOAD AND RQ-PCR PERFORMANCE

I Della Starza[1*], M Cavalli[1], I Del Giudice[1], D Barbero[2], B Mantoan[2], A Guarini[1], R Foà[1], G Gaidano[3], M Ladetto[2], L Monitillo[2]

[1]Cell Biotechnologies and Hematology, Sapienza University, Rome, [2]Molecular Biotechnologies and Health Sciences, University of Turin, Turin, [3]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: Minimal residual disease (MRD) evaluation in B-cell acute lymphoblastic leukemias (ALL) and chronic lymphoproliferative disorders (B-CLD) requires the identification at the time of diagnosis of patient-specific molecular targets, i.e. immunoglobulin heavy chain (IGH) genes, on which primers and probes are constructed, and used to monitor MRD during the follow-up.
Aims: In the context of the MRD network of the Fondazione Italiana Linfomi (FIL), we compared two different approaches for the design of specific primers/probes for RQ-PCR, to assess their applicability, specificity and sensitivity for the MRD evaluation of B-CLD characterized by a variable mutational load of IGH genes.
Methods: A total of 25 samples of peripheral blood or bone marrow mononuclear cells from patients with chronic lymphocytic leukemia (CLL) (n=18) or mantle cell lymphoma (MCL) (n=7), were analyzed and sequenced to identify the functional germline V-D-J segment and the IGH mutation load, at the time of diagnosis. RQ-PCR quantitative analysis was performed using specific primers/probes generated with two design strategies, whose difference mainly consists in the positioning of the primers/probes on the V-D-J regions. In one method (method 1), the sense and antisense primers, both patient-specific, are positioned on the CDR2 and the CDR3 regions, respectively, while the probe is placed on the FR3 (Voena et al, Leukemia 1997); in the other (method 2), the sense primer, the only patient-specific, is positioned on the CDR3 region and the antisense primer together with the probe, both in germline configuration, on the FR4 region, where a portion of the JH is included. Method 2 derives from the European Study Group guidelines on MRD detection for ALL.
Results: Based on the IGHV mutation analysis, 22/25 (88%) samples carried >2% mutations and were classified as mutated; 20/25 (80%) samples showed a mutation load >5%. IGHJ genes showed a percentage of mutations between 0 and 29.41%, with a median value of 10.42%. 21/25 (84%) samples carried >2% mutations and 18/25 (72%) showed a mutation load >5%. 92% (n= 23) of samples resulted evaluable using the method$_1$, while 24% (n= 6) were evaluable with the method 2. Samples evaluable by both methods were 20% (n= 5), while samples evaluable with at least one method were 96% (n= 24). The poor performance of the method 2 was evident in the present series, enriched of mutated IGHV/J cases; on the contrary, selecting a CLL series with a germline IGHV/J configuration, the method 2 was successful in 21/23 cases (91%). Nevertheless, we could not find a specific mutation load of the IGHV/J region above which the RQ-PCR performance failed.
Summary / Conclusion: IGH genes mutations in B-CLD are a phenotypic marker which influences the analysis. In this context, the success or failure of RQ-PCR are strongly influenced by both the positioning of the primers/probes and their specificity i.e. the method 1 is based on 2 patient-specific primers, while the method 2 on one patient-specific and one germline. However, it was not possible to identify a specific mutation load determining the RQ-PCR failure. Therefore, it is necessary to reformulate the molecular strategies to evaluate MRD according to the B-cell receptor features of the disease investigated.

B1323

IMPACT OF THE BIOLOGICAL AND CLINICAL FEATURES OF THE DISEASE ON THE REAL LIFE OF THE CLL PATIENTS. A RETROSPECTIVE SINGLE CENTRE STUDY.

F Autore[1*], B Vannata[1], I Innocenti[1], M Tarnani[1], L De Padua[1], F Santini[1], P Chiusolo[1], F Sora[1], T Za[1], S Bellesi[1], P Bulian[2], V Gattei[2], D. Efremov[3], S Sica[1], G Leone[1], L Laurenti[1]

[1]Hematology, Catholic University of Sacred Heart, Rome, [2]Clinical and Experimental Oncohematology Unit, IRCCS Centro di Riferimento Oncologico, Aviano, [3]Molecular Hematology, International Center for Genetic Engineering & Biotechnology, Monterotondo Scalo, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is the most common lymphoproliferative disorder of the elderly population in Western countries. Clinicians collect many clinical and biological data useful for prognosis and management of the disease. No comprehensive data on epidemiological, clinical and biological characteristics and evolution of the B-CLL population are available in a single centre analysis.
Aims: This retrospective study has the purpose to analyse demographic, clinical and biological characteristics of our B-CLL population, diagnosed and followed at Hematology Institute of Catholic University of Rome.
Methods: From our database consisting of 507 diagnoses during the last 15 years, we excluded 105 patients previously treated in other centre or referred to our centre for consultancy. Thus we selected 402 patients affected by B-CLL diagnosed from January 1997 to December 2011 and followed until December 2012. The diagnosis of B-CLL was made according to criteria from the National Cancer Institute. For each patient in the database we reported clinical and biological features at diagnosis, comorbidities, any relevant clinical condition developed during the B-CLL history, time to progression (TTP), time to treatment (TTT), overall survival (OS) and cause of death.
Results: We recorded a mean of 27 B-CLL diagnosis per year.The median age at diagnosis was 66 years (range 35-89 years) with a ratio M:F of 1.68:1 (249 males, 153 females). The Binet stage was A in 286 patients (71.1%), B in 82 pts (20.4%) and C in 34 pts (8.5%). The median value of absolute lymphocyte count was 10.100 lymphocytes/mmc (range 1000 to 312.000). Fifty-four patients (13.4%) were diagnosed as Monoclonal B lymphocytosis because clonal lymphocytes were less of 5000/mmc. Positivity of biological parameters was detected for ZAP-70 in 133 pts (36.0%), for CD38 in 94 pts (24.9%), for CD49d in 71 pts (40.6%) and for CD69 in 35 pts (26.1%). Fish analysis was performed in 364 patients: del(13q14) resulted in 97 pts (26.6%), +12 in 52 pts (14.3%), del(11q22) in 30 pts (8.2%) and del(17p13) in 23 pts (6.3%). The analysis of the IgVH mutational status showed 200 pts (60.1%) mutated and 133 pts (39.9%) unmutated.
Analysing the time dependent outcomes, the median TTP was 4 years with 220 patients who showed progressions (63%), the projected rate of progressions at 5-years and 10-years was 57% and 76% respectively. The median TTT was 5 years:193 patients (55%) were treated in our series; 51% of all patients were untreated at 5 years and 32% after 10 years. All 34 patients lost at follow-up were considered censored and excluded by the analysis for OS (median observation time of 5 years). At last follow-up (December 2012) ninety-six patients were dead (28%); median overall survival was 14 years: 56% of the deaths due to B-CLL, 31% to extra-haematological diseases (especially neoplasia, cardiovascular and respiratory diseases), 8% to infections and 4% undetermined. The 5 and 10-year OS was 86% and 68% respectively. Most of the deaths seem to be related to CLL: among the extra-haematological deaths only 13% did not experience progression. ZAP-70, del(17), unmutated-IgVH, beta-2-microglobulin and CD49d identified a group of patients with significantly shorter TTP and OS, while CD38, del(11) and CD69 only for TTP.
Summary / Conclusion: By comparison with the data reported in the literature,

our cohort is representative of the B-CLL population. A comprehensive characterization of the clinical features and these standard biological prognostic parameters of the disease is essential to allow to the clinicians the best management of the patients.

B1324

COMPARISON OF THE PI3K-DELTA INHIBITORS TGR-1202 AND GS-1101 IN INDUCING CYTOTOXICITY AND INHIBITING PHOSPHORYLATION OF AKT IN CLL CELLS IN VITRO

D Friedman[1*], M Lanasa[1], D Brander[1], S Allgood[1,2], E Davis[1,2], H Miskin[3], S Viswanadha[4], S Vakkalanka[5], J Weinberg[1,2]
[1]Duke University Medical Center, [2]Durham VA Medical Center, Durham, [3]TG Therapeutics, Inc., New York, United States, [4]Incozen Therapeutics Pvt. Ltd., Hyderabad, India, [5]Rhizen Pharmaceuticals S A, La Chaux-de-Fonds, Switzerland

Background: The PI3K pathway is a central pro-survival mechanism in chronic lymphocytic leukemia (CLL). Expression of the delta isoform of PI3K is largely restricted to lymphocytes with *in vitro* inhibition inducing CLL cell apoptosis and death. Clinical evaluation of PI3K-δ inhibitors, such as GS-1101, has been promising, with responses seen in Rel/Ref CLL patients (pts). TGR-1202 is a novel PI3K-d specific inhibitor previously demonstrated to inhibit Akt phosphorylation and induce apoptosis in B-cell lymphoma cell lines.
Aims: Given the efficacy of other PI3K-δ inhibitors observed in CLL, we assessed the ability of TGR-1202 to induce cytotoxicity and apoptosis, and inhibit Akt phosphorylation in primary CLL lymphocytes.
Methods: We collected blood from consented CLL pts seen at the Duke Center for CLL and enrolled in IRB approved protocols at the Duke University and Durham VA Medical Centers. CLL lymphocytes were isolated using negative selection (> 95% purity). Primary CLL cells were incubated with serial dilutions of TGR-1202 or GS-1101 for 48 hours and tested for apoptosis by activated caspase-3 and 7AAD staining measured by flow cytometry. After 72 hours of incubation, CLL cells were evaluated for cytotoxicity using the colorimetric MTS reagent. Phosphorylated Akt (S473) was measured by flow cytometry after one hour of incubation with either compound and ten minutes of incubation with anti-IgM or anti-IgD. Akt phosphorylation was quantified by median fluorescent intensity (MFI).
Results: We evaluated TGR-1202 and GS-1101 in CLL lymphocytes collected from 7 pts. Five had mutated IGHV, 5 had 13q deletion or normal cytogenetics determined by FISH, 3 were ZAP-70 negative, and 7 were CD38 negative. IgM expression ranged between 13% and 90%, whereas IgD expression was uniformly elevated. Both TGR-1202 and GS-1101 significantly induced apoptosis (caspase-3+/7AAD+) and cytotoxicity in a dose-dependent manner in concentrations between 0.1 and 25.6 μM (P<0.05 in pairwise Wilcoxon signed rank tests). There was no significant difference observed between the compounds in terms of induction of apoptosis or cytotoxicity at any of the concentrations tested (0.1 – 25.6 μM) except 0.4 μM, where GS-1101 induced more apoptosis and cytotoxicity (median of 18.6 vs. 13.7% caspase-3+/7AAD+; median of 55.2 vs. 48.6% cytotoxicity, P=0.03 for both, Wilcoxon signed rank test). Incubation with anti-surface immunoglobulin significantly induced Akt phosphorylation compared to media alone (median MFI 1011.5 and 369, respectively, P=0.03, Wilcoxon rank sum test). The addition of either TGR-1202 or GS-1101 significantly abrogated this effect (P=0.03 for 0.1, 0.4, and 1.6 μM, Wilcoxon rank sum test) and returned Akt phosphorylation to baseline (P> 0.05 comparing drug treatment to media control, Wilcoxon rank sum test).
Summary / Conclusion: TGR-1202 is a potent PI3K-δ inhibitor that suppresses Akt phosphorylation and induces apoptosis-dependent cytotoxicity in primary CLL lymphocytes. These effects are comparable to those seen with GS-1101. Differences seen at the 0.4 μM concentration were not observed at higher or lower concentrations. Given the improved selectivity for the delta isoform of PI3K seen with TGR-1202 compared to GS-1101, these results suggest that TGR-1202 may have benefit in treating CLL while inducing fewer off-target effects and toxicities. Additional *in vitro* studies in high risk cytogenetic CLL patient samples are underway. TGR-1202 is currently being evaluated in a Phase I clinical trial in patients with hematologic malignancies.

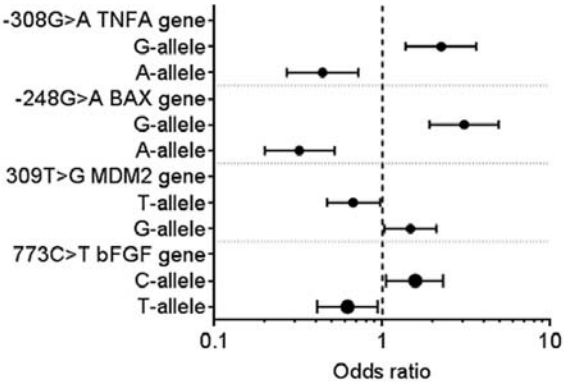
POLYMORPHISM OF APOPTOSIS REGULATORY AND GROWTH FACTOR GENES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

D Karimov[1*], B Bakirov[2], I Poddubnaya[3]
[1]Institute of occupational medcine and human ecology, [2]Bashkir State Medical University, Ufa, [3]Russian Medical Academy for Postgraduate Education, Moscow, Russian Federation

Background: Introduction
Chronic lymphocytic leukemia (CLL) is an oncohematological disease of the lymphatic tissue which is characterized by accumulation of lymphocytes in the peripheral blood, bone marrow and lymph nodes. CLL has a B□cell origin and is the most common type of all leukemias in adults.
Characteristic clinical symptoms of CLL include anemia, thrombocytopenia, enlargement of lymph nodes and hepatosplenomegaly. It has been established that at the time of diagnosis such symptoms appear to be absent in approximately 40% of patients. In most cases CLL is diagnosed in the later stage safter the development of complications. Thus, the important task of oncohematology is to determine the prognostic criteria and to assess the risk for the development of the disease at the earliest stages possible.
Like any other oncological process, CLL is most commonly caused by the disorder of apoptosis (tumor necrosis factor□α (TNFA), main p53 protein regulator (MDM2), proapoptotic protein (BAX) and by interferences with cell proliferation control (vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF)).
Aims: The purpose of this study was to make a comparative analysis of polymorphic loci of TNFA gene (□308G>A), BAX gene (□248G>A), MDM2 gene (309T>G), VEGF gene (936C>T) and bFGF gene (773C>T) in patients with CLL and healthy individuals from Bashkortostan Republic. The study also aimed to search for possible associations of polymorphic variants of these genes related to the development of CLL.
Methods: Molecular and genetic analysis of DNA samples was performed in 329 persons, all residents of the Bashkortostan Republic. The group of patients with CLL included 133 patients hospitalized to the hematology unit of the Republican Clinical Hospital of the Ufa city (2008□2010). All patients were selected at random. Clinical examination of the patients was carried out by hospital doctors and combined essential and optional methods of examination. DNA samples were isolated from lymphocytes of the peripheral venous blood by the method of phenol□chloroform extraction. The polymorphic loci were studied by the method of polymerase chain reaction (PCR) of DNA synthesis. Mathematical processing of the results was performed with the use statistical programs BIOSTAT.



Results: In the group of patients with CLL the GG□genotype was significantly more common than that compared with the control group (82 and 65% respectively, χ2= 10.67, P=0.002). The frequency of G□allele of polymorphic locus□308G>A of TNFA gene in patients with CLL was higher than the corresponding result in the control group (91 and 81% respectively, χ2= 10.41, P=0.002). The comparative analysis of the frequencies of polymorphic variants of locus□248G> A of BAX gene revealed significant differences in GG□genotype, which accounted for 74.30% in CLL patients and 46,30% in the control group (χ2= 16.25, P=0.001). Analysis of the polymorphic locus 309T>G of MDM2 gene revealed that the frequency of G□allele in patients with CLL was 46% compared to 37% in healthy individuals (χ2= 4.14, P=0.042; OR = 1.47; 95% CI: 1.03□2.11).
Comparison of genotype and allele frequencies of polymorphic locus 936 C>T of VEGF gene in patients with CLL and in the control group did not reveal any significant differences. TT genotype frequency of polymorphic locus 773C>T of bFGF gene was higher in the control group than that in the group of patients (40.65% vs. 56.44%, χ2= 4.92; P=0.027). In contrast, the allele T was more frequent in the group of patients (35.00% vs. 25.25%, χ2= 4.48, P=0.03).
Summary / Conclusion: Thus, as a result of the study the following risk markers for CLL have been identified: GG□genotype of the polymorphic locus □308G>A of TNFA gene (OR = 2.46), GG□ genotype and G□allele of the polymorphic locus□248G>A of BAX gene (OR =3,35; OR =3,07, respectively), G□allele of the polymorphic locus 309T>G of MDM2 gene (OR = 1.47), allele T of the polymorphic locus 773C>T of bFGF gene (OR = 1.57).

B1326

FACTORS THAT MAY INFLUENCE THE KINETICS OF B LYMPHOCYTE DEPLETION IN RELAPSED CLL PATIENTS TREATED WITH OFATUMUMAB – A SINGLE CENTRE EXPERIENCE

A Dagorne[1*], J Ianotto[1], Y Renaudineau[2,3], C Berthou[1,3], A Tempescul[1,3]
[1]Clinical Hematology, [2]Laboratory of Immunology, [3]EA2216, Teaching Hospital Brest, Brest, France

Background: Chronic lymphocytic leukemia (CLL) is the leading cause of leukemia in Western countries and preferentially affects men after age of 65s. The advent of monoclonal antibodies has led to a more effective management

of this disease. Ofatumumab is an anti-CD20, second-generation humanized monoclonal antibody with anti-tumor activity mainly dependent on complement. The activation of the classical complement pathway is assumed as a key mechanism of B cell depletion.
Aims: We conducted a retrospective, monocentric, cohort study, to characterize the kinetics of C4 and C3 fractions of complement during treatment with Ofatumumab for relapsed, refractory CLL. We also analysed the phenotype of FcgammaR3 and the impact on leukaemia cell depletion.
Methods: Between 2009 and 2011 we identified12 patients treated with Ofatumumab for a relapsed CLL. We analyzed complement data from blood assays: C4 fragments for the classical pathwayand the C3fragments for alternative pathway activation, data available for 7 patients.A patient had 2 courses of Ofatumumab, a year apart, thanks to an excellent initial, therapeutic response.We also collected the phenotype of FcgammaR3 (CD16) and we then analyzed, based on the phenotype, objective responses and the kinetics of blood leukemic cell depletion, by flow cytometry (double staining CD19, CD5).
Results: Of the7 patients analyzed for complement fragments, 5 patients obtained a biological response.We identified 3 complete remissions and 2 partial remissions. Patients who had a biological response had a strong activation of the classical complement pathway (C4). The alternative complement (C3) pathway is not enabled for any patient. The initial values and the variations during the treatment of C4 fragment does not influence complement activation or the response to ofatumumab.
We identified 4 patients with a VF and 8 with a FF phenotype of CD16. Of the 4 patients VF,2 patients presented an objective response: complete response and partial response. All the FF phenotype patients had a response: 3 patients had a complete remission and 5 patients had a partial remission. The kinetics of the response is quite variable, weidentified 3 early complete responses, from the second cycle of Ofatumumab and a later response, after the 6th Ofatumumab perfusion. Partial responses obtained in the VF group stabilized after the fourth infusion of Ofatumumab, those of the FF group had continued beyond , arriving to stabilization during the monthly (maintenance) perfusions.
Summary / Conclusion: This descriptive analysis of our cohort confirm the fact that Ofatumumab has cytolytic activity by complement activation. The Ofatumumab will activate the classical pathway of complement; the alternative pathway is not involved in any of the biological response.The values of C4 does not influence complement activation or responseto Ofatumumab. The descriptive analysis also highlights differences between patients treated with Ofatumumab for relapse CLLby looking to FcγRIII receptor phenotype (CD16): VF compared to FF.Interestingly, response rate is moreimportant and kinetics of the response more pronounced into the FF group Our data suggests that ADCC may be influenced by the phenotype of CD16 (VF / FF).Further, larger studiesare required to confirm these observations.

B1327
POSSIBLE MODIFYING ROLE OF PDE4D SNP83 POLYMORPHISM FOR IGHV REPERTOIRE IN CLL PATIENTS
G Pleskach[1*], N Bilous[1], I Abramenko[1], A Chumak[1]
[1]Clinical Immunology, National Research Center for Radiation Medicine, Kiev, Ukraine

Background: T cells are important component of microenvironment for chronic lymphocytic leukemia (CLL) B-cells and may influence on their activation, proliferation and apoptosis (Stevenson, Caligaris-Cappio, 2004). Type 4 phosphodiesterases (PDE4), expecially PDE4D, are critical regulators of T-cell activation (Peter et al., 2007).Opposite, expression of PDE4D isoforms in B-CLL cells decreased (Peiro et al., 2011). Genetic variation in PDE4D family members are associated with some clinical disorders, while a functional relevance for any of these single nucleotide polymorphisms (SNPs) and distribution in CLL have not been reported so far.
Aims: To evaluate the distribution of the PDE4D SNP83 genotypes in CLL patients depend on mutational status of immunoglobulin heavy chain (IGHV) genes.
Methods: The study of the PDE4D SNP83 polymorphism and IGHV gene mutation status was performed in 171 CLL patients and 271 age- and sex-matched controls (only SNP83). Polymerase chain reaction with restriction of product reaction by Tail was used for the PDE4D SNP83 polymorphism. IGHV-D-J rearrangements were amplified according to the BIOMED-2 consortium rules (van Dongen et al., 2003).
Results: The distribution of the SNP83 genotypes in CLL patients was as follows: T/T carriers, n = 60 (35.1%); T/C carriers, n = 77 (45.0%); and C/C carriers, n = 34 (19.9%). The frequencies of the SNP83 genotypes were not significantly different in CLL patients and controls: T/T carriers, n = 93 (38.1%); T/C carriers, n = 115 (47.5%); and C/C carriers, n = 34 (14.0%); P=0.287. CLL patients with T/T genotype comparing with T/C and C/C carriers were more likely to have mutated IGHV genes (T/T genotype - 50.0%; T/C genotype -62.3%; C/C genotype - 71.7; P=0.076) and expressed mutated IGHV4 gene family (T/T genotype - 50.0%; T/C genotype - 42.9%; C/C genotype - 7.1; P=0.006). Expression of IGHV3-21 gene was lower in T/T+T/C carriers comparing with C/C carriers (3.6% and 11.7%, correspondingly; P=0.04).
Summary / Conclusion: Our preliminary data showed a possible modifying role of PDE4D SNP83 polymorphism for IGHV repertoire in CLL patients.

B1328
CELL SURFACE CD20 ANTIGEN EXPRESSION ANALYSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA
A Giordano[1*], P Curci[1], R Rizzi[1], T Perrone[1], M Delia[1], A Mestice[1], G Nardelli[1], I Di Tardo[1], G Specchia[1]
[1]Hematology, AZIENDA OSPEDALIERO UNIVERSITARIA POLICLINICO CONSORZIALE BARI, Bari, Italy

Background: Chronic lymphocytic leukemia (CLL) is an heterogeneous disease with variable outcome. The identification of factors that could predict the clinical course of CLL is a crucial objective. Flow cytometry makes it possible to evaluate malignant B cell immunophenotypic characteristics and study important prognostic factors, such as either CD38 or ZAP 70 expression.
Aims: We investigated the relationship between immunophenotypic variables such as the CD20 intensity of expression and clinical outcome in CLL. Correlation between time to progression, measured as the time elapsed between diagnosis and first treatment, was addressed.
Methods: We retrospectively evaluated 102 patients (pts) with *de novo* CLL treated at the University Hospital of Bari (Italy) between April 2006 and February 2011. At diagnosis all pts were studied for clinical characteristics and peripheral blood multicolor flow cytometric analysis. The intensity of CD20 Antigen expression was analyzed by means of flow cytometry. A cut-off of 70% was considered to define weak (<70%) and strong (≥70%) expression of the antigen. Median time to progression was calculated for all pts and related to CD20. In addition among these pts two groups were choosed: the first group included 38 pts treated within 3 months from diagnosis; the second group included 11 pts treated after 5 years of observation. Univariate analyses of each group were performed to evaluate the correlation between CD20 antigen expression and time to treatment.
Results: Among all pts a statistically significant difference was found in median time to progression comparing pts with weak (<70%) and strong (≥70%) cell surface antigen (P< 0,05). Moreover, in the group of pts treated within 3 months from diagnosis 10 % pts presented CD20 expression <70% and 90 % CD20 expression ≥70%; in the group of pts treated after 5 years of observation 67% presented weak CD20 expression and 33% strong; the difference was statistically significant (P: 0.005).
Summary / Conclusion: In this study a lower CD20 expression was associated to a shorter time to first treatment. CD20 is a transmembrane phosphoprotein involved in the activation, proliferation, and differentiation of B lymphocytes. The immunophenotypic intensity of CD20 expression could help to recognize at diagnosis that subset of patients that may show rapid evolution to progressive disease. Multicentric studies and more consistent cohorts of patients are warranted to confirm these preliminary data.

Chronic lymphocytic leukemia and related disorders

DESCRIPTION OF A FAVORABLE GROUP OF PATIENTS WITH CD5(+) MONOCLONAL B-CELL LYMPHOCYTOSIS AND CHRONIC LYMPHOCYTIC LEUKEMIA RAI-0

C Kalpadakis [1*], G Pangalis[2], T Vassilakopoulos[3], S Sachanas[2], P Tsirkinidis[4], M Moschogiannis[2], P Korkolopoulou[5], A Dimitrakopoulou[6], S Kokkoris[3], X Yiakoumis[2], E Dimitriadou[2], P Tsaftaridis[7], M Kyrtsonis[3], D Rontogiannis[8], E Plata[7], P Panayiotidis[3], H Papadaki[1], M Angelopoulou[3]
[1]Hematology Department, University Hospital Of Crete, Heraklion, [2]Hematology Department, Athens Medical Center, [3]Hematology Department, University of Athens, [4]Hematology Department, 401 Military Hospital, [5]Pathology Department, University of Athens, [6]Immunology Department, [7]Hematology Department, Laikon General Hospital, [8]Pathology Department, Evangelismos General Hospital, Athens, Greece

Background: CLL-like MBL has been recently recognized as a distinct entity and displays many similarities with B-CLL Rai-0. Prognosis is variable and the distinction between these two entities is not well established.
Aims: To describe the clinical, laboratory and biological features of patients with CLL-like MBL and CLL-Rai 0 with favorable clinical outcome.
Methods: Selection of patients was based on the following criteria: Patients with a diagnosis of CD5(+) MBL or CLL RAI-0 who had available data and were not in need for treatment after a follow up time of at least 5 years.
Results: 177 patients were included in this study: 56 with MBL and 121 with CLL Rai-0. The median age was 63 years (37-81). Females predominated (54%). All patients were asymptomatic in a good performance status, without lymphadenopathy or organomegaly as these were assessed by physical examination and CT scanning. No cytopenias were identified. LDH was elevated in only 1 pt. Hypoglobulinemia was observed in 40/126 pts (32%) and paraproteinemia in 7/62 (11%). The median lymphocyte count was 10.290/μL (1650-121.440) and the median absolute B-cell count was 7700/ μL (820-98.366). Bone marrow was evaluated in 124 pts. The median percentage of infiltration was 35% (5-95), while the pattern of infiltration was interstitial in 34 (27%), nodular in 24 (19%), diffuse in 3 (2%) and mixed in 63 (52%). FISH analysis for the identification of del11q and del17p was performed in 70 pts and all were negative for the presence of these cytogenetic abnormalities. 45 pts were evaluated with PCR analysis for the identification of the monoclonal IgVH rearrangement and sequence analysis for the identification of mutational status (table). All studied cases were mutated, while the most common used VH families were: VH3-23 (5/45), VH4-34 (4/45), VH3-7 (4/45), VH1-2 (3/45). After a median follow-up time of 101 months (60-361), 5 unrelated deaths were recorded, 50 pts remained stable, 119 presented with increase in ALCs, while 3 pts had a decrease in ALCs.

VH FAMILY	% HOMOLOGY	VH FAMILY	% HOMOLOGY	VH FAMILY	% HOMOLOGY
VH3-23*01	5.56	VH4-b*02	10.38	VH3-74*03	8.05

VH2-70*12	7.66	VH5-51*01	6.45	VH4-59*02	5.33

Summary / Conclusion: This study presents the clinical and biological characteristics of pts with MBL CD5(+) and Rai-0 CLL with a favorable outcome. In all cases the IgVH genes were mutated while no adverse risk cytogenetic findings were identified. These results are preliminary and the study is ongoing in order to compare this favorable group with a similar group of patients [CD5 (+) MBL, CLL Rai-0] who were in need of therapy. Furthermore to identify differences between CD5 MBL versus CLL Rai-0 patients.

B1330

CHEMOIMMUNOTHERAPY WITH RITUXIMAB AND LOW-DOSE ORAL FLUDARABINE AND CYCLOPHOSPHAMIDE (R-FC-LOW DOSE OS) AS INITIAL TREATMENT FOR ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A Gozzetti[1*], A Fabbri[1], L Schiattone[1], V Candi[1], E Cencini[1], A Frasconi[1], R Crupi[1], D Raspadori[1], M Defina[1], M Bocchia[1]
[1]hematology, university of siena, siena, Italy

Background: Current standard therapy for fit young patients with chronic lymphocytic leukemia (CLL) is rituximab, fludarabine ,cyclophosphamide (R-FC). This therapy is highly effective in standard risk patients with CLL, however in the elderly it can be troublesome since it can give unacceptable myelotoxicity and increased risk of infection. Because median age at diagnosis for CLL patients is 72, the majority of patients cannot receive RFC, the best therapy available. Fludarabine and cyclophosphamide (FC) given intravenously at low doses in relapsed or refractory indolent lymphoid malignancies (CLD) can decrease the incidence of severe myelosuppression and infectious complications. Based on this background in the past we demonstrated that low-dose oral fludarabine and cyclophosphamide (FC-low dose-os) given to pretreated elderly patients with CLD enabled response rates that were comparable to those obtained with standard i.v. regimens with very few side effects and complications. These responses were confirmed in a population of untreated elderly low grade non Hodgkin lymphoma patients. Finally we showed that in 26 elderly CLL patients who cannot benefit of more aggressive schedules, FC low-dose-os was very effective especially in the untreated population. The regimen was easy to administer on an outpatient basis with mild haematological and extra-haematological toxicity.
Aims: To test efficacy and safety of the addition of rituximab to the oral regimen of FC (R-FC).
Methods: Biological prognosticators were assessed at diagnosis and at disease relapse. In particular IGHV gene use and mutational status, ZAP-70 protein and CD38 expression by flow cytometry, deletions of 11q22.2, 13q14.1, 17p13.1 loci and chromosome 12 trisomy were determined by fluorescent in situ hybridization (FISH) as previously reported. Rituximab 375 mg/m^2 was administered day 1 of each 28 days cycle. Fludarabine 40 mg total dose was given orally (os) days2,3,4,5; cyclophosphamide 200 mg total dose was given orally days2,3,4,5. Bacterial and antiviral prophylaxis were given during all period of treatment. For cycles were planned, when possible (unsatisfactory response) patients received a maximum of 6 cycles.
Results: Fifty one patients were treated. In particular 25 patients received R-FC, while 26 patients received FC. Median age was comparable in the two groups of patients (75, range 67-88). A median of 4 cycles was received by each patient (range1-6). R-FC led to an overall response in 21/25 (89%) patients; in particular a CR was achieved in 13/21 (61%) patients a PR in 8/21 (28%). Median PFS was 39 months. Poor prognosticators for PFS were IGHV unmutated, del11q/del17p, ZAP70 positivity (19 months, 15 months, 19 months respectively; P=0.002). Toxicity was acceptable and manageable and mostly hematological (grade III-IV leucopenia and thrombocytopenia in 15% of the patients). FC led to an overall response in 21/26 (80%) patients. 6/21 (29%) obtained a CR, while 15/21 (71%) a PR. Toxicity was comparable to the RFC regimen (grade III-IV hematological 10%). Median PFS was 19 months and poor prognosticators were IGHV unmutated, del11q/del17p, ZAP70 positivity (15,12,18 months respectively; P=0.001). Including patients with chronic lymphoproliferative disorders such as low-grade Non Hodgkin Lymphomas we treated with the oral formulation of fludarabine and cyclophosphamide at our Institution 107 elderly patients, with good efficacy and good safety profiles.
Summary / Conclusion: Considering the median age of the patients, the R-FC regimen was well tolerated and led to impressive durable responses.

B1331

EFFICACY AND SAFETY OF RITUXIMAB AND HIGH-DOSE DEXAMETHASONE (R-DEX) IN THE TREATMENT OF RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

M Simkovic[1*], D Belada[1], M Motyckova[1], P Zak[1], L Smolej[1]
[1]Department of Internal Medicine - Haematology, University Hospital and Medical School Hradec Kralove, Hradec Kralove, Czech Republic

Background: Refractory chronic lymphocytic leukemia (CLL) has an extremely unfavourable prognosis with overall survival frequently shorter than 12 months. High-dose methylprednisolone (HDMP) in combination with monoclonal anti-CD20 antibody rituximab is active in treatment of relapsed/refractory CLL but infectious toxicity is serious. Recently published pilot data suggest that high-dose dexamethasone might be equally effective but less toxic than HDMP.
Aims: To assess efficacy and safety of high-dose dexamethasone combined with rituximab (R-dex) in relapsed/refractory CLL.
Methods: We retrospectively evaluated medical records from patients (pts) with relapsed/refractory CLL treated with R-dex at 4th Department of Internal Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, between September 2008 and October 2012. A total of 52 pts were included (38 males [73 %], median age, 66 years [range,

37-86], Rai III/IV stage in 61%). The median number of therapies prior to R-dex was 2 (range, 1-6). The schedule of R-dex was as follows: rituximab, 500 mg/m^2 i.v. day 1 (375 mg/m^2 in 1st cycle), dexamethasone 40 mg orally on days 1-4 and 10-13, cycles repeated every 3 weeks for the maximum of 8 cycles. All pts received antimicrobial prophylaxis with sulfamethoxazole/trimethoprim and aciclovir. The median number of R-dex cycles was 5 (range, 1-8).
Results: The overall response (ORR)/complete remissions (CR) were achieved in 70/4%. With regard to side effects, serious infections (grade III/IV according to Common Terminology Criteria for Adverse Events) occurred in 29% of the patients; 19% pts developed steroid diabetes requiring temporary use of short-acting insulin. At the median follow-up of 12.7 months, median progression-free survival was 7.6 months and median overall survival 22.6 months.
Summary / Conclusion: Our data show that R-Dex is an active and feasible treatment for patients with relapsed/refractory CLL; however, major infections remain relatively frequent despite combined antimicrobial prophylaxis. In addition, significant and long-term disease control can be expected in a minority of patients only. Updated results will be presented.

Monroy" (IBIM) – Consiglio Nazionale delle Ricerche (CNR), , Palermo, Italy, [4]Human Pathology, Institute of Biomedicine and Molecular Immunology "A. Monroy" (IBIM) – Consiglio Nazionale delle Ricerche (CNR), , Palermo, Italy

Background: It is now clear that chronic lymphocytic leukemia (CLL) is a proliferative disorder that requires the help of its microenvironment to be maintained and to progress. In CLL neoplastic B cells inhibit normal T lymphocytes, and the alteration of several cytokines may also contribute to this T-cell dysregulation. In this context particular relevance may have some recently discovered cytokines, such as interleukin (IL)-33 and IL-31. IL-33 can activate dendritic cells directly driving polarization of naïve T cells towards a Th2 phenotype. IL-31 coordinates the interaction of different immune cells, including T-cells, mast cells, and eosinophils, with epithelial cells.
Aims: We analyzed the plasma levels of IL- 33, and IL-31, in patients with B-CLL. In the same subjects we also evaluated the lymphocyte immunophenotypical pattern, and we performed IgVH gene analysis, CD38 positivity and ZAP-70 expression to evaluate a possible correlation between interleukin concentrations and biological risk.
Methods: The study population included 77 patients with B-CLL (38 F –39 M) with a median age of 72.38±11.1 years. In a small group of patients the dosage of the cytokines was performed before and after different treatment protocols. Plasma from 63 normal subjects were also included as controls. IL-31 and IL-33 protein levels were measured using the commercially available ELISA kits. Data were presented as interquartile range IQR and range except age presented as mean±Standard deviation.
Results: The IL-31 was detectable in 40/77 (40.05%) CLL patients and in 36/63 (57.14%) controls, and there was not statistical difference between patients and controls (c2 = 1.15, P=0.28). The IL-33 was detectable in 50/77 (64.94%) CLL patients and in 35/63 (55.56%) controls. There was no statistical difference in detectability between them (c2 = 1.28, P=0.26) therefore the two groups were statistically comparable. There was a significant difference (P<0.0001) between the levels of IL-33 in patients affected by CLL (411.5 and 617.2 pg/ml) and those measured in controls (1,375.3 and2,035.4 pg/ml). There was not a significant difference between the levels of IL-31 in patients affected by CLL (1,783.5 and 10,692.8 pg/ml) and those measured in controls (3,278.4 and 10,067.1 pg/ml). There was a significant difference, although not in a statistically way (P=0.072), between the IL-33 levels in CLL patients before and after therapy (83.67 and1,421 vs. 837.22 and1,790.38 pg/ml). There was a positive correlation in CLL patients between IL-31 plasma levels and IL-33 (rho = 0.962, P<0.0001), while we found a negative correlation in patients between IL-31 levels and IL-33 and CD20 expression (respectively rho = -0.6, P=0.014 and rho = - 0.43, P=0.031). There was a positive correlation in patients between levels of IL-33 and CD3 expression (rho = 0.81, P=0.027).
Summary / Conclusion: : In leukemia patients, T-cell function has been suppressed with the disease progress. Cytokines play a critical role in the control of the immune responses. To the best of our knowledge, ours is the first study that demonstrated decreased concentrations of IL-33 in patients with CLL, and this reduction might justify the reduction of the Th2 response observed in these patients. In conclusion, our study might contribute to better understand the cellular immune features in CLL patients, confirms the value of multicytokine analyses for the evaluation of CLL patients, and could open a new scenario in understanding the pathophysiology of CLL.

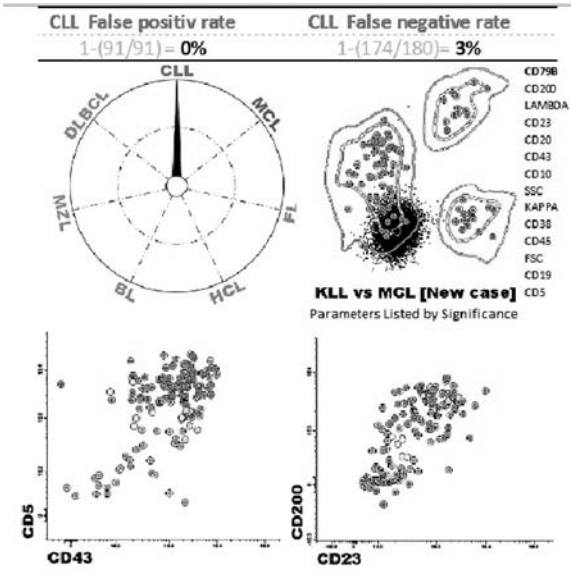
B1333
THE EFFICACY AND SAFETY OF FIRST-LINE TREATMENTS FOR CHRONIC LYMPHOCYTIC LEUKEMIA - A SYSTEMATIC REVIEW OF CLINICAL EVIDENCE
M Woods[1], S Lock[1], C Stapelkamp[2], A Haiderali[3*]
[1]RTI Health Solutions, Manchester, [2]GlaxoSmithKline, Stockley Park, United Kingdom, [3]GlaxoSmithKline, Collegeville, United States

Background: Fludarabine/cyclophosphamide/rituximab (FCR) is the standard of care as first line treatment for healthy, fit patients with chronic lymphocytic leukemia (CLL). However, a majority of patients with CLL are elderly and suffer from comorbidities which tend to make them inappropriate for fludarabine-based therapies. A number of therapeutic options are available for these medically less-fit or 'slow-go' patients.
Aims: The objective of this systematic review is to identify evidence for the clinical efficacy and safety of therapies for the first-line treatment of CLL patients for whom fludarabine-based therapies are not appropriate.
Methods: The following electronic databases were searched (without limitations on publication date or language): MEDLINE, MEDLINE In-Process, Embase, BIOSIS, and the Cochrane Library. Search terms included combinations of free-text and Medical Subject Heading terms, including terms for CLL, and the interventions (ofatumumab, chlorambucil (Chl), bendamustine (B), rituximab (R), lenalidomide, and GA-101) and study types of interest (RCTs; open-label, follow-up studies, nonrandomized, controlled trials; single-arm trials; and prospective cohort studies). Conference proceedings from January 2010 to January 2012 and clinical trials.gov also were searched. Articles were screened for relevance by two researchers using predefined inclusion and exclusion criteria.
Results: A total of1,650 records were identified for manual screening; 124 publications were progressed for full text screening and 14 were included: 8 primary and 6 secondary reports. The 8 primary articles included a randomized trial comparing B with Chl (Knauf et al., 2009); an ongoing randomized trial comparing R + B with R + Chl (MaBLe; Leblond et al., 2012); and five single-arm studies investigating R + B, lenalidomide, R monotherapy, R + Chl, and B. One study comparing fludarabine (F) + Chl with F + cyclophosphamide in a population eligible for F therapy was included in this review, as it was the only retrieved frontline study which reported quality of life data (Else et al., 2012). Knauf et al. (2009) reported a median progression-free survival of 21.6 months for B and 8.3 months for Chl (P<0.0001). Overall response (OR; 68% vs. 31%) and complete response (CR) rates (31% vs. 2%) were higher for B than for Chl (P<0.0001). In the MaBLe study, the CR rate was higher in the R + B arm (30%) than in the R + Chl arm (13%) (P=0.054). ORR also was higher in the R + B arm (88%) than in the R + Chl arm (80%). Seven of the included studies reported adverse events. Knauf et al. (2009) reported a greater incidence of adverse events with B than with Chl, with the most common adverse event being neutropenia or granulocytopenia. The MaBLe study (Leblond et al., 2012) reported a similar rate of serious adverse events for R + B (35%) when compared with R plus Chl (34%). Conversely, the rate of withdrawals due to adverse events was higher for R + Chl.
Summary / Conclusion: This review highlighted a paucity of RCT evidence for the treatments of interest in CLL patients who are unsuitable for fludarabine-based treatments. Only two published RCTs were identified. One of these studies was an abstract presenting interim results of an ongoing RCT and thus contained little data. The management of patients with CLL who are unsuitable for fludarabine-based therapies remains a primary unmet clinical need.

B1334
NEW ANALYSIS STRATEGIES MAKE FLOW CYTOMETRY MORE RELIABLE IN THE CLASSIFICATION OF B-CELL CHRONIC LYMPHATIC LEUKEMIA
E Hjalmarsson[1*]
[1]Clinical Pathology and Cytology Karolinska Huddinge, Stockholm, Sweden

Background: The the old way of analyzing flow cytometry data requires years of experience and still consistent interpretation is challenging.
Improved software makes it now possible to simplify instrument settings and compensation which enable comparison of mean fluorescence intensity(MFI) between samples. With new analysis software you can build a reference database which simplifies comparison and automatic separate cases based on the expression of all analyzed markers. New cases can be matched and compared with the reference cases which should make the interpretation more consistent and flow cytometry more reliable in disease classification.
Aims: Develop a database with diagnosed B-cell lymphoma cases. Develop an analysis strategy that focus on simplicity and reproducibility. Use the database and the new analysis strategy to classify Chronic lymphatic leukemia cases and evaluate the diagnostic usefulness.
Methods: Bone marrow, peripheral blood and cell suspension from glands were prepared with a lyse-wash-incubate-wash procedure.
FACSCanto II (BDBiosciences) were used for flow cytometry analysis, instrument setup and compensation according to Euroflow and BD userguide.
Infinicyt 6.0 were used for analysis. Tube-1 and 2 were merged and calculed according to Infinicyt manual. The lymphoma were classified as CLL if the

immunophenotypic fingerprint matched the database, or if MFI matched CLL variants.



Results: The reference file are based on 50 CLL, 30 MCL, 10 FL, 4 HCL, 1 BL, 9 MZL, 10 DLBCL
Of the 180 CLL cases 162 cases matched the refference cases (RED), 5 cases expressed low levels of CD5 but were classified as CLL (BLUE), 7 cases expressed low levels of CD43 but were classified as CLL (PURPLE). 6 cases did not match the CLL criteria (YELLOW).
Summary / Conclusion: In this study we show that with new software and analysis strategy the majority of all CLL cases can be classified, reproducible and with high reliability using only flow cytometry. We conclude that using a software to analyze MFI and match with reference cases a high consistency in classifying CLL is obtained. Using MFI and reference cases as background in dot plots a high consistency in interpretation of staining intensity is obtained. We propose that the new analysis strategy make CLL classification more reliable but also simplifies identification of cases with poor prognosis. To further validate this procedure more cases have to be analyzed and all different lymphomas have to be included in the reference database.

B1335
THE DIAGNOSTIC VALUE OF CD123 IN HCL AND OTHER B-CELL DISORDER WITH HAIRY LYMPHOCYTES SINGLE CENTER EXPERIENCE
D Dukovski[1,2*], L Cevreska[1,2], S Trajkova[1,2], M Ivanovski[1], M Popova-Simjanovska[1], L Cadievski[3], I Panovska-Stavridis[1,2]
[1]Hematology, University Clinic for Hematology, [2]Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of, [3]Hematology, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Hairy cell leukemia (HCL) and hairy cell leukemia-variant (HCL-v) are rare B-cell lymphoproliferative disorders (BC-LPD) with overlapping clinico-pathological features. However, certain morphological features of HCL, such as villous cytoplasmic projections or characteristic tissue specific infiltrative patterns, including red pulp expansion with pseudosinuses, may be seen in other B-cell lymphoproliferative disorders. A methodical and comprehensive approach including the evaluation of the immunophenotypic features further improves diagnostic work-up. CD123 is an antibody that identifies and binds to the Alfa chain of the human interleukin – 3 receptor. It is expressed at the normal hematopoietic cells at most of the hairy cells. The coexpression of CD123, in conjunction with bright CD11c, bright CD20, bright CD22, CD25, and CD103, is the immunophenotypic sine qua non in diagnosing HCL.
Aims: The aim of the study was to determinate the diagnostic value of CD123 expression in HCL and other B-cell lymphoproliferative disorder cases with hairy lymphocytes.
Methods: We investigated the diagnostic value of CD123 expression in neoplastic cells from 50 patients with B – cell disorder with circulating hairy lymphocytes We performed flow cytometry analysis (FCM) of 50 cases (30 HCL, 5 HCL-v, 15 splenic marginal zone lymphoma (SMZL)), correlating results with available corresponding clinical and morphological data. Immmunophenotype analyses were performed by using the FAXS Canto II BD flow cytometer analyzer on 50 samples, from peripheral blood (23) and bone marrow (27). Acquired data were analyzed with the software FACS Diva version 6.1.2 by using CD19 gating strategy according to revised guidelines for the diagnosis and management of hairy cell leukemia and hairy cell leukemia variant according to British Committee for standards in hematology (BCSH).We used the panel recommended by which incorporates the following markers : CD11c, CD25, CD103, CD123, that are specific for HCL combined with common B-cell markers (CD19, CD20, CD22) and T cell markers..
Results: Our findings show that cells from 100% of typical HCL expressed CD123 with strong intensity, while cells from other B – cell disorder with hairy lymphocytes did not expressed CD123. HCL expressed bright CD20, bright CD22, bright CD11c, bright CD25, CD103, and bright homogeneous CD123(100%). HCL-v expressed bright CD20, bright CD22, CD11c(20%) and uniformly lacked CD103(100%), CD123(100%),CD25(100%) antigens. SMZL cases were CD103(-) and CD123(-). Detection of BRAFV600E mutation by using PCR methods was examined in a subset of cases from our study group. All HCL-v cases were negative for BRAFV600E mutation, in contrast to HCL (50% positive for BRAFV600E mutation).Those results further validate our FCM diagnostic criteria.
Summary / Conclusion: We conclude that CD123is a useful marker for distinguishing B cell disorder with villous lymphocytes from HCL with high sensitivity and specificity.

B1336
THE PROGNOSTIC VALUE OF THYMIDINE KINASE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN THE VARIOUS TYPES OF MODERN THERAPY
T Zagoskina[1*], E Zotina[1], M Kryukova[1], V Shardakov[1], I Grishina[2]
[1]Kirov Research Institute of Hematology and Blood Transfusion, [2]Kirov State Medical Academy, Kirov, Russian Federation

Background: Thymidine kinase (TK) is recognized as the predictor of disease progression in chronic lymphocytic leukemia (CLL). But the answer to the current chemotherapy and immunochemotherapy has not been still estimated according to the contents of TK.
Aims: Determine the prognostic value of TK in patients with CLL in different types of modern therapy.
Methods: The research included 230 patients with CLL. The median age was 59 years. Patients were divided into 3 groups according to the type of received treatment. The first group included 36 patients, who were prescribed leukeran, the second one – 96 patients who received treatment FC (fludarabine, cyclophosphamide), the third – 98 patients who received RFC (rituximab, fludarabine, cyclophosphamide). The enzyme content, exceeding the maximum rate of its normal level twice, was used as a cut-off value (20 U/L).
Results: The answer to the therapy manifested the achievement of partial remission (PR) among 16 (73%) patients and complete remission (CR) among 2 (9%) patients from 22 ones (61%) of the first group with TK levels < 20 U/L. There was no treatment effect among 13 (93%) patients from 14 ones (39%) with TK ≥ 20 U/L (P=0.001). Median overall survival (OS) in patients with TK levels < 20 U/L has not been reached after 62 months of follow-up, but it was 31 months in patients with TK levels ≥ 20 U/L (P=0.041). Median time to progression (TTP) was 7 months with the concentration of TK < 20 U/L, and 2.7 months with the rate of TK ≥ 20 U/L (P=0.023). CR and PR were achieved among 22 (40%) and 29 (53%) patients accordingly from 55 ones (57%) of the second group with the content of TK < 20 U/L. The lack of therapeutic effect was observed in 4 (7%) patients. At the same time, CR and PR were achieved in 7 (17%) and 16 (39%) patients accordingly from 41 ones (43%) with TK levels ≥ 20 U/L, there was no response to therapy in 18 (44%) patients (P=0.001). Median OS in patients with TK levels < 20 U/L has not been reached, whereas it was equal to 56 months among patients with TK levels ≥ 20 U/L (P=0.015). Median TTP in patients with TK levels ≥ 20 U/L was 28 months, but it was 18 months in ones with TK ≥ 20 U/L (P=0.028). The effect of the therapy was independent of RFC TK content in blood serum. CR was achieved in 41 (76%) and 28 (64%) cases among the patients of the third group with TK levels < 20 U/L and ≥ 20 U/L accordingly (P=0.692). Medians OS of the patients with different levels of TK and treated by the program RFC have not been achieved (P=0.367). Median TTP of patients with TK levels < 20 U/L and ≥ 20 U/L was 60 and 44 months accordingly (P=0.156).
Summary / Conclusion: TK maintains its prognostic value among patients with CLL treated with leukeran and FC: OS and TFT depend on the level of this enzyme. At the same time immunochemotherapy RFC eliminates the negative effect of TK as a tumor marker for the direct effect of treatment and duration of response. The contents of TK among patients with CLL can be used as additional prognostic factors of response, as well as for the selection of appropriate treatment programs.

B1337
AUTOIMMUNITY AND CHRONIC LYMPHOCYTIC LEUKEMIA
M Santos[1*], J Carda[2], S Ramos[2], R Guilherme[2], P César[2], P Olim[2], E Cortesão[2], E Magalhães[2], L Rito[2], B Luz[2], C Geraldes[2], A Espadana[2], A Teixeira[2]
[1]Clinical Hematology, CHUC-HUC, Portugal, [2]Clinical Hematology, CHUC-HUC, Coimbra, Portugal

Background: Chronic Lymphocytic Leukemia (CLL) is frequently related with autoimmune diseases. The relation between CLL and autoimmune cytopenias, like autoimmune hemolytic anemia (AIHA) or immune thrombocytopenia (IT), is well known. The presence of these phenomena was considered as an adverse prognostic factor. However, recently, it was demonstrated that patients with immune cytopenias at diagnosis have better prognosis than those with cytopenias secondary to diffuse bone marrow involvement.
Aims: Identify clinical, laboratory, immunophenotypic and cytogenetic parameters potentially related with autoimmune complications in a group of patients with CLL-B.
Methods: Review of demographic, clinical and laboratorial data, particularly the Rai/Binet staging, immunophenotypic and cytogenetic characterization (FISH) of patients diagnosed with CLL-B in our department, from January 1st, 1988 to July 30th, 2012.
Results: 382 patients were identified, M/F ratio 1.6:1, median age 71 years (38-95) and median lymphocytosis 21 G/L (5-1050). Accordingly to the Rai/Binet staging system, 245 were low risk patients, 60 were intermediate risk and 77 were high risk (64, 16 and 20%, respectively). The most frequent autoimmune disease observed was AIHA in 51 patients (13.4%), followed by IT in 22 patients (5.8%) and pure erythroid aplasia in 9 patients (2.3%). Other non-hematological autoimmune diseases were observed, as rheumatoid arthritis (n=9), autoimmune thyroiditis (n=7), and others (n=9). After statistical analysis, we observed a relationship between autoimmune cytopenias and advanced stage diagnosis (P=0.02), beta-2 microglobulin two times higher than the normal level (P=0.02) and immunophenotypic atypia (P=0.02). We dit not find any relationship between cytogenetic abnormalities and immune cytopenias. Non-hematologic autoimmune pathologies are not related with the factors described. Overall survival (OS) is 75%, 58% and 35% at5, 10 and 15 years, respectively. The 5 years OS is 62% in the group of patients with autoimmune cytopenias and 80% in the other patients (P=0.024).
Summary / Conclusion: The results suggest that patients in advanced stage at diagnosis, high beta-2 microglobulin and immunophenotypic atypia have a higher risk for autoimmune cytopenias. Patients with autoimmune disease seem to have lower survival.

B1338

VEMURAFENIB IS HIGHLY ACTIVE IN ADVANCED HAIRY-CELL LEUKEMIA: A REPORT OF TWO CASES

E Willenbacher[1], A Pircher[1], U Strasser[2], W Willenbacher[1], A Brunner[3], M Steurer[1*]
[1]Division of Haematology & Oncology, Innsbruck Medical university, Innsbruck, [2]Laboratory of Pathology, Zams, [3]Department of Pathology, Innsbruck Medical university, Innsbruck, Austria

Background: Hairy cell leukemia (HCL) is a rare indolent B-cell lymphoma characterized by splenomegaly, profound pancytopenia and frequent infectious complications. Standard therapy consists of purine analogs±rituximab and for most patients survival is not compromised. However, in rare cases HCL may become chemoresistant resulting in a more aggressive course. Recently, it was shown that almost all HCLs harbor a distinct mutation of the BRAF gene (BRAF V600E). Thus, targeted treatment with BRAF inhibitors may represent an attractive treatment option for refractory HCL.
Aims: To report preliminary clinical data on the use of vemurafenib in advanced HCL.
Methods: We herein report two cases of HCL treated with the BRAF inhibitor vemurafenib.
Results: Case one is a 79 years old woman refractory after 2-CdA + rituximab as 4th line treatment suffering from pronounced pancytopenia and repeated life-threatening infectious complications despite repeated G-CSF administration. Within one week after the initiation of vemurafenib (960mg/d) blood counts improved significantly and after 105 days a complete remission was achieved and vemurafenib was stopped. With a follow-up of currently seven months the patient is still in complete remission. The second case is a 68 years old man with subtotal HCL bone marrow infiltration resulting in G-CSF refractory °IV neutropenia, transfusion-dependant anemia and °III thrombocytopenia. In view of a concomitant life-threatening invasive pulmonary aspergillosis and a one week history of STEMI requiring dual antiplatelet therapy with ASS and clopidogrel the patient received firstline treatment with vemurafenib (960mg/d) to avoid prolonged pancytopenia and immunosuppression commonly observed after 2-CdA therapy. One week after the initiation of vemurafenib blood counts began to improve and after 80 days the patient had achieved an excellent remission with near-complete normalization of blood counts and splenomegaly, recovery from pulmonary aspergillosis and only residual HCL infiltration in the bone marrow. Treatment with vemurafenib is planned to continue until a complete remission is achieved.In both patients treatment with vemurafenib was safe and well tolerated
Summary / Conclusion: Vemurafenib is highly active in advanced HCL and represents an attractive novel treatment option in particular for refractory patients.

B1339

AN OPEN-LABEL, SINGLE-ARM, PHASE I STUDY TO ASSESS SAFETY AND EFFECT OF OFATUMUMAB ON B-CELL COUNTS, COMPLEMENT, AND CYTOKINES/CHEMOKINES IN PATIENTS WITH REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

N Patton[1*], R Lindeman[2], A Butler[3], T Kipps[4], L Fang[5], R Jewell[5], K Laubscher[5], E Lewis[5], D Sedoti[6], P Witman[6], G Chan [6]
[1]Auckland Clinical Studies Ltd., Auckland, New Zealand, [2]Prince of Wales Hospital, New South Wales, Australia, [3]Christchurch Clinical Studies Trust, Christchurch, New Zealand, [4]Moores UCSD Cancer Center, La Jolla, [5]GlaxoSmithKline, Research Triangle Park, [6]GlaxoSmithKline, Upper Providence, United States

Background: Ofatumumab is a human monoclonal antibody against CD20 approved for treatment of fludarabine- and alemtuzumab-refractory CLL. Clinical and lab correlative data from a study conducted to collect QTc data in fludarabine-refractory CLL patients are presented here.
Aims: Assess the safety and effect of ofatumumab on complement, B-cell counts , and cytokines/chemokines in patients with refractory CLL.
Methods: Adult subjects with active CLL refractory to at least one fludarabine-containing regimen received 300 mg at Week1, followed by 11 infusions of 2000 mg (Weeks 2-8, 13, 17, 21 and 25). Infusion rate started at 12 mL/h (first infusion) or 25 mL/h (later infusions) and escalated by doubling the rate every 30 min up to 400 mL/h to administer 1000 mL. Biomarker samples were collected prior to dosing at Weeks1,2,5, 9, 13, 17, 21, 25, 29, 37 and 49. The study assessed safety and the effect of ofatumumab on circulating B-cell counts ($CD5^+CD19^+$, $CD5^-CD19^+$), complement (C2, C3, CH50), cytokines (IFNg, TNFa, IL-1b, IL-2, IL-6, IL-8, IL-10, IL-12 p70), and chemokines (MCP-1, GM-CSF, MIG, IP-10) at the maximum studied dose of 2000 mg.
Results: Fourteen patients were enrolled. Median number of prior treatments was 3. Five (36%) patients completed the study, 2 (14%) patients died of pneumonia, 5 (36%) patients withdrew due to disease progression, and 2 (14%) withdrew consent. Thirteen patients completed the first 8 weekly infusions, and 8 patients completed all 12 infusions. Median duration of the first infusion dose was 4.9 h (range 4.7-8.9 h) and for later doses was 4.1 to 4.4 h. Infusion reactions were seen in 79% of patients at first dose, 57% at second dose, and 0-30% of patients at later doses. No grade 4 or 5 infusion reactions were observed; two subjects (14%) had grade 3 infusion reactions, which resolved. No patient withdrew from treatment due to infusion reactions. Most common AEs and SAEs included diarrhoea, headache, decreased appetite, fatigue, pyrexia and neutropenia. Overall response rate was 43% (0 CR, 6 PR, 7 SD, 1 NE). Circulating B-cell counts were greatly reduced by Week 8 and remained low during treatment. By the 6-month follow-up visit, median normal B-cell counts had returned to near-baseline, while median tumor B-cell counts remained below baseline. Baseline C2, C3, and CH50 levels did not appear to differ between responders and nonresponders. Median C2 and CH50 levels decreased in both groups initially and remained below normal for responders; levels returned to normal range during monthly dosing in nonresponders. C3 had smaller changes. Median levels of TNFa, GM-CSF, and IL-2 appeared higher and median levels of MCP-1, IL-6, and IL-8 appeared lower in responders than in nonresponders throughout the study. Median IFNg and IL-10 levels were initially higher in responders than in nonresponders, then became lower after Week 9. No trends emerged with other cytokines/chemokines.
Summary / Conclusion: Maximum infusion rates of 400 mL/h at the first two doses were well tolerated; infusion reactions were similar in frequency and severity to previous results with ofatumumab. Overall response rate was similar to previous data (42-51%). B-cell depletion was observed along with complement consumption; median C2 and CH50 levels remained lower during monthly dosing in responders. Responders also appeared to have higher median levels of certain pro-inflammatory cytokines and lower median levels of certain immunotolerant cytokines during the course of the study than nonresponders. Further investigation of the role of complement and cytokines in patients treated with ofatumumab is warranted.

B1340

MULTIVARIABLE MODEL CONSISTED OF CLINICAL AND BIOLOGICAL MARKERS FOR TIME TO FIRST TREATMENT IN CLL PATIENTS: PRELIMINARY RESULTS FROM SINGLE CENTRE EXPERIENCE

S Trajkova[1,2*], I Panovska -Stavridis[1,2], M Ivanovski[1], A Stojanovic[1,2], D Dukovski[1], S Stankovic[1,2], M Popova-Simjanovska[1], L Cadievski[1], A Eftimov[3], A Dimovski[3], L Cevreska[1,2]
[1]Hematology, University Clinik for Hematology, [2]Medical Faculty, [3]Faculty of Farmacy, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: The clinical course for patients with chronic lymphocytic leukemia is extremely heterogeneous, one of the most important challenges in the clinical management of those patients is the decision of initiating their treatment, but there is no available prognostic system that will resolve this issue. Usually, criteria for active disease are used to initiate therapy. Recently, some authors proposed prognostic models, scoring systems involving a set of clinical and biological risk factors and estimates individual patient survivals.
Aims: Here, we report our initial results from a study designed to evaluate the statistical association of the distinct clinical and biological parameters with the

prognosis and time to initiating treatment for patients with CLL.
Methods: Our study incorporated 100 consecutive, treatment naïve CLL patients. In each patient all traditional laboratory, clinical and biological prognostic factors were evaluated at their first visit to our Institution. Than we combined the following independent characteristics: age, β-2 microglobulin, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups, which are included in some of the already published CLL prognostics index, in association with the CD38 expression and mutational status of the IGVH gene regions. Further, we correlate those factors by multivariable analysis with time to first treatment. This multivariable model was used to develop a nomogram-a weighted tool to calculate 5- and 10-year survival probability and estimate median time to first treatment.
Results: According to prognostic index a classification tree was built that identified three subsets of patients who scores were 1-3 (low risk- 32pts- 32%), 4-7 (intermediate risk-48pts- 48%) and >8 (high risk-20pts- 20%). Estimated median survival at low risk subset of patients is 14,1years, 10,7 and4,6 years respectively at intermediate and high risk subsets of patients. Projected survival in respectively low, intermediate and high-risk groups are 100%, 100%, 25%, and 34%, 43%, 25% at 5-year and10-year, respectively. Also, statistical analyses showed that three involved lymph node sites, increased size of cervical lymph nodes, increased serum lactate dehydrogenase ,CD38 expression and unmutated IGHV mutation status are associated with shorter time to first treatment.
Summary / Conclusion: Our prognostic model that combines and correlates the distinct clinical and biological markers of CLL patients enables identification of the patients that are at high risk for progression. This prognostic model may facilitate clinical decision for initiating treatment.

B1341
CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): EPIDEMIOLOGY, COMORBIDITIES AND TREATMENT PREFERENCE IN DAILY CLINICAL PRACTICE
R Pileckyte[1*], T Zvirblis[1], V Ivanauskaite[1], I Klimiene[1], L Griskevicius[1,2]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, [2]Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

Background: CLL diagnosis and management data come mainly from clinical trials. Little is known about the spectrum of the disease as well as comorbidities in daily practice.
Aims: To assess the CLL epidemiology, comorbidities and treatment preference in daily clinical practice.
Methods: A questionnaire including demographics, disease characteristics, comorbidities, and treatment from the date of diagnosis, was distributed to all outpatient and inpatient hematologists who take care of CLL patients in a tertiary healtcare facility Vilnius University Hospital with the catchment area of about ⅓ of Lithuanian population of 3 million people. Data were collected during 6 month period of 2012, presuming that all CLL patients were about to visit a hematologist during this interval at least once.
Results: 455 CLL patients were registered. The CLL diagnosis was confirmed in 86% of cases by flow cytometry or histology. Estimated prevalence was 30 patients per 100 000 inhabitants. Male to female ratio was 1:1. Median age at the time of visit was 70 years (range 38-90), and 16% were > 75 years old or older. Sixty-four persent of the patients had comorbidities, mainly hypertension (66%), coronary heart disease (34%) and musculoskeletal disorders (27%). Six (1.3%) patients had concomitant cancer. Cumulative illness rating scale (CIRS) was evaluated and the median score was 2 (range 0-14). FISH analysis of 17p deletion/*TP53* mutations was carried out in 128 (67%) of treated patients and was positive in 13 cases (10%). Three persent of the patients had autoimmune hemolytic anemia and 2% had immune thrombocytopenia.Treatment was administered in 58% of the patients at any point of their disease and 20% received more than 3 lines of therapy, 11 (2.4%) patients were allografted. First line treatment was mainly chlorambucil (60%), FCR was given to only to 6%. Combinations containing rituximab were more often used in relapsed patients. Treatment preference (chemoimmunotherapy (CIT) vs alkylating agents) did not differ much according to CIRS (≤6 vs >6), but differences were noted according to age: 65 years old or younger patients were more often treated with rituximab containing regimens compared to older ones: first line treatment 15% vs 2%, second line 28% vs 11%, respectively. There was a trend of more use of CIT in 2012 compared to previous years: first line FCR 23% vs 6%, second line FCR 26% vs 10%, respectively.
Summary / Conclusion: CLL prevalence in Lithuania is comparable to Western countries (SEER). More than half of the patients are followed untreated. Though many CLL patients have comorbidities, intensity of treatment (alkylating agents vs CIT) is more related to age. There is a trend for more CIT use in 2012, which can be explained by the fact that rituximab was approved for CLL in Lithuania only in 2011. Data from this study will help to refine CLL management in different patient groups.

B1342
INTEGRATION OF AUTOMATED MORPHOLOGICAL FEATURES RESOLVES A DISTINCT GROUP OF ATYPICAL CHRONIC LYMPHOCYTIC LEUKEMIAS WITH CHROMOSOMAL ABERRATIONS
Y Herishanu[1*], S Kay[1], R Rothman[2], R Braunstein[3], V Deutsch[1], E Naparstek[1], B Katz[1]
[1]Hematology, [2]Genetics, [3]Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: In recent years, automated morphological assessment of peripheral blood slides has become a powerful modality that allows better characterization and quantification of cells in a uniform, fast and robust manner, associated with a reliable management of illustrative data. However, the capacity of this automated laboratory approach in the diagnosis of lymphoproliferative disorders has not been established yet.
Aims: To evaluate the morphological diversity in peripheral blood films of patients with chronic lymphocytic leukemia (CLL)
Methods: Blood films of 80 patients with CLL were analyze using the DM1200 CellaVision automated microscopy system. Aberrant lymphocytes and smudge cells were enumerated and correlated with CLL immunophenotype, prognostic parameters and clinical outcome.
Results: An increased proportion of aberrant lymphocytes were associated with trisomy 12 and an atypical immunophenotype. CLL patients with $\geq$7.5% aberrant lymphocytes had a shorter time from diagnosis to first treatment compared to patients with <7.5% lymphocytes with atypical morphology. While the percentage of smudge cells was extremely variable among patients, a low percentage of smudge cells correlated with trisomy 12 and atypical immunophenotype. The ratio between percentages of smudge cells to aberrant lymphocytes appeared to be the most powerful index for morphological CLL scoring. Low ratio values highly correlated with an atypical immunophenotype and trisomy 12.
Summary / Conclusion: Automated morphological analysis of peripheral blood leukocytes is a powerful and robust tool for the quantitative morphological stratification of CLL. Integration of the automated morphological features discriminates between different CLL phenotypes and distinct chromosomal aberrations.

B1343
SMALL LYMPHOCYTIC LYMPHOMA/ CHRONIC LYMPHOCYTIC LEUKEMIA : A RETROSPECTIVE SURVEY OF PROGNOSIS FACTORS
L Dang[1*], B Stamatopoulos[2], P Heimann[3], B Cantinieaux[4], R Dewind[5], M Maerevoet[2], N Meuleman[2], D Bron[2]
[1]Hematology, UPNT, Ho Chi Minh, Viet Nam, [2]Hematology, [3]Cytogenetic, Institut Jules Bordet, [4]Hematology, Hopital St Pierre, [5]Cytology, Institut Jules Bordet, Brussels, Belgium

Background: Small lymphocytic lymphoma (SLL) is a mature (peripheral) B-cell neoplasm characterized by a progressive accumulation of monoclonal B lymphocytes. It is considered to be identical to chronic lymphocytic leukemia (CLL) with similar pathologic and immunophenotypic features. Distinction is usually made based upon clinical presentation and an arbitrary cut-off of $5x10^9$/L lymphocytosis.
Methods: We retrospectively reviewed 117 patients (pts) (20 SLL and 97 CLL patients) registered in our data, between 1995 and 2012, comparing outcomes with emphasis on cytogenetic data and biological prognostic factors. Beta-2 microglobulin, flow cytometry (CD19, CD20, CD5, CD23, CD38, CD11c,FMC7), IgV_H mutation status and caryotype or FISH were studied in both groups. The χ^2 test was used to identify significant differences between groups. Overall survival (OS) curves were estimated using the Kaplan-Meier.
Results: Median age of SLL pts (58.5 y.o.) was somewhat younger than the median age (65 y.o.) in CLL pts. The 97 CLL pts were classified according to the Binet staging (55 stage A, 21 stage B, 21 stage C). SLL were classified according to the AA staging (stage II, n=2 - stage III-IV, n=18). 5 and 10/yrs OS were respectively 71% and 19% in SLL pts. 5 and 10 yrs OS of CLL was 90% and 82% in stage A, 83% and 75% in stage B, 53% and 40% in stage C. Advanced stage SLL behaves such as CLL Stage C in terms of OS. Further analyses on biological factors showed that SLL and CLL share similar patterns in terms of phenotypes. We confirm the prognostic relevance of the disease staging system (Binet) for CLL. Biological prognostic factors such as CD38+, β2microglobulin >3mg/dl, $IgGV_H$ mutational status, cytogenetic abnormalities were also significantly discriminant in OS for pts with SLL/CLL. In our small series, cytogenetic abnormalities such as 11q or 17p del were more frequent in SLL (30%) than in CLL (14%) (P=0.01). The CD11C expression had no significant prognostic value in SLL pts (P=0.54) but a good prognosis factor in CLL pts (P=0.03).
Summary / Conclusion: SLLs express similar phenotypic features, similar biological prognostic markers and similar overall survival for advanced diseases. However, at the time of diagnosis, our small series suggests that median age is lower and poor cytogenetic abnormalities are more frequently described.

B1344

RITUXIMAB IN COMBINATION WITH CLADRIBINE IN HAIRY CELL LEUKEMIA (HCL)

S Basic-Kinda[1], D Dujmovic[2*], P Roncevic[1], I Radman[1], S Dotlic[3], K Kuvezdic[3], K Dubravcic[4], I Aurer[1,2]
[1]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [2]Department of Internal Medicine, Medical School, University of Zagreb, [3]Department of Pathology, [4]Department of Laboratory Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: HCL is characterized by exquisite responsiveness to purine analogues, cladribine and pentostatin. Therefore, despite the fact that it is one of lymphoid neoplasms with highest density of CD20, there are only limited data on the efficacy of rituximab in combination with purine analogues.
Aims: We performed this study to analyze the toxicity and efficacy of the combination of rituximab and cladribine in patients with HCL.
Methods: We retrospectively analyzed outcomes of patients who were treated with this combination at our center.
Results: We identified 10 patients, 7 men and 3 women, 44-82 years old (median 53). Three were treated up-front and 7 for refractory or relapsing disease. Patients in the latter group have previously received between 1 and 2 treatment lines (median 2), at least one including purine analogues. Cladribine was administered at the standard dose, continuously in 8 and intermittently in 2 patients, rituximab was administered concurrently in 8 and after cladribine in 2 patients for 2-8 (median 6) cycles. Cotrimoxazole and acyclovir were administered for infection prophylaxis. Duration of severe granulocytopenia was 0-17 days (median 7), 2 patients received RBC transfusions and 1 platelet transfusions. Five had serious infections, one died early due to an infection that was present at time of treatment start. All 9 evaluable patients responded. One frail elderly lady died 4 months after treatment start of cerebrovascular disease. The median follow-up of survivors is 37 months (range 8-84 months), none relapsed. Three-year OS and PFS is 79%. Duration of remission was longer than the previous in 4/4 patients with sufficient follow-up.
Summary / Conclusion: The combination of rituximab and cladribine is an effective treatment for HCL relapsing after or refractory to cladribine monotherapy. In comparison to historical controls treated with cladribine monotherapy, time to hematological recovery seems shorter (possibly due to increased tumor cell killing) but infectious complications seem more frequent.

B1345

CHOLESTEROL LEVELS IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC LYMPHOCYTIC LEUKEMIA

I Yavasoglu[1*], G Kadikoylu[1], G Pektas[1], A Bolaman[1]
[1]hematology, Adnan menderes university medicine faculty, aydın, Turkey

Background: The cholesterol levels may be low in solid tumors and hematological malignancies such as multiple myeloma. The cholesterol levels in the patients with chronic lymphocytic leukemia (CLL) decreased in some experimental studies. Some patients have indolent disease and never need treatment, but in others the clinical course is aggressive and soon after diagnosis requires intensive treatment.

	CLL (n:73)	Control (n:71)	P value
TC(mg/dl) 179±38	217 ± 36	0.000	0.000
HDL-C(mg/dl)	37 ± 12	53 ± 14	0.000
LDL-C(mg/dl)	113 ± 30	131 ± 29	0.000
Triglycerid(mg/dl)	142 ± 78	147 ± 68	> 0.05
VLDL-C(mg/dl)	28 ± 15	31 ± 17	> 0.05

Aims: In this study, according to the International CLL study group, 73 patients with newly diagnosed CLL (38 male and 35 female with mean age of 67±11 years) were retrospectively evaluated for lipid parameters.
Methods: 71 (43 females and 28 males with mean age of 55±9 years) healthy subjects were enrolled to the study as control group. Architect C800 instrument and enzymatic/ calorimetric method was used to measure lipid parameters including total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), very low density lipoprotein cholesterol (VLDL-C), and triglyceride levels. Low-density lipoprotein-cholesterol (LDL-C) values were calculated according to the formula of Friedwald. Lipid parameters were compared between Binet A and C stages using with student's t test.
Results: While 59% of the patients with Binet A, while 36% were Binet C. TC, HDL-C, LDL-C values in the patients with CLL lower than control group (P<0.001), Triglyceride and VLDL-C levels were not significantly different (P>0.05) between two groups (Table 1).There was no difference for lipid parameters between Binet stages.
Summary / Conclusion: Low cholesterol levels in patients with CLL may occur due to increased use of cholesterol by lymphocytes.

B1346

THE ASSOCIATION OF FLUDARABINE AND CYCLOPHOSPHAMIDE AS FRONT LINE TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: HAS IT STILL A ROLE IN THE IMMUNE THERAPY ERA?

L De Padua[1*], B Vannata[2], I Innocenti[2], P Falcucci[3], G D'Arena[4], F Autore[2], F Santini[2], N Piccirillo[2], P Chiusolo[2], F Sorà[2], S Sica[2], G Leone[2], L Laurenti[2]
[1]Oncology and Hematology, Regina Apostolorum Hospital, Albano Laziale (Rome), [2]Hematology, Catholic University Hospital A.Gemelli, Rome, [3]Hematology, Belcolle Hospital, Viterbo, [4]Hematology, San Giovanni Rotondo Hospital, San Giovanni Rotondo, Italy

Background: The combination of Fludarabine and Cyclophosphamide (FC) was widely used in Chronic Lymphocytic Leukemia (CLL) for its tolerability and higher response rate in respect to the alkylator based regimens. Nowadays the association of monoclonal antibodies with chemotherapy is considered the standard treatment of CLL.
Aims: Here we report the long term results and late toxicities of FC combination administered orally or intravenously, taking into account biological profile of patients, in order to establish its role in the era of monoclonal antibodies.
Methods: We retrospectively enrolled 65 CLL patients with a median age of 65 years (range 44-78 years) treated with oral FC (30/250 mg/m^2) (38 patients) or intravenous FC (25/250 mg/m2), administered for 3 consecutive days every 4 weeks for 6 cycles. All patients were studied at baseline for IgVH, CD38, Zap 70, FISH abnormalities.
Results: No statistical differences were noticed in terms of efficacy between the two routes of administration. Seven patients did not complete the treatment: two developed immune thrombocytopenia (ITP), one pure red cell aplasia and one skin toxicity. Two patients in the intravenous arm died of pneumonia and one for sudden cardiac death. We observed a good compliance, especially in the oral FC group. Overall response rate (ORR) was 84% (53% complete response); median progression free survival (PFS) was 37 months (range 2-199); median time to re-treatment (TTR) was 42 months (range 2-199). At a median follow-up of 6 years (range 1-199 months) median overall survival (OS) was reached at 96 months. Thirty-two patients are still alive. Three patients developed lymphoproliferative diseases: two of them a Richter's syndrome respectively 11 and 51 months after FC (the second patient died) and one a Hodgkin lymphoma 74 months after FC. One patient showed a myelodysplastic syndrome 36 months after FC. One patient with previous surgery for gastric ulcera developed a gastric cancer 32 month after FC and died. Eighteen patients died of progressive disease at median of 47 months after FC and five due to infective late complications. One patient, who received only 2 cycles of FC and immune therapy for ITP, died of hepatic cancer. Other late fatal events unrelated to CLL were two heart diseases, one liver disease, and one respiratory failure. Among patients who required salvage therapy, our data suggest that the combination of Rituximab with chemoterapy (Chlorambucil, FC, Bendamustine) is the best strategy as second line therapy. A significantly lower OR (HR 0,093; CI 0,015-0,580; P=0,011) and reduced PFS (HR$_{3,857}$; CI$_{1,766}$-8,424; P=0,001) was noticed in the high risk (Del 17p- and/or Del 11q-) FISH group compared to standard risk. Unmutated IgVH (HR$_{2,857}$; CI$_{1,207}$-6,762; P=0,017) and high risk FISH (HR$_{4,641}$; CI$_{1,929}$-11,164; P=0,001) emerged as independent prognostic factors on TTR. Patients with high risk FISH showed reduced OS (68 months versus 96 months standard risk), without statistical significance.
Summary / Conclusion: These results confirmed the safety and tolerability of FC. Even if in the era of monoclonal antibodies in which BTK and PT3K inhibitors showed surprising results, this association could be still used especially as oral formulation in patients not eligible for more aggressive protocols, allowing a home therapy.

Chronic myeloid leukemia - Biology

B1348

BCL-XL EXPRESSION AS A POTENTIAL PROGNOSTIC PARAMETER IN CHRONIC MYELOID LEUKEMIA

A Kamel[1*], G Mossallam[1], S Meshaal[2], D Labib[2], R Abdelfattah[3], M Samra[3], M Sherif[2], O Goher[2]
[1]Clinical Pathology, NCI, Cairo University, [2]Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, [3]Medical Oncology, NCI, Cairo University, Cairo, Egypt

Background: Chronic myeloid leukemia (CML) is characterized by the presence of the Ph chromosome (*BCR/ABL* chimeric gene) in hematopoietic stem cells. Clinically, it is manifested in three distinct phases: chronic, accelerated, and blastic. *BCR-ABL* expression results in constitutive activation of STAT5 which contributes to increased expression of the anti-apoptotic Bcl-2 family member *Bcl-xL*.
Aims: The aim of this work was to investigate the role of *Bcl-xL* expression in CML progression into advanced phases and its possible significance as a prognostic parameter.
Methods: The study was conducted on 32 CML patients including 12 males and 20 females with an age range of 21-79 and a median of 41.5 years. They included 18 in chronic (Group I), 3 in accelerated and 11 in blastic crisis phase (Group II). Hasford score was available for 30 patients. They were divided into 3 risk groups: Low risk group: score 780 (8 patients), Intermediate risk group: score 781-1480 (13 patients) and High risk group: score > 1480 (9 patients). Patients received standard therapy. *Bcl-xL* expression was assessed by RT-PCR; it was studied in relation to various hematological and clinical parameters. The study was approved by the IRB of the NCI, Cairo University and a written informed consent was obtained from all participants.
Results: *Bcl-xL* expression did not differ according to the disease stages. Within group I, TLC and % basophils were significantly higher in patients with *Bcl-xL* positive than those with *Bcl-xL* negative (P=0.004 and 0.02 respectively). Hasford Score was available for 15 cases in group I and 15 in group II; it was significantly higher in group II (1383.16±1259.98 vs.1122.97±474.43, p value=0.01). Within group I, *Bcl-xL* showed a statistically significant higher expression in patients in high risk group according to Hasford score than patients in intermediate or low risk groups The difference was statistically significant in the total cohort (P=0.01) and in group II (P=0.046) but insignificant in group I. A statistically significant better outcome was observed in *Bcl-xL* negative patients as compared to *Bcl-xL* positive ones (P=0.05).
Summary / Conclusion: *Bcl-xL* is not involved in the mechanism(s) underlying the progression into accelerated phase or blastic crisis in CML. However it might serve as a prognostic parameter.

B1349

BCR-ABL KINASE DOMAIN MUTATION FREQUENCY IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS RESISTANT TO IMATINIB THERAPY

Background: The major mechanism of resistance to imatinib and another inhibitors of tyrosine kinases of patients with chronic myeloid leukemia (CML) is the mutations in the locus between exon a3 and exon a11 in *ABL* gene, which present in *BCR-ABL* fusion tyrosine kinase and its mRNA. According to recommendations European Leukemia Net (ELN) sequencing of the *BCR-ABL* kinase domain is a necessary analysis for all patients with CML with primary reduced capacity of imatinib to inhibit kinase activity.
Aims: Analysis of incidence mutations frequency in the BCR-ABL kinase domain in patients with chronic myeloid leukemia (CML) with resistance to imatinib therapy.
Methods: Present study involves 846 CML patients with resistance to imatinib therapy in 68 hospitals of 53 cities of Russia during 85 months from January 2006 to February 2013. The patients had different disease stage. Efficiency of imatinib therapy was analyzed in GeneTechnology LLC Molecular Oncology and Hematology Lab in Moscow by RQ-PCR of *BCR-ABL* transcript according IS (International Scale). Identification of point mutations in the locus between exon a3 and exon a11 in mRNA *BCR-ABL* was performed by direct sequencing of the *BCR-ABL* kinase domain.

Fig. 1. Distribution among CML stages and frequency of mutations coursing resistance to 2nd generation ITKs.

Mutation	CML (CP), N=129	CML (AP), N=78	CML (BC),N=55	Resistance
T315I	5,4%	16%	27%	Imatinib, Nilotinib, Dasatinib
E255K/V F359V/C Y253H	6,2% 9,3% 5,4% } 20,9%	12,8% 7,7% 8,9% } 29,4%	16,4% 2,7% 7,3% } 26,4%	Imatinib, Nilotinib
F317L/I	4,6%	12,8%	16,4%	Imatinib, Dasatinib

Results: 31% (n=262) patients with CML and resistance to imatinib therapy had mutations in the *BCR-ABL* kinase domain, among them 59,9% men (n=157) and 40,1% women (n=105), median age – 50 (from 15 to 74). As well as5,7% patients (n=16) had two mutations, we were detected 278 mutations from 262 patients with CML. Total amount of mutations comprise 40 variations sorting by decrease: T315I or G250E (35/262 – 12%); T317L (33/262 –7,9%); M244V (21/262 –7,5%); F359V, H396R or Y253H (18/262 –5,6%); E255K (16/262 –5,7%); E255V, L248V or M315T (11/262 –3,9%); E355G (8/262 –2,8%); F359C (7/262 –2,5%); del ex7, Q252H or L387F (5/262 –1,8%); S348L (4/262 –1,4%); Ins 98-72 bp, F317I or E255D (3/262 –1,1%); E275K, E279A, K247R, L387M or V299A (2/262 – 0,7%); E292V, E334G, E450K, E459A, E459K, F359I, F486S, L383F, P441L, Q252M, Q491L, T305I, T345I, Y312C, T520S or G425Stop (1/262 – 0,3%). Double mutationswere associatedwith the variations in the P-loop domain. The median of detecting mutations was 27 months (from 3 to 83 months). Part of the mutations (include T315I) with resistance to nilotinib comprised 40,3%, to dasatinib – 21% (Table). 69% (n=584) patients with CML and resistance to imatinib therapy had not mutations in the *BCR-ABL* kinase domain, among them 46% men (n=268) and 54% women (n=316), median age – 51 (from 24 to 74).
Summary / Conclusion: Present study confirmed essential influence mutations in *BCR-ABL* kinase domain on resistance to imatinib therapy (for 31% patients). But in 2/3 cases resistance to inhibition of the tyrosine kinases associated with no *BCR-ABL* mutations. We also indicated that besides well know point substitutions took place another mutations that lead to essential alteration in protein structure and cause resistance. Patients during imatinib therapy had significant count mutations in *BCR-ABL* domain of leading to resistance to second-line inhibitors of tyrosine kinase. As the result it is necessary to identify *BCR-ABL* mutations for changing therapy to using dasatinib and nilotinib. Similar structure of imatinib and nilotinib explained that common sets of mutations of resistance to nilotinib therapy are prevailed over mutations of resistance for dasatinib. If dasatinib and nilotinib will move to first-line therapy the change of this situation is expected.

B1350

LOWER INCIDENCE OF CML IN O BLOOD GROUP AND SECRETOR INDIVIDUALS

M Jaff[1*]
[1]Council of Diagnostics, Kurdistan Board for Medical Specialities, Erbil, Iraq

Background: ABO blood groups have been associated with many bacterial, fungal infections, and malignancies.
Aims: To examine such association and the possibility of explaining it, through studying (591) patients with hematological malignancies (HM); AML, ALL, CML, CLL, HL, NHL, and MM, compared to (196) blood donor controls
Methods: Standard conventional techniques were used for ABO; Rh grouping. Secretor status was determined by Lewis blood grouping and haem-agglutination inhibition test.Informed consents were obtained from both patients and controls according to medical ethics regulation.
Results: ABO & Rh blood groups and secretor status results showed no significant difference from controls, except in CML patients; where blood group A incidence was significantly (*P: 0.0007*) higher (55.0 %) than normal control (32.1%) and than other (HM) (31.3%) (*P: 0.0001*). Blood group O was significantly (*P: 0.0074*) lower in CML (21.7%) than normal (38.3%) and than other (HM) (41.4%) (*P: 0.0015*). No significant difference in the secretor status was found between different (HM) but a significant lower incidence was found in CML (60%) as compared to controls (74.0%)(*P: 0.0187*), and to other (HM) (73.6%)(*P: 0.0127*). Also there was a lower incidence of secretor status in CML patients with O blood group (45.5%) as compared to controls and to other (HM) patients (*P: 0.0197)(P: 0.0198*) respectively.
Summary / Conclusion: A significant lower frequency of O blood group was found in patients with CML. This means blood group O individual are protected from CML. This can be explained at least partially, by the higher frequency

of secretor status in these patients. Evidences, from other studies, have shown that ABO antigens can modulate cellular interactions making them more accessible for glycan-binding proteins through their sialic acid constituents, also have shown an increased EDF binding sites on normal blood group A1 RBCs (which are also present on other hematopoietic cells) as compared to group O and B individuals. Which means more ability to bind EDF and then after, more Tyrosine Kinase activity with it's known implicated role in the pathophysiology of cancer

B1351

BCR-ABL1 GENOMIC MOLECULAR CHARACTERIZATION IN CHILDREN WITH CML: DESCRIPTION AND INTEREST FOR MOLECULAR FOLLOW-UP

Background: Chronic myeloid leukemia (CML), is a rare disease in children characterized by *BCR-ABL1* fusion. Molecular follow-up is a major factor for evaluation of treatment efficiency. However, BCR-ABL1 transcript fusion quantification is sometimes technically difficult due to RNA extraction and stability. Breakpoints genomic regions, never described in pediatric CML, are classically along a 3 Kb intronic region on *BCR*, and more than 140 kb intronic region in *ABL1*.
Aims: Characterize breakpoints regions in pediatric CML and quantify *BCR-ABL1* genomic fusion to design a molecular follow-up
Methods: 20 patients, between 10 months and 16 years old, are studied. They present CML with M-BCR transcript. After sequencing analysis of M-BCR transcript, genomic fusions are amplified by a long-range multiplex PCR, using 2 forward primers on *BCR* and 25 reverse primers on *ABL1* all along potential breackpoint region. Amplification product is sequenced and a patient specific PCR is designed among genomic fusion. A FISH based method, using 6 contiguous fosmides on *ABL1*, allows limiting the patient potential breackpoint region to about 30 kb. If failing, a LDI-PCR (Long Distance Inverse PCR) technique is used on *BCR* to amplify *BCR-ABL1* genomic fusion.
Results: Genomic fusion has been characterized for 17 patients (85%). Method used was long range multiplex PCR for 14 patients and LDI-PCR for 3 patients. FISH were used for 3 patients. *BCR* breackpoints are located all along M-BCR region. *ABL1* breackpoints are located along the 2 first intronic regions, and for 2 patients, before 5' end of the gene. There is no genomic particularity for breakpoints regions. Only 3 breakpoints on *BCR* and 6 on *ABL1* occurred in repeated sequences.
Summary / Conclusion: 70% of genomic fusions are characterized by multiplex long range PCR. With additional LDI-PCR and FISH techniques, 85% are characterized. These techniques are more difficult to use than transcript quantification by quantitative PCR, but DNA extraction is easier and stability much better. Molecular follow-up, with patient specific genomic quantitative PCR, could be more precise and reproducible. We think that genomic characterization of BCR-ABL1 fusion for CML patients is technically more fastidious than RQ-PCR, but possible in routine procedures, and could improve molecular follow-up for CML patients.

IDENTIFICATION OF IL-6-174G/C PROMOTER POLYMORPHISM IN CHRONIC MYELOID LEUKEMIA

S Yalcin[1], P Mutlu[2], G Ozgur[3], T Cetin[3*], O Nevruz[3], F Avcu[3]

[1]Food Engineering, Ahi Evran University, Kirsehir, [2]Biology, Middle East Technical University, [3]Hematology, Gulhane Medical School, Ankara, Turkey

Background: Cytokines such as interleukin and interferon are immunomodulating agents that are secreted by active lymphocytes, macrophages, endothelial and epithelial cells in case of inflammation and immune reactions. Interleukin-6 (IL-6) is secreted by the T-cells and macrophages and serves both pro-inflammatory and anti-inflammatory effect in addition to B-cell growth. IL-6 has been shown to be associated with many diseases including hematological malignancies, being a positive growth factor. However, the highest levels of cytokines which are produced by immune cells vary between individuals due to genetic polymorphisms. It has been shown that these genetic polymorphisms influenced the total cytokine expression and release, being an important distinguishing factorfor risk of disease occurrence, course of illness and disease prevention.
Aims: In this study, promoter polymorphism of IL-6 (-174G/C) was identified and investigated in chronic myeloid leukemia (CML) patient group whether it is a risk factor for the occurrence of the disease.
Methods: Twenty five unrelated CML patients were selected for this study. Control blood samples were obtained from 30 unrelated, healthy volunteers. The consent of the local ethics committee was obtained for this study. Genotyping of -174G/C polymorphism was performed by polymerase chain reaction (PCR) and restriction fragment polymorphism analysis (RFLP) using specific primers and NlaIII restriction enzyme, respectively.
Results: Seventeen of 25 (68.0%) CML patients were found as homozygote for G/G genotype. Five of 25 (20.0%) were heterozygote and 3 of 25 (12.0%) were homozygote for C/C genotype. In the control group, 29 of 30 (96.7%) were homozygote for the G/G genotype and only 1 of 30 (3.3%) was heterozygote. Homozygote C/C genotype was not observed. The ratio of the C/C genotype in CML patient group was significantly higher than the control group ($P<0.05$).
Summary / Conclusion: IL-6 -174G/C polymorphism may be a risk factor for the occurrence of chronic myeloid leukemia.

CREATION OF A RESOURCE GROUP ON "GENOMICS IN THE CLINIC IN LOW RESOURCE SETTINGS": AN EXAMPLE USING A LONGITUDINAL STUDY OF A CML CASE

A Chacko[1*], S Patil[1], A Upadhyay[1], A Nagrajan[1], R Khatri[1], D Arya[1], S Krishna[1], C Ross[2], S Ramanathan[1]

[1]National Centre for Biological Sciences, [2]St. John's Medical college and Hospital, Bangalore, India

Background: Genome sequencing has emerged recently as a technology that can be used to address questions regarding the clonal evolution of cancers such as CML and has potential to be translated into practical applications in a clinical setting. In order to lay the foundation for exploring the possible use of such technologies in a lower resource clinical setting, we have created a consortium involving basic experimental biologists, scientists with expertise in bio-informatics and structural biology along with clinicians. In the first such exercise, we have undertaken a whole exome sequence of a patient with CML, as its clinical outcome varies amongst patients during the progression of disease.
Aims: This study attempts to understand the variability of the clinical outcome to standard treatment from a genomics perspective. Our case study includes a patient who has been responding to Imatinib at 200 mg once a day or sometimes on alternate day because of symptomatic neutropenia for two years with no progression, both clinically and molecularly.
Methods: The exome sequencing of the bone marrow aspirate was performed at the time of diagnosis and after two years of treatment with Imatinib. Matched skin biopsy was used as a control. This study has been approved by the Institutional Ethical Review Board of St. John's Medical college and Hospital.
Results: We present the relevant clinical information and the initial analysis. The novel mutations are being mapped on genes to identify which functional domains could be affected and to provide a structural basis of such mutations. A bioinformatics pipeline has been established to map domain architecture and to perform homology modelling of genes of interest. These polymorphisms would allow us to use such readout as a screen across CML patients to identify cases with better disease prognosis.
Summary / Conclusion: In addition to adding insights on the evolution of CML and providing an opportunity to develop screens for better CML prognosis, this study also offers insights on organizing such studies in India, where genomics is still in the early stages. With the distinct population groups and diverse spectrum of diseases, we believe that our work lays the foundation for larger studies in both CML and other diseases requiring such approaches.

B1354

WHOLE EXOME SEQUENCING ANALYSIS IN CHRONIC MYELOID LEUKEMIA

A Lavrov[1], S Smirnikhina[1], E Chelysheva[2], E Adilgereeva[1], O Shukhov[2], V Kozlov[1,3], A Turkina[2], S Kutsev[1,4*]

[1]Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of Medical Sciences , [2]Federal State Budgetary Institution "Hematological Research Centre" of Ministry of Health of the Russian Federation, [3]State Budgetary Educational Institution of Higher Professional Education "Moscow Institute of Physics and Technology", [4]State Budgetary Educational Institution of Higher Professional Education "Russian National Research Medical University named after N.I. Pirogov" of Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: Tyrosine kinase inhibitors (TKI) therapy of chronic myeloid leukemia (CML) has shown impressive results last decade. However, around 25% of patients on imatinib have failed to achieve optimal and 10% patients have lost the achieved response in 5 years. The resistance to TKI therapy remains in CML patients on TKI of second generation too. Exome analysis is now-a-days one of the most powerful tool in the search for the new prognostic markers and molecular targets for therapy.
Aims: We launched prospective study aiming to sequence exomes in CML patients to find out possible exomic differences of leukemic cells between

responders and non-responders as well as between leukemic and normal cells in the same patients.
Methods: Whole exome sequencing by NGS technology of 5 primary CML patients who achieved complete cytogenetic response in 6 months of TKI therapy were included in analysis.
Results: To the date there are 5 CML exomes sequenced with 26K variations found in average. About 8K of the found variants are non-synonymous. Preliminary analysis demonstrated that from 756 to 789 of these non-synonymous variants in each patient are not described in dbSNP. The comparison of the revealed non-synonymous variants between patients did not reveal identical SNP.
Summary / Conclusion: Preliminary findings shown that NGS analysis did not revealed identical non-synonymous variants in exomes of leukemic cells in CML patients with optimal response to TKI therapy. These and new data with deep bioinformatics analysis of comparison of leukemic and normal cells exomes will be discussed.

B1355
MESENCHYMAL STEM CELLS FROM CHRONIC MYELOGENOUS LEUKEMIA (CML) PATIENTS, A PROJECT TOWARDS EXPANDING AN AUTOGRAFT FOR TRANSPLANTATION
M Salamoon[1*], M Kenj[2]
[1]medical oncology, al Bairouni university hospital, [2]molecular biology, mazen kenj lab, damascus, Syrian Arab Republic

Background: Human Mesenchymal stem cells (MSCs) are group of cells able to give rise to different types of stem cells and now that they do exist in bone marrow they can differentiate into hematopoietic stem cells.CML is a monoclonal myeloproliferative disorder characterized by Philadelphia chromosome t (9;22) and a fusion gene BCR-ABL at molecular level.
Aims: The goal of the study is to isolate MSCs from patients diagnosed with CML in chronic phase proven to be Philadelphia chromosome positive by means of Karyotype and fusion gene BCR-ABL positive by FISH, then to prove that MSCs are Philadelphia negative cells which enable us to differentiate them into hematopoietic stem cells in vitro.
Methods: The study was performed at the molecular cytogenetics section of Kenj cytogenetics laboratory in Damascus (SYRIA). Bone marrow samples were taken from 20 newly diagnosed patients with CML still in chronic phase. All samples were Philadelphia positive by karyotype and BCR-ABL fusion gene positive by FISH. Samples were cultured and Mesenchymal stem cells were isolated after proper passages , and were phenotyped by flowcytometer to reveal positive CD105 and negative CD14, CD34 and CD45 which meets the MSCs criteria.
Results: isolated MSCs, showed normal Karyotype, negative BCR-ABL fusion by FISH, and negative BCR-ABL cDNA by rt –PCR, out of 10^6 cells showing that MSCs completely isolated from the leukemic cells. MSCs reserved its osteogenic differentiation potential and we tried to trigger hematopoietic differentiation of those cells , and have got promising results. confirmed by increasing percentage of CD34 positive cells which were in turn BCR-ABL negative by rt-PCR.
Summary / Conclusion: Results showed that the bone marrow is an abundant source of MSCs and the genetic abnormality in CML is taking place in a certain phase post-hematopoeitic stem cell. Also expansion of CD34 population in vitro beginning from a MSC derived from the bone marrow opens a spectrum of ideas such as making an autologous stem cell transplantation in CML patients which seems like a dream nowadays.

B1356
CO-EXPRESSION OF P190 AND P210 TRANSCRIPT IN A PEDIATRIC CHRONIC MYELOID LEUKEMIA PATIENT AT THE TIME OF BLAST CRISIS
I Eker[1*], O GURSEL[1], O BABACAN[1], A KUBAR[2], A KUREKCI[1]
[1]Pediatric Hematology, [2]Microbiology,Virology, GATA, Ankara, Turkey

Background: It has been suggested that the co-expression of p190 BCR-ABL transcript (p190) being detected frequently at a low level in adult p210 BCR-ABL transcript (p210) positive chronic myeloid leukemia (CML), but of no pathogenetic significance. On the contrary, the pathogenetic significance of this co-expression remains unclear in pediatric population.
Aims: Here we report a pediatric CML patient, who presented co-expression of the p190 and p210 at the time of blast crisis.
Methods: A fifteen years old boy, who had been diagnosed as CML in Iraq before one years of his referral to our service, had been receiving imatinib treatment for seven months until his first lymphoid blast crisis. Complete hematologic response had been achieved with two course of hyperfractionated cyclophosphamide, vincristine, doxorubicin, dexamethasone (Hyper CVAD). He had been transmitted to our service with imatinib treatment after two months from his second course of Hyper CVAD, for the plan of hematopoietic stem cell transplantation. At the time of his admission he had fullnes and weakness complaints and found to have 4 cm palpable spleen below costal margin. Laboratory findings showed an anemia (10 g/dL) and leukocytosis (70x109/L). Bone marrow aspiration revealed diffuse L1 type lymphoblastic infiltration. Flow cytometry was positive for CD10, CD19 and he was diagnosed as second lymphoid blast crisis relapse of CML. Bone marrow karyotype revealed the presence of %50 Philadelphia chromosome in 100 interphase and RT-PCR revealed the presence of both the p210 and p190. He had failed the antileukemic remission induction therapy with ALL-REZ-BFM-2002 treatment protocol while the search was going on for match unreleated donor, because of not having a match releated donor. Bcr-Abl kinase domain mutational analysis was performed and revealed no mutations. He was given imatinib treatment with clofarabine, cyclolphosphamide and etoposide combination chemotherapy, He finished the induction phase of the combination therapy without a major complication. Complete cytogenetic response was achieved. RT-PCR control revealed negativity of the p190 but very weak persistence of the p210. After one month when he became clinically stable, a second course of the combination chemotherapy was given as consolidation. Despite not having Bcr-Abl kinase domain mutation, he was considered as having clinical resistance to imatinib and was given dasatinib treatment with the beginning of consolidation chemotherapy. Bone marrow analysis on the fourteenth day of the consolidation chemotherapy revealed complete response at the cytogenetic and molecular level, neither p210 nor p190 were detected on PCR analysis. He is now clinically stable, on dasatinib treatment and match unreleated donor search is going on.
Results: Although p210 is present in majority of pediatric CML patients, p190 is very rare.It is suggested that p190 may be a secondary event in at least some cases of childhood CML, suggesting an association with imatinib resistance and progression to a blastic crisis in these patients. In conclusion it is worthful of searching p210 and p190 with RT-PCR in Philadelphia chromosome positive pediatric CML patients both at the diagnosis and during the course of therapy, because co-expression of p210 and p190 may be associated with resistance to imatinib and progression to the blastic phase.
Summary / Conclusion:
This case shows that there is need to further molecular hematological researchs and gathering data with interpretation in pediatric CML.

B1357
ASSESMENT OF THE EFFICACY OF HESA-A ON THE PROLIFERATION AND APOPTOSIS OF CHRONIC MYELOGENOUS LEUKEMIA CELL LINE
F Nadali[1*], M Ghasemi[1], N Ostad[2], S Rostami[3], F Zaker[1]
[1]Hematology Department, [2]Toxicology, Tehran University of Medical Sciences, [3]Hematology-Oncology and BMT Research Center, Tehran, Iran, Islamic Republic Of

Background: Chronic myelogenous leukemia is characterized by philadelphia (ph0 chromosome, the presence of BCR-ABL fugene gene and constitutive activation og the ABL1 tyrosine kinase. Despite an excellent result of target therapy by imatinib, some patients develope resistance to imatinib. HESA-A has produced as an anti-cancer drug by Iranian scientists in order to reduce sid effects of conventional therapy.
Aims: In this study efficacy of HeSA-A on proliferation and apoptosis of K562 cell line was assessed.
Methods: In this study doubling time of K562 cell line was calculated.The cells were affected by various concentrations of HESA-A (1,2,4 and 8 mg/ml respectively). Cytotoxicity and IC50 dose of HESA-A were detected by MTT and trypan blue exclusion assay. Appoptosis was assessed by flowcytometry after 48 h cell treatment in the presence of IC50 dose.
Results: Doubling time of K562 was 24 hours. HESA-A reduced the number of viable K562 cells in a concemtration manner dependent. IC50 dose was 3.5 mg/ml. In flowcytometry analysis of apoptosis, 19.22% of the treated cells were located in the position of the necrotic cells.
Summary / Conclusion: The results of MTT and trypan blue exclusion assay suggest that HESA-A inhibits the growth of K562 cells in a concentration dependent manner and induce necrosis in K562 cells.

Chronic myeloid leukemia - Clinical

SECONDARY MALIGNANCIES IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS.

A Enrico[1*], C Pavlovsky[2], R Mariano[3], B Moiraghi[4], G Bendek[5], J Milone[1]
[1]Hematology, Hospital Italiano de La Plata, La Plata, [2]Hematology, Fundaleu, Ciudad Autonoma de Buenos Aires , [3]Hematology, Hospital de Parana, Parana Entre Rios , [4]Hematology, Hospital Ramos Mejia, ciudad Autonoma de Buenos Aires, [5]Hematology, Hospital Centro de Salud Zenon Santillan, San Miguel de Tucuman, Argentina

Background: Tyrosine kinase inhibitor (TKIs) in CML has become such a success that it has given patients hope for a large disease free-survival. Preclinical studies with Imatinib in rats showed neoplastic changes in kidney, urinary bladder, urethra, preputial and clitoral gland, small intestine, parathyroid glands, adrenal glands and non glandular stomach. The question about the possibility of late effects if TKI treatment includes the possibility of developing other malignancies arises in patients with long disease free survival.
Aims: We analyzed our CML patient population (in 5 sites of Argentina) to investigate the frequency and characteristics of second malignancies among patients with CML treated with TKIs.
Methods: All patients with CML treated with TKI between November 2001 December 2012 were included in this analysis. All the patients had a medical history and physical examination, complete blood counts and blood chemistry before the beginning of therapy and every month for the first 3 months, then every 3 months until 12 months, from the beginning of the therapy and then every 6 months. Cytogenetic response was assessed in the BM and the molecular response was assessed by real-time PCR. The records of 383 patients with CML in chronic phase (CP) treated with TKI were reviewed. The patients with CML included in CP treated with Imatinib Mesylate (IM) after IFN failure, and patients treated with second generation TKI in front line therapy. Fifty patients (0,03%) developed 15 different second cancers. Of these 15 patients 8 were men. 14 patients received frontline therapy with IM for CML, and one patient with dasatinib. 8 patients received IM after IFN treatment failed. None of the 12 patients had received stem cell transplantation. The types of second cancer during TKI therapy were: gastrointestinal (GI cancer); colon: 4 patients; breast cancer: 1; lung cancer: 3 patients; genitourinary (GU cancer): urinary bladder, kidney , uterine, and penis 6: patients; and Non Hodgkin Lymphoma 1 patient. The most common second cancer were GU cancer representing 0,4 % of all the cancers. The median time from the start of TKI therapy to diagnosis of the initial second cancer was 46,1 months (range 2-22 months) After a median follow up of 21,2 months from diagnosis of a second cancer, 9 patients had died among the dead, 4 had died of CML related cause. The best response to TKI at the time of detection of the second cancer was HCR in all patients, and RCyC in 10 patients. The CMR was observed in 8 patients.
Results: In our analysis, the incidence rate of secondary malignancies inCML patients was 0,03%. The most common second malignancies was GU cancer. A Continuous long term monitoring of these patients, together with a report of the patients who developed a second cancer, is necessary
Summary / Conclusion: In our analysis, the incidence rate of secondary malignancies inCML patients was 0,03%. The most common second malignancies was GU cancer. A Continuous long term monitoring of these patients, together with a report of the patients who developed a second cancer, is necessary

B1359

SUCCESSFUL MANAGEMENT OF CML DURING PREGNANCY AND IN POST-PARTUM PERIOD

H Klamová[1*], D Srbová[1], M Šišková[2], K Poláková[1], J Březinová[2], P Cetkovský[1], M Marková[1]
[1]Institute of Hematology and Blood Transfusion, [2]1st Department of Internal Medicine, General University Hospital, Prague, Czech Republic

Background: The occurrence of any leukemia during pregnancy is rare, with an estimated incidence of 1:100,000 pregnancies annually. Chronic myeloid leukemia (CML) covers less than 10% of leukemias during pregnancy. The median onset age of CML is in the sixth decade, however about 10-15% of cases occur in women in childbearing age. Possibility of pregnancy is therefore a current topic. The CML therapy during pregnancy is limited by teratogenic side effect risk. Except some case reports Pye at al. (2008) reported relevant cohort of these patients. Data on human fetal development in pregnant women and patient partners withCML are still limited, which led us to report data of our centre.
Aims: To verify a possibility of effective CML treatment during running pregnancy without fetal development hazard together with achievement of optimal response after delivery.
Methods: Between the years 2000-2012 we determined 12 pregnancies in 11 patients with CML and 9 pregnancies in 8 patients´ partners.
Four patients decided for artificial abortion. Remaining 8 pregnancies in 7 patients continued to delivery. Except one patient who recognized the pregnancy in 20th week, all the others were found out in the first trimester. Five pregnancies were confirmed in parallel with CML diagnoses without pretreatment. One patient was pretreated with imatinib (IM) for 18 months, one with interferon (IFN) for 24 months. One patient after successful delivery, who achieved major molecular remission (MMoR) on dasatinib (DA), discontinued treatment because of planning the second pregnancy.
In the first trimester, patients were either untreated or leukodepleted, in the second and third trimester they were treated with lekapheresis and/or interferon, or were without treatment. Seven male patients were treated with imatinib and one with dasatinib median 18 months (range 8-101) before conception. One patient became twice father during tyrosine kinase inhibitors consumption.
Results: All these 8 pregnancies (in 7 women) terminated with birth of healthy infants carried to term (4 girls and 4 boys). Current age of children is 1 month to 12 years. In 5 patients after the delivery IM treatment was initiated, in 4 of them followed with DA, one patient continued on IFN treatment. In all 6 patients complete cytogenetic response was achieved (median 18 months), in 5 subsequently MMoR as well. One patient has not been evaluated yet due to short time of treatment. One patient was treated with dasatinib with lasting MMoR prior pregnancy. At her request to have a baby (second child during CML therapy), the treatment was interrupted before conception. Although she lost MMoR, she did not need any treatment during pregnancy and she gave birth to healthy child. In 3 months after dasatinib return MMoR was restored. Pregnancies of CML patients´ partners were without complication terminated with birth of healthy children, only one child required surgical resolution of umbilical hernia. All women have good quality of life 8 to 172 months from CML diagnosis and 1 to 111 months from delivery.
Summary / Conclusion: All female patients who had decided to keep going their pregnancies gave birth to healthy children and subsequently achieved very good treatment response. The treatment of CML during pregnancy did not jeopardize fetal development and did not negatively influence long lasting results. Also pregnancies of CML patients´ partners seem to be mostly without any complications. However the treatment of pregnant CML patients requires close cooperation between experienced hematologist and obstetrician.

Supported by IGA NT13899.

BCR-ABL TRANSCRIPT LEVELS AT 3 AND AT 6 MONTHS ARE PREDICTIVE FOR SURVIVAL, TIME TO TRANSFORMATION AND TIME TO SECOND LINE TREATMENT ONSET IN CHRONIC MYELOID LEUKEMIA PATIENTS ON IMATINIB THERAPY

T Sacha[1*], S Czekalska[1], M Gniot[2], K Lewandowski[2], M Dudziński[3], A Kopacz[3], D Hawrylecka[4], E Wasilewska[5], I Florek[6], M Zawada[6], D Link-Lenczowska[6], M Jakóbczyk[7], K Kamska[6], A Skotnicki [6]
[1]Klinika i Katedra Hematologii Uniwersytetu Jagiellońskiego w Krakowie, Kraków, [2]Katedra i Klinika Hematologii i Chorób Rozrostowych Układu Krwiotwórczego, Poznań, [3]Oddział Hematologii Wojewódzkiego Szpitala Specjalistycznego, Rzeszów, [4]Hematology, Oddział Hematologii Onkologicznej Szpital Specjalistyczny Podkarpacki Ośrodek Onkologiczny, Brzozów, [5]Klinika Hematologii Uniwersytet Medyczny, Białystok, [6]Klinika i Katedra Hematologii Uniwersytetu Jagiellońskiego, Kraków, Poland, [7]Hematology, Klinika i Katedra Hematologii Uniwersytetu Jagiellońskiego, Kraków, Poland

Background: The assessment of molecular response at 3 and at 6 months of imatinib treatment has been shown to play important role in predicting achievement of deep molecular response and survival of patients with chronic phase CML. The result of early assessment of BCR-ABL transcript level might indicate the group of patients who need more intensive therapy. The influence of clinical factors before introduction of TKI therapy on early molecular response is largely unknown.
Aims: We investigated the influence of some clinical factors (time from diagnosis to TKI, previous IFN alfa therapy, EUTOS score) on early molecular response and the outcome of patients with BCR-ABL transcript levels of ≤ 1%, > 1% to ≤ 10%, and > 10% at 3 and 6 months
Methods: A total of 270 patients (pts) treated with imatinib were investigated. The median age was 52 years (range 22-92, 43% female). Median follow-up was 5.5 years (range 2-12). Transcript levels of BCR-ABL, and ABL were determined by standardized RQ-PCR method from samples taken at 3 and 6 months. Only patients with typical BCR-ABL transcripts (b2a2 and/or b3a2) were included. Disease progression was defined by the incidence of accelerated or blastic phase, or death from any reason. Time to transformation (TFS) was defined by the incidence of accelerated or blastic phase, time to second line therapy onset (TFSA) by the incidence of start of second line treatment due to a failure or suboptimal response to imatinib. Patients were grouped based on BCR-ABL transcript levels of ≤ 1%, > 1% to ≤ 10%, and > 10% at 3 and at 6 months. A Kaplan – Meier analysis was performed for progression free survival (PFS) overall survival (OS), time to transformation (TFA) and time to second line therapy onset (TFSA).
Results: The level of BCR-ABL transcript after 3 months of imatinib therapy was not predicted by EUTOS score. The reduction of BCR-ABL transcript at 3 months below 10% was observed in 74% of patients with onset of imatinib therapy within first 6 months from diagnosis (P=0,005). The presence of addition-

al cytogenetic aberrations at diagnosis diminished the chance for BCR-ABL transcript reduction below 10% at 3 months (P<0,001). The influence of previous IFN alfa therapy on RQ-PCR result at 3 months was not significant. The chance for optimal response (according to ELN recommendations) was significantly reduced in pts with >10% transcript level. The same pattern were observed when the possibility for achievement of stable molecular remission 4 (MR4) and MR4.5 was analyzed. At 6 months the reduction of BCR-ABL transcript to ≤1% was important for the chance for further achievement of stable MR4 (P<0,001). There was no significant differences between other groups. The possibility to achieve a stable MR4.5 was not significantly different in all 3 transcript level groups assessed at 6 months. At 3 months the Kaplan – Meier analysis showed that OS was significantly worse (P=0,04) in patients with transcript >10% (differences between groups levels ≤ 1%, and > 1% to ≤ 10% were not significant). PFS was not significantly different for group with BCR-ABL > 1% to ≤ 10% and >10% and was significantly better for patients with transcript level of ≤ 1% versus > 1% to ≤ 10% (P=0,05) and versus >10% (P=0,01). Patients with transcript level >10% had significantly shorter time to transformation (TFA) (P=0,007%). At 6 months Kaplan – Meier analysis showed the similar results as at 3 months as far as OS and PFS are concerned, TFA was significantly longer for pts with BCR-ABL ≤ 1% versus > 1% to ≤ 10% (P=0,01) and versus >10% (P=0,01) and were not different between groups with level of > 1% to ≤ 10% versus >10%. The time to second line therapy onset (TFSA) was strongly correlated with the BCR-ABL transcript level at 3 and at 6 months and was the longest for patients with reduction to ≤ 1% (differences between all 3 groups were statistically significant).

Summary / Conclusion: Time from diagnosis to introduction of imatinib therapy could influence the reduction dynamics of BCR-ABL transcript level. Neither previous treatment with IFN alfa nor EUTOS score did not have significant influence on the BCR-ABL transcript level assessed at 3 months. The absolute transcript level at 3 months can be used to predict survival, progression free – and transformation free survival as well as the chance for optimal response and time to the onset of second line therapy with TKIs.

APPLICATION OF THE EUTOS SCORE IN A SERIES OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) IN CHRONIC PHASE (CP) TREATED WITH TYROSIN KINASE INHIBITORS (TKI)

B Xicoy[1*], C Boque[2], C Fernandez[3], R Vallansot[4], M Cortes[5], X Ortin[6], L Rodriguez[7], E Plensa[8], J Buch[3], S Marce[1], O Garcia[1], P Velez[2], L Abenoza[2], L Miguel[1], A de Sevilla[2], J Grau[1], N Estrada[1], J Ribera[1]

[1]Hematology, Institut català d'Oncologia-Josep Carreras Research Institute-Hospital Germans Trias i Pujol, Badalona, [2]Hematology, Institut català d'Oncologia-Hospital Duran y Reynals, Barcelona, [3]Hematology, Institut català d'Oncologia-Hospital Josep Trueta, Girona, [4]Hematology, Hospital Joan XXIII, Tarragona, [5]Hematology, Hospital de Granollers, Granollers, [6]Hematology, Hospital Verge de la Cinta, Tortosa, [7]Hematology, Hospital de Vic, Vic, [8]Hematology, Hospital de Mataró, Mataró, Spain

Background: In patients diagnosed with CML in CP treated with TKI the applicability of the EUTOS score and its superiority compared to the Sokal score are controversial. According to this score, one third of high-risk patients do not achieve complete cytogenetic response (CCyR) at 18 months and this predicts a poor progression-free survival (PFS). On the other hand, BCR-ABL/ABL ratio <10% at three months is associated with a better overall survival (OS) and PFS.

Aims: The objective of this study was to evaluate the prognostic value of the EUTOS score and the molecular response (MR) at three months in a series of 182 patients with CML in CP treated with IM and second generation TKI.

Methods: 182 patients in whom EUTOS score plus CCyR at 18 months and or MR at three months was available were studied. EUTOS score (high, low) was calculated based on splenomegaly (cm) and percentage of basophils in peripheral blood. CCyR at 18 months, OS and PFS according to EUTOS score and OS and PFS according to MR (BCR-ABL/ABL ratio <10% *vs.* >10%) at three months were analysed.

EUTOS	Low (n=151)	High (n=30)	p value
CCyR at 18 months, n (%)	118/125 (94%)	20/25 (80%)	0.03
8 yr. OS (95%CI)	94% (89%-99%)	53% (18%-88%)	0.01
8 yr. PFS (95%CI)	90% (80%-100%)	63% (35%-91%)	0.01
BCR-ABL/ABL ratio < 10% at three months	52/83 (63%)	6/16 (38%)	0.095

Results: 108 (59%) of patients were males. Median (range) age was 53 (20-85) years. Median follow-up (range) was 4.3 years (0.3-11.8). 58 patients received second generation TKI and 8 patients received an allogeneic stem-cell transplantation. EUTOS score: low 151 (83%), high 30 (16%), not evaluable 1 (1%). CCyR at 18 months, OS and PFS were analysed according to EUTOS score (Table). There were statistical significant differences in OS according to MR at three months: 98% (95%CI (93%,100%)) for MR group and 86% (95%CI (75%,97%)) for non MR group (P=0.041).

Summary / Conclusion: In this series of patients with CML in CP treated with ITK, high EUTOS score predicted poor OS and PFS. There was a trend for a better MR at three months in patients with low EUTOS score. These data confirm the applicability and prospective value of EUTOS score in an unselected series of CML patients.

Pirogov" of Ministry of Health of Russian Federation, [8]Federal State Budgetary Institution for Obsterics, Gynecology and Perinatology named after V.I.Kulakov of Health Ministry of Russiabsterics, Gynecology and Perinatology named after V.I.Kulakov, Moscow, Russian Federation

Background: Tyrosine kinase inhibitors (TKI) at pregnancy in females with chronic myeloid leukemia (CML) are very rarely implemented because TKI usage is known as unsafe for fetus due to teratogenic risk. On the other hand imatinib was reported in literature not able to cross placenta. The question of possibility to use TKI after appearing placenta barrier remains opened.

Aims: To provide an information about pregnancy outcomes and newborns characteristics in CML women who had to use TKI therapy during pregnancy, especially in 2nd-3rd trimester.

Results: We inform about **11** cases of using TKI during pregnancy, mostly in 2nd-3rd pregnancy trimester in females with CML in chronic phase. In 9 of 11 cases imatinib in dose 400 mg daily was used. In 2 of 11 cases nilotinib was used in dose 600 and 800 mg daily. The *reasons for TKI usage* during pregnancy were the following: newly diagnosed CML in 3 cases, hematologic relapse in **3** cases (1 on imatinib treatment, therefore switched to nilotinib); cytogenetic relapse in **2** patients (1 of them switched to nilotinib due to previous resistance for imatinib) and high levels of BCR-ABL expression corresponding usually with cytogenetic relapse (7.7 and 10% BCR-ABL IS) in **2** patients. In **1** case imatinib was used for whole pregnancy period by decision of physician and female in a patient with major molecular response before pregnancy. In 7 of 9 cases imatinib was used from 17th-34th week of pregnancy, in 2 of those 9 during whole pregnancy period. Nilotinib was taken from 25th week of pregnancy and from 10th week of pregnancy for mentioned above 2 females. *Pregnancy outcomes:* 2 of 11 pregnancies are ongoing at the moment of publication (28 and 35 gestation weeks), 1 on nilotinib, 1 on imatinib; no abnormalities in fetus development are being reported. 9 of 11 pregnancies resulted in delivery, in 1 case (on nilotinib) delivery was premature at 35th week, in other cases at 37th-40th week. *Characteristics of children:* The infants had no abnormalities at birth and good development during further observation (aged from 2 to 45 month now). The noticed feature was low weight in 5 of 9 newborns (2080-2500 g). The weight growth was rapidly gained during further artificial feeding as the lactation was suppressed. *Transbarrier penetration of leucemic cells and drugs* In 1 case the BCR-ABL expression measurement by cartridge-based GeneXpert system showed BCR-ABL 25% (IS) in female blood and 0% in umbilical blood. In 1 case tandem mass spectrometry showed that imatinib concentration in maternal blood, umbilical blood and breast milk was 813 ng/ml, 105 ng/ml and 647 ng/ml correspondingly.

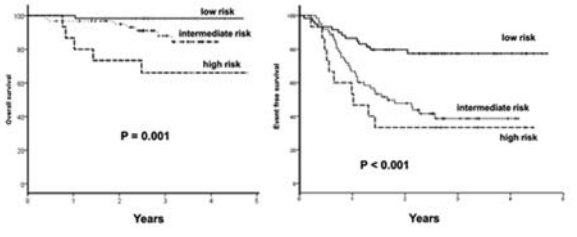
Summary / Conclusion: In spite of successful pregnancy outcomes the risk of using TKI at pregnancy cannot be precisely predicted due to the fact that a small proportion of TKI probably can penetrate through placenta barrier. In particular cases TKI therapy possibly can be used to control considerable leukemic cell mass for strict indications. Generally pregnancy should be safely planned in CML women who achieved deep remission of disease with no need of TKI therapy at pregnancy.

B1363

VALIDATION OF A PROGNOSTIC SCORING SYSTEM IN PATIENTS TREATED WITH SECOND-GENERATION TYROSINE KINASE INHIBITORS FOR CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE AFTER IMATINIB FAILURE

C Boquimpani[1,2*], R Schaffel[2], D Graça[2], C Mesquita[3], D Peixoto[1], T Madeira[1], P Wendling[1], F Eller[1], I Biasoli[2], N Spector[2]
[1]Hematology, Hemorio, [2]Internal Medicine/Hematology, [3]Hematology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background: Imatinib was the first tyrosine kinase inhibitor (TKI) to induce high rates of cytogenetic and molecular responses in patients with chronic myeloid leukemia (CML). Second-generation TKIs were introduced to treat patients with failure or intolerance to imatinib. A prognostic scoring system was recently proposed to stratify CML patients after imatinib failure into groups with different outcomes and cytogenetic responses (Jabbour E et al. Blood 2011;117:1822). Validation of this scoring system in an independent cohort was needed.
Aims: To validate the scoring system in an independent sample of CML patients treated with second-generation TKIs after imatinib failure.
Methods: 136 patients with chronic phase CML who switched to a second-generation TKI because of failure (N=134) or intolerance (N=2) to imatinib were included. All patients were treated at Hemorio (Rio de Janeiro, Brazil). The second generation TKI was nilotinib in 53% and dasatinib in 47% of the patients. Chronic phase CML was defined as blasts < 15%, blasts and promyelocytes < 30%, basophils <20%, and platelet count between 10^5 and 10^6/mm^3. Imatinib failure was defined according to European LeukemiaNet criteria. The prognostic scoring system was calculated by adding 1 point if performance status > zero and 1 point if there was a failure to achieve at least a minor cytogenetic response (Ph1 < 65%) during treatment with imatinib. Patients with score zero were defined as low risk, score 1 as intermediate risk and score 2 as high risk. Survival curves were determined from the start of the second-generation treatment, and were compared by the log-rank test. The probabilities of major cytogenetic response (MCyR) according to the risk groups were compared by the chi-square test.



Overall survival and event free survival according to the prognostic score system

Results: The median age at CML diagnosis was 45y (4-79), and 56% were male. Complete hematologic response was obtained in 91%. The best cytogenetic response during imatinib was: complete in 23.5%, major in 13%, minor in 9%, minimal in 23.5% and no response in 31%. The performance status at the start of the 2nd-generation TKI was zero in 87% of the patients. The prognostic scoring system was low risk in 59 patients (43%), intermediate risk in 62 patients (46%) and high risk in 15 patients (11%). Median follow-up was 33 months. Event-free survival (EFS) at 2 years was 75% in low risk patients, 45% in intermediate risk and 33% in high risk patients (P<0.001). Overall survival (OS) at 2 years was 98% in low risk patients, 95% in intermediate risk and 73% in high risk patients (P=0.001). The probability of attaining a MCyR at 12 months was 84% in low risk patients, 52% in intermediate risk and 40% in high risk patients (P<0.001).
Summary / Conclusion: The scoring system predicted the probability of OS, EFS and MCyR after a treatment switch from imatinib to second-generation TKIs. The information needed to generate the score was available in all patients, and the score was easy to calculate. Treatment outcomes were quite similar to thoseobserved in the original publication, indicating that treatment results are reproducible in the context of a public institution caring for underprivileged patients in a developing country. This scoring system is useful to inform patients about their prognosis and treatment choices, and can also identify a subgroup of patients in whom new treatment alternatives are needed.

B1364

CARTRIDGE-BASED AUTOMATED METHOD FOR BCR-ABL QUANTIFICATION IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH COMPLETE MOLECULAR RESPONSE ON TYROSINE KINASE INHIBITORS THERAPY

S Smirnikhina[1], G Tsaur[2], A Lavrov[1], Y Yakovleva[2], EChelysheva[3], O Shukhov[3], A Abdullaev[3], ASudarikov[3], A Turkina[3], S Kutsev[1,4*]
[1]Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of Medical Sciences , Moscow, [2]Regional Children Hospital N1, Research Institute of Medical Cell Technologies, Ekaterinburg, [3]Federal State Budgetary Institution "Hematological Research Centre" of Ministry of Health of the Russian Federation, [4]State Budgetary Educational Institution of Higher Professional Education "Russian National Research Medical University named after N.I. Pirogov" of Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: According to the current European LeukemiaNet recommendations molecular monitoring of chronic myeloid leukemia (CML) therapy has to be performed by quantitative RT-PCR with results expressed in % on international scale (%IS). Automated cartridge-based GeneXpert Dx System for detection of *BCR-ABL* transcript level was recently developed. High sensitivity and reproducibility of GeneXpert system was shown but there is lack of findings concerning the results concordance obtained by routine and automated methods
Aims: To compare the results of *BCR-ABL* gene expression analysis obtained by GeneXpert and manual standardized quantitativeRT-PCR in CML patients with complete molecular response (CMR).
Methods: 37 CML patients on tyrosine kinase inhibitors therapy with CMR were included in this study. Standardized quantitative RT-PCR and "Xpert BCR-ABL Monitor" assay aligned with the WHO reference standard allowed to express results in %IS were used.
Results: CMR$^{4.0\text{-}6.0}$(0.0001-0.01 %IS) was detected in 8/37 cases and 14/37 patients were negative by both methods. Concordance rate in those 22/37 patients was 59.5% (Pearson correlation r=0.6012, P=0.00008). Discrepant results were mainly RT-PCR-negative, but GeneXpert-positive: GeneXpert system revealed 8 extra cases negative by manual quantitative RT-PCR with appropriate sensitivity level. Median value of *BCR-ABL* in this discordant group was 0.004 %IS (range 0.00088-0.0074 %IS). It indicates that GeneXpert results were more sensitive than manual ones. 4/37 results showed to be within CMR^4 by standard RT-PCR and within major molecular response (MMR) by GeneXpert but the obtained *BCR-ABL* levels were expressed in very close values (0.005-0.009 %IS and 0.014-0.017 %IS, respectively). In 3/37 cases GeneXpert demonstrated less sensitive results than ones obtained by conventional method: negative results by GeneXpert were CMR$^{4.0\text{-}4.5}$ by quantitative RT-PCR. Probably it could berelated to samples' quality due to nonobservance of temperature conditions during transportation of blood samples.
Summary / Conclusion: The obtained results have demonstrated appropriate concordance rate of GeneXpert Dx System and conventional quantitative RT-PCR for *BCR-ABL* transcript quantification. GeneXpert allows detecting fusion gene transcript in higher percentage of cases. Cartridge-based PCR is a powerful and sensitive instrument to characterize the very low level of minimal residual disease in CML patients.

B1365

SKIN ADVERSE EFFECTS OF TYROSINE KINASE INHIBITORS IN THE THERAPY OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA – SINGLE CENTRE EXPERIENCE

D Zackova[1*], Z Racil[1,2], M Kovacevicova[3], J Feit[4], B Dobesova[1], M Palackova[1], T Jurcek[1], F Razga[1], D Dvorakova[1,2], J Mayer[1,2]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Masaryk University, [2]Central European Institute of Technology (CEITEC), Masaryk University , [3]Department of Dermatovenerology, [4]Department of Pathology, University Hospital Brno and Masaryk University, Brno, Czech Republic

Background: Therapy with tyrosine kinase inhibitors (TKI) has significantly improved prognosis of patients with chronic myeloid leukemia (CML). Along its high efficacy, significant adverse events (AE) can occur during the therapy with TKI, among them skin AE are ones of the most frequent. Pathogenesis of skin AE remains to be elucidated and also the information about their incidence and severity in every-day clinical practice is insufficient.
Aims: To evaluate real prevalence of skin AE of TKI therapy in patients with CML treated in the large hemato-oncological centre and to provide detailed dermatologic investigation including skin biopsy.
Methods: Based on a prospective surveillance of skin AE prevalence in our institution, when 178 patients with CML treated with TKI were seen at the outpatient clinic during 3-months interval, real prevalence of skin AE of ≥ grade 2 according to CTCAEv0.4 was 3/128 (2%), 0/27 (0%), and 5/23 (22%) for patients treated with imatinib, dasatinib, and nilotinib, respectively. Thus, in further analysis we focused on skin effects of nilotinib. Except of detailed investigation by dermatologist including the photo-documentation, the patients with active skin manifestations underwent a skin biopsy with histological, histochemical and imunohistochemical investigation.
Results: In total, 47 patients with CML were treated with nilotinib in our centre in a period of 11/2006 – 2/2013; 24 females and 23 males. Median age at the time of nilotinib administration start was 58 years (range, 27-74). Forty three patients were diagnosed in chronic phase, 4 patients in accelerated phase. Except of 12 patients treated with nilotinib as the first-line therapy, other 35 patients were given nilotinib because of previous therapy resistance or intolerance. Six patients experienced skin AE during previous TKI therapy. Skin AE of nilotinib occurred in 13 (28%) patients in a median of 14 days (range, 1-40)

since the start of treatment. The nilotinib dose was 2 x 300 mg/day in 6 patients, 2 x 400 mg/day in 6 patients and 1 x 300 mg/day in 1 patient, respectively. Most frequent type of skin changes was exanthema maculopapulosum in follicular distribution (N=12), in 1 patients painful skin indurations were found. Regarding the severity of skin AE, grade 1 occurred in 8 patients, grade 2 in 2 patients and grade 3 in 3 patients, respectively. Nilotinib was interrupted in 4 patients for a median duration of 6 days. Complete resolution of skin findings was present in 9 patients after a median duration of 88 days (range, 4-269). Four patients experienced skin AE recurrence in a median of 12 days after the first episode resolution and the third episode occurred in 3 patients. No patient discontinued nilotinib therapy because of skin AE. Skin biopsy was performed in 5 patients and in all cases nonspecific folliculitis was found.

Summary / Conclusion: In every day clinical practice, we showed similar frequency of nilotinib skin AE as was reported in clinical trials. In most cases, skin findings were of mild to moderate intensity, easily manageable by nilotinib interruption or dose reduction. Histological investigation revealed unspecific findings of folliculitis. Thanks to nilotinib approval as a first-line therapy for newly diagnosed CML patients, the study will be extended to a larger group of patients with the aim of more detailed imunohistochemical, perhaps even proteomic analysis of skin biopsy specimens.

The project was supported by the Czech Leukemia Study Group - for Life (CELL) and by the educational grant MUNI/A/0723/2012.

Background: *Hospital or clinical registry* is defined as a DATASET regarding all cases of a particular disease or other relevant health conditions, restricted to the scope of one or more hospitals or clinical care system within a defined population. Andalusia is a big region in the south of Spain with over than 8.5 million habitants in 2012, where the Andalusian Registry of CML (RALMC) was created in 2005 within the Andalusian CML working group. In 2012, the RALMC was remodeled with a new version of the website www.registroandaluzlmc.es which contains an updated CRF according to the current guidelines for CML treatment and monitoring from the ELN group published in 2009.

Aims: 1) To know about the CML burden in Andalusia: incidence, prevalence, mortality, overall survival, event-free survival and disease progression survival by age and sex. 2) To describe the characteristics of epidemiological, clinical, diagnostic and treatment of CML patients in the RALMC.

Methods: Autonomous, multicentric, epidemiological and observational registry for the study of more than 14 years old patients diagnosed of CML Ph+ in Andalusia, prior signed of the mandatory informed consent. The study complies with the Declaration of Helsinki and was approved by the Andalusian Ethics Committee. The BCR-ABL results are expressed in international scale. The patient visits are completed every 3 or 6 months according to each internal protocol. Patients are cataloged and monitored according to ELN guidelines, 2009. In February 2012, a cross-descriptive study was performed to analyze the current status of 165 patients treated with Imatinib in front line in terms of optimal response, suboptimal response, failure and intolerance to Imatinib.

Results: 467 patients from 35 hospitals. By the end of 2013 the registry is expected to collect data from 650 patients. Median age is 54 (19-86), gender distribution: 54% male and 46% female, distribution by Sokal groups: low-risk 43%, intermediate-risk 37% and high-risk 20%. Only 10cases were diagnosed in AP. 2GTKIs were used as first-line therapy in 30 patients outside of clinical trials. We performed a subanalysis on data from 165 patients classified following the 2009 ELN guidelines.

165 patients were treated in first line on Imatinib 400mg QD: 121 (73.4%) had optimal response [54 (44.6%) $MR^{5.0}$; 35 (29%) $MR^{4.5}$; 16 (13.2%) $MR^{4.0}$; 12 (10%) MMR; 3 (2.4%) CCyR; 1 (0.8%) CHR]. 19 (11.6%) had suboptimal response; 10 (6%) were failures and 15 (9%) intolerants.

43 patients were on 2nd line therapies: 27 on Dasatinib 100mg QD: 18 (66.7%) had optimal response (7 $MR^{5.0}$; 7 $MR^{4.5}$; 1 $MR^{4.0}$; 3 MMR); 2 had suboptimal response, 4 were failures and 3 intolerants. 16 on Nilotinib 400mg BID: 11 (68.7%) had optimal response (6 $MR^{5.0}$; 2 $MR^{4.5}$; 3 MMR); 2 had suboptimal response and 3 were intolerants.

On third-line, 2 patients were on Dasatinib ($MR^{4.5}$) and 3 on Nilotinib ($MR^{4.0}$).

Summary / Conclusion: The usefulness of the registries has been widely demonstrated in different matters such as health planning, analysis of the technology used, evaluation of the quality of health services in clinical research as well as in epidemiological studies and strong arguments to request its implementation. Clinical registries show a real overview of CML patients. They allow to be aware of the real incidence and prevalence of the disease in a determined area, without for example underestimating the true average age at diagnosis and controlling elderly patients which are excluded from clinical trials.

COST-EFFECTIVENESS ANALYSIS IN NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA (CML) IN JAPAN

I Matsumura[1*], K Shimozuma[2]

[1]Department of Hematology and Rheumatology, Kinki University, Osaka-Sayama, [2]Department of Biomedical Sciences, Ritsumeikan University, Kusatsu, Japan

Background: The new tyrosine kinase inhibitors (TKIs), nilotinib and dasatinib, have been approved to treat newly diagnosed chronic phase (CP) chronic myeloid leukemia (CML) in Japan since 2010. In addition to efficacy and safety, comparative cost –effectiveness may be considered when selecting medication.

Aims: This experimental analysis aimed to evaluate the cost-effectiveness of nilotinib versus dasatinb as a frontline therapy in newly diagnosed CML in Japan.

Methods: This cost-effectiveness analysis was performed from the perspective of the healthcare payer, and considered only direct Japanese drug costs as of 2013. The daily dose of each drug was based on the indicated dose in the package insert. A Markov model was used to estimate the risk of disease progression to accelerated phase (AP)/blast phase (BP) or death for newly diagnosed CML patients taking either dasatinib or nilotinib. Since there are no published head- to- head comparative clinical studies between the two drugs, rates of progression for the model were acquired from a published indirect comparison (Signorovithch et al.2011). The cost per life-year gained (LYG) was derived from the Markov model and incremental cost-effectiveness ratios (ICERs) were calculated for 1 year, 10 years and 30 years.

Results: The model predicted the incremental effectiveness of the nilotinib treatment arm at 1 year to be 0.022 LYG with an incremental cost of -11,439.21€ and at 10 years, 1.0997 LYG with an incremental cost of -62,663.95€. For patients with newly diagnosed CML, the model predicted that treatment with nilotinib was more effective and less costly than treatment with dasatinib at the point of 1 year and 10 years. At the point of 30 years, treatment with nilotinib extended 7.504 years of life compared with that of dasatinib , and the incremental cost was 57,773.75€, resulting in an ICER of7,698.81€per LYG for nilotinib.

Summary / Conclusion: Based on this experimental analysis, treatment of newly diagnosed CML patients with nilotinib is a cost-effective treatment option relative to dasatinib in Japan. Although limitations of this analysis include a lack of direct comparative data and considers only direct drug costs, this analysis suggests further investigation of the relative cost-effectiveness of these two treatment options is warranted.(exchange rate; 1Euro =124JPY)

PREGNANCIES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYSOSINE KINASE INHIBITORS

A Wang[1*], L Zhou[1]
[1]Department of Hematology, Shanghai Jiao-Tong University School of Medicine, Ruijin Hospital, Shanghai, China

Background: Tyrosine kinase inhibitors (TKI) have completely revolutionized the management of chronic myeloid leukemia (CML), significantly improving the long term prognosis of the disease. The efficacy of these drugs combined with their ease of administration and a low level of toxicity has resulted in many patients leading relatively normal lives. For many patients, one of the clearest indications of normal life is the ability to conceive children and raise a family. We used to conduct a retrospective study to review the newly diagnosed CML patients administered in Shanghai from 2001 to 2006. A total of 615 cases entered study. High incidence was observed in the child-bearing age (20-50 years old), which accounted for 48.2%. The management of CML during pregnancy remains a great challenge for both physicians and patients.
Aims: Little is known about the effect of exposure to TKI during conception and pregnancy in human. In this report, we presented our experience accumulated to date in CML patients who conceived children and/or became pregnant while receiving TKI.
Methods: The records of all patients with CML treated with TKI were reviewed from Jan. 2003 to Sep. 2012 in our hospital. Data associated with pregnancy, delivery and neonate were collected retrospectively.
Results: We reported the experience on 22 pregnancies involving 22 patients (7 males and 15 females) who conceived while receiving TKI(21 imatinib and 1 nilotinib) for the treatment of CML. (1) Among male patients (6 imatinib and 1 nilotinib), 7 pregnancies resulted in the birth of 7 healthy babies. None of the patients interrupted therapy with TKI after the conception. Afterwards, 55 male patients of child-bearing age with imatinib therapy were tested with gonadal hormone level and were within the normal range. No significant relationship was confirmed between the hormone levels and imatinib treatment duration.5 patients who wished to have a baby in the near future agreed to do the semen examination. 2 were found oligospermia. (2) Among 8 female patients who diagnosed CML during pregnancy, 2 had spontaneous abortion; 5 had elective abortion; 1 continued pregnancy unevently and gave birth to a normal infant and started imatinib treatment after delivery. Among 7 female patients who became pregnant while they were receiving imatinib, 2 ended in elective abortion; 2 carried on pregnancy without imatinib interruption, following one intrauterine growth restriction and one spontaneous abortion; 3 other pregnancies carried to term with imatinib discontinuation, resulting in the birth of 4 healthy babies. (3) The median age of all 12 children at the date of this report is 23 months (range, 2 to 88 months) and they all have a normal growth and development. All patients remain in TKI therapy and in good response.
Summary / Conclusion: Patients who receive TKI at the time of conception or are treated with TKI during pregnancy can have normal pregnancies. There still remains an increased risk of spontaneous abortion or serious fetal malformaitons. Female patients are advised to practice adequate contraception and avoid breast-feeding while on therapy with TKI. In case of planned or unplanned pregnancy, risk/benefit evaluation must be carried out individually. No special precautions apply for male patients receiving TKI.

B1369

EARLY RESPONSE RATES TO THERAPY IN CHRONIC PHASE CML ARE HIGHER WITH NILOTINIB COMPARED WITH IMATINIB FRONTLINE THERAPY AND ARE PREDICTED BY THE EUTOS SCORE

A Apel[1*], M Nagar-Marciano[1], N Amariglio[1], L Trakhtenbrot[1], Y Volcheck[1], A Nagler[1], M Koren-Michowitz[1]
[1]Sheba Medical Center, Ramat Gan, Israel

Background: Since the introduction of imatinib, a BCR-ABL tyrosine kinase inhibitor (TKI) a decade ago, a dramatic change in treatment of CP CML has occurred with great improvement of patients' outcome. The second generation TKI, nilotinib was designed to overcome imatinib resistance and is more potent and selective than imatinib. In the frontline therapy setting, nilotinib results in a more rapid achievement of CCyR and MMR compared with imatinib. Recently, early responses at the 3 months landmark were shown to predict long term outcomes including overall survival.
Aims: In this analysis we aim to compare the efficacy of imatinib versus nilotinib as first line treatment for CP CML in achieving an early 3 months response. We also studied whether the clinical prognostic scoring systems including Hasford, Sokal, and the Eutos score are predictive for the early response.
Methods: Clinical data was collected on all CP CML patients with frontline therapy imatinib or nilotinib. Prognostic scores were calculated based on presentation data. Results of RQ-PCR according to the IS, karyotype and FISH analysis in the first 18 months of therapy were extracted. An optimal 3 months response was defined as and RQ-PCR< 10% on the IS, >1 log reduction from baseline value in the absence of an IS result or FISH <10% in the absence of RQ result at this time point. Results of the 3 months response are presented.
Results: 77 CP CML patients with available response data at 3 months (64-RQ-PCR, 13-FISH), median age of 48 years (range 20-89), F-23 M-54 are included in this analysis; 56 (73%) treated with first line imatinib and 21 (27%) with first line nilotinib. The distribution of patients according to clinical prognostic scores was 61%, 30% and 9% for Sokal low, intermediate and high risk; 67%, 30% and 3% for Hasford low, intermediate and high; 91% and 9% for EUTOS low and high, respectively. An optimal 3 months response was achieved in 73% in the study cohort, 69% in imatinib and 90% in nilotinib treated patients, P=0.07. Optimal response rates at 3 months were significantly higher in EUTOS low (77%) compared to high risk (29%) patients in the entire cohort, P=0.01. Neither Sokal nor Hasford scores predicted responses at 3 months. Responses in subgroups according to TKI were not significantly different in EUTOS low compared to high risk score, probably due to low pt numbers in each subgroup.
Summary / Conclusion: Optimal response rates at 3 month were higher in patients treated with second generation TKI, nilotinib as reported in the literature. Response to treatment at 3 months was predicted by the EUTOS score, but not by Hasford or Sokal scores. This is in accordance with previous reports showing that predictive value of the EUTOS for TKI treated pts, but we show here for the first time its relevance to predict response as early as the first 3 months' time point. The EUTOS score may assist in clinical decision at diagnosis on which TKI to choose for newly diagnosed CP CML patients. Longer follow up of this pts cohort will be presented.

B1370

EXPRESSION OF DRUG TRANSPORTER GENES IN CHRONIC MYELOID LEUKEMIA WITH IMATINIB RESISTANCE TREATED BY SECOND GENERATION TYROSINE KINASE INHIBITORS

Y Kim[1*], S Cheong[1], J Ahn[1], D Yang[1], J Lee[1], H Kim[1]
[1]Hematology, Chonnam National University Hwasun Hospital, Jeollanam-do, Korea, Republic Of

Background: Second generation tyrosin kinase inhibitors (2nd TKIs) have demonstrated that about half of patients failing to respond to imatinib can be rescued.
Aims: This study investigated the treatment outcome of dasatinib or nilotinib in patients showing imatinib resistance. To elucidate the mechanism of their action, the expression of three drug transporters before and after imatinib treatment was evaluated.
Methods: Twenty adult patients with chronic myeloid leukemia (CML) (aged 34-72 years) who showed resistance to imatinib as a first line therapy were enrolled. After detecting imatinib resistance, twelve and eight patients received dasatinib and nilotinib as a salvage treatment, respectively. Bone marrow (BM) samples were obtained twice, before administering imatinib and at the time of detecting imatinib resistance and were analyzed for the mRNA expression of OCT-1, ABCG2 and ABCB1 genes.
Results: Using pair-wise analyses, OCT-1 expression was significantly reduced in the samples at the time of imatinib resistance compared with imatinib-naïve samples (P<0.001). In addition, ABCG2 expression also significantly decreased (P<0.001). ABCB1 expression was not different before and after imatinib (P=0.22). However, ABCB1 expression was significantly higher in patients with primary resistance than in those with secondary resistance to imatinib treatment (P=0.02). mRNA expression of OCT-1 was lower in secondary resistance than in primary resistance group, however, there was no statistical significance (P=0.06). With salvage therapy with 2nd TKIs, 65% and 40% of the patients with imatinib resistance could achieve complete cytogenetic response (CCyR) and major molecular response (MMR), respectively. Achieving CCyR (P<0.001) and MMR (P=0.07) were also associated with higher progression-free survival (PFS). In multivariate analysis, achieving CCyR was the most powerful prognostic factor in PFS. In 8 nilotinib-treated patients, ABCG2 expression after imatinib was lower in patients achieving MMR than in those without MMR (P=0.05). Patients with lower OCT1 expression after imatinib showed shorter PFS compared to those with higher OCT1 expression, however, there was no statistical significance (47.0 months vs. N.A., P=0.46).
Summary / Conclusion: In this study, dasatinib and nilotinib as a salvage treatment could achieve appropriate optimal responses in some patients failing to imatinib treatment. OCT-1 and ABCG2 mRNA expressions showed significant changes after imatinib treatment. However, the expression levels of OCT-1, ABCG2 and ABCB1 at the time of salvage treatment may not affect the treatment outcome of dasatinib or nilotinib.

B1371

THROMBOPOIETINE RECEPTOR AGONISTS ARE EFFECTIVE TO MANAGE THROMBOCYTOPENIA ON TKI-TREATMENT

M Fominykh[1*], V Shuvaev[1], V Udal'eva[1], S Voloshin[1], A Kuvshinov[1], A Schmidt[1], K Abdulkadyrov[1]
[1]Clinical department, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russia, Saint-Petersburg, Russian Federation

Background: The adoption of tyrosine kinase inhibitors (TKI) in chronic myeloid leukemia (CML) gave a possibility of long-term disease control. Continuous TKI treatment could bring various adverse events. Hematologic toxicity can occur in considerable part of patients and cause TKI therapy interruption. The use of erythropoiesis stimulating agents and granulocyte growth factor (G-CSF)

for the management of TKI-related cytopenia is considered as a treatment option for such patients. Management of immune thrombocytopenic purpura has been changed dramatically with introduction of thrombopoietin receptor agonists (TRA), which were highly effective. It is possible that administration of TRA will demonstrate treatment effects with respect to increasing platelet levels in CML patients.
Aims: The objective of our study was to assess TRA potential in the management of TKI-related thrombocytopenia.
Methods: TRA – Romiplostim (Rom) was administered as a subcutaneous injection weekly at dose of 1 mcg/kg in CML patients with severe thrombocytopenia which could lead to TKI interruption.
Results: Three adult CML patients on TKI treatment were prospectively treated with TRA. Patient#1, male, 52-years. CML chronic phase, first-line treatment with Imatinib 400 mg/day. There was no cytogenetic response with 49.249% of BCR-ABL in 6 months. Patient was switched to Nilotinib 800 mg/day, treatment was complicated with recurring neutropenia grade III and thrombocytopenia grade III-IV. Hematological toxicity led to temporary interruption and dose reduction of Nilotinib to 400 mg/day. Cytogenetic response was not achieved in 3 months of TKI therapy, but BCR-ABL level was decreased to 14.4%. Minor cytogenetic response (Ph+ 55%) was achieved in 6 months. Unfortunately, thrombocytopenia and neutropenia were not ameliorated. We have used G-CSF 5 mcg/kg and Rom 1 mcg/kg to manage hematologic toxicity. Two weekly administrations of G-CSF and TRA resulted in neutrophil recovery and rising of platelet level up to $61x10^9$/l. Nilotinib administration was continued with 400 mg daily dose without subsequent interruptions. At 11 months of Nilotinib therapy neutropenia and thrombocytopenia were only grade I and complete cytogenetic response was reached. Patient#2, male, 49-years: CML chronic phase with Nilotinib 600 mg/day as first-line. There was no cytogenetic response with 16.1% BCR-ABL level at 6 months. Nilotinib dosage was increased up to 800 mg/day. BCR-ABL level was 7.6% in 9 months, but recurrent neutropenia grade IV and thrombocytopenia grade IV put obstacles in the treatment. G-CSF 5mcg/kg and Rom 1 mcg/kg were used to correct toxicity. Complete neutrophil restoration and rising platelets up to $66x10^9$/l were achieved in a week after the injections. Patient#3, male, 64-years: CML chronic phase with Nilotinib 300 mg BID as first-line. There were no cytogenetic response and BCR-ABL level was 11.7% at 3 months of therapy. Nilotinib dosage was increased up to 800 mg/day. Recurrent neutropenia grade III-IV led to temporarily interruption of Nilotinib that needed G-CSF use. There was no cytogenetic response with 9.7% BCR-ABL level in 6 months of therapy. Patient was switched to Dasatinib 100 mg/day. Dasatinib-related adverse events were also hematologic, neutropenia grade III and thrombocytopenia grade III. To correct this toxicity G-CSF 5mcg/kg and Rom 1mcg/kg were used. Neutrophils normalized and platelet level increased up to $87x10^9$/l in a week.
Summary / Conclusion: These cases are proof of TRA role in management of thrombocytopenia in CML patients on TKI treatment.

B1372
SCREENING OF ABL KINASE DOMAIN MUTATIONS USING NEXT GENERATION SEQUENCING IN CHRONIC MYELOID LEUKAEMIA: IMPACT IN THE RESPONSE TO TREATMENT WITH TYROSINE KINASE INHIBITORS
P Couceiro[1], S Soverini[2], M Ferreira-Teixeira[1,3], P Freitas-Tavares[4], P Santos[3,5*]
[1]Laboratorio de Imunologia e Oncologia, Centro de Neurociencias e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal, [2]Dep Hematology/Oncology, University of Bologna, Bologna, Italy, [3]Instituto de Imunologia, Faculdade de Medicina, Universidade de Coimbra , [4]Serviço de Hematologia, Centro Hospitalar e Universitario de Coimbra, [5]Laboratorio de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal

Background: Mutations in ABL kinase domain (KD) are associated with the resistance to tyrosine kinase inhibitors (TKIs) in CML patients. Sanger sequencing is the gold standard method for KD mutation detection. However, Next Generation Sequencing (NGS) approach presents a significantly better sensitivity (1%) when compared to conventional Sanger sequencing (c.a. 20%).
Aims: This study aimed to test NGS as a high sensitive method for screening ABL KD mutations in CML patients and to correlate them with TKI response.
Methods: The present study included 62 different CML patients followed quarterly at the Hematology Service of CHUC (Coimbra, Portugal). A total of 494 peripheral blood samples collected in Paxgene RNA blood tubes were analysed by 4 distinct overlapping HRM PCR reactions, using specific primers covering the entire ABL KD region. In a similar approach, four fragments where analysed using Roche 454 GS Junior NGS system.
Results: From routine nested-PCR and RT-qPCR BCR-ABL analysis, 13.3% of the samples were suggested from HRM profiles for sequencing. Using NGS, we confirmed known mutations in 20% of these samples in an frequency as low as 1.1%. Additionally, one patient presented a 72 bp deletion (nt 1450-1521; GenBank M14752.1) in3,58% of the analysed fusion transcripts.
Summary / Conclusion: Sequencing is an expensive and a time-consuming procedure to test for ABL KD mutations. Nevertheless, combining routinely HRM PCR strategy with NGS allows a higher sensitive method that should be considered for screening of ABL KD mutations in CML patients.

B1373
NEUROMUSCULAR TOXICITY OF TYROSINE KINASE INHIBITORS IN THE THERAPY OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA
V Zmoraj[1*], D Zackova[1], Z Racil[1,2], B Micankova[3], L Semerad[1], F Razga[1], T Jurcek[1], D Dvorakova[1,2], J Mayer[1,2]
[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Masaryk University, [2]Central European Institute of Technology (CEITEC), [3]Department of Neurology, University Hospital Brno and Masaryk University, Brno, Czech Republic

Background: Prognosis of patients with chronic myeloid leukemia (CML) has been fundamentally improved with highly effective treatment with tyrosine kinase inhibitors (TKI). There are, however, adverse events (AE) occuring during treatment with TKI, which can modify expected excellent quality of life of patients with CML. One of the most frequent AE is neuromuscular toxicity (muscular cramps, weakness or pain) with its unclear pathogenesis mostly after treatment with imatinib. Although muscular symptoms occur usually in lower or moderate grade, they disturb patients in every day life.
Aims: To find out prevalence of neuromuscular AE in patients with CML treated with TKI in one large centre, to reduce therapeutically symptoms and to provide detailed analysis including muscle biopsy.
Methods: Our pilot project consists of two parts – analysis of patients already on TKI therapy who developed muscular AE and prospective follow up study for newly diagnosed patients, who are examined by taking family history (myopathy in parents), history of medication (statins), symptoms (muscle cramps, myalgia) and tested for blood levels of creatinphosphokinase (CK), myoglobin (Mb), Ca, ionis. Ca (Ca i), Mg, P, TSH, fT4, parathormone, 24-h urinary ion excretions (Ca, P, Mg) and myodynamic test (knee-bend, stand up test) before treatment and after start of TKI in 1 month, 3 months and then each 3 months. By elevation of CK grade II (according to CTCAE v4.0) is indicated electromyography (EMG) or then muscular biopsy for analysis on molecular basis.
Results: There have been so far 20 patients with CML in chronic phase (CP) (10 females, 10 males) included in our pilot prospective study in a period of 3/2012 – 2/2013. Median age at the time of TKI administration start was 52 years (range, 26-92). As a first line treatment 13 patients received imatinib (ima) and 7 nilotinib (nilo). Muscular AE occurred in 3 (23%) patients treated by ima within the first 3 months of therapy, each one of three patients expierenced different symptom - muscular pain, weakness, cramps - all in grade I-II. CK was elevated in 3 (23%) patients treated by ima, all of them in grade I. None of the patients treated by nilo developed muscular AE nor elevation of CK within 3 months of follow up. TKI treatment also leads to significant hypophosphatemia, which seems to be more severe after therapy of imatinib.
Summary / Conclusion: Our preliminary results show trends of higher elevation of CK in patients treated with imatinib raising in time, significant hypophosphatemia in both groups patients with imatinib and nilotinib. It is also suggesting higher prevalence of muscular AE in patients with imatinib with mostly low and moderate grade. As the study is extending in number of patients and time check ups we are ready to perform more detailed analysis including EMG and muscular biopsy.

B1374
COMPARISON OF BCR-ABL1 GENE EXPRESSION ASSESSED BY GENEXPERT V1 AND V1-IMPROVED CARTRIDGES VERSUS ELN STANDARDIZED RQ-PCR METHOD IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TKIS
T Sacha[1*], M Zawada[1], S Czekalska[1], I Florek[1], D Link-Lenczowska[1], A Skotnicki[1]
[1]Hematology Department, Jagiellonian University Hospital, Krakow, Poland

Background: The GeneXpertSystem was introduced to facilitate the molecular monitoring of therapy with tyrosine kinase inhibitors (TKI) of patients suffering from chronic myeloid leukemia (CML).
Aims: The aim of the study was to compare the expression of *BCR-ABL1* gene obtained by novel V1-improved PCR GeneXpert System cartridges and V1 cartridges with and without IS-correction-tool *versus* internationally standardized RQ-PCR method.
Methods: The comparison of the *BCR-ABL1* gene expression using GeneXpert System was performed in Molecular Diagnostics Laboratory in Krakow – national polish reference EUTOS laboratory for *BCR-ABL1* gene expression assessment. Patients with chronic phase chronic myeloid leukemia expressing e13a2 or e14a2 *BCR-ABL1* transcripts and treated with tyrosine kinase inhibitors were subdivided into three groups according to *BCR-ABL1* transcript level estimated by standardized RQ-PCR method. Group 1 consisted of patients with *BCR-ABL1/ABL1* ratio below 0,1% [IS], group 2 with *BCR-ABL1/ABL1* ratio between 0,1% and1,0% [IS], and group 3 with *BCR-ABL1/ABL1* ratio between1,0% and 10,0% [IS]. Samples obtained from 48 patients were analysed by V1 improved GeneXpert cartridge and results were compared with the results of RQ-PCR TaqMan methodology aligned to International Standard (IS).
Results: The comparable results were observed in (27/48) 56,2% of samples. The Wilcoxon test did not reveal statistically significant differences between the

results obtained by both techniques and (P<0,2871). The comparable results of both techniques in group1, 2 and 3 were noted in 42%, 68% and 100% respectively. The differences were not statistically significant in each evaluated group. Samples from 35 patients were analyzed by V1 GeneXpert System (Lot #05001) corrected with IS-correction-tool and the results were compared with standardized RQ-PCR methodology. The comparable results obtained by V1-corrected with IS-correction-tool *versus* standardized RQ-PCR *BCR-ABL1/ABL1* method were observed in (23/35) 65,7% of samples. The Wilcoxon test did not reveal statistically significant differences between the results of both techniques and (P<0,2529). The comparable results of both techniques in group1, 2 and 3 were noted in 46%, 50% and 75% respectively. The differences were not statistically significant in each evaluated group.

Summary / Conclusion: The GeneXpert system provides very easy to use and rapid diagnostic platform, which could be very useful in evaluating CML patients' response to TKI therapy. Either V1-improved system cartridges or use of V1 with IS-correction-tool increases the concordance of BCR-ABL1 expression analysis results by GeneXpert and results of internationally standardized RQ-PCR method in patients with CML monitored for the response to TKI therapy.

Background: As the number of studies of imatinib discontinuation is increasing, the information on post-discontinuation quality of life is becoming of considerable important for patients with CML and physicians.
Aims: The purpose of this study was to investigate whether chronic myeloid leukemia (CML) patients who maintained undetectable molecular residual disease (UMRD) with long-term imatinib therapy show different health-related profiles after cessation of imatinib.
Methods: Thirty four patients with UMRD (> 2 yrs) discontinued imatinib and were given questionnaire for 3 times (before discontinuation, at 1 month and at 6 month post-discontinuation). The health surveys were modified SF-36 + FACT.leu composed of imatinib-related adverse events, laboratories, physical and mental health parameters.
Results: All blood forming cells, serum electrolytes, cholesterol, triglyceride, lipase, and lactate dehydrogenase returned to normal ranges quickly but fasting blood sugar, total bilirubin, arginine aminotransferase, amylase, and g-GT did not change after cessation. The changes were remarkable within 2 months. Anorexia, abdominal discomfort, skin and hair whitening, and muscle cramp constantly improved. Night sweat, skin rash showed delayed improvement whereas nausea, vomiting, indigestion, skin fragility, edema, sore throat, night spasm, cold intolerance, easy bruise, easy bleeding, and easy fatigue improved promptly. Enjoy life, well-being sense, vulnerable to illness, hope in the fight against the illness constantly improved. Satisfy to good QoL or treatment, limited daily and social activity, healthy as anyone I know, sleep well, do for fun, satisfaction with family communication, and worry about getting worse improved immediately and deteriorated late. Feel achievement and worry about dying improved early whereas sadness, accept the illness, and emotional instability improved slowly. Sense of isolation and nervousness deteriorated constantly after cessation.
Summary / Conclusion: Late disappearances of early improvements (sleep well, do for fun, satisfy to good QoL, satisfy to treatment, and worry about getting worse and so on) may be due to apprehension about healthy future. Patients who are planned to stop imatinib should be carefully monitored their emotional stresses at least for 6 months as well as immediate after cessation.

B1376

IDENTIFICATION AND CHARACTERISTICS OF CANDIDATES FOR CESSATION OF TYROSINE KINASE INHIBITORS AMONG PATIENTS WITH CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA SHOWING DURABLE COMPLETE MOLECULAR RESPONSE

V Papadopoulou[1*], T Iliakis[1], P Diamantopoulos[1], K Zervakis[1], G Tsilimidos[1], F Kalala[1], M Siakantaris[1], N Giannakopoulou[1], G Pangalis[2], M Angelopoulou[3], K Peste[4], P Panayiotidis[5], E Variami[1], N Viniou[1]
[1]1st Department of Internal Medicine, Hematology Unit, University of Athens, [2]Hematology Clinic, Iatriko Kentro Psychikou, [3]Hematology Clinic, University of Athens, [4]Cord Blood Bank, Stem Health Hellas, [5]1st Propaedeutic Department of Internal Medicine, Hematology Unit, University of Athens, Athens, Greece

Background: Tyrosine kinase inhibitors (TKIs) are currently the standard of care in the front-line treatment of chronic phase chronic myelogenous leukemia (CP-CML). Side effects and cost of TKI compounds, along with some patients' complete molecular response (disappearance of BCR-ABL transcripts) have raised the question whether TKIs can be safely withdrawn from these patients. Results from relevant clinical trials, such as the STIM study, are encouraging, showing that among patients with a complete molecular response (CMR) maintained for at least two years, CMR was sustained in 39% of them after 24 months of discontinuation of the drug, while 83% of those who relapsed upon withdrawal managed to re-gain CMR upon re-introduction of the drug.
Aims: We sought to identify candidates for TKI cessation according to the criteria of the currently recruiting EURO-SKI trial (EUROpean Stop tKI). We studied their clinical characteristics and will follow their outcome after TKI discontinuation in the context of this trial.
Methods: The archived data of our alive CP-CML patients were examined. We identified non-transplanted patients with CP-CML having received TKI therapy for at least 3 years and demonstrating sustained CMR4 for a continuum of at least 12 months, with at least three PCR results with CMR4 within the last year (± 2 months) before study entry and no results > 0.01% during the same period. CMR4 was defined as either (i) detectable disease ≤0.01% BCR-ABL (IS) or (ii) undetectable disease in cDNA with ≥10,000 ABL or ≥ 24,000 GUS transcripts).
Results: A total of eight patients that fulfilled criteria for getting off TKIs were identified out of our fifty-numbered CP-CML patient pool. All patients currently receive IM, except one being on nilotinib on grounds of imatinib and dasatinib toxicity. All of the patients achieved their CMR being initially on imatinib. Median age of these patients at diagnosis was 54,5 years (range: 27 - 73 years) and sex ratio was M:F 0.6. Sokal score at diagnosis was low in 4 patients, intermediate in 3 patients, and high in 1 patient, while the relevant Hasford score ratio was 4:4:0. The median interval from start of treatment to CMR was 20 months (range, 6-40 months), while the median interval to CCyR and MMR was 9 and 14 months, respectively. The median duration of detected CMR was 67,2 months (range 27- 101 months), which corresponds to a median of 84,7 months (range, 66 – 121 months) of total TKI treatment. Interestingly those who demonstrated more rapid CMR where the ones with low Sokal score at diagnosis (median time 11 months), while the ones with intermediate/ high score took longer (26,4 months) to reach this goal.
Summary / Conclusion: Durable complete molecular response is frequent among CP-CML patients. In our centre it was identified at a percentage of 16%. Achievement of CMR is feasible even with adverse prognostic factors at diagnosis, although it may require a longer treatment duration in this case, as far as our sample permits us a conclusion. Trials of discontinuation of TKIs could well identify a subgroup of patients who could transiently or permanently stay off therapy, changing the landscape of treatment in CML.

B1377

EVALUATION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS EFFICACY AND SAFETY IN NOVO CML-CP THERAPY. RESULTS OF 29 PATIENTS OUTSIDE OF CLINICAL TRIALS FROM THE CML ANDALUSIAN GROUP

Background: Results of clinical trials ENESTnd and DASISION have shown

more efficacy and safety of Nilotinib and Dasatinib, respectively, compared to Imatinib. This allowed their authorization as first-line treatment in patients diagnosed with chronic myeloid leukemia (CML) in 2011. Patients treated with second-generation tyrosine kinase inhibitors (2GTKIs) achieve faster and deeper responses and a smaller amount of progressions to accelerated phase (AP) and blast crisis (BC), with a good profile of safety and tolerability. A recent paper by Marin *et al* (*JCO, 2012*) indicates that a single measurement of *BCR-ABL* transcript at 3 months is the most accurate way to identify the risk of progression and overall survival in patients with chronic-phase (CP) CML treated with TKIs. In this sense we have analyzed the efficacy and safety of the 2GTKIs on first-line treatment in patients with CP-CML focused the attention on the molecular response (MR) at the third month of treatment in CML Andalusian Group Registry (RALMC).
Aims: To evaluate the 2GTKIs efficacy and safety in first-line treatment and the MR at 3 and 12 months.
Methods: We have analyzed retrospectively 29 adult patients diagnosed with CP-CML. They started with Nilotinib or Dasatinib in first-line treatment in Andalusia between July 2011 and November 2012 outside of clinical trials. Clinical and analytical data were obtained from the CML Andalusian Registry. BCR-ABL values are expressed in international scale and patients have been cataloged and monitored according to the ESMO 2012-guidelines.
Results: 16 males and 13 females have been included in the study. Median age is 45 years (19-78), distributed by Sokal score in: 14 (48.3%) low risk, 7 (24.1%) intermediate risk and 8 (27.6%) high risk. Eutos score: low 23 (79.3%) and high 6 (20.7%). All patients were diagnosed in CP, 18 (62%) were treated with Nilotinib 300mg BID and 11 (38%) with Dasatinib 100mg QD. Median follow-up is 12 months (3-20). At month3, 29 (100%) patients evaluated for MR had BCR-ABL transcript less than 10% and 24 (82.7%) less than 1%. Cytogenetic response was evaluated at 3 months in 21 patients: CCyR 18 (85.7%) and PCyR 3 (14.3%) while at month6, 22 (100%) achieved CCyR, 6 (27%) MMR, 3 (13.6%) $MR^{4.0}$, 3 (13.6%) $MR^{4.5}$ and 5 (22.8%) $MR^{5.0}$ and 5 did not achieve MMR. 3 (23%) out of 13 patients evaluated in the year achieved MMR, 1 (7.7%) $MR^{4.0}$, 2 (15.4%) $MR^{4.5}$ and 5 (38.5%) $MR^{5.0}$. 1 patient without MMR had BCR-ABL > 1% at month 3 and other patient that lost MMR and CCyR due to T315I mutation, the only treatment failure of the entire series. All patients in $MR^{4.0}$, $MR^{4.5}$ and $MR^{5.0}$ at month 12 had BCR-ABL ≤ 0.1% at month 3. Patients in MMR at month 12, had BCR-ABL > 0.1% at month 3. There has not been any AP/BC progression, as well as any death, and there has been only an interruption of Dasatinib for pleural effusion and congestive heart failure.
Summary / Conclusion: Despite the small number of patients treated with 2GTKIs in first-line, all patients, regardless their prognosis stadium and age, achieved a rate of BCR-ABL< 10% at month 3 and 83% achieved BCR-ABL transcript < 1%. According to other investigations, it shows the effectiveness of Nilotinib and Dasatinib in our patients. We have observed in our data that patients who achieve MMR at month 3 of treatment, they achieve $MR^{4.0}$, $MR^{4.5}$ or $MR^{5.0}$ at month 12. In this way, safety of the 2GTKIs in our series is reflected. There have not been hematological alterations grade 3/4 and only one patient with Dasatinib has withdrawn treatment due to adverse events.

B1378
TYROSINE KINASE DOMAIN MUTATIONS AND CYP3A4-CYP3A5 GENE POLYMORPHISMS IN IMATINIB RESISTANT CHRONIC MYELOID LEUKEMIA
S Vaidya[1*]
[1]Department of cytogenetics, National Institute of Immunohaematology, ICMR,, Mumbai, India

Background: Imatinib Mesylate (IM) resistance in CML patients is most frequently associated with point mutations in tyrosine kinase domain (TKD), whereas metabolization of IM by isoenzymes CYP3A4 and CYP3A5 is also one of the important BCR/ABL independent mechanisms of resistance. We have recently designed a detailed study to determine mutations in TKD and regulatory regions of BCR/ABL and also CYP3A4 -CYP3A5 polymorphisms, and correlate it with drug resistance and disease progression in Indian CML patients. Understanding the mechanism of drug resistance is important, as the therapy protocols can be modified.
Aims: To identify tyrosine kinase domain mutations and CYP3A4-CYP3A5 gene polymorphisms in imatinib resistant chronic myeloid leukemia patients.
Methods: 75 IM resistant CML patients were screened for mutations in TKD and regulatory regions of BCR/ABL gene by direct sequencing, for BCR/ABL gene amplification by FISH and for CYP3A4*1B and CYP3A5*3 polymorphism.
Results: Among 75 IM resistant patients, 41.33% of patients showed mutations in the TKD while 8% of patients had mutations in the regulatory region (SH3-SH2). Three novel mutations were detected, 185bp ΔD363-W423, Y167 and K84E. Y253F/H mutation was predicted to be possibly most damaging with a score of1, according to Polymorphism Phenotyping v2. 42 IM resistant patients not harboring mutations were screened for BCR/ABL gene amplification and for CYP3A4*1B and CYP3A5*3 polymorphism. 23 long term IM responders were considered as controls. None of the patients showed BCR/ABL gene amplification. Of 42 IM resistant patients, only two patients (4.7%) showed CYP3A4*1B polymorphism, one heterozygote and other mutant homozygote, as compared to control population (17.4%). The occurrence frequency of CYP3A5*3 (non-expressor) and CYP2A5*1 (expressor) in 42 IM resistant patients was 20% and 80% respectively, whereas the frequency in case of controls was 37% in non-expressor and 63% in expressor group.
Summary / Conclusion: Our study identified three novel mutations. Also, suggested that CYP3A4*1B and CYP3A5*3 polymorphisms are not associated with IM response

B1379
APPLICATION OF D-FISH ON BONE MARROW AND PERIPHERAL BLOOD SAMPLES FOR THE EVALUATION OF CYTOGENETIC RESPONSE TO TKIS THERAPY IN CHRONIC MYELOID LEUKEMIA
L Luciano[1,2*], I Pisano[2], V Cacciapuoti[2], E Seneca[1], L Marano[1], F Pane[1]
[1]Hematology, Federico II University, [2]1Ceinge-BiotecnologieAvanzate, 1Ceinge-BiotecnologieAvanzate, Naples, Italy

Background: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder induced by the fusion of the *ABL* gene with the *BCR* gene.The hallmark of CML is the translocation (9;22)(q34;q11). The translocation is observed in up to 100% of metaphase cells at diagnosis. After the introduction of the tirosyn kinase inhibitors (TKIs), it has become more relevant to monitor cytogenetically the response to treatment. The achievement and the maintenance of a complete cytogenetic response (CCgR) is of particular importance because it is the most solid marker of progression-free survival and overall survival. The cytogenetic response by CBA requires marrow cells, which cannot be always sampled, and an adequate number of banded metaphases, which cannot be always obtained. Finally, cytogenetic analysis requires bone marrow harvesting, which prevents repetitive analyses. Fluorescence in situ hybridization (FISH) enables a rapid detection of chromosomal rearrangements, even on interphase cells, and thus, avoids the requirement of metaphase obtention and is applicable to a variety of cytological samples, including peripheral-blood samples (PB). Thus, FISH is used, with increasing frequency, as a substitute for CBA. Given the need for frequent monitoring in patients with CML, interest in non-invasive methods has increased over years.
Aims: In this study, we investigated the usefulness and accuracy of dual color double fusion FISH (D-FISH) on bone marrow and peripheral-blood specimens to evaluate the cytogenetic response in CML patients treated by TKIs.
Methods: We performed the comparison of cytogenetic analysis by CBA and D-FISH on bone marrow specimens and by D-FISH on peripheral blood samples, simultaneously collected paired sets, from this set of patients. The analysis was performed on 62 samples obtained from 44 patients with BCR-ABL positive CML, representative of the different cytogenetic response groups.
There were 62 triplicate patient collection: 4 samples were selected at diagnosis and prior of treatment, while all others were collected at the follow-up visit during the treatment. We performed cytogenetic analysis (20 metaphase for sample) and FISH analysis (330 nuclei counted for sample) on bone marrow samples, while only FISH analysis (330 nuclei counted for sample) on peripheral blood samples. To attempt the accuracy and the utility of FISH analysis, we have correlate the data obtained by the software Graph Pad Prism 4.
Results: In our series , we demonstrate a tight correlation in quantifying BCR-ABL burden between bone marrow cytogenetic, bone marrow D-FISH and peripheral blood D-FISH. In all three paired studies analized, the strength correlation between the variables is reflected in a p value of <0.0001 in all cases and a correlation coefficient of r^2= 0.8749 at worst (fig1,2 and 3). Moreover, the D-FISH results on BM and PB samples are in agreement with the results of CBA on BM samples, classifying the patients rightly on the basis of the different cytogenetic response classification. By D-FISH it was possible quantify the percentage of Ph+ cells too in 7 patients with uninformative BM cytogenetic analisys. These results indicate that peripheral blood D-FISH yields a clinically equivalent detection of BCR-ABL fusion to CBA, expecially in long term management of CML patients. Thus, cytogenetic response might reliably be monitored by analyzing interphase peripheral-blood cells in MRD.
Summary / Conclusion: This study confirms the results of other reports that suggested the feasibility of D-FISH on peripheral blood specimens to monitor cytogenetic response.

B1380
SIGNIFICANCE OF EUTOS AND HAMMERSMITH SCORE IN SECOND LINE TYROSINE KINASE INHIBITORS
A Zaritskey[1,2*], E Lomaia[1], E Sbitiakova[1], E Romanova[1], N Ilina[1], T Silina[1], O Kulemina[1], A Abdulkadyrova[3], V Udalieva[3], E Usacheva[3], I Zotova[3], R Golovchenko[3], L Martynenko[3], M Ivanova[3], N Cybakova[3], E Petrova[3], M Kozlovskaya[3], M Fominykh[3], E Machiulaytene[2], V Shuvaev[3], I Martynkevich [3] Abdulkadyrov[3]
[1]Almazov federal centre for Heart, Blood and Endocrinology, [2]Pavlov State medical university, [3]Russian research institute hematology and transfusiology, Saint Petersburg, Russian Federation

Background: Although Imatinib is very effective for CML CP patients but CCyR are not reachable for whole patients. Second line tyrosine kinase inhibitors could provide to achieve CCyR nearly in half of patients, who resistant or intolerant to Imatinib. But in cases of ineffectiveness of 2nd line TKI this patients

today must get allo-BMT for chance of long-term survival. It is very important to predict cytogenetic response in 2nd line TKI treatment.
Aims: The aim of our study was to estimate prognostic value of EUTOS risk score and Hammersmith scale for patients on 2nd line TKI therapy.
Methods: 62 patients with chronic phase of CML were included in our study. There were male/female ratio as 28/34 respectively. Median age at diagnosis was 47 years (range 24-71). Median of age at start of 2nd line TKI therapy was 51 years (range 25-72). Patients were treated with Nilotinib (n=37) or Dasatinib (n=25). Median time on previous Imatinib therapy was 15.4 months (range 1-64). Median time from diagnosis to 2nd line TKIs initiation was 27 months (range 3-190). The majority of patients were resistant to first line Imatinib (57/62). Follow up time from start of 2nd line TKIs was 33 months (2-90). EUTOS score was low in 32 (51%) and high in 12(18%) patients. It was unknown in 18 (29%) patients. Hammersmith score was low in 11 (17%), intermediate in 27 (43%), high in 6(9%) and unknown in 17 (27%) patients. Median time of 2nd line TKI therapy was 14 months (0.7-78). The therapy was discontinued in 34/62 (55%) patients, mainly due to resistance to TKIs (67%).
Results: Probability of CCyR was not significantly differing according EUTOS risk groups. It was 58% and 41% by 12 months respectively for low and high EUTOS risk groups (P>0.05). None of patients with high Hammersmith score had achieved CCyR. It was significantly higher in patients with low (63.6%) than intermediate (48.1%) Hammersmith score (P=0.042) (Fig.1). Probability of CCyR by 12 months was 78% and 40% in low and intermediate risk groups. Median time to CCyR in low and intermediate groups was 3 months and 6 months respectively. During follow up 15/62 (24%) dead (12 deaths were CML-related). 5-years estimated overall survival was 73%. Both EUTOS and Hammersmith scores were not predictable for survival in our study.
Summary / Conclusion: In our study EUTOS score calculated at diagnosis was not valid for predicting both CCyR and overall survival on 2nd line TKI treatment. It could be due to the fact of late switching to 2 TKI in this cohort of pts. The prognostic value of Hammersmith scale was high for forecast CCyR, but not for overall survival. Other prognostic models should be applied for overall survival in 2TKI treated pts.

B1381

BENEFITS/RISKS OF DASATINIB THERAPY IN PATIENTS WITH IMATINIB-RESISTANT OR -INTOLERANT CHRONIC MYELOID LEUKEMIA: PHYSICIAN'S AND PATIENT'S PERSPECTIVE

T Ionova[1*], T Nikitina[1], T Gritsenko[2], V Ivanova[3], G Kuchma[4], T Shnaider[5], I Sannikova[6], D Fedorenko[7], K Kurbatova[1]
[1]Multinational Center for Quality of Life Research, St. Petersburg, Saint-Petersburg, [2]Samara State Medical University, Samara, [3]Botkin Clinical City Hospital, Moscow, [4]Orenburg State Medical Academy, Orenburg, [5]Regional Hospital, Saint-Petersburg, [6]Regional Clinical City Hospital, Voronezh, [7]National Pirogov Medical Surgical Center, Moscow, Russian Federation

Background: Comprehensive evaluation of benefits and risks of second-line therapy in patients in chronic phase chronic myeloid leukemia (CML-CP) is worthwhile to better define treatment outcomes in this patients' population.
Aims: We aimed to study clinical and patient-reported outcomes in patients with imatinib resistance or intolerance receiving dasatinib as the second-line therapy during the first year of treatment.
Methods: 62 CML-CP patients resistant or -intolerant to imatinib were enrolled in the study (mean age – 51.5 years old, SD 15.5; range – 22–84 years; male/female – 32/30). The median of disease duration was 5.8 years (0.75–17 years). 51 patients had resistance to imatinib; 11 patients were intolerant to imatinib; the median duration of imatinib treatment – 41 months (3–106 months). All the patients received dasatinib as the second-line therapy (100 mg daily). Median follow-up was 11.5 months. For quality of life (QoL) and symptom assessment patients filled out the SF-36 and Comprehensive Symptom Profile in Chronic Myeloid Leukemia Patients (CSP Leuk-CML), respectively, at baseline, in1,3, 6 and 12 months after treatment start. For comparisons Mann-Whitney test was used. Mean symptom severity and percentage of patients with moderate-to-severe (ratings ³5) symptoms was evaluated.
Results: At 12 months of treatment the majority of patients had high rates of hematologic (complete, 82%) and cytogenetic (major, 57%; complete, 25%) response. Dasatinib was well tolerated in the majority of cases. Four cases of pleural effusion events were registered: they were easily managed in 3 cases; one patient died at 1 month after treatment start due to accompanied infection complication. No severe hematological adverse effects were observed except two cases of grade III-IV neutropenia. Two patients were resistant to dasatinib. One patient died of disease progression at 6 months of follow-up. During dasatinib treatment QoL parameters were stable with a slight tendency of improvement in vitality, mental health and pain scales. At 12 months after the start of therapy QoL treatment response in terms of stabilization or improvement was registered in the majority of patients (81%). In nearly all the patients symptom severity became lower or did not change at different time-points of treatment as compared with base-line. Before treatment 75% of patients experienced at least one moderate-to-severe symptom; more than 40% had more than 7 moderate-to-severe symptoms. The majority of patients (96%) experienced fatigue; half of them suffered from moderate-to-severe fatigue. While treatment the number of patients with moderate-to-severe symptoms decreased. After 12 months of therapy only 25% of patients experienced moderate-to-severe fatigue. Remarkably, in the subgroup of patients (21%) with critical or severe QoL impairment at base-line dramatic QoL improvement was observed: QoL index increased 3.7 fold (P<0.05). In this group severity of common symptoms significantly decreased.
Summary / Conclusion: Thus, dasatinib as second-line therapy in CML-CP patients is effective both in terms of clinical outcomes and patient-reported outcomes, as well as exhibits good tolerability. Comprehensive evaluation of the outcomes of the second-line treatment of CML-CP allows to assess the benefits and risks of therapy both from physician's and patient's perspective.

B1382

STRUCTURE OF MORTALITY DURING INTERNATIONAL RESEARCH PROJECT THE EUROPEAN OUTCOME AND TREATMENT STUDY FOR CML, OUT STUDY PATIENTS (EUTOS OSP) IN RUSSIA OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA

O Lazareva[1*], E Chelysheva[1], I Tischenko[2], E Vasil'ev[3], T Klitochenko[4], E Burnasheva[5], N Bederak[6], L Visotskaya[7], V Ivanova[8], I Krylova [9], S Kulilov[2], A Turkina[1]
[1]Scientific Advisory Department for chemotherapy of myeloproliferative disorders, Federal Budget State Institution Hematology Research Center of Health Ministry of Russia, [2]Department of Biomedical Statistics, Federal Budget State Institution Hematology Research Center of Health Ministry of Russia, Moscow, [3]Regional Clinical Hospital, Krasnoyarsk, [4]Clinical Oncology Dispensary, Volgograd, [5]State Medical University of Health Ministry of Russian Federation, Rostov, [6]Central City Hospital №7, City hematology center, Ekaterinburg, [7]Moscow Science Clinical Institution, [8]City Hematology Center of Moscow , Moscow, [9]Regional City Hospital №1, Ekaterinburg, Russian Federation

Background: Highly effective treatment by tyrosine kinase inhibitors (TKI) provides increased survival rates and good life quality to patients (pts) with chronic myeloid leukemia (CML). Therefore long-term treatment results, analysis of additional events not related to CML and analysis of the causes of death are very important.
Aims: To analyze structure of mortality in CML pts treated in routine clinical practice in Russian Federation.
Methods: The analyzed cohort consisted of 607 pts from 29 regions of Russia (OSP EUTOS): Ph'/bcr-abl-positive CML diagnosed in 2002- 2006, initiation of imatinib (IM) therapy ≤6 months (mo) after diagnosis. Median (Me) age was 48(18-82) years (y), M:F% ratio 47:53% pts. Pretreatment: hydroxyurea 454(76%) pts; chemotherapy 25(4%) pts, IFN-α 37(6%) pts. Me follow-up from starting of IM treatment was 60(1-112) mo. Chronic phase (CP) of CML was diagnosed in 557 (93%) pts, accelerated phase (AP) and blast crisis (BC) – in 38(6%) and 6(1%) pts respectively. Due to retrospective data collection we found that in first 3 y of observation the data were not described completely and we considered that fact.
Results: Mortality in a cohort of 607 pts was 15% (93 pts). Of these 93 pts, 48 (52%) pts death was the result of progression to AP or BP. 32 (34%) were reported dead in CP CML, 3 pts (3%) - after allogeneic stem cell transplantation (2 of them due to infection), in 10 (11%) cause of death was unknown. So, mortality due to progression CML in CP and AP+BC was in 58 (63%) of 93 pts. The cause of death in 32 pts in CP without progression to AP was reported as following: 10 pts with CML progression with no signs of advanced phases; 22 pts with reasons not related to CML. Among 22 (24%) CML not related causes of death there were: coronary artery disease/myocardial infarction/heart failure in 11 cases, a second malignancy in 5 cases (tumor pulmonis, esophageal cancer with metastases, stomach cancer, cancer of the sigmoid colon, metastasis of melanoma), blood stroke (acute ischemic stroke) in 2 cases, accident - 2 cases, cirrhosis of the liver in 1 pts, in 1 case as opposed to infection bilateral pneumonia (during virus epidemic). This subgroup of 22 pts was male and female in equal proportions with Me age 63.5 (47-76) y.
Summary / Conclusion: Retrospective data collection does not always allow to adequately evaluating the structure of mortality. Feature of presented cohort of Russian pts- mortality in 15% of 607 pts, with 3.6% (22pts) the cause of death was not associated with CML. Eventually the rate of death due to progression of CML in CP decreases and in AP+BC remains a leading cause. Mortality from cardiovascular causes and secondary tumors in pts with CML is a significant proportion (14 and 5%, respectively), and should be considered when analyzing the long-term results of therapy.

B1383

CO-EXPRESSION OF P190 AND P 210 BCR-ABL FUSION TRANSCRIPTS AND RESPONSE TO TKI THERAPY IN CHRONIC MYELOID LEUKEMIA: THE RET (RETE EMATOLOGICA TOSCANA) EXPERIENCE

C Biagiotti[1*], B Scappini[1], F Pancani[1], A Gozzini[1], B Caciagli[1], U Occhini[2], S Birtolo[3], F Innocenti[4], V Ponziani[1], V Santini[1], A Bosi[1]
[1]Hematology Section, Careggi Hospital and University of Florence, Florence, [2]Hematology Section, S. Donato Hospital, Arezzo, [3]Hematology Section, Medical Oncology ASL 3 , Pistoia, [4]Hematology Section, Casa di cura Villa Ulivella e Glicini, Florence, Italy

Background: The hallmark of chronic myeloid leukemia (CML) is the presence of the Philadelphia chromosome and its resultant fusion gene *BCR-ABL*, and fusion protein, p210. Occasionally patients with CML can have a smaller *BCR-ABL* fusion transcript possessing only the first exon of *BCR* fused to *ABL*, resulting in a p190 protein, more frequent in Philadelphia positive acute lymphoblastic leukaemia (ALL). A co-expression of both proteins, p190 and p210 has been described in CML, even in chronic phase; p190 mRNA usually is expressed at low level and may arise through alternative or missplicing. Its presence seemed to have no impact on prognosis in the pre-TKI era.
Aims: A co-expression of both proteins, p190 and p210 has been described in CML, even in chronic phase; p190 mRNA usually is expressed at low level and may arise through alternative or missplicing. Its presence seemed to have no impact on prognosis in the pre-TKI era.
Methods: 82 patients with new diagnosis of CML have been referred to our institution between 2008 and 2013, within the RET (Rete Ematologica Toscana) project. 13 cases (16%) expressed both transcripts. Median age was 55 years (range 31–83 years). At diagnosis 11 patients were in chronic phase (CP), 2 in accelerated phase (AP), none was in blastic phase (BP). Sokal risk was low in 2 patients, intermediate in 6 patients, and high in 3 patients. As frontline therapy, 8 patients received Imatinib 400 mg/day, 3 Nilotinib 600 mg/day, two patients in AP Dasatinib 100 mg/day and Imatinib 600 mg/day. The median follow-up was 22 months (range 3–57 months).
Results: Amount of p190 transcript was always low at the diagnosis (ratio *BCR-ABL/ABL* <1% in IS), becoming undetectable within 12 months of treatment in all patients; occasional, sporadic positivity at very low levels (ratio *BCR-ABL/ABL* ratio always in the range of MR4-MR.4.5 in IS) was frequently documented during the follow up , with no correlation with raise in p210 amount. One of two patients in AP obtained a CCyR (complete cytogenetic response) and a MMR (major molecular response) within 6 months of starting the treatment with Dasatinib, the other one was resistant to Imatinib and underwent allogeneic bone marrow transplant (HSCT) from an unrelated donor; 3 of 8 patients in CP treated with Imatinib obtained a MMR at 12 months, 3 patients were resistant and switched to second generation tyrosine kinase inhibitors, a case at 18 months showed still a ratio of 0,21, while BCR-ABL/ABL ratio of the last patient with only three months of follow up is not available. Nilotinib as first line therapy induced a MMR at six months in 3 patients.
Summary / Conclusion: Co-expression of p210 and p190 transcripts is not a common event in CML, especially in chronic phase. Presence of low levels of p190 transcripts at the diagnosis appears to be related to an increased Sokal risk and/or advanced phases, and to an apparent reduced probability of response to Imatinib. The majority of patients showed fluctuating, very low levels of p190 transcripts over the time, with no correlation with changes in p210 transcript amount.

B1384

FREQUENCY OF HYPOCALCEMIA IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA RECEIVING TYROSINE KINASE INHIBITOR THERAPY

A Mahdi[1*], E Robinson[1], S Vora[2], H Sati[1]
[1]Haematology, [2]Singleton Hospital, Swansea, United Kingdom

Background: The introduction of tyrosine kinase inhibitors (TKI) have revolutionised the treatment of chronic myeloid leukaemia (CML). Despite the wide range of signalling pathways inhibited by Imatinib mesylate, the drug is relatively well tolerated by the majority of patients. Hypocalcemia is one of the side effects that was suggested to occur very frequently in patients with GIST tumours receiving Imatinib therapy. We have noticed hypocalcaemia in a number of patients with CML receiving Imatinib and Dasatinib treatment.
Aims: We aimed to study calcium levels in patients with chronic phase-CML within the first 12 months of the introduction of TKI therapy. The need for relevant replacement therapy in the presence or absence of hypocalcaemia symptoms was also assessed.
Methods: A retrospective observational study was undertaken at Singleton hospital (Swansea, UK) of patients receiving TKI therapy for chronic phase-CML. Symptoms related to hypocalcaemia and need for calcium replacement therapy were recorded by examination of the clinical notes. Blood results were reviewed by comparing pre-treatment serum adjusted calcium (SAC) level (reference range: 2.15-2.60 mmol/l) to the mean post-treatment levels over the 12 month period following the commencement of TKI therapy.
Results: The records of 28 patients who received 1st line TKI therapy between Feb 2004-Aug 2012 were examined. The median age was 55 years (range 24-77 years) and 36% were males. All patients received Imatinib (400mg/day) except 3 patients who received Dasatinib (100mg/day). A post therapy fall in the mean SAC was noticed in 21 patients (75%). The median decrease in SAC was 6.2% (range 0.92% to 12.5%). The mean reduction of SAC was 5.6 % in the Imatinib cohort (range 1.75% to 11%) as compared to 5% (range, 0.92% to 12.5%) in patients who received Dasatinib. Hypocalcaemia, defined as the mean SAC during the 1st year post TKI therapy <2.15 mmol/l, developed in 10 patients (36%). Only three of these patients had documented symptoms of muscle aches and cramps. Ten patients (36%) received combined oral calcium and vitamin D replacement therapy. One patient on Imatinib did not tolerate calcium supplements but had a spontaneous improvement in SAC. In three patients with hypocalcaemia, the SAC did not normalise with daily supplements of calcium (1 gm) and vitamin D3 (Colcalciferol 20 mcg). Serum vitamin D levels were checked and found to be significantly low in these patients (median 11 ng/ml, range (10-12 ng/ml) and required the addition of a treatment dose of vitamin D, given as Ergocalciferol 1.25mg for 5-10 doses and achieved normocalcemia. No difference was found in cytogenetic and molecular responses between the hypocalcemic and normocalcemic cohorts of patients.
Summary / Conclusion: In our study population of patients with chronic phase-CML, the reduction in SAC was a frequent laboratory but asymptomatic finding following introduction of Imatinib therapy. This was reported in 75% of all patients. Hypocalcaemia was seen in 36% of patients and responded to conventional dose calcium and vitamin D replacement therapy in the majority of these patients. However, in three of these patients, normal SAC was achieved only after addition of high dose vitamin D therapy. These three patients had significantly low serum vitamin D levels. This suggests that vitamin D deficiency may potentiate the hypocalcemic effect of TKI therapy. Clinicians need to be aware of this frequent side effect that may need treatment. Serum vitamin D levels should be checked in those patients who remain hypocalcemic despite conventional dose supplements. Further studies looking at effects of long-term TKI therapy on bone and calcium dysregulation are warranted.

B1385

EVALUATION OF TWO THERAPEUTIC STRATEGIES IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA IN SUBOPTIMAL RESPONSE TO IMATINIB

A Lang[1*], M Roques[1], D Caillot[1], M Boulin[1]
[1]University Hospital, Dijon, France

Background: There is no consensus about the optimal treatment regimen in patients with Chronic-Phase Chronic Myeloid Leukaemia (CP-CML) presenting a suboptimal response to first-line imatinib.
Aims: The aim of our study was to evaluate the efficacy and safety of two therapeutic strategies in the management of CP-CML patients in suboptimal response to first-line imatinib.
Methods: Methods: All CP-CML patients treated in our teaching hospital with imatinib as first-line for CP-CML since the availability of the drug were eligible. Among them, those presenting a suboptimal response (according to the 2009 European LeukemiaNet criteria) to imatinib 400 mg once daily were included in this retrospective study. Patients were assigned in two groups regarding the treatment modification: group1, increase in imatinib dose (600 to 800 mg daily); group2, imatinib discontinuation and initiation of a Second-Generation Tyrosine Kinase Inhibitor (SG-TKI; nilotinib 800 mg daily, or dasatinib 100-140 mg daily). Cytogenetic response (CyR) was assessed 12 months after treatment modification and molecular response (MolR) was assessed every 3 months. Adverse events (AEs) were graded according to the National Cancer Institute Common Terminology Criteria for AE v 3.0.
Results: Out of the 150 CP-CML patients receiving imatinib 400 mg daily, 27 patients (18%) presented a suboptimal response. Twenty-two and five patients were assigned in group 1 and2, respectively. At 12 months, all patients except one in group 1 were in complete CyR. At 12 and 18 months, the rate of complete MolR was 23% and 36% in group 1 *vs.* 60% and 60% in group 2 (P=.13 and P=.37, respectively). The rate of treatment discontinuation was 40% in group 2 vs 0% in group 1. Two patients receiving nilotinib were hospitalized for one grade 4 cardiac AE, and one for grade 3 pain and deterioration in general condition. In group1, 50% of the patients developed at least one grade 1 or 2 AE; the most frequent imatinib-related AEs were muscle cramps, edema (eye, orbital, periorbital), and digestive disorders.
Summary / Conclusion: In CP-CML patients in suboptimal response to imatinib 400 mg daily, the use of a SG-TKI led to a higher non significant complete MolR rate but more severe toxicities at 18 months compared to an increase of the imatinib daily dose.

B1386

EXTREME THROMBOCYTOSIS IN CHRONIC MYELOID LEUKEMIA(CML) IN THE ERA OF TYROSINE KINASE INHIBITORS (TKIS)

f autore[1*], f ora[1], p chiusolo[1], l laurenti[1], s giammarco[1], b vannata[1], g ausoni[1], e metafuni[1], i innocenti[1], g leone[1], s sica[1]
[1]haematology, ucsc, roma, Italy

Background: Thrombocytosis is a common feature in chronic myeloproliferative diseases disorders. The incidence of thrombocytosis in CML is reported to be around 30 to 50% . Extreme thrombocytosis defined as a platelet count > $1.000x10^9$/l is uncommon in CML as well as isolated thrombocytosis. According to the WHO classification criteria, persistent thrombocytosis (> 1000 × 10^9/L) unresponsive to therapy defines accelerated phase of CML while this is not the case when standard criteria for the definition of CML staging in imatinib and second generation inhibitors of tyrosine kinase trials are adopted.
Aims: The aim of our study was to review the behavior of CML with extreme thrombocytosis at our center analyzing the problems associated to the clinical management of haemorrhagic and thrombotic risks and the therapeutic response in the era of tyrosine kinase inhibitors
Methods: From November 1997 to February 2013 we observed and treated one hundred consecutive patients affected by CML in chronic phase . All

patients were studied for JAK2 V617F mutation, and coagulation cascade.
Results: Only 11 patients (11%) presented at diagnosis an extreme thrombocytosis. There were 8 females and 3 males with a median age of 42 years. At diagnosis, median hemoglobin level was 12.2 g/dl, median white blood cell count 19.240/mmc and platelets count 1.160x109/l. The Sokal score was high in5, intermediate in 3 and low in 3 patients. In all cases PCR analysis showed the presence of p 210 and absence of JAK2 V617F mutation. Bleeding time (Ivy test) was prolonged with a median of 10.68 minutes. aPTT was within the normal range in all but two patients. Iron levels were normal in all but one female patient. Only one patient developed thrombosis of the caephalic vein in the left forearm at diagnosis while no patient reported history of bleeding. All but three patients received initial treatment with hydroxyurea and allopurinol. One patient underwent plateletpheresis. Platelet count was largely unresponsive to initial treatment. Low dose aspirin (100mg/day) was administered in 5 out of 11 patients. Upfront treatment with TKIs included imatinib in 8 patients and nilotinib in 3 patients. Platelet count normalization was rapidly achieved after introduction of TKIs. Haematological response according to ELN criteria was reached at a median of 1 month, complete cytogenetic response was achieved after a median of 3 months and major molecular response was achieved in 9 out of 11 patients after a median of 9 months. One patient was in suboptimal molecular response at 18 months of imatinib according to ELN recommendations and he was shifted to dasatinib. He achieved MMR on dasatinib and is now at 37 months on second line treatment. One patient lost MMR after 5 years of imatinib and she was shifted to nilotinib achieving MMR and she is now at 25 months on second line treatment . All patients are alive and in optimal response at a median follow up of 67 months from CML diagnosis.
Summary / Conclusion: Extreme thrombocytosis in CML is unfrequent. Prolonged bleeding time was detected in all patients although it was not accompanied by bleeding diathesis. Cytoreduction with hydroxiurea was not able to achieve normalization of platelet count that was easily and rapidly achieved by tyrosine kinase inhibitors. Response to treatment according to ELN criteria was optimal in all but two patients requiring second line TKIs respectively for suboptimal molecular response and secondary resistance to imatinib.

B1387

BLAST CRISIS OF CHRONIC MYELOID LEUKEMIA: LABORATORY, IMMUNOPHENOTYPC, AND CYTOGENETIC HALLMARKS AND RESPONSE TO THERAPY

A Vidovic[1,2*], G Jankovic[1,2], D Tomin[1,2], N Suvajdzic[1,2], I Djunic[1], N Colovic[1,2], M Virijevic[1], M Mitrovic[1], A Bogdanovic[1,2], N Kurtovic[1], V Djordjevic[1], M Fekete[1], S Pavlovic[3], M Perunicic[1], B Mihaljevic[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

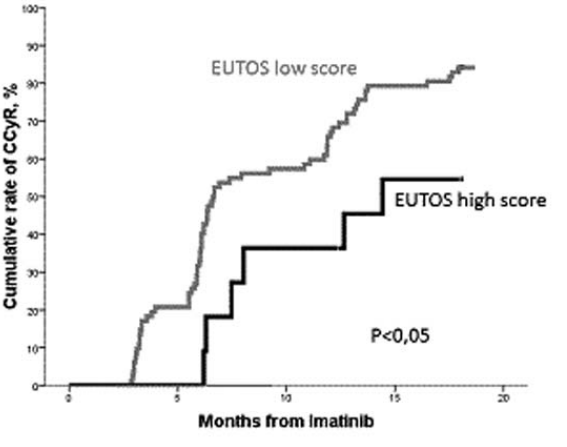
Background: Whereas the chances for cure have been improved in chronic phase (CP) and occasionally even in the accelerated phase (AP) of chronic myeloid leukemia (CML) by using tyrosine kinase inhibitors and hematopoietic stem cell transplantation, the blast crisis (BC) is extremely rarely curable and is usually a fatal phase of CML.
Aims: To evaluate clinical, laboratory, immunophenotypic and cytogenetic features of the BC-CML and response to therapy
Methods: We studied 48 patients in BC-CML treated at the Clinic of Hematology between 2004 and 2012. The physical examination of the patients included the estimation of organomegaly, lymphadenopathy and hemorrhagic manifestations. The type of BC was established by cytology and flow immunocytometry/immunohistochemistry of the bone marrow aspirates. The HD technique of chromosome banding and the RT-PCR procedure were applied in genetic studies.
Results: The median age of patients was 52 years (range:20 – 78), the M/F ratio was 27/21. The median of duration of CP was 57 months (spread: 0 – 96). The Sokal score was estimated in 40/48 patients: 9/48 were low risk, 20/40 were intermediate, and 11/40 were high risk patients. Nine patients with CP-CML were treated with imatinib mesylate, 20 patients with hydroxyurea, 13 patients with interferon-α with or without cytosine arabinoside, three patients with busulfan, and three patients with cytosine arabinoside alone. The following cytological types of the BC-CML were demonstrated: myeloblastic in 32/48, lymphoblastic in 8/48, megakaryoblastic in 3/48 and biphenotypic in 5/48 patients. Cytogenetic analyses in BC-CML demonstrated the sole presence of Ph chromosome in 20/48; double Ph chromosome in 4/48, additional chromosome aberrations in 6 patients [trisomy 8 in two patients and t(2;11); t(4;11); i(17)(q10); add 21; i 4q in a single patient each]. The complex karyotype was evidenced in five patients. Adequate mitoses were not obtained in 7 patients. Thirty patients received intensive combined chemotherapy (cytosine arabinoside+ daunoblastin: "3+7" or "2+5" and Flag-Ida, HyperCVAD, and CHOP protocols) relevant to cytological type of the BC-CML. Palliative cytoreduction was conducted in ten patients (busulfan, hydroxurea). Eight patients received only supportive therapy due to a poor performance status or an advanced age. The overall median survival in BC-CML was 3 months (range, 0.5-31). The median survival was longer in patients treated with high-dose chemotherapy,8,8 months, compared to palliation, 2 months (P=0,043). Out of ten patients who survived longer than 10 months, 7 patients were treated with Imatinib mesylate for their CP-CML. The median duration of CP was significantly longer in patients treated with Imatinib, 58 months (range: 38-96, P=0,02). The patients with an inferior (low and intermediate) Sokal score had a longer CP (P=0,025). The cytogenetic changes were not significantly related to survival in BC-CML.
Summary / Conclusion: This study provides yet another confirmation of the severity of BC-CML and a disappointing outcome of therapy. Only intensive chemotherapy lends a certain hope in prolonging the survival of patients in BC-CML. Hopefully, novel therapies of CP-CML shall have devalued BC-CML in the future to an exceptionally uncommon and unfamiliar clinical incident.

B1388

PROGNOSTIC VALUES EUTOS AND SOKAL SCORES IN NEWLY DIAGNOSED CML CP PATIENTS

K Abdulkadyrov[1], I Martynkevich[1], V Shuvaev[1], S Evgenia[2], E Romanova[2], T Silina[2], O Kulemina[2], A Abdulkadyrova[1], V Udaleva[1], E Usacheva[1], N Ilina[2], R Golovchenko[1], L Martynenko[3], M Ivanova[1], I Zotova[1], N Cybakova[1], E Petrova[3], M Kozlovskaya[1], M Fominykh[4], E Machiulatene[3], E Lomaia[5], A Zaritskey[2,4*]
[1]Russian Research Institute Hematology and Transfusiology, [2]Almazov Federal Centre for Heart, Blood and Endocrinology, [3]Russian Research Institute Hematology and Blood Transfusiology, [4]Pavlov State medical university, [5]Almazov Federal Centre for Heard, Blood and Endocrinology, Saint-Petersburg, Russian Federation

Background: Imatinib is highly effective in newly diagnosed patients with chronic myeloid leukemia (CML) in chronic phase (CP). Nevertheless some patients never obtained CCyR or loss it later. It seems that EUTOS score is predictable for CCyR at 18 months, but it's prognostic value for survival is questionable. In some studies SOKAL risk groups influenced on Imatinib efficacy.
Aims: The purpose of our study was to assess prognostic significance of EUTOS and SOKAL scores in newly diagnosed CML CP patients.
Methods: In our study 137 (male 67, female 70) newly diagnosed patients with CML CP treated with Imatinib as first line were included. Median age at diagnosis was 50 years (range 18-86). Median time from diagnosis to Imatinib therapywas 1.2 months (range 0-6). The median duration of imatinib therapy was 37 months (range 1.6-107). EUTOS score was low in 118 (86%) and high only in 11 (8%) patients. It was unknown in 8 (6%) patients. SOKAL score was low in 68 (50%), intermediate in 44 (32%), high in 17 (12%) and unknown in 8 (6%) patients.
Results: In our retrospective study 119/137 (87%) patients were evaluable for cytogenetic response. The best cytogenetic responses cumulative rates were: CCyR in 93/119 (78%), PCyR in 9/119 (8%), minor CyR in 4/119 (3%), minimal CyR in 2/119 (2%), non CyR 11/119 (9%). CCyR was obtained in 79/99 (80%) and 7/13 (53%) cases with EUTOS low and high scores respectively. Cumulative rates of CCyR by 12 months and 18 months were 73/115 (63%) and 79/96 (86%) respectively. By 18 months CCyR was obtained in 70/82 (85%) and 7/11 (64%) patients with EUTOS low and high scores (P<0.05) respectively. Median time to CCyR was shorter in low (6.7 months) risk group more than two times than in high (14 months) risk IFig. 1). There were no differences in the rate of CCyR (overall or by fixed time-points) between Socal risk groups. Only 14/137 (10%) of patients dead during follow up time. 9-years estimated overall survival was 86%. In our study both EUTOS and SOKAL scales were not predictable for overall survival.
Summary / Conclusion: In our study EUTOS score had high prognostic value for CCyR. Both SOKAL and EUTOS scores were not predictable for overall survival. Perhaps it was because of small number of patients in high SOKAL and EUTOS risk groups.



B1389

IMATINIB THERAPY RESPONSE IN CML PATIENTS WITH DIFFERENT BCR/ABL P210 TRANSCRIPTS

I Dmytrenko[1,2*], I Dyagil[1], J Minchenko[1], V Fedorenko[1], T Shliakhtychenko[1]
[1]Hematology and Transplantology Department, National Research Center for Radiation Medicine , [2]Tissue Typing Laboratory, Kyiv Bone Marrow Transplantation Center, Kyiv, Ukraine

Background: Multiple clinical trials showed extremely high efficiency of tyrosine kinase inhibitors (TKI) in the therapy of chronic myeloid leukemia (CML). However, despite the achieved progress, there is a group of patients who have almost no response to the therapy, or lose response at different stages of treatment. Mechanisms underlying the resistance to TKI have not been clarified yet. The main pathogenetic event which leads to the development of CML is the translocation t(9;22)(q34;q11.2) in stem cells which results into formation of a chimeric fusion gene *BCR/ABL*. Study of genetic mechanisms of TKI therapy resistance development and genetic prognostic markers of treatment response determines success of TKI therapy in patients with CML.
Aims: The ***aim*** of this research was to describe *BCR/ABL* transcripts pattern and to study prognostic value of different type *BCR/ABL* transcripts for imatinib therapy response in patient with CML.
Methods: Expression of *BCR/ABL* gene was studied by qualitative nested reverse transcriptase polymerase chain reaction (RT-PCR) in 900 patients with CML prior to the start of imatinib therapy. Patients' age ranged from 20 to 70 years old at the time of disease. Therapy response was assessed in 110 CML patients at 6 and 12 months of imatinib therapy (dose of imatinib 400 mg/day) by the level of Ph-positive metaphases in bone marrow. For this purpose results of bone marrow cells karyotyping by G-banding were used. Response was considered optimal if a major cytogenetic response (reduction of Ph-positive metaphase plates in the bone marrow to less than 35%) was achieved at 6 months and complete cytogenetic response (complete absence of Ph-negative metaphase plates in the bone marrow) - after 12 months of imatinib therapy.
Results: It was found that in 511 patients (56,8%) b3a2 *BCR/ABL* transcript was expressed, in 305 patients (33,9%) expression of b2a2 transcript was revealed. Three patients (0.3%) had only e1a2 transcript and in the 54 patients (6%) coexpression of several *BCR/ABL* transcripts took place. 27 patients (3%) had expression of houskeeping gene without expression of the examined *BCR/ABL* transcript. Such cases were considered as variant transcripts because primers only for widespread *BCR/ABL* transcripts b3a2, b2a2 and e1a2 were used.Assessment of the prognostic value of b2a2 and b3a2 transcripts for the imatinib therapy response showed that the number of patients who achieved optimal and complete cytogenetic response at 6 month of therapy was equal in both groups. However, among patients with the partial cytogenetic response (level of Ph-positive metaphases 5 - 35 %) at 6 month therapy more often achieved complete cytogenetic response at 12 month of therapy those who had transcript b2a2, while most part of patients with b3a2 transcript saved partial cytogenetic response. Thus, patients with b2a2 transcript respond to the standard dose of imatinib (400 mg/day) significantly earlier.
Summary / Conclusion: Accumulation of knowledge about molecular features of disease is the way to further improve CML treatment outcomes.Obtained results indicate that groups of patients with CML are not uniform. Patients with atypical forms of *BCR/ABL*transcripts require in-depth study and expansion of surveillance. Patients with expression of b2a2 *BCR/ABL* transcript have more stable and earlier cytogenetic remission with imatinib therapy than those with b3a2 transcript. To summarize, the type of transcript does have prognostic value for response to imatinib therapy.

B1390

A FRET-BASED DRUG SENSITIVITY TEST PREDICTS A CLINICAL OUTCOME OF CML PATIENTS AT THE DIAGNOSIS

T Kondo[1*], Y Ohba[2], M Tsuda[3], A Kaneyasu[2], J Tanaka[1], M Imamura[4], J Sakamoto[5], Y Ishida[6], T Teshima[1]
[1]Hematology, Hokkaido University Graduate School of Medicine, [2]Cell Physiology, Hokkaido University Graduate School pf Medicine, [3]Cancer Pathology, Hokkaido University Graduate School of Medicine, [4]Hematology, Hokuyu Hospital, Sapporo, [5]Tokai Central Hospital, Kakamigahara, [6]Hematology and Oncology, Iwate Medical University, Morioka, Japan

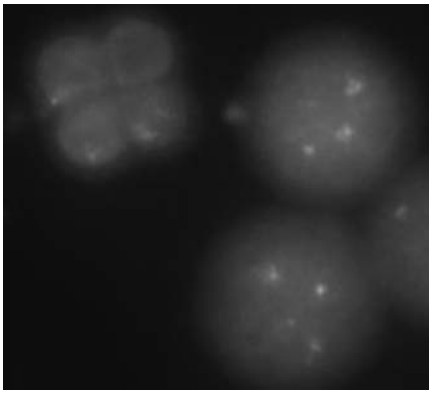
Background: The tyrosine kinase inhibitors (TKIs), imatinib, nilotinib and dasatinib are used as the first-line therapy for newly diagnosed chronic myeloid leukemia (CML). To predict a clinical outcome, Sokal, Hasford and EUTOS scores are widely used. But at this moment, we don't have a good tool to predict which TKI is most effective at the diagnosis. We have developed a FRET(fluorescence resonance image transfer)-based method to evaluate sensitivity of CML cells to TKIs (Mizutani et al. Clin Cancer Res. 2010).
Aims: We designed this study to evaluate a clinical utility of FRET-based drug sensitivity test.
Methods: Inter-MIchinoku DAsatinib Study (IMIDAS) group conducted a Phase II clinical study to evaluate the efficacy and safety of dasatinib. Newly diagnosed CML-CP patients were enrolled into this study after obtaining a written informed consent. In this multicenter phase II clinical trial, dasatinib (100 mg QD) was administered orally for one year and the molecular responses were monitored. FRET analysis was also conducted as an accompanying study. Bone marrow mononuclear cells at the diagnosis were isolated and transfected with FRET probe, Pickles. After 18 to 24 hours of transfection, the cells were treated with 0.1 microM dasatinib and then subjected to microscopic analysis to determine FRET efficiency. RQ-PCR evaluation of BCR-ABL mRNA was performed to monitor the clinical efficacy of dasatinib. Totally 45 patients were analyzed here, since they were subjected to FRET analysis and followed longer than three months.
Results: The samples form 45 patients were subjected to FRET analysis. Among them, 9 patients were defined as dasatinib-sensitive and 36 patients were categorized into dasatinib-insensitive. At 3 months analysis, MMR rate was 44% in the sensitive group (n=9) and 39% in the insensitive group (n=36). At 6 months analysis, MMR rate was 89% in the sensitive group (n=9) and 62% in the insensitive group (n=29). At 9 months analysis, MMR rate was 88% in the sensitive group (n=8) and 83% in the insensitive group (n=18). At 12 months analysis, MMR rate was 100% in the sensitive group (n=3) and 85% in the insensitive group (n=13). One treatment failure and one transformation to BC were observed in the insensitive group.
Summary / Conclusion: The FRET analysis to determine dasatinib-sensitivity in vitro could predict the clinical efficacy of treatment with dasatinib. Our method will add the new tool to stratify the patients with CML-CP.

B1391

FOUR CASES OF CML BLAST PHASE AS INITIAL PRESENTATION DIAGNOSED BY FLUORESCENCE IN SITU HYBRIDIZATION SHOWING BCR-ABL1 SIGNALS IN MATURE NEUTROPHILS

W Choi[1*], Y Kim[1]
[1]Laboratory Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Leukemia with t(9;22) and granulocytic hyperplasia at initial presentation can be diagnosed as acute leukemia with t(9;22) or chronic myelogenous leukemia – blast phase (CML-BP). These two entities have clinical, pathologic, immunophenotypic, and genetic similarities. However, CML is multilineage disease involved by the Philadelphia (Ph) chromosome and Ph+ acute leukemia is blast-restricted.
Aims: We experienced two adult and two pediatric patients with CML-BP as initial presentation who were initially suspected as having Ph+ acute leukemia. Identification of *BCR-ABL1* gene in mature neutrophils by fluorescence in situ hybridization (FISH) analysis led us to diagnose CML-BP.
Methods: All our patients showed peripheral leukocytosis due to blasts and granulocytic hyperplasia with or without absolute basophilia. We performed complete blood cell count (CBC), bone marrow study, immunophenotyping study, molecular study, and cytogenetic study. Fluorescence in situ hybridization (FISH) analysis was done to distinguish CML presenting in BP from Ph+ acute leukemia.
Results: We had initially suspected Ph+ acute leukemia based on molecular study and high proportion of blasts in the bone marrow, but the peripheral granulocytic hyperplasia with shift to the left of maturation pattern led us to finally find the *BCR-ABL1* fusion signals in mature neutrophils by FISH analysisindicating CML-BP. Three cases had mixed phenotype blasts and one case had lymphoblasts on the immunophenotyping study. Three patients had been treated with induction chemotherapy alone before adding tyrosine kinase inhibitor (TKI). At follow-up, high proportion of Ph+ cells by cytogenetic study and/or high level of the BCR-ABL1 transcript by Real-time quantitative PCR (RQ-PCR) were still detected, although the proportion of the blasts was much lower than before in the bone marrow. This supported the diagnosis of CML presenting in blast phase.
Summary / Conclusion: While interpreting FISH results for leukemia with t(9;22) and peripheral granulocytic hyperplasia as initial presentation, care should be taken to find the *BCR-ABL1* fusion signals in mature neutrophils to diagnose CML-BP. The exact diagnosis is needed to pool rare cases of Ph+ acute leukemia and CML-BP as initial presentation correctly and helps patients to be involved in proper clinical trials.



B1392

A POPULATION STUDY OF OUTCOMES IN CHRONIC MYELOID LEUKAEMIA IN N.IRELAND FROM 2000-PRESENT.

C Mcconville[1*], d finnegan[1], r cuthbert[1], c arnold[1], f mcnicholl[2], k boyd[3], m mcmullin[1]
[1]Haematology, Belfast City Hospital, Belfast Trust, Belfast, [2]Haematology, Altnagelvin Hospital, Western Trust, Derry, [3]Haematology, Craigavon Area Hospital, Southern Trust, Craigavon, United Kingdom

Background: Imatinib mesylate given orally at a dose of 400my once daily is the standard of care as initial therapy of patients with chronic myeloid leukaemia in chronic phase (CML-CP). In 2009 the European LeukaemiaNet (ELN) released reviewed guidelines which are the current standard of care of patients with CML-CP.
Aims: Reviewing our CML-CP population, diagnosed and treated in the imatinib mesylate era, for response to therapy using current guidelines.
Methods: All patients aged 16 years or more with newly diagnosed CML-CP from 2000-present are included in this study. Considerable effort was taken to include all CML cases, from the regional cytogenetic laboratory, case note review and specific enquiry of clinical haematologists. Response rates were defined as per the 2009 ELN recomendations.
Results: 77 cases of CML-CP were diagnosed pre-2009. 52 (67.5%) achieved complete haematological response (CHR) and subsequent complete cytogenetic response (CCyR) as per the 2009 ELN recommendations. 35 (68.7%) of the 51 continued to a major molecular response (MMolR) by the recommended milestone. 68 were imatinib mesylate-treated, with 50 (73.5%) in CCyR at 12 months, and 35 (51.5%) having MMolR at 18 months.
20 (77%) of the 26 assessable cases achieved CCyR within 12 months in the CML-CP patients diagnosed from 2009 onwards. 17 (71%) of the 24 cases assessable achieved MMolR at 18 months.
Summary / Conclusion: Lucas et al, showed 40% of all patients to be in complete cytogenetic response equivalence (CCRe) at twelve months, and 41% for imatinib mesylate-treated patients. The outcome of our population-based study are markedly superior to similar studies outside of a trial setting. Compliance appears to be an issue in some patients failing to meet the recommended milestones of response.

B1393

ASSOCIATION OF GENE HLA-DRB1 POLYMORPHISM WITH THE OUTCOME OF THERAPY OF CHRONIC MYELOID LEUKEMIA WITH IMATINIB

E Ovsyannikova[1*], I Davydkin [2], E Popov[1], K Kaplanov [3], L Zaklyakova[1], Z Israpilova[1], T Klitochenko [4], B Levitan[1]
[1]Astrakhan State Medical Academy, Astrakhan, [2]Scientific Research Institute of Hematology, Transfusiology and Intensive Care in Samara State Medical University, Samara, [3]Volgograd Regional Oncological Dispensary, [4]Volgograd Regional Oncological Dispensary, Volgograd, Russian Federation

Background: The outcome of chronic myeloid leukemia (CML) therapy with imatinib mesylate depends on a number of the proved factors: risk group, mutation status, presence of chromosomal aberration. In some patients with CML imatinib therapy at the chronic phase with the dose 400-600 mg gives quick and deep response, the other part of the patients is resistant to treatment. This group of patients needs earlier transition to the second line and, what is more important, to begin treatment CML in those patients without administration of imatinib (it is preferable).
Aims: The search of immunogenetic markers, making it possible depending on the presence of the certain specificity of the HLA-DRB1 gene to choose the individual set of therapy, including the first line group medicine.
Methods: HLA-typing (PCR-SSP) of the 50 patients with CML under chronic phase treated with imatinib during 24 month has been carried out. Average age 50,3±15,0, correlation of males and females in the research was 1:1. The dose of imatinib was increased more that 400 mg per day in 35(70%) patients. The results of genotyping of the 94 donors (L.V. Saroyants) were used as the control data. All the patients with CML and the donors referred to the group of eastern-European Slavs. Statistical processing has been carried out with the use of x^2. The index of the association RR strength relative risk, etiologic fraction – EF, preventive fraction – PF. Critical level of the significance under control of the statistical hypotheses in the given research was considered equal to 0,05.
Results: It is found that in the patients with CML, having reached complete cytogenetic response (CCyR) in 24 month of imatinib therapy there noted the increase more than 4 times, specificity rate DRB1*16(02), (20% versus5,3%; RR-4,37, EF-0,154). Rate increase of the gene HLA DRB1*14(06) in comparison with the control was 12% versus 0% (RR-29,4, EF-0,116, P<0,01) in the patients with CML who have not got CCyR in 24 month of therapy. The rate of DRB1*15(02) in this group in comparison with the control was decreased, i. e. 8% versus 28,7% (RR-0,26, PF-0,188, P<0,025). Under comparative analysis of the gene profile HLA DRB1 in the patients with CML at the CCR and with the absence of CCyR in 24 month of therapy negative associations with the specificity if DRB1*11(20% versus 48%; RR-0,29, PF-0,363, P<0,025); DRB1*12(0% versus 8%; RR-0,18, P<0,05); DRB1*14(0% versus 14%; RR-0,13, p,<0,025) have been found. The increase of the rate of HLA-DRB1 (in comparison with the control) 14(06) –8,8% versus 0% (RR-21, EF-0,084, P<0,025) and the decrease of HLA-DRB1*15(02)-8,8% versus 28,7% (RR-0,27, PF-0,195, P<0,01) have been noted in the patients with CML, who have not got complete molecular response (CMR) in 24 month of therapy.
Summary / Conclusion: The marker of the unfavorable prognosis of CML without CCyR and CMR in 24 month of therapy with imatinib in the specificity of DRB1*14(06); the markers of the unfavorable prognosis of CML without CCyR in 24 month of therapy with imatinib are the specificities of DRB1*11(05), DRB1*12(05). It is more advisable to begin therapy of the patients with CML, having specificity DRB1*14(06), 11(05), 12(05), with the inhibitors of tyrosinkinases of the second line. The marker of the favorable prognoses having CCyR and CMR in 24 month of therapy with imatinib is the specificity of DRB1*16(02). Specificity of DRB1*15(02) possesses protective property. Under the presence of the specificities HLA DRB1*16(02), DRB1*15(02) in the genotype of the CML patient it is possible to use imatinib as the medicine of the first line.

B1394

ACCELERATED PHASE OF CHRONIC MYELOID LEUKEMIA: THE IMPACT OF THE DIFFERENT CRITERIA ON TREATMENT RESPONSE AND SURVIVAL

V Funke[1*], V Fiorini[1], G Santos[1], T Fagundes[1], L Sinamura[1], C Sola[1], D Setubal[1], L Medeiros[1], R Pasquini[1], M Malvezzi[1]
[1]Hematology, Federal University of Parana, Curitiba, Brazil

Background: Chronic Myeloid Leukemia (CML) is a clonal myeloproliferative disease which progresses from an indolent to a more aggressive phase, the accelerated phase (CML-AP). Unless effective therapy is instituted, it transforms to a blastic phase (CML-BP). Even though CML-AP is well recognized, the criteria that define this phase vary in the literature. Thus, different definitions of AP have been described and the heterogeneity among patient outcomes and response is marked.
Aims: This study was designed to analyze the several existing criteria and correlate them with treatment response and prognosis in a CML-AP Brazilian population of a referral center.
Methods: This is a retrospective study from January 2000 to November 2011 in which data from the chart of 143 patients with CML-AP (according to any of aforermentioned criteria) treated with imatinib, were selected from BMT Center database of Hospital de Clínicas of Universidade Federal do Paraná, Brazil. Survival data was analysed by Kaplan-Meier method. P level of signifcance was defined as 0,05. Univariated and Multivariated analysis were performed using STATA program version 8.0. Primary endpoints were minor cytogenetic response, survival and death.
We evaluated as risk factors all variables included in previous reported classification of accelerated phase CML (blasts >10% in peripheal blood, basophils >10% in peripheral blood, spleen >10 cm from left costal margin, hemoglobin ‹10 g/dl, platelets >1.000.000 and <100.000, clonal evolution) as well as the development of hematologic toxicity after imatinib.
Results: 43.4% of the patients were female and 56.6% were male. Median age was 45 years. Multivariate predictors of poor outcome were hematologic toxicity (P=0.003) hazard ratio (HR) of 2.53; 95% confidence interval (95%CI), 1.36-4.70, blasts (P=0.003) (HR of 2.99; 95% CI, 1.45-6.16, WBC (P=0.008) HR of 3.80; 95% IC, 1.41-10.22) and anemia (P=0.005), HR of 2.53; 95%CI 1.32-4.84)
Summary / Conclusion: These data indicate that patients with the above risk factors have a worse prognosis than some other also classified as AP patients. This information can guide therapy to be instituted. Prospective multicenter studies are necessary to achieve a classification that can be used universally in the era of TK inhibitors.

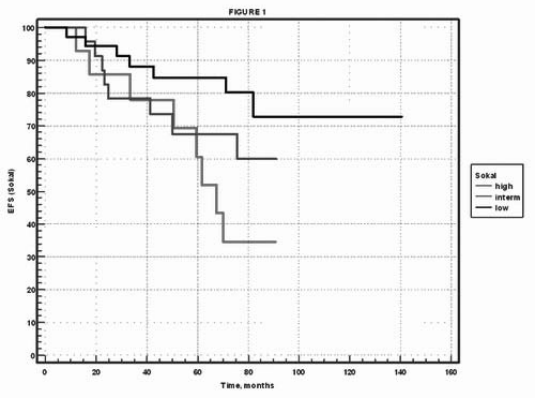
B1395

COMPARISON OF THE SOKAL AND EUTOS PROGNOSTIC SCORES IN PATIENTS WITH CML: ONE CENTER'S EXPERIENCE

K Kotlyarchuk[1*], Z Maslyak[1], L Lukavetskyy[1], A Lukjanova[1], O Danysh[1], R Lozynsky[1]
[1]SI "Institute of Blood Pathology and transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: European Treatment and Outcome Study (EUTOS) score is the new prognostic system developed by the European LeukemiaNet for newly diagnosed chronic myeloid leukemia (CML) patients in chronic phase (CP) treated with imatinib (IM). Its prognostic value has been discussed by several study groups with some discrepancies in their results.
Aims: This retrospective study was intended to compare EUTOS score against conventionally used Sokal score in CML-CP patients treated in our institution with imatinib either frontline or after different pretreatments.
Methods: 72 CML patients treated with imatinib were analyzed. In 23 of them IM was administered frontline; in 25 – after interferon failure; in remaining 24 – after long term treatment with hydroxyurea. Risk subgroups were determined using Sokal and EUTOS criteria at disease diagnosis. Each subgroup was evaluated for the rate of complete cytogenetic response (CCyR) at3,6, 9, 12, 18 and 24 months of IM treatment, as well as for event-free survival (EFS), measured

from the start of IM until one of the following events: death from any reason, acceleration phase, blastic phase, loss of complete hematologic response or loss of CCyR.
Results: High risk criteria were found in 14 patients (19,4%) according to the Sokal and 8 (11,1%) - according to EUTOS systems. Low risk subgroup accounted for 35 (48,6%) and 64 (88,9%) patients according to Sokal and EUTOS respectively; 23 (32%) patients were considered as Sokal intermediate risk subgroup. No significant difference in CCyR was found between all risk groups at 3 months of imatinib therapy. Beginning from 6 months CCyR was clearly lower in high risk patients according to both scores as compared to low EUTOS or low and intermediate Sokal risk patients. Importantly, no difference was revealed between low and intermediate Sokal risk groups in terms of rate of CCyR and time to its achievement. As to the EFS, no significant difference was revealed for all risk groups according to both scores at 12, 24 and 36 months. Starting from 48 months EFS was clearly better in low risk patients than in high risk following Sokal and EUTOS. Notably, no difference was detected between intermediate and high risk Sokal patients at this point. However, at 5 years further decrease of EFS in high risk patients was detected resulting in discrimination between high and intermediate Sokal risk groups, which grew even more prominent at 72 and 80 months (Fig.1). Difference between EFS of the two EUTOS risk groups appeared to be less apparent.
Summary / Conclusion: Analyzing collected data we conclude that for our group of patients both Sokal and EUTOS scoring systems effectively prognosed cumulative rate of CCyR at different time points dividing the investigated group into 2 prognostic subgroups with intermediate Sokal risk group losing its prognostic importance. As to the EFS, however, Sokal score seemed to discriminate more distinctly than EUTOS between low risk and high risk patients distinguishing also prognostically valuable intermediate risk group. These results however may be significantly influenced by the heterogeneity of the investigated sample in terms of their pretreatment.



B1396
DYNAMICS OF T315I MUTATION IN PHILADELPHIA POSITIVE PATIENTS ON TYROSINE KINASE INHIBITOR THERAPY
I Horvat[1*], M Antolic[1], D Sertic[2], R Zadro[1]
[1]Department of Laboratory Diagnostics, [2]Department of Internal Medicine, University Hospital Center Zagreb, Zagreb, Croatia

Background: The discovery of imatinib, as a first smart drug, brought revolution into treatment of patients with Philadelphia positive chronic myeloid (CML) or acute lymphoblastic (ALL) leukemia. Development of ABL kinase domain mutations is still one of the major reasons for resistance to imatinib therapy. Second generation tyrosine kinase inhibitors (TKI) have the power to overcome all ABL mutations except T315I mutation which still represents one of the biggest challenges for treatment and indicates in most cases very low survival rate.
Aims: The aim of the study was to investigate the dynamics of T315I mutation development and bcr-abl1 transcript level kinetics in Philadelphia positive CML and ALL patients.
Methods: Ten patients with T315I mutation (6 women and 4 men), median age of 49.5 years at the time of diagnosis (range 34-62 years) were included in the study. Nine of them had CML with major bcr-abl1 transcript (7 with b3a2 type and 2 with b2a2 type) and one had ALL with minor bcr-abl1 transcript (type e1a2). T315I mutation was detected by allele specific oligonucleotide PCR (Kang et al, Haematologica, 2006;91:659) with declared sensitivity of 0.001%. Bcr-abl1 transcript level was measured by real time quantitative PCR and results were expressed according to International Scale (IS - CML patients only). Bcr-abl1 transcript quantification and T315I mutation detection were done in 8 diagnostic samples and in all follow-up RNA samples.
Results: Three patients who were diagnosed with CML before 2001 were treated with interferon-alpha, busulfan or hydroxyurea while the ALL patient was on chemotherapy before switching to imatinib. Other six patients had imatinib as a first line of therapy. After imatinib failure in 3 patients, therapy was switched to second generation TKI. Eight patients progressed to blast crisis (5 ALL and 3 AML) and 2 to accelerated phase. Eight patients died and 2 patients in whom T315I mutation was detected in August of 2012 and January of 2013 are still alive, one is in blast crisis and the other on chemotherapy after relapse and is waiting for hematopoietic cell transplantation. None of the investigated patients had T315I mutation at the time of diagnosis. Median time of the T315I occurrence after diagnosis was 30.5 months (1-121 months). Retrospective analysis of T315I mutation showed that in 3 patients mutation could be detected in earlier follow-up samples that correlated with bcr-abl1 transcript level elevation. Three patients became T315I positive after therapy with dasatinib, which can be the effect of dasatinib on other existing mutations that allow progression of T315I mutation clone. CML patients (except 1 unavailable patient's RNA) had median of bcr-abl1 transcript level 28.2% IS (range 16.0-41.3) at the time of detecting T315I while bcr-abl1 transcript level in ALL patient was 32.1%. Two patients developed T315I in less than 3 months from the time of diagnosis. Although other 4 patients had good response to therapy (3 patients were in MMR for 4-48 months), bcr-abl1 transcript level escalated because of T315I. Last 4 patients had constantly high bcr-abl1 transcript levels during follow-up, similar to diagnostic ones despite the fact that T315I mutation was detected 39-113 months after diagnosis.
Summary / Conclusion: In conclusion, the use of sufficiently sensitive molecular method in patients with bcr-abl1 transcript level elevation is important because early detection of small numbers of mutated clone, particularly for T315I, can prevent inadequate treatment with TKI as well as blast crisis, allowing more time to search for hematopoietic cell donor.

B1397
LOSS OF PREVIOUS COMPLETE CYTOGENETIC RESPONSE AND ABRUPT BLAST TRANSFORMATION DURING LONG TERM FOLLOW UP OF CHRONIC MYELOID LEUKEMIA PATIENTS IN CHRONIC PHASE TREATED WITH IMATINIB
A Bogdanovic[1*], V Milosevic[2], V Djordjevic[2], D Lekovic[2], J Jovanovic[2], M Fekete[2]
[1]Outpatient&Diagnostic Dept, Clin Hematology CCS, Faculty of Medicine, Unv Belgrade, [2]Outpatient&Diagnostic Dept, Clinic of Hematology, Clin Ctr of Serbia, Belgrade, Serbia

Background: Most of patients with CML in chronic phase achieving complete cytogenetic response (CCgR) have excellent long term results. But in small proportion of patients the events, like loss of previous good response or sudden transformation can influence treatment outcome.
Aims: To analyze occurrence of two events: loss of previous achieved CCgR (LCCgR) and occurrence of abrupt blast transformation (BC) of CML and factors associated with those events.
Methods: Cohort analysis in 151 patient with CML in chronic phase treated with frontline imatinib (IM, Gleevec®) and subsequently with other TKI (nilotinib and dasatinib) in 8 year period (2004- Sept 2012) in single academic medical center.
Results: We identified 11 patients with LCCgR and 3 patients with sudden BC in observed period. Patients without previous CCgR were not included.
Abrupt BC was seen in 3 Ph+ patients. At diagnosis, all Sokal score groups were present (one patient each) and two patients were younger than 40y. In all patients, BC occurred within two years of treatment, in 5th, 8th and 14th month. In two patients with BC (at 14th and 8th mo) previous cytogenetic follow up revealed good therapeutic response to imatinib (twice CCgR and 5% Ph+), without blasts in corresponding bone marrow. One patient was treated with dasatinib, achieving again CCgR but relapsed after SCT. Two young patients were treated with chemotherapy, one died within several days, and second one achieved remission but later died due to complications in SCT. Loss of CCgR occurred 12 to 76 months of IM treatment (mean 45 mth). Seven patients had intermediate and two had low or high risk Sokal score respectively. All patients had low EUTOS score, mean 41 (range 11 to 82). 8 of 11 pts achieved CCgR up to 6 mth, and 3/11 up to 1 year. In time of LCCgR mean age was 44 years. None of patients lost CHR, and LCCgR was detected only by regular cytogenetic follow up according to guidelines. In time of relapse, mean number of Ph+ cells was 43%, ranging from 5-90%, and 4 of 11 patients had additional cytogenetic aberrations /-Y in two, -8, and t(5;6;12)/. Bone marrow was corresponding to CML in most of cases, but in two cytological features of CML were almost absent. Six pts were treated with IM 800mg and 4 of them achieved second CCgR. One failed and other one was transferred to nilotinib with achievement of second CCgR on nilotinib. Four pts are treated with nilotinib only, and all of them achieved second CCgR. One patient progressed to BC and subsequently died. Additional cytogenetic aberrations had no influence on treatment outcome in patients treated with both TKIs. From 11 patients with LCCgR, 9 of them are still alive and are in second CCgR.
Summary / Conclusion: Occurrence of sudden BC of CML is rare but deleterious event in course of CML, and unfortunately it could not be predicted. LCCgR is also not frequent event, occurring in 7% of patients in our cohort, or less than 1% a year. Successful treatment result can be gained by second generation TKI (5 of 5 pts) but also in some patients with IM escalation to 800mg (4/6). Regular molecular follow-up can identify patients who are at risk for LCCgR.

B1398

CYTOGENETIC AND MOLECULAR RESPONSE AT 3 MONTHS AFTER SECOND-TKI THERAPY AND CORRELATION WITH LONG-TERM OUTCOMES FOR CML CHRONIC PHASE PATIENTS. EXPERIENCE IN ONE CENTER

M Campos[1*], A Limon[1], P Giraldo[2]
[1]Department of Haematology and Hemotherapy, [2]Department of Haematology and Hemotherapy / Traslational Research Unit, Miguel Servet University Hospital, Zaragoza, Spain

Background: The use of tirosin kinase inhibitors (TKIs) are the major advance in the therapeutic of Chronic Myeloid Leukemia in chronic phase (CML-CP). Imatinib was the first TKI and the results was encouraging but about 30% of patients will be discontinue it in the first 5 years by resistance or intolerance. Monitoring response to TKI therapy is a critical component of managing CML, and molecular response seems to be the most important milestone for predicting long-term outcomes. Marin et al (JCO 2011 38.6565) created a new score for predict long-term outcomes in patients treated with TKI's in first-line, but for second-line therapy, this still remain blinded, recently the MD Anderson group (Clin Lymphoma Myeloma Leuk: S2152-2650(12)00291-1) published that the achievement of a complete cytogenetic response (CCyR) at 3 months after switch to a second TKI predict a 98% of event free survival (EFS) for patients in chronic phase CML (CML-CP)
Aims: To describe characteristics of CML patients who were switched to a second-TKI after Imatinib failure/intolerance in our institution and applied the monitorization at 3th months after second-TKI therapy and correlated with outcomes
Methods: A review of clinical records of patient treated with second generation TKI since May 2005 to February 2013 was performed. Data on clinical characteristics, date of diagnosis, first ITK therapy and date of switched to second-TKI and outcomes were registry
Results: 19 CML patients have been treated with a second-TKI in this period, all in chronic phase. Median age: 60.68 years (38-80); 11:8 male/female ratio. Mean causes of change was resistance (9/47.8%): lost of response (8/42.1%), suboptimal molecular response (1); adverse effects to imatinib (10/52.2%). Dasatinib was the second choice for 16 patients and Nilotinib was for 3 patients. The time between diagnosis and use of ITK was variable and not have improved outcomes, on the other hand the presence of mutations have been negative impact in Overall Survive (OS), one patients developing T315I mutation and progress to blast crisis, 2 patient present M244V and 1 present E355G all of them lost response to imatinib, but had response to dasatinib. Overall response: at the moment of change 6 patients were in non-cytogenetic response (NCyR), two in partial cytogenetic response (PCyR), 4 in MCyR and 7 in CCR/MMR. At 3th month molecular assessment (MA) 6 patients remain without response (1 without mutation identified and switched to imatinib by failure, one for M244V mutation and one for T315I mutation without response), 3 in MMR and 6 in CMR, for 4 patients 3 months MA were unavailable at the moment of redaction. Actual status: 2/6 patients classified as high risk at 3 months MA shows a suboptimal molecular response (one of them only achieved a PCyR), three achieved a MMR and for 1 actual status was unavailable for missing control, of the rest of patients (13) achieved a MMR, 9 are in CMR. A second change to another TKI were registered for 4 patients, of them 1 were for the presence of M244V mutation who were switched from Nilotinib to Dasatinib, another for pleural effusion who were changed to Nilotinib, but later the patient requested to change to Dasatinib for digestive intolerance; the third-one was switched from Nilotinib to Dasatinib for dermatologic toxicity and the last-one after a suboptimal response to imatinib, nilotinib and dasatinib was recently switched to bosutinib.
Summary / Conclusion: Cytogenetic and molecular response at 3 months after switched to a second-TKI in patients with CML-CP could be an unvalued tool for an appropriated follow-up and predict long-term outcomes. More studies on this field are warranted

B1399

INCIDENTAL FINDING AND EVOLUTION OF PH+ CLONE IN TWO PATIENTS WITH KIDNEY/PANCREAS TRANSPLANT AND DIFFUSE LARGE B-CELL LYMPHOMA

A Branca[1*], G Binotto[1], L Pavan[1], L Bonaldi[2], G Semenzato[1]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, [2]Immunology and Molecular Oncology Unit, Istituto Oncologico Veneto, IRCCS, Padova, Italy

Background: Detection of the Philadelphia (Ph) chromosome, a derivative of the reciprocal translocation t(9;22)(q34;q11.2) is a recognized clinical hallmark for chronic myeloid leukemia (CML) diagnosis. CML is often suspected on the basis of peripheral blood (PB) leukocytosis with "left shift", eosinophilia and basophilia. At the time of diagnosis, hematopoiesis results mostly from Ph+ clone, which is quickly debulked by target therapy with tyrosin kinase inhibitors (TKI).
Aims: Here we update the clinical course of two previously described patients incidentally diagnosed with CML, followed with cytogenetic and molecular monitoring and subsequently treated with imatinib after Ph+ clone expansion.
Results: A 65 years old woman was diagnosed with stage IVA Diffuse large B-cell lymphoma, in april 2011. Unexpectedly, bone marrow (BM) cytogenetic analysis showed 22% of 25 metaphases carrying the t(9;22) as sole alteration; RT-PCR identified b3a2 variant of BCR-ABL transcript. CBC count was normal and no splenomegaly was present. The patient underwent six courses of R-CHOP with achievement of complete remission. BM evaluation after the completion of chemotherapy (October 2011) did not show evidence of lymphoma or leukemia; conventional cytogenetic analysis was not evaluable but FISH analysis detected BCR-ABL fusion signal in 1.6% of 300 interphase nuclei; PB RT-PCR showed 1.5% IS of BCR-ABL transcript. Subsequent molecular evaluations showed a progressive increase of PB BCR-ABL transcript (5.9%IS on February and 22.7% IS on November 2012) and concomitant cytogenetic analysis revealed expansion of Ph+ clonal hematopoiesis (50% Ph+ in 14 metaphases). Therefore, TKI therapy was started and, after 3 months, a major molecular response was achieved. A 51-year-old man with type one diabetes mellitus who underwent kidney/pancreas transplantation in June 2005. Shortly after transplant, he developed stable mild leukocytosis with neutrophilia, which was not furthly investigated as it was ascribed to steroid therapy. However, an unscheduled quantitative RT-PCR analysis performed in October 2011 revealed the presence of 1.01% IS BCR-ABL transcripts (both b3a2 and b2a2 variants). Bone marrow evaluation showed normal cellularity but cytogenetics confirmed peripheral blood findings disclosing 12% of metaphases with t(9;22) translocation and 11%IS BCR-ABL transcript. As concomitant immunosuppression was considered a risk factor for disease progression, imatinib therapy was started and rapid reduction of BCR-ABL transcript was achieved (0.5%IS after 45 days). Unfortunately, renal function worsened, leading to TKI discontinuation. While off-therapy, the patient was monitored with PB RT-PCR analysis every three months, but a further increase of the BCR-ABL transcript was observed (on August 2012 PB RT-PCR 6.23%IS). In addition, cytogenetic analysis demonstrated an increase from 13% to 30% of 30 metaphases carrying the t(9;22), therefore TKI therapy was resumed, with rapid achievement of major molecular remission after 3 months of treatment and no side effects were reported.
Summary / Conclusion: The follow-up of these patients demonstrated a significant raise of BCR-ABL transcript in both cases within few months. As progression to overt CML seems to be ineluctable because of Ph+ clone growth advantage over normal hematopoiesis, we consider a reasonable approach starting TKI treatment even in the absence of classical hematological hallmarks of disease.

B1400

EXPRESSION PATTERN OF CANCER-TESTIS ANTIGENS SP17, GAGE1, HAGE, NY-ESO1, MAGE1, PASD1, SCP, SEMG, SLLP1, SPANXA, SSX1 AND PRAME IN CML.

V Misyurin[1*], AMisyurin[1,2,3], A Krutov[1], L Kesaeva[1], I Soldatova[1], E Misyurina[1], A Mastchan[4], S Rumyantsev[4], A Rumyantsev[4], A Baryshnikov[2]
[1]Lab for Molecular Oncology and Genetic Engineering, Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, [2]N.N. Blokhin Russian Cancer Research Center, [3]GeneTechnology LLC, [4]Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: This study was performed to evaluate mRNA expression of cancer-testis (CT) antigens SP17, GAGE1, HAGE, NY-ESO1, MAGE1, PASD1, SCP, SEMG, SLLP1, SPANXA, SSX1 and PRAME in peripheral blood of CML pts.
Aims: We sought to analyze cancer-testis genes expression profile in peripheral blood cells of CML pts and its association with distinct stages of the disease (CP and AP&BC).
Methods: In this study we used RQ PCR to analyze and compare mRNA expression of SP17, GAGE1, HAGE, NYESO1, MAGE1, PASD1, SCP, SEMG, SLLP1, SPANXA, SSX1 and PRAME. Quantitative expression analysis of cancer-testis antigens was carried out relatively using the expression of a housekeeping gene ABL as endogenous control to compensate for irregular cell numbers.
Results: In blood of CML chronic phase pts (N=36) we observed HAGE, SLLP1, SPANXA and PRAME gene expression with frequencies of 61,11% (22/36), 36,11% (13/36),2,78% (1/36) and8,33% (3/36), respectively. In the case of AP&BC of CML we observed not only HAGE (30,77%, 4/13), SLLP1 (15,38%, 2/13), SPANXA (23,08%, 3/13) and PRAME (38,46%, 5/13) gene expression, but also antigens SP17 (7,69%, 1/13), GAGE (7,69%, 1/13) and MAGE1 (23,08%, 3/13). In contrast to CP, expression frequency of some genes in AP&BC was lower (HAGE 30,77% against 61,11% in CP and SLLP1 15,38% against 36,11% in CP) and some higher (SPANXA 23,08% against2,78% in CP and PRAME 38,46% against8,33% in CP). Expression level of genes found in CP did not differ significantly to compare with AP&BC. The following antigens showed no mRNA expression both in CP and AP&BC of CML: NY-ESO1, PASD1, SCP1, SEMG and SSX1.
Summary / Conclusion: While the CT-gene expression profile was rather similar both in CP and AP&BC, there is a clear trend for some gene expression incidence to decrease or to increase during progression of CML from CP to AP&BC. Interestingly, the former group of genes corresponds to those known to be active in the later stages of spermatogenesis and the latter group corresponds to earlier stages of this process. It seems that progression of CML depends at

least partially on the activation of molecular mechanisms responsible for an early stage of spermatogenesis.

B1401
THE STUDY OF THE INFLUENCE OF PRIOR THERAPY ON RESPONSE TO TYROSINE KINASE INHIBITORS THERAPY IN CML PATIENTS
T Perekhrestenko[1*], I Dyagil[2], I Dmytrenko[2], N Tretyak[1], A Gordienko[1]
[1]blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», [2]department of hematology, State Institution «National Research Center for Radiation Medicine of NAMS of Ukraine», Kyiv, Ukraine

Background: Despite the high efficiency of the treatment of tyrosine kinase inhibitors (TKI) part of patients with chronic myeloid leukemia (CML) in the chronic phase (CP) , and the most patients in phase of acceleration (AP) and blastic phase (BP) are initially insensitive to TKI or lose the response during the treatment. There are many causes that lead to treatment failure to TKI. Moreover, the mechanisms of primary and acquired resistance to TKI still is not completely clear. One possible factor of resistanse is the impact of prior therapy of various drugs on the response to TKI.
Aims: To study the effects of previous therapy of busulfan and hydrea on response to imatinib therapy in CML patients.
Methods: We observed 87 patients with CP-CML pretreated by busulfan and 387 patients with CP-CML pretreated by hydrea. Diagnostics and monitoring of CML were perfomed on the basis of cytogenetic examination of bone marrow cells by G-banding, and also molecular-genetic research of bone marrow and peripheral blood.
Results: The efficiency of TKI application was evaluated after 12, 18, 24, 30, 36 monthsof therapy. The complete cytogenetic response (CCyR) in patients pretreated by busulfan was received approximately in 17 % of patients, and more than 80% of patients had the failure to achieve a complete response. The effect of the duration of previous busulfan therapy to the achievement of response to imatinib in CML patients has also been studied. The patients who reached CCyR had been taking the prior busulfan therapy no more than 22 months. The failure to Imatinib treatment was observed after 43 months of busulfan therapy. Studying the impact of the previous therapy of hydrea on the effectiveness of TKI therapy showed that the optimal response achieved 5.5 times more frequently in patients who previously had received hydrea not more than 6 months comparing with the group of patients receiving this drug for more than 6 month (71.6%±3.9% and 13.0%±2.1% respectively, P<0.05).
Summary / Conclusion: The previous use in patients with CML hydrea which lasts more than 6 months and busulfan significantly deteriorates results of TKI therapy.

B1402
FAST PROGRESS OF A CML PATIENT WITH UNUSUAL GENETIC ABNORMALITIES – A CASE STUDY
R Marschon[1*], M Erdel[1], W Kranewitter[1], S Hasenschwandtner[2], G Webersinke[1]
[1]Labor für Molekularbiologie und Tumorzytogenetik, Interne I: Internistische Onkologie, Hämatologie und Gastroenterologie, [2]Interne I: Internistische Onkologie, Hämatologie und Gastroenterologie, Krankenhaus der Barmherzigen Schwestern, Linz, Austria

Background: Tyrosine kinase inhibitors have revolutionized therapy of CML (chronic myeloid leukemia) in the last decade. However, different genetic events may influence therapy success and survival. Here we present a CML patient with a *BCR-ABL1* minor breakpoint rearrangement uncommon in CML and a mosaic of two different isodicentric Philadelphia chromosomes.
Aims: As rare genetic alterations may influence outcome of CML patients, we wanted to characterize these events in more detail.
Methods: Thirty metaphases were analyzed by conventional cytogenetics using Giemsa-banding. FISH was performed using Abbott *BCR-ABL* dual color dual fusion probes. *BCR-ABL1* PCR was done according to the EACR protocol (Gabert et al). Bidirectional sequencing of *BCR-ABL1* cDNA covered the amino acids 239 to 415 of the *ABL1* gene. For SNP array, Affymetrix Cytoscan HD platform was used according to the manufacturer.
Results: Conventional cytogenetics showed a t(9;22)(q34;q11) in all metaphases. Two subclones with a small (23%) and a large (27%) isodicentric Philadelphia chromosome were detected. *BCR-ABL1* FISH confirmed a *BCR-ABL1* gain in these two subclones with three and about seven fusion signals, respectively. PCR detected a *BCR-ABL1* minor breakpoint rearrangement rarely described in CML. Neither a *BCR-ABL1* nor a *JAK2* (V617F) mutation could be found. SNP array indicated a gain of 9q34.12q34.3 and 22q11.1q11.23 with a copy number state of 3. Interestingly, a small segment on 22q11.22 showed a copy number state of4, including micro RNA 650. Alterations of this miRNA seem to influence aggressiveness in colorectal and gastric carcinomas, melanoma and chronic lymphocytic leukemia.
Summary / Conclusion: We describe a CML patient with rare genetic events and death by insult few days after initial diagnosis. Beside a mosaic of two different isodicentric Philadelphia chromosomes resulting in *BCR-ABL1* gain, we could detect a possible involvement of miRNA 650, which is suspected to alter aggressiveness in different cancer types.

B1403
THE ALTERATION OF CPK IN CML PATIENTS TREATED WITH IMATINIB HAS IMPACT ON RESPONSE AND TOXICITY?
L pezzullo[1*], U Sessa[2], s rocco[3], o finizio[3], r fabbricini[3], v mettivier[3]
[1]san giovanni di dio e ruggi d'aragona, salerno, [2]ematologia, aorn a cardarelli, Napoli, [3]aorn a cardarelli, napoli, Italy

Background: The observation of increased CPK in some CML patients treated with imatinib, has raised the question how to affect this change in patients managment.
Aims: The aims of this study was to evaluate wheter ther are differences in treatment response and toxicity betwen the two groups of patients. From 2003 to now we followed 47 consecutive new patients with chronc myeloid leukemia. 44 was evaluable. 57% of these, showed an increase of CPK (cpk+), and 43 % did not show this increase (CPK-).
Methods: We observed that there is no differences between the two groups of patients in terms of OS, PFS and EFS. In CPK+ group, 11/25 (44%) are in COMPLETE MOLECULAR RESPONSE, 10/ 25 (36%) in MAJOR MOLECULAR RESPONSE , whereas in CPK- group, 7/19 (37%) patients were in CMR, 6/19 (32%) in MMR, and 6/19 (31%) in suboptimal response. The median months for the major molecular response in these cohorts of patients was 12 and 17 months in CPK+ and CPK- groups respectively. In CPK+ group 76% patients suffered of muscle pain and fatigue of grade I-II (sec CTC), correlated with the values of CPK. In CPK- group only 5% suffered of muscle pain. No patiens discontinued treatment for toxicity in both group.
Results: 5/44 (11%) patients changed TKI, two for progression (1 CPK+ and 1 CPK-), three for suboptimal response (0 CPK+ and three CPK-)
Summary / Conclusion: In conclusion although the number of patients is low, the alteration of CPK in patient with CML treated with imatinib seems to correlate with increased muscle toxicity. More rapid and intense achievement of major molecular respnse with significant difference (80% vs 69%). Such observation may be considered CPK as a prognostic factor for response and compliance treatment and may affect the managment of early shift therapy in these patients to other TKI.

B1404
CHRONIC MYELOID LEUKEMIA ASSOCIATED WITH OTHER HEMATOLOGIC AND NON-HEMATOLOGIC MALINANCIES: REPORT OF FOUR CASES
F Pinto[1,2*], M Schaum[3]
[1]Hematology Department, Hospital Federal da Lagoa, [2]Hematology Department, [3]Oncology, Clínicas Oncológicas Integradas, Rio de Janeiro, Brazil

Background: Chronic Myeloid Leukemia (CML) accounts for approximately 15 to 20 percent of leukemias in adults with an annual incidence of 1 to 2 cases per 100,000, and a slight male predominance. The median age at presentation is approximately 50 years for patients enrolled on clinical studies, but around 60 years in real life. CML secondary to other malignancies has been described in medical literature, in patients that received previous chemotherapy ou radiotherapy and at least one study showed increased risk of secondary leukemia up to 25 years after the first diagnosis. Less frequently has CML been diagnosed concomitant to other hematologic or non-hematologic malignacies. The unregulated growth of predominantly myleoid cells in the bone marrow seen in CML is caused by chromosomal translocation t(9;22)(q34;q11) - Philadelphia chromosome - generating the Bcr/Abl fusion kinase. This leukemogenic tyrosine kinase has a key role in the pathogenesis of this desease which promotes the survival and proliferation of CML cells. Other cellular pathways, including the process of angiogenesis, a targeted therapy in solid tumors, has been proposed as a potential role in leukemogenesis.
Aims: This presentation reviews the association of CML with other hematologic or non-hematologic malignancies, ocurring after or concomitant with these diseases. While chemotherapy ou radiotherapy for previous neoplasias may be implicated in the pathogenesis of CML in some patients, the concomitant diagnosis of CML and a hematologic or non-hematologic malignancy is a rarer condition that requires a new insight concerning the biologic, cytogenetic and biomolecular aspects of the problem.
Methods: We describe four cases of patients with CML treated at Hospital Federal da Lagoa and at Clínicas Oncológicas Integradas (COI) since 2003. Two of them have had the diagnosis of CML at least two years after the previous neoplasia (breast cancer and plasmocytoma) and the other two had the leukemia concomitant to other diagnosis (breast cancer and MALT non-Hodgkin´s lymphoma). We discuss the difficulties in the diagnosis and in the treatment of these patients. The cytogenetic, biomarkers of each condition and the biomolecular (Bcr/Abl level) evolution in each patient are described when available.
Results: The patients that presented with CML after the first malignancy have had good response to treatment with imatinib with major molecular responses. The patient with MALT non-Hodgkin´s lymphoma received rituximab based chemotherapy treatment which brought his leucocyte count to normal values during the treatment. The fourth patient that had breast cancer and CML diagnosed at the same time developed pancytopenia secondary to myelodisplasia and became transfusion dependent during imatinib (and later dasatinib) and

letrozole concomitant treatment. All patients are alive from two to ten years of follow up.
Summary / Conclusion: The coexistence of two different malignancies in the same patient is a very rare condition. Secondary malignancies in survivors of cancer after chemotherapy or radiotherapy, especially in breast cancer and lymphoma can be seen since the life expectancy in these disorders is long. The drugs or the radiation these patients receive during their treatment could provide the etiopathological basis for development of secondary cancers. However, other cytogenetic abnormalities besides the development of Ph cromossome, the production of certain cytokines and even angiogenesis may be implicated in the concomitant appearence of CML and other malignancies leading to new therapeutic possibilities.

B1405
LMO2 EXPRESSION DOES NOT EFFECT CYTOGENETIC AND MOLECULAR RESPONSE IN CML PATIENTS TREATED WITH IMATINIB
D Ozatli[1*], M Atay[1], P Buyukkaya[1], E Kelkitli[1], L Yıldız[2], N Guler[1], M Turgut[1]
[1]Hematology, [2]Pathology, Ondokuz Mayis University, Medical Faculty, SAMSUN, Turkey

Background: Chronic myeloid leukemia (CML) is a stem cell disease characterized with proliferation of mature and progenitor myeloid cells. The Philadelphia chromosome (Ph), resulting in the formation of the *BCR–ABL* fusion oncogene, is a specific cytogenetic abnormality in CML. Ph encodes different proteins, usually p210 in CML, with dysregulated tyrosine kinase activity causing leukemogenesis. Imatinib mesylate (IM) is the first tyrosine kinase inhibitor that specifically inhibit the activity of the BCR-ABL protein. Cytogenetic and molecular responses to IM treatment in patients with CML vary among users. A lot of factors have been accused that affect the treatment response. LIM domain only-2 (LMO2) is a transcript factor and its gene is localized in chromosome 11p13. LMO2 has a function of regulating erythropoiesis, embryogenesis, angiogenesis, and hematopoietic stem cell development. LMO2 protein is secreted from precursor of myeloid and red blood cells in the bone marrow. It is not detected in mature cells. LMO2 was first studied in patients with acute T-cell leukemia and has been typically recognized as a T-cell oncogene. LMO2 was also reported as aberrantly expressed in acute myeloid leukemia, CML, B-ALL and some non-Hodgkin B cell lymphomas. Though it is discussible LMO2 has suggested having prognostic significances on those diseases. In one study, it was shown that LMO2 protein expression was correlated with improved hematologic remission and overall survival in the CML patients treated with IM.
Aims: The aim of this study was to investigate the relationship between LMO2 protein expression, and cytogenetic and molecular response in the CML patients receiving IM, which has not been studied before.
Methods: This study included 32 patients diagnosed as CML between May 2007 and January 2011 in Ondokuz Mayıs University, Hematology Department. Imatinib 400 mg/day was started for all patients after diagnosis. According to European Leukemia.net (ELN) criteria's, the optimal responses to imatinib were evaluated at$_{3,6,}$ 12 and 18 months of the treatment. Hematological response was used for evaluation of the response at 3 months of the treatment, cytogenetic response for 6 and 12 months, and molecular response for 18 months.
LMO2 protein was studied with immunohistochemical methods in bone marrow biopsy materials at the time of diagnosis. Staining in greater than 30% of myeloid lineage cells was assigned as positive.
Results: All 32 patients were in chronic phase at the time of diagnosis. Average follow-up period was 29.4 (12-58) months. The Sokal risk scores of the patients were determined. Of 32 patients, 10 (31%) patients were in low risk group, and 17 (53%) patients in intermediate risk group and 5 (16%) patients in high risk group. LMO2 was stained as positive in 20 (62.5%) of patients and negative in 12 (37.5%). LMO2 staining did not significantly differ among Sokal risk groups (P=0.54). There were not statistically significant differences in LMO2 staining between patients who had optimal responses or not according to the ELN criteria's at$_{3,6,}$12 and 18 months of the treatment (P>0.05).
Summary / Conclusion: In our study, we did not find any relationship between LMO2 protein expression, and cytogenetic and molecular response in the CML patients receiving IM.

B1406
EIGHT YEAR RESULTS OF THE THERAPY OF CML TYROSINE KINASE INHIBITOR IN A LARGE INDUSTRIAL CENTER OF SIBERIA
A Lyamkina[1,2*], T Pospelova[1,2], I Nechunaeva[2]
[1]Novosibirsk State Medical University, [2]City hematological center, Novosibirsk, Russian Federation

Background: The use of tyrosine kinase inhibitors (TKI) has significantly changed prognosis in patients with chronic myelogenous leukemia (CML). Thanks to a wide range of currently available approaches to the treatment of CML, modern cytogenetic and molecular techniques for the diagnosis and monitoring of treatment efficacy tyrosine kinase inhibitors has become possible to effectively control the previously incurable disease.
Aims: To evaluate eight year results of therapy of chronic myelogenous leukemia treatment with tyrosine kinase inhibitors.
Methods: For the period of January 2004 and up until now the 74 CML patients have been observed at the municipal hematology center of Novosibirsk – capital of Siberia, specifically: 65 patients in the chronic phase (CP), 7 patients in the accelerated phase (AP), and 2 patients with blast crisis. Those 74 patients included 29 men (38.2%) and 47 women (61.8%), with age ranging from 16 to 78 years, and the mean value being 44.7±15.1years. 82.9% patients was included in the analysis (63 patients): 56 people in the chronic phase, 5 - in the acceleration phase and 2 in blast crisis phase. All patients in the chronic phase started taking the TKI in the first 6 months after diagnosis of CML. Patients in accelerated phase and blast crisis were diagnosed before 2003, these patients were significantly pre-treated with various cytotoxic medications and interferons. All patients are receiving treatment by various tyrosine kinase inhibitors (imatinib at a dose of 400-800 mg per day, 3 patients - nilotinib at 800 mg per day, 2 of them - as first-line treatment, dasatinib 100-140 mg per day). In Russia, imatinib therapy became available only in 2004, as part of the charity program GIPAP (on treatment 10% of patients). All the patients treatment became available in 2005. Today in Russia are using generic medications Philachromin® and Genfatinib®, instead of using original medication Glivec® , their effectiveness requires further observation. 13 patients have died: 8 patients in chronic phase, for reasons not related to hematological malignancies, 2 patients in accelerated phase, and 3 patients in blast crisis phase because of the progression of the underlying disease.
Results: Administration of a TKI as a single agent was followed by a complete clinical and hematological response in 94.6% patients, complete cytogenetic response (CCyR) – in 80%, major molecular response (MMO) – in 66,1%. In 4 patients AP - clinical and hematological response, 3 patients in AP and patients in blast crisis - the stabilization process. Survival was analyzed in patients administered TKI, as compared to patients not administered TKI (data based on the retrospective review of medical records of CML patients observed at Novosibirsk municipal hematology center for the period of 1999 – 2004). A statistical method of calculating the cumulative fraction of survivals (Kaplan-Meier) was used to evaluate survival, with P<0,05 established as the reliability criterion. No medial survival was established in the group administered TKI, the 8-year survival - 82.9%, the estimated 10-year survival was 70%. In the group treated with other cytotoxic agents median survival was 4.1 years, the estimated 10-year survival rate - 9%, P<0,000001. Overall event-free survival rate was 56.6%, in the chronic phase - 68.3%.
Summary / Conclusion: TKI are considered an effective and safe method of treatment for CML in CP, associated with a high MCyR rate in the chronic phase, which leads to a significant increase in the overall and event-free survival.

B1407
DASATINIB IS EFFECTIVE IN ETV6-ABL1 CML LIKE DISORDER WITH COMPLEX TRANSLOCATION INVOLVING CHROMOSOME 9, 12 AND 14
S Auger[1*], J Gaillard[2], T Lavabre-Bertrand[2], D Donadio[1], C Exbrayat[1]
[1]hematology, Clinique du Parc, montpellier, [2]cytology, Cytogenetic, Immunology, University Hospital, Nimes, France

Background: A rare group of myeloproliferative disorders has been described associated with gene rearrangements producing novel tyrosine kinases other than BCR/ABL. A rearrangement involving the ETV6 and ABL1 genes, associated with t(9;12)(q34;p13) translocation, has been detected in Ph-negative chronic myeloproliferative disorders and has been demonstrated to have tyrosine kinase activity in signal transduction pathways similar to the BCR/ABL fusion protein. The ETV6 gene is a member of the E26 transformation-specific family (ETS) of transcription factors located at 12p13. It has been implicated in the rearrangement of over 48 different chromosome bands, ultimately playing a role in leukemogenesis. Thus far, only eleven BCRABL1-negative CML patients with a variant ABL1 gene (9q34) rearrangement, involving fusion to ETV6 aka TEL (12p13) have been reported. ETV6-ABL1 rearrangement have also been implicated in other hematologic diseases including 6 acute B lymphoid leukemia, 1 acute T lymphoid leukemia, 3 acute myeloid leukemia, 1 myelodysplastic syndrome, and 3 chronic myeloproliferative disorders.
Aims: We present a new patient with ETV6-ABL1 rearrangement and check the efficiency of second generation TKI.
Methods: He is a 62 year old male who sought medical attention for acute coronary syndrome with bone pain and asthenia in May 2011. Physical exam showed a splenomegaly. He was found to have hemoglobin of 9.9g/dL, WBC 90G/L and platelets 105G/L. The peripheral blood differential count revealed 67% segmented neutrophils, 2% eosinophils, 0 basophils, 3% monocyte, 28% immature stages and 5% lymphocytes per 100 white blood cells. Bone marrow biopsy revealed myeloid hyperplasia suggestive of a myeloproliferative disorder. The genetic characteristic of this patient is to present an exceptional chromosomal complex rearrangement according to Pellestor classification, involving 3 chromosomes 9, 14, 12 with five breakpoints: 9q, 12p, 12q, and two different on 14q. More precisely, it probably compounds of a three way translocation t(9;12;14)(q34,p13,q?) associated with a independent translocation between both long arms of chromosomes 12 and 14. FISH analysis using BCR/ABL TC DFusion (Kreatech) shows involvement of ABL1 probe in a translocation with short arm of chromosome 12 and no evidence of rearrangement of BCR gene suggesting the possibility of juxtaposition of ABL1 gene with a gene different than the BCR gene. Moreover whole chromosome 14 painting

confirms various involvements of chromosome 14. Molecular biology confirmed the suspected ETV6-ABL1 fusion gene and allows us to follow minimal residual disease. It should be noted that a t(9;12;14)(q34;p13;q22) has already been described as a variant of the t(9;12)(q34;p13) with complex insertions of ETV6 into ABL1. Other chromosome than the 14 has known to be implicated in t(9;12) variant as chromosome 17.
First, he was treated with imatinib with progression despite the addition of hydroxyurea. Treatment was switched at 3 months for dasatinib
Results: At 3 months, ETV6-ABL1/ABL1 is 0.32% and at 6 months he obtains a Major Molecular Response (defined as MRD under 0.1% like in BCR-ABL measurement). After 18 months, he remains in $MR_{4.5}$.
Summary / Conclusion: In conclusion, we present a new case of ETV6-ABL1 myeloproliferative disorder due to complex rearragement which experiments good response to dasatinib suggesting that second generation TKI are a good option for treatment of such disease.

B1408

IMMUNOLOGICALLY DETECTION OF BCR/ABL FUSION PROTEIN WITH FLOW CYTOMETRY IN K562 CHRONIC MYELOID LEUKEMIA CELLS AND COMPARISON WITH RT-PCR RESULTS

I Kozanoglu[1,2*], B Aygun[2], I Boga[2], C Cansun[2], N Ustundag[2], Y Baran[3], E Maytalman[2], C Sarıturk[4], C Boga[2], H Ozdogu[2]
[1]Physiology, Baskent University Medical Faculty, Ankara, [2]Hematology, Baskent University Adana Adult Bone Marrow Transplantation Center, Adana, [3]Moleculer Biology and Genetics, Izmir Institute of Technology, Izmir, [4]Biostatistic, Baskent University Adana Hospital, Adana, Turkey

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disease arising from a neoplastic transformation of hematopoietic progenitor cells, usually characterized with a specific chromosomal abnormality called Philadelphia (Ph) chromosome. Ph chromosome occurs with reciprocal translocation of BCR and ABL genes located on chromosomes 9 and 22, respectively. Follow up of minimal residual disease in CML patients is based on the detection of BCR/ABL mRNA by RT-PCR. Showing BCR/ABL oncogene by RT-PCR is a difficult and technician dependent method. Development and use of novel methods for diagnosis and follow up of CML patients are of importance in routine practice due to the difficulties in RT-PCR technique and its standardization.
Aims: In this study, we aimed to standardize detection of BCR/ABL protein using a flow cytometric method in K562 cells, and to compare the results with the molecular method which is the gold standard.
Methods: The study consisted of two arms. In the first arm, RT-PCR and flow cytometry methods were compared using nine different cell groups with gradually increasing amounts ($1x10^3$, $1x10^4$, $5x10^4$, $7.5x10^4$, $1x10^5$, $5x10^5$, $1x10^6$, $1.5x10^6$, $2x10^6$) in K562 cells. In the second arm, $1x10^7$ K562 cells were incubated for 72 hours with each of the 6 groups(1 control group and 5 different concentration of imatinib applied groups). Afterwards, cell viability analysis was performed and the results of the RT-PCR and flow cytometric analyses were compared.
Results: While BCR-ABL/ABL ratio was found to be positive in all groups with RT-PCR in the first arm of the study, BCR/ABL fusion protein could not be detected by flow cytometry in groups with 1.000 and 10.000 cells. BCR/ABL protein was found to be positive in the groups that contain 50.000 or more cells ($P<0.05$). Specifity and sensitivity were 100% when flow cytometry results of the groups thatcontain 50.000 or more cells as compared with RT-PCR. RT-PCR and flow cytometry results were positive in all groups in the second arm. The mean fluorescence intensity was observed to decrease in flow cytometry methods in those groups with reduced viability. However, RT-PCR and BCR-ABL/ABL ratios were not affected by the viability.
Summary / Conclusion: In conclusion, BCR/ABL fusion protein can be detected by using flow cytometry method, when a minimum of 50.000 viable cells are studied.

B1409

COMPARISON OF FLUORESCENCE IN SITU HYBRIDIZATION AND CHROMOSOME BANDING ANALYSIS FOR THE DEFINITION OF COMPLETE CYTOGENETIC RESPONSE IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH GLEEVEC.

D Roko[1*], A Babameto-Laku [1], T Caja[2], D Bali[3]
[1]Service of medical genetic, [2]Adults Haematological Service, [3]Pediatric Department, Oncohematological Service, University Hospital Center Mother Theresa, Tirana, Albania

Background: Background: Chronic Myeloid Leukemia (CML) is a clonal disease characterized by balanced translocation between chromosomes 9 and 22 (Philadelphia chromosome). Imatinib mesylate (Gleevec) is the most successful among a new generation of specific inhibitors of signal transduction. It inhibits the BCR/ABL tyrosine kinase activity by competing with ATP at the ATP binding site of BCR/ABL. The BCR/ABL rearrangement is an important tumor classification marker and a useful prognostic factor allowing an adequate therapy management. Clinical trials of imatinib mesylate have shown promising results in chronic phase of CML.
Aims: The aim of our study is to determine the effectiveness of Gleevec in the treatment of patients with chronic myeloid leukemia (CML) during the chronic phase through cytogenetic and molecular responses and to compare these results
Methods: Methods: From March 2009 to September 2012, we analyzed 28 CML patients aged 18 -70 years old at chronic phase of disease in parallel with CA and interphase FISH. All patients were diagnosed at the Hematological Service in University Hospital Center ¨Mother Theresa¨ in Tirana. Eligible patients should not have received treatment for CML before and were randomly assigned to receive imatinib as the initial therapeutic treatment ambulatory at an effective oral (300-600 mg/day). Results were determined by analysis of peripheral blood, bone marrow aspiration, chromosome banding analysis (GAG banding) at 0,3, 9, 12 months and FISH (fluorescence in situ hybridization) at 12 months.
Results: Results: Fish results and the results of banding methods were directly compared. Based on the analyses of > 200 nuclei per patient, FISH correlated closely with CA. After 12 months therapy, 22 of these patients (78%) had cytogenetic responses, of which 9 patients or (32%) achieved complete cytogenetic responses and 2 of these patients (7%) had partial cytogenetic responses evaluated by chromosome banding analysis. In 3 cases with no Ph^+ metaphases in CA, interphase FISH detected 2 to10% BCR-ABL^+ rearrangements and 19 of 28 patients (67%) had complete molecular cytogenetic responses.
Summary / Conclusion: Conclusions: CA and interphase FISH give reliable results but in our study we confirmed that FISH is a sensitive technique for the evaluation of cytogenetic response in patients with CML. Furthermore, FISH probe detected BCR/ABL rearrangement, which were not visible by CA. We conclude FISH reliably detects standard Ph chromosomes as well as its variant translocations and accurately quantifies BCR/ABL rearrangements prior and during cancer treatment, in daily routine tumor cytogenetic diagnostics.
Continuation of the study with a larger number of patients is needed to confirm these preliminary observations.

Hodgkin lymphoma - Biology

B1410

B-CELL CLONES IN HODGKIN'S LYMPHOMA DETECTED BY NEW GENERATION SEQUENCING

J v Sidorova[1], B Biderman[1], N Ryzhikova[1], A Kovrigina[2], A Sudarikov[1*]
[1]Department of Molecular Hematology, [2]Department of Pathology, National Hematology Center, Moscow, Russian Federation

Background: In Hodgkin lymphoma few tumor Hodgkin/Reed-Sternberg (HRS) cells are scattered among the reactive cellular environment. B-cell nature of the tumor has been proven by single-cell PCR of immunoglobulin (Ig) genes from HRS cells isolated from histology sections [Küppers R et al, 1994]. It has been shown that in most cases Ig gene rearrangements result in functional alleles that carry significant amount of VH mutations [Marafioti T, et al 2000]. However approximately 25% of Hodgkin's lymphomas carry the nonfunctional rearranged IgH genes with "crippling" mutations [Kanzler H et al, 1996]. The presence of VH mutations indicates germinal or post-germinal nature of HRS cells. In a small percentage of cases (2 of 25 patients), subclonal differences in HRS has been reported [Marafioti T et al, 2000]. Despite the fact that 60% of patients carry functionally rearranged both IgH and IgK genes in HRS cells, Ig are not expressed on the cell surface, presumably due to the transcription errors [Re D et al, 2001; Jundt F et al, 2002; Theil J et al, 2001]. We set out to detect B-cell clonality in Hodgkin's lymphoma and subclonal variations in HRS cells using next generation sequencing (NGS) circumventing single cell PCR.
Aims: To study Ig genes, B-cell clonality and subclonal variations in Hodgkin's lymphoma by NGS.
Methods: The study included biopsy samples (5 FFPE and 2 frozen tissues) from 7 patients with classical Hodgkin lymphoma, verified by immunohistology (nodular sclerosis subtype, EBV-negative). Patients were 20 to 40 years old (mean 29 years), 6 women and 1 man. In 4 of the patients clear signs of monoclonality were obtained previously in IgH genes (FR1, FR2, FR3) using Biomed-2 concerted action primer sets [van Dongen JJ et al, 2003] and GeneScan analysis (ABI 3130). One patient had oligoclonal GeneScan profile and 2 patients were polyclonal. PCR amplified (35 cycles IgH FR1+10 cycles IgH FR2) DNA fragments were analyzed on GS Juniour (Roche) sequencing platform. Data analysis was performed with GSMapper (Roche).
Results: We obtained 7437 to 48673 sequence reads (average 17850) for each patient. More than 95% of the sequences were in 260-320 bp range as expected. Clusters of reads with more than 0.2% representation were analyzed. We observed 3 to 16 clones (mean 9.9) in the samples from patients previously shown to be clonal by GeneScan analysis. "Monoclonal" patients had one dominant clone with 7% to 35% abundance, with the length (+/- 1-2 nucleotides) matching that obtained by GeneScan. The only "oligoclonal" patient carried 4 clones with 11.8%, 11.6%,6,7% and 4.67% representation. Finally, two "polyclonal" patients also revealed low abundance clones (one patient - 3.1% and 2.7%, the other - 3.4%). Most dominant clones were productive. We also found subclones of dominant clones with minor nucleotide substitutions and deletions. It should be noted that some clones from different patients, being unrelated by nucleotide sequence, were translated to CDR3s wich were almost identical in amino acid sequence. It may indicate the possibility of antigen-driven clonal selection.
Summary / Conclusion: NGS allows to sequence rearranged Ig genes in Hodgkin's lymphoma without microdissection. Intraclonal variations occur in HRS cells. Possible signs of antigen selection also observed.

B1411

IDO IS FREQUENTLY EXPRESSED IN STROMAL CELLS OF HODGKIN LYMPHOMA AND IS ASSOCIATED WITH ADVERSE CLINICAL FEATURES

J Choe[1*], J Yun[1], Y Jeon[1], S Kim[2], G Park[3], J Huh[4], J Kim[5]
[1]pathology, Seoul National University Hospital, [2]pathology, Yonsei University College of Medicine, [3]pathology, Seoul St. Mary's Hospital, The Catholic University of Korea, [4]pathology, Asan Medical Center, [5]pathology, Seoul National University Boramae Hospital , Seoul, Korea, Republic Of

Background: Hodgkin lymphoma(HL) is characterized by relatively fewer numbers of tumor cells and excess of reactive cellular components. Regulation of tumor microenvironment is thought to be involved in the prognosis of HL. Indoleamine2,3-dioxygenase(IDO), is an immune modulator acting through increase of regulatory T-cells and induction of T-cell anergy.
Aims: Purpose of the study is to investigate role of IDO in the microenvironment of HL.
Methods: A total of 124 cases of HL were enrolled to do immunohistochemistry for IDO, CD163, CD68 and FoxP3. Positivity was evaluated from area fractions of positive cells using automated image analyzer. The results were compared between the subtypes of HL and with various clinicopathologic parameters.
Results: IDO were variably expressed in histiocytes, dendritic cells, endothelial cells, but not in tumor cells. IDO positive cells were more frequently found in mixed cellularity type than nodular sclerosis, cases with EBV+, high Ann Arbor stages, presence of B symptoms, and high IPS(all P<0.05). Patients showing high IDO expression revealed significantly poorer overall survival(P<0.001).
Summary / Conclusion: IDO might be actively involved in microenvironment of HL and is related to adverse clinical outcomes of HL.

B1412

PROGNOSTIC SIGNIFICANCE OF CD68, CD20, FOXP3 EXPRESSION; PRESENCE OF EPSTEIN-BARR VIRUS AND MAST CELL INFILTRATION IN CLASSICAL HODGKIN LYMPHOMA PATIENTS

A Salihoglu[1*], A Demiroz[2], T Elverdi[1], E Gulturk[1], E Eskazan[3], C Ar[4], S Ongoren[1], Z Baslar[1], T Soysal[1], Y Aydin[1], N Tuzuner[2], B Ferhanoglu[1]
[1]Hematology, [2]Hematopathology, Cerrahpasa Medical Faculty, Istanbul, [3]Hematology, Diyarbakir Training and Research Hospital, Diyarbakir, [4]Hematology, Istanbul Training and Research Hospital, Istanbul, Turkey

Background: Classical Hodgkin Lymphoma (cHL) is a highly curable B cell lymphoma characterized by the presence of Reed-Sternberg (RS) cells in a background of mixed inflammatory cells and stromal reaction. The disease is unique in that the malignant RS cells constitute only the minority of the total tumor mass. Recently, emphasis is given to the contribution of the non-tumoral cells to disease outcome.
Aims: The aim of this study was to find out if there is a relationship between the composition of the immune infiltrate and clinical outcome in our cases with cHL.
Methods: Patients (pts) were retrospectively collected from 2000 to 2010 in one center (Cerrahpasa Medical Faculty, Istanbul). From approximately 250 adult cHL pts diagnosed at our center during this time period, tissue and data regarding clinical outcome were available for 57 pts (all HIV negative). The diagnosis derived from lymph nodes in all pts except one (spleen). Immunohistochemical analysis was performed on histological sections of formalin-fixed paraffin-embedded tissue samples from previously untreated in 51 (90%), and relapsed in 6 (10%) of the cases. The slides were stained for CD68 (Dako, KP-1), CD20 (Dako), FOXP3 (Leika), LMP1 (Dako) and tryptase (Dako). CD68 was scored 1: CD68+ cells <5%, 2: CD68+ cells from 5% to 25%, 3: CD68+ cells >25% relative to overall cellularity. Using cutoffs of <10%, 10% to 50% and >50% relative to overall cellularity, 3 scores were defined for FOXP3. RS cell positivity of CD20 was scored 0: when no staining, 1: <5%, 2: from 5% to 25%, 3: >25% relative to a total of RS cells. CD20 positivity of the surrounding reactive small B cells and presence of B cell follicles were also scored. Mast cell infiltration was evaluated by counting the cells and was scored 1: 0 to 10, 2: 11 to 25, 3: >26 cells. Expression of LMP1 on RS cells showed EBV infection. Clinical and laboratory data available on presentation and follow up were recorded. Sex ratio was 1.6, median age was 38 (range 13-77) years. Histologic subtypes according to the WHO classification system were nodular sclerosis in 30 pts (53%), mixed cellularity in 23 (40%), lymphocyte-depleted in 2 (3.5%) and unclassified in 2 (3.5%). 61% of the pts had Ann Arbor stage I-II and 39% had stage III-IV disease. 26 pts (46%) had B symptoms, 8 (15%) presented with bulky disease ($\geq$10 cm). Extranodal involvement was seen in 23 pts (40%). Among pts with advanced stage disease 71% had an IPS >2. Treatment protocol was ABVD in 55 pts (96.5%). Additional radiotherapy was performed in 20 (35%) pts. Median follow up was 59 (range 9-144) months. 1 patient included in the study had a follow up time less than 24 months (9 mo). Statistical analysis was made with STATA software (version 11). The study was approved by the institutional ethics committee.
Results: CD20 expression of both RS cells and reactive B cells, mast cell infiltration in the microenvironment and EBV positivity were not predictive of outcome. 18 pts (32%) were EBV positive. EBV status did not influence expression of any of the biomarkers analyzed. No significant association of mast cell infiltration with existence of B symptoms was found. CD68 expression and absence of lymphoid follicles were predictive of inferior overall survival. Overall survival was improved for patients with increased FOXP3 cell density.
Summary / Conclusion: Microenvironment composition is of prognostic value in cHL patients. For obtaining more accurate and reliable results we are intending to double the number of pts until the time of the congress of EHA.

B1413

PROGNOSTIC IMPACT OF PERIPHERAL BLOOD LYMPHOCYTE IMMUNOPHENOTYPES IN CLASSICAL HODGKIN'S LYMPHOMAS

F Gaudio[1*], T Perrone[1], D Pastore[1], F Laddaga[1], A Mestice[1], G Specchia[1]
[1]Hematology, University of Bari, Bari, Italy

Background: Classical Hodgkin's lymphoma (cHL) is characterized by the presence of tumoral cells in a rich background of T and B cells, macrophages, and other inflammatory cells. The contribution of these non tumoral cells to the pathogenesis of HL is still poorly understood.
Aims: In our study we evaluated the prognostic significance of peripheral blood B,T, NK cells at diagnosis in 118 immunocompetent patients (pts) with cHL treated at our institution between January 2006 and December 2010.
Methods: 54 (46%) were male and 64 (54%) female. Median age at diagnosis was 33 years (range 15-82), 71 pts (60%) presented advanced stage (IIB-IV), 54 (46%) a bulky disease, 55 (47%) presented B symptoms.

Results: At the end of treatment, 94 patients (80%) were in complete remission (CR), while 24 in partial remission. 18 patients (15%) relapsed after a median follow-up of 54 months. The variables that had a negative impact on PFS in univariate analysis were advanced stage, bone marrow involvement, IPI score 3-5, PET2 positive, NK cells<200/mcl, CD19<85/mcl, CD3/CD19 ratio>13, CD4/CD19 ratio>10 ; by multivariate analysis, advanced stage, PET2 positive, CD4/CD19>10 were independent prognostic factors of PFS.
Summary / Conclusion: New biological markers could be predictive of response to treatment and survival in cHL. Pts with a CD4/CD19 ratio >10 seem to be associated with worse outcome.

B1414
PROCALCITONIN (PCT) LEVELS IN NEWLY DIAGNOSED PATIENTS WITH HODGKIN LYMPHOMA (HL) PRESENTING WITH FEVER AND/OR ELEVATED C-REACTIVE PROTEIN (CRP)
T Vassilakopoulos[1*], E Zografos[1], K Petevi[1], G Boutsikas[1], A Kanellopoulos[1], G Chilas[1], M Dimou[1], G Gainaru[1], E Sinni[1], M Kyrtsonis[1], V Pappi[1], T Tzenou[1], A Bilalis[1], A Euthymiou[1], I Vardounioti[1], E Pessach[1], P Flevari[1], L Papageorgiou[1], V Telonis[1], K Koutsi[1], A Zannou[1], P Tsaftaridis[1], P Panayiotidis[1], P Beris[1], M Angelopoulou[1], J Meletis[1]
[1]Haematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: CRP (and other inflammatory biomarkers) is elevated in 70-75% of newly diagnosed HL patients and nearly always in the 30-40% of them who present with fever and/or other systemic B-symptoms, in which the presence of infection must be ruled out. Serum PCT levels, which are potentially useful for this purpose, have not been studied in HL.
Aims: To assess PCT levels in patients with HL at diagnosis in correlation with conventional inflammatory biomarkers.
Methods: Serum PCT levels were determined in 69HL patients with "inflammatory activity" at diagnosis(fever and/or elevated CRP>5 mg/L).PCT values >0.5ng/mlwereconsideredtobeabnormal. PatientswithnormalPCTconcentration were further divided into those with undetectable PCT (<0.1 ng/mL) and those with measurable PCT(0.1-0.5 ng/ml).
Results: 1/69 patients had very high PCT levels (15 ng/mL) in the setting of bacteremia. Four additional patients had measurable but normal PCT levels (range, 0.10-0.24 ng/mL) in the presence of urinary tract infection (n=2), probable respiratory tract infection and C. dificillae colitis. Thus, the main analysis was restricted to the 64 patients with no evidence of infection [median age 32 years (16-82), 55% males, 47% stage III/IV, median CRP 45.65 mg/L (5.92-227.0), CRP≥100 in 19%]: Elevated PCT levels were found in 1/64 (1.6%). Serum PCT concentration was 1.6 ng/ml, without clinical evidence of infection, and returned to normal one week after the start of chemotherapy without antibiotic administration.49/64 patients(77%) had undetectablePCT(<0.10 ng/ml) and 14 (21%) exhibited measurable but normal PCT(0.10-0.50 ng/ml). A strong association between PCT and CRP was observed: The median CRP of patients with undetectable PCT levels was 36.2mg/L versus 89.4mg/Lin those with measurable but normal PCT(P=0.008). The percentage of patients with CRP>100 mg/L in the above groups were 10% versus 47% (P=0.005) respectively. CRP levels strongly correlated with ESR, ferritin, haptoglobin and the a_2-globulins (Spearman's rho 0.634-0.791, P<0.001) and moderately with gamma globulins (Spearman's rho 0.419, P=0.001) and platelets (Spearman's rho 0.342, P=0.007).Instead, PCT levels correlated moderately only with ESR (Spearman's rho 0.350, P=0.007), a_2-globulins (Spearman's rho 0.323, P=0.014) and serum haptoglobin levels (Spearman's rho 0.268, P=0.04). Marginal associations were observed with serum ferritin levels and platelet counts. Prognosis did not differ according to PCT levels: The 2-year Freedom From Progression was 74% versus 81% for patients with undetectable and measurable levels (P=0.74).
Summary / Conclusion: PCT is normal in 98% of patients with newly diagnosed HL that present with elevated CRP and/or fever without obvious infection, even when CRP levels are extremely high. Thestrongassociationbetween-PCTandCRPsuggestsacommoncytokine-regulated initialpathwayfortheirproduction. However, the development of abnormal PCT levels occurs only in the case of infection. These observations support the use of PCT as a marker for the exclusion of infection in newly diagnosed patients with HL with fever and/or elevated CRP. These findings might also apply to relapsed/refractory patients, where the possibility of a concomitant infection is much higher, although this needs further confirmation.

Hodgkin lymphoma - Clinical

B1415
CHEMOTHERAPY ALONE VERSUS CHEMOTHERAPY PLUS RADIOTHERAPY FOR ADVANCE STAGE HODGKIN'S LYMPHOMA: A SYSTEMATIC REVIEW
G Alotaibi[1*], K Alsaleh[1], H Almodaimegh[2]
[1]Medicine, King Saud University, [2]Pharmacy, Kind saudi bin abdulaziz university, Riyadh, Saudi Arabia

Background: The role of radiation therapy in the management of patients with advanced stage Hodgkin's lymphoma (HL) remains controversial and some study groups recommend chemotherapy only for the management for this stage.
Aims: The purpose of this meta-analysis is to examine the effect of added radiation therapy to chemotherapy (CMT) compared with chemotherapy-alone (CT) regimen on the prognosis of patients with advanced stage HL with respect to overall survival (OS) and tumor control.
Methods: This is a systematic review with meta-analysis of randomized clinical trials comparing chemotherapy alone versus chemotherapy plus radiation in the treatment of advanced stage HL. Databases were searched from inception through October 2012. Studies included patients with advanced HL were selected.
Results: Pooled results of 12 trials with2,059 participants showed improvement in overall survival of patient receiving CMT compared to CT alone [Hazard ratio [HR] 0.76, 95% confidence interval (CI) 0.69-0.85, *P*<0.0001]. It also did not improve tumor control significantly [HR 0.89; 95 CI% 0.78-1.02, *p* <0.09]. CMT was associated with higher incidence of secondary cancers, especially solid tumors [Relative risk [RR] 1.81; 95%CI 1.1-2.98, *P*=0.02]. CMT was also associated with slight increase in the incidence of hematological toxicities mainly leukopenia and thrombocytopenia.
Summary / Conclusion: The addition of radiation to chemotherapy in the management of advanced stage HL is associated with an improvement in the overall survival but with modest effect on tumor control including progression-free survival and event-free survival. However, CMT is associated with an increased incident of secondary cancers.

B1416
SURVEILLANCE IMAGING OF HODGKIN'S LYMPHOMA – IS THERE ANY ADVANTAGE?
A Tome[1*], F Costa[1], J Schuh[1], L Monteiro[1], T Fernandes[1], A Monteiro[1], A Sousa[1]
[1]Serviço de hematologia, Hospital dos Capuchos, Lisboa, Portugal

Background: Post-treatment surveillance of lymphoma patients in complete remission (CR) usually relies on routine imaging, in an attempt to detect early asymptomatic relapse. Hodgkin's lymphoma (HL) patients undergo surveillance computed tomography (CT) imaging for several years after treatment. Although this practice seems reasonable, there is no proof of benefit in terms of overall survival (OS) or duration of second remission (CR2) and the resulting costs and radiation exposure are undeniable.
Aims: To determine the contribution of surveillance CT to the detection of disease relapse, as compared with clinical findings, and its correlation with CR2 and OS.
Methods: From 06/1998 to 06/2012, 58 first relapses of HL were detected or referred to our center (45 after treatment with Stanford V regimen, 13 after ABVD). We retrospectively reviewed the data from these patients to determine whether the suspicion of disease recurrence was based on imaging or clinical features. Correlation was made to relapse site and extension, time to relapse detection and OS.
Results: Median duration of first CR was 17 months (range 2 to 192); 58% (34) of relapses were localized, 77% (45) in a previously affected site and 67% (39) were histologicaly confirmed. From the 58 relapses, 42 (72%) were detected based on symptoms or physical examination findings and only 16 (26%) were detected by imaging. Among the 25 relapses within the first year after therapy (during which most relapses occur), only 4 (16%) were detected by imaging. CR2 rate was 82% and post-relapse OS was 62% at 5 years (22 deaths, 17 from disease progression, 2 from a second cancer and 3 from other causes), both regardless of the method of recurrence detection.
Summary / Conclusion: The majority of HL relapses were detected on clinical changes. The detection method had no influence on CR2 rate or post-relapse OS. These findings, in agreement with previous similar studies, strongly suggest that there is no advantage in routine CT surveillance imaging for patients in CR from HL. Neither the radiation exposure nor the financial and psychological costs are worth it. Therefore, routine CT surveillance imaging for detection of disease recurrence should not be performed.

B1417

RESULTS OF ABVD AND BEACOPP CHEMOTHERAPY IN ADULT PATIENTS WITH EARLY STAGE HODGKIN`S LYMPHOMA- A SINGLE CENTER RETROSPECTIVE STADY

O Tarabar[1*], L Tukic[1], D Stamatovic[1], S Marjanovic[1], M Elez[1], J Knezevic[1], A Ivic[1], L Atanackovic[1], J Trimcev[1]
[1]Clinic of Haematology, Medical Military Academy , Belgrade, Serbia

Background: More than 85% of patients (pts.) with early-stage Hodgkin's lymphoma (HL) may achieve a durable disease-free survival. Despite the excellent initial remission rates obtained with ABVD chemotherapy (CT) and radiotherapy (RT), approximately 15% of pts. in early unfavorable stages relapse within 5 years and about another 5% of pts. have a primary refractory disease. The optimal CT regimen, the number of CT cycles, the field sizes and the dose of radiation within these fields are the subjects of number studies.
Aims: To compare the efficacy and toxicity of two CT regimens, ABVD and bBEACOPP in early stage HL patients.
Methods: A retrospective study was performed on a cohort of 125 pts., ages 18 years and older, with newly diagnosed, histology-proven HL in clinical (CS) stage II in the period between 1998. to 2009. Patients with CS II HL were stratified into favorable and unfavorable risk cohorts on the basis of the presence of any of the following criteria: age ³ 50, elevated erythrocyte sedimentation rate ³50mm without or ³ 30mm with B symptoms, large mediastinal mass, lymphocyte depletion and mixed cellularity histology, and/or more than three lymph node areas involved. Of the 125 pts., 84 pts were considered with unfavorable risk and received 4-6 cycles ABVD (38 pts.) or 4-6 cycles bBEACOPP (46 pts.) regimens, whereas favorable risk pts. received 2-4 cycles ABVD (28 pts.) or 2-3 cycles bBEACOPP (13 pts.) therapy. Involved field RT (30-36Gy) was applied in 97% of pts. No difference in pts. characteristics were observed among different treatment group.
Results: Median follow-up for all pts. was 64 months. The 5-year overall survival (OS) and 5-year event-free survival (EFS) for 125 pts. was 90.5% (95% CI, 89-91.5) and 80.5% (95% CI, 79-81.5), respectively. We observed a significant difference in OS (100% vs. 85.5%; P< 0.05) and EFS (89.5% vs. 76.0%; P<0.05) at 5 years between favorable and unfavorable cohort. In a subset analyses according pts. stratified into the unfavorable cohort, no differences in complete remission rate (86.8% vs. 94.6%; P=0.40), 5-year OS (82.5 vs. 88.0; P=0.87) and 5-year EFS (70% vs. 81%; P=0.55) in relation to the chemotherapy (ABVD vs bBEACOPP) was seen. Toxicity was mild and comparable in two treatment arms. There are no secondary malignancies to date
Summary / Conclusion: This retrospective study demonstrated the efficacy of both chemotherapy in early-stage HL patients. At present, no statistically significant differences have emerged in favor of bBEACOPP over ABVD chemotherapy.

B1418

BENDAMUSTINE-BASED THERAPY IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA.

N Pugliese[1*], C Cerchione[2], F Grimaldi[1], M Raimondo[1], M Di Perna[1], S Pagliuca[1], F Pane[1], M Picardi[1]
[1]Hematology, [2]University of Naples Federico II, naples, Italy

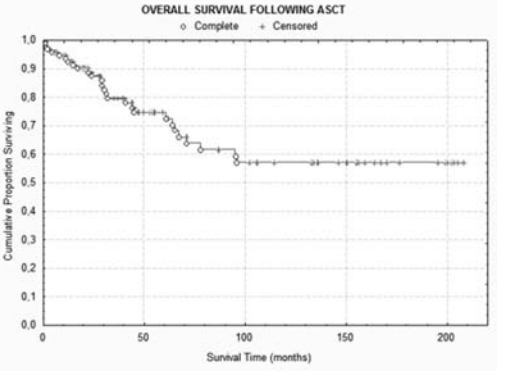
Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after stem cell transplantation (SCT) remains controversial.
Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possibile combinations for a synergic effect.
Aims: The objective of this phase II study was to evaluate efficacy and safety of bendamustine combined with other cytotoxic drugs in patients with refractory and/or relapsed HL. Two different schedules of bendamustine-based regimens were evaluated (high dose *vs.* standard dose).
Methods: From May 2011 to December 2012, 9 patients (6M/3F) with a median age of 25,5 years (range 18-34) received bendamustine as salvage treatment. Patients were divided by chance into 2 groups of treatment: 5 patients received standard intensity treatment (standard-B; bendamustine 90 mg/m^2 days 1-2 and Ara-C 0,5-0,75 g/m^2 day 1) and 4 patients received high intensity treatment (high-B; bendamustine 150 mg/m^2 days 1-2 combined with Ara-C 1-2 g/m^2 day 1 or modified BEACOPP$_{escaleted}$ regimen without adriamycin). Each cycle was repeated every 28 days and growth factor support was sistematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in both group was evaluated according to Revised Response Criteria for Malignant Lymphoma. Any adverse event occurred was recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).
Results: The median number of previous chemotherapy lines was 3 for both groups(first line therapy was ABVD for all patients). Three patients had failed prior autologous-SCT in the high-B group and 2 in the standard-B group, 2 patients were primary refractory to ABVD in each group. A total of 26 cycles was administered (median3,5; range 1-6) according the above reported schedules. In the high-B group, 3 (75%) patients achieved complete remission (CR) and then underwent to SCT (two autologous and one haploidentical-SCT) and are in complete remission while one patient died for progressive disease (PD). By contrast, among the 5 patients who received standard-B, three (60%) were in stable disease (SD), one was in PD and one patient obtained partial remission (20%) and underwent to autologous-SCT. When bendamustine was used at standard doses, it didn't exert grade 3-4 side effects except for transient transaminase increase observed in only one patients. Grade 3-4 treatment related adverse events (AEs) reported in the high-B group were thrombocytopenia (75%) and anemia (50%).
Summary / Conclusion: Bendamustine used at high dose and in combination with Ara-C or a modified BEACOPP$_{escalated}$ regimen, seems to be effective in heavily pretreated patients with HL, suggesting a possible non cross-resistance with other agents. Its safety profile is acceptable and adverse events manageable also at this high dosage.

B1419

RISK FACTORS IN AUTOLOGOUS STEM CELL TRANSPLANTATION IN HODGKIN LYMPHOMA : A SINGLE-CENTRE EXPERIENCE

V Milunovic[1*], M Patekar[1], V Zatezalo[1], D Radić-Krišto[1], A Planinc-Peraica[1,2], B Jakšić[1,2], S Kolonic[1,2]
[1]Department of Hematology, Clinical Hospital Merkur, [2]School of Medicine, Zagreb, Croatia

Background: High dose therapy followed by autologous stem cell transplantation (ASCT) is used in the setting of refractory or relapsed Hodgkin lymphoma (HL). Several independent risk factors associated with poor outcome following ASCT were indentified such as clinical stage (III, IV), anemia and early relapse (≤ 1 year) (Josting et al., 2002.)
Aims: The aim of this retrospective study was to show single centre experience in treating refractory/relapsed Hodgkin lymphoma by high dose chemotherapy followed by ASCT and identify possible risk factors associated with poorer disease free survival (DFS) and overall survival (OS).
Methods: 98 consecutive patients (41 males, 57 females, median age at ASCT; 30 years, median time to ASCT after diagnosis: 18 months) with HL who underwent BEAM myeloablative conditioning followed by ASCT were included in analysis in the period from November 1995 to November 2012 . OS and DFS were analyzed in the context of several features during first relapse (clinical stage, extranodal disease, presence of B symptoms, early relapse (≤12 months) and anemia), time to transplantation, age at transplantation, type of harvesting and clinical factors at the diagnosis.



Results: Median time from the diagnosis to the first relapse was 15 months. The most common harvesting therapy used was miniBEAM (64%). Following ASCT, clinical CR rate was 75.5% and PR rate was 16.5%. 27 patients died during the observation period. Median for OS and DFS has not been reached at the maximum observation time of 208 months. Estimated OS at 96 months was 0.574 (S.E. 0.06). However as shown on the graph1, there is plateau after 96 months extended to the maximal observation time. Out of 74 patients, who achieved CR, DFS at 167 months was 0.66 (S.E=0.09). Median OS for patients not achieving CR was 41 months (95% CI 17-64 months). None of the parameters at the diagnosis (age, sex, clinical stage, extranodal disease, bulky disease, presence of B symptoms, German Hodgkin Study Group stage, International Prognostic Score) were associated with OS. Poorer OS was significantly associated with the presence of anemia during relapse (defined as Hb<105 g/l for females and <120 g/L for males) (P=0.048) and B symptoms (P=0.047), while other factors (early relapse, extranodal disease, advanced stage, type of harvesting, time to transplantation, age at transplantation) were not significant. We have not been able to identify any factors associated with poor DFS. Also, there was no significant differences in OS and DFS between group period from 1995. to 2003. (N=41) and period from 2004. to 2012. (N=57) when adjusted for the factors present at the diagnosis.
Summary / Conclusion: We have demonstrated successful treatment of refractory/relapsed HL by miniBEAM harvesting followed by BEAM/ ASCT with high remission rates. As seen in graph1, the observed plateau indicates prob-

able cure for this subset of patients. Anemia and B symptoms, present at relapse, were related with poorer outcome, while some previously described risk factors have not been confirmed probably due to small number of events. In line with previous studies, our results imply that ASCT represents adequate approach towards relapsed/refractoty HL.

B1420

BRENTUXIMAB VEDOTIN IS AN EFFECTIVE TREATMENT OF CLASSICAL HODGKIN LYMPHOMA TYPE POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER (PTLD)

W Zinke-Cerwenka[1], K Troppan[1], C Beham-Schmid[2], F Pucher[3], W Linkesch[1], P Neumeister[1*]
[1]Department of Hematology, Medical University of Graz, [2]Institute of Pathology, Medical University Graz, Graz, [3]Pathology, State hospital Villach, Villach, Austria

Background: Posttransplant lymphoproliferative disorders (PTLDs) occurring as serious complication after solid organ or allogeneic stem transplantation embrace a heterogeneous group of lymphoproliferative diseases. The optimal treatment is not well defined and rely on the histological subtype and stage. In advanced stage of Hodgkin lymphoma chemotherapy with AVBD is suggested. As previously reported brentuximab vedotin, is an antibody-drug conjugate that combines an anti-CD30 antibody with monomethylauristatin E, a potent antimicrotubule agent able to induce responses in CD30-positive lymphomas with mild toxic effects.
Aims: The goal was to achieve remission of the PTLD without compromising the graft.
Methods: We report on a 50-year-old male patient with blastic plasmacytoid dendritic cell neoplasm (BPDCN) undergoing umbilical cord blood transplantation in 1st CR employing a reduced conditioning regimen (cyclophosphamide: 50mg/kg, fludarabine: 150mg/m^2 and fractionated total body irradiation: 400cGy) comprising anti-thymocyte globulin as graft versus host prophylaxis in May 2011. The post-transplant course was uneventful and in the absence of graft versus host disease Cyclosporin A was stopped after 6 months. Eleven months after transplantation the patient presented with abdominal pain and a CT scan revealed a bowel tumour with multiple enlarged mesenterial lymph nodes and a single liver lesion. An extended right hemicolectomy and a liver wedge resection were performed revealing a classical Hodgkin lymphoma type post-transplant lymphoproliferative disorder (PTLD) with typical immunphenotype (CD30+, CD15+ in the majority of the HRS-cells and and EBV+). After completion of wound healing the patient received 6 cycles of brentuximab vedotin at a dose of 1.8 mg/kg BW every 3 weeks on a compassionate use basis.
Results: Eleven months after diagnosis of the PTLD the patient is in good clinical condition and experiencing a continuous complete remission as demonstrated by multiple PET-CT scans. Side effects of Brentuximab were mild and did not compromise the graft.
Summary / Conclusion: Targeted therapy with brentuximab vedotin seems to be an effective treatment in classical Hodgkin lymphoma type PTLD even in advanced stage.

B1421

THE ROLE OF POSITRON EMISSION TOMOGRAPHY (PET) IMAGING IN THE TREATMENT STRATIFICATION OF STAGE I-II HODGKIN LYMPHOMA

T Rider[1*], J Jones[1], J Brewin[1], G Horne[1], J Wills[1], K Boyd[1], T Corbett[1]
[1]Haematology, Royal Sussex County Hospital, Brighton. UK, Brighton, United Kingdom

Background: PET imaging has become integral to staging and assessment of treatment response in Hodgkin lymphoma (HL). Minimising long term treatment side effects is of direct clinical importance, given the high remission and cure rates in localised disease. Our centre has adopted an approach of omitting radiotherapy (RT) when post-chemotherapy PET is negative, which is also the focus of on-going phase III trials.
Aims: To retrospectively determine the relapse rates of stage I-II HL patients whom underwent PET evaluation in comparison with those monitored by CT only.
Methods: 67 Ann-Arbour stage I-II patients were identified from hospital records that were treated at our centre from 1998 onwards. Traditionally patients received consolidative RT on completion of chemotherapy, with response to treatment being monitored by CT. Overall survival (OS), relapse free survival (RFS) and site of relapse in this group of patients were compared with patients who did or did not receive RT based on post-chemotherapy PET evaluation. Patients with HIV (n=5) or lymphocyte predominant disease (n=2) were excluded from analysis.
Results: The median age at diagnosis was 33 (range 16-85). 28 were male and 39 were female. 58% of patients had stage 2a disease, 22%, 18%, and 1% had 2b, 1a, and 1b disease respectively. The average length of follow-up was 64 months (range 2-181 months). 64 patients had chemotherapy of which 62 received ABVD as first line therapy, median of 4 cycles (range 2-8). The median age was 84 for those who did not receive chemotherapy.
46 patients had PET assessment post-chemotherapy. Of these 38 patients had complete response (CR) post chemotherapy and 8 had partial response (PR). All those with PR received RT and three patients with CR also received RT. Patients imaged via PET had an average length of follow-up of 53months (range 2-145). 21 patients were imaged with CT of which 9 were deemed to have achieved a CR. 15 of the 21 patients imaged with CT received radiotherapy post-chemotherapy. 8 patients in total relapsed during the follow-up period, at an average at 37 months (range 7-98months). None of the 38 patients in CR on PET scanning post-chemotherapy relapsed. However, three of the nine patients in CR by CT criteria post-chemotherapy suffered a relapse which was significantly higher (P=0.01 Fisher's exact two tailed test). However, one patient with a positive PET scan post-chemotherapy did relapse 14 months later but at a site outside the radiotherapy field. There was no difference in overall survival (Chi-squared P=0.624) or relapse free survival (Chi-squared P=0.127) between those who did or did not receive radiotherapy irrespective of imaging modality used. Three patients relapsed within a previous radiotherapy field, two of these were during a second relapse. One patient relapsed both inside and outside the radiotherapy field at their first relapse. In total three patients died, two of whom were elderly (aged 79 and 84) and received no RT or chemotherapy. The other patient died during salvage chemotherapy prior to a planned BEAM autograft.
Summary / Conclusion: Our data indicate that a negative post-chemotherapy PET following HL diagnosis is a strong predictor of sustained complete remission. These results support an approach of omitting involved field radiotherapy in this cohort of patients, which will spare this group of patients the long term morbidity and mortality associated with this treatment.

B1422

EVALUATION OF THE MANAGEMENT OF HODGKIN'S DISEASE IN BLIDA, ALGERIA

L Fatima[1*], O Salima[1], T Souad[1], G Cherifa[1], R Nabila[1], B Mounira[1], A Tayeb[1]
[1]Hematology, EHS ELCC CAC, Faculty of Medicine, Saad Dahleb University, BLIDA, Algeria

Background: Considerable progress has been made in the management of Hodgkin's disease in order to improve treatment outcomes but also reduce long-term side effects.We present a retrospective study over a period from 1998 to 2009 during which patients with Hodgkin's disease have been supported
Aims: to evaluate outcome of our patients treated with conventional therapy.
Methods: Patients were included after additional tests: lymph node excision biopsy for histology , chest X-ray, thoracic abdominal and pelvic computed tomography, bone marrow biopsy, inflammatory balance. The therapeutic approach consisted of chemotherapy combined or not with radiotherapy according to clinical stage.
Results: During this period, 372 patients were included, 178 men and 194 women (sex ratio 0.92), mean age 31.47 (men 34.77 years, women 28.17 years). The histological type was specified in 350 cases (94 %): type 1: 15 cases (4.2%), type 2: 222 cases (63.4%), type 3: 102 cases (29.1%), and type 4: 11 cases (3.1%). Classification: favorable stage I: 15 cases (4%), unfavorable stage I: 13 cases (3.5%), unfavorable stage II: 28 (7.5%), favorable stage II: 118 (31.7%), stage IIIA: 17 (4.5%), Stage IIIB: 80 (21.5%) stage IV 101 (27.1%). Chemotherapy regimens: 367 patients were treated : 277 (74.4%) patients were treated with ABVD protocol, 68 with cisplatine + ABVD, 22 with MOPP / ABV, radiotherapy was associated in 219 patients (58.8%). Among these patients, failure was observed in 52 cases (14 %) with 40 (77 %) in disseminated stages. Evolution : 232 (62.3%) patients are still alive in Complete Response (CR) or Incomplete Response (IR) ; relapse: 32 patients (8.6%); deaths: 61 patients (16.4%), however 43 patients (11,6) were lost to CR or IR. Complications: Pulmonary fibrosis: 16 patients the cause of recurrent chest infections, cardiac toxicity: 6 patients, endocrine disorders: 14 patients (hypothyroidism, early menopause, impotence), neuropathy : 9 patients, herpes zoster : 5 patients, ENT neoplasia : 2 patients, Myelodysplasia: 4 patients.
Summary / Conclusion: The adaptation of therapeutic indications stage prognosis will improve our results, especially in adverse localized stages and disseminated stages, which represent the majority of our patients. ASCT will represent a treatment of choice for these patients who relapse after initial chemotherapy or for those primary refractory to first chemotherapy. Unfortunatly, this methode of treatment is not yet feasible in our country.

B1423

PROGNOSTIC VALUE OF 18F-FDG PET/CT IN HODGKIN LYMPHOMA

B De Rueda[1*], L Costilla[1], S Catalina[1], J Grasa[1], D Rubio[1], P Giraldo[1,2,3]
[1]Hematology Department, [2]Research Traslational Unit, [3]IACS, Miguel Servet University Hospital, Zaragoza, Spain

Background: Hodgkin Lymphoma (HL) has been converted from a uniformly fatal disease to one that is curable in about75 % of patients.
Toxicity related with treatment and second malignancy being considered as comorbidities to long term follow-up in survivors. The radiation dose and field, chemotherapy agents and doses administered, gender and patient age at treat-

ment are considered as common risk factors.
The combination of 18F-FDG positron emission tomography and computed tomography scans (18F-FDG PET/CT) is considered as a good tool for diagnosis and follow-up of the patients with HL in addition 18F-FDG PET/CT, provides prognostic information.
Aims: To determine the value of 18F-FDG PET/CT after the second and sixth cycle of first line therapy with ABVD (doxorrubicin, bleomicyn, vinblastine, dacarbazine) or BEACOPP (bleomicyn, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine and prednisone) in the outcome of HL patients.
Methods: Observational and retrospective study performed in HL patients diagnosed in our centre between January 2007-December2012. All patients were treated with ABVD or BEACOPP according subtype and Ann Arbor stage and were evaluated with 18F-FDG PET/CT after second and sixth cycle of treatment. 18F-FDG PET/CT were considered positive when the SUV≥ 2'5. Response, overall survival, progression free survival (PFS) and comorbidities were considered.
Results: Seventy nine patients have been included, M/F: 52 (66%) /27 (34%). Mean age 39 years (range: 17-86). Histologic classical subtype: 56 nodular sclerosis HL (NSHL), 15 mixed cellularity HL (MCHL), 5 lymphocyte rich HL (LRHL) and 3 lymphocyte depleted HL (LDHL). Early stages 48.1 % (n=38): IA (n=5), IIA (n=24) and IIB (n=9). Advance stage: 51.9 % (n=41): IIIA (n=14), IIIB (n=11), IVA (n=7) and IVB (n=9). In 62 patients (78.5%) 18F-FDG PET/CT were performed after second cycle: Positive in 9 patients (11.4%) and negative in 53 patients (67 %). After completed therapy 18F-FDG PET/CT was performed in 74 patients, in 8 showed positive results (10.1 %) and negative in 66 patients (83.5 %). 4 of 9 patients with positive 18F-FDG PET/CT after second cycle, became negative results when completed therapy.
Relapse HL was observed in 24 patients (30.4%), in12 (15.2%) showed early relapse (<12 months). Progression-free survival (PFS) was of 35.8 months.
Summary / Conclusion: 18F-FDG PET/CT is the most accurate tool for staging, treatment monitoring, and response evaluation in HL. In our experience to check an early 18F-FDG PET/CT could be predict a good outcome in the majority of HL patients and avoid to be over treated.

B1424

COMPARISON OF BONE MARROW INVOLVEMENT BY FDG PET/CT AND HISTOPATHOLOGY IN PATIENTS WITH LYMPHOMA

E Umit[1], B Serim[2], G Altun[2], F Puyan[3], G Pamuk[1], M Demir[1*]
[1]Hematology, [2]Nuclear Medicine, [3]Pathology, Trakya University Faculty of Medicine , Edirne, Turkey

Background: The diagnosis of either Hodgkin's disease(HD) or non-Hodgkin lymphomas (NHL) is incomplete without an accurate staging. Identification of an advanced disease changes the intensity of the theraphy as well as the duration of the treatment period. The conformity of staging is dependent on the findings of computed tomography (CT) scanning and bilateral iliac crest trephine biopsies to determine a possible infiltration of the bone marrow. Bone marrow biopsy (BMB) is a routine procedure in the algorithm of the lymphoma management and involvement of the bone marrow (BMI) is regarded as stage IV disease with poorer outcome. BMB, though precious in the initial evaluation of lymphomas, may miss focal disease, has its own complications such as infections and bleeding. The need for less invasive with less complications and also more sensitive method led hematologists towards imaging, especially nuclear imaging. ^{18}F-fluoro-2-deoxyglycose positron emission tomography (FDG-PET) is the late imaging method of choice in especially the initial staging of HH and NHL.

Parameters Hodgkin	FDG-PET positive for BMI # of patients	Histopathology positive for BMI # of patients	p values
# of patients	10	6	
LDH elevation	9	5	0.001
Presence of leucocytosis/leucopenia	8	5	0.001

Parameters Non-Hodgkin	FDG-PET positive for BMI # of patients	Histopathology positive for BMI # of patients	p values
# of patients	15	14	0.000
LDH elevation	13	11	0.000
Presence of leucocytosis/leucopenia	12	12	0.000

Aims: The aim of this study is to evaluate the value of FDG-PET in determination of BMI in comparison with histopathological findings in patients with Hodgkin (HL) and non-Hodgkin lymphoma (NHL).
Methods: 30 patients with HL, aged between 20-73 years (mean 38.87) and gender 10 female (35.5%) and 20 male (64.5%), 55 patients with NHL, aged between 28-78 years and gender 24 female (43.6%) and 31 male (56.4%) were enrolled in the study. Presence of leucocytosis or leucopenia and LDH elevation at the time of diagnosis, initial stages and findings of BMI with FDG-PET and BM histopathology were recorded.
Results: In patients with HH, FDG-PET positivity was observed to be related with pathological BMI (P=0.001). FDG-PET positivity was also related with the stage, prognostic score, LDH elevation and presence of leucocytosis/leucopenia (p values 0.000, 0.004, 0.000, 0.001 respectively). Likewise, in patients with NHL, FDG-PET positivity was observed to be related with pathological BMI (P=0.001). FDG-PET positivity was also related with the stage, prognostic score and presence of leucocytosis/leucopenia (p values 0.001, 0.000 and 0.001 respectively) while was not related with LDH elevation (P=0.009).
Summary / Conclusion: FDG-PET seems to be relevant and valuable as BM biopsy regarding BMI. As being non-invasive, it may be useful to replace with BM biopsy especially in patients who are observed to be low stage.

B1425

OUTCOME OF HIGH RISK HODGKIN'S LYMPHOMA IN THE SOUTH-EST OF ALGERIA.

S Chichoune[1*], S Touati[1], h menia[1], m hamzaoui[1], m bitam[1], r ounissi[1], m aiche[1], m saidi[1]
[1]hematology, University Hospital of Batna, Algeria., Batna, Algeria

Background: Hodgkin's lymphoma (HL) is considered as one of the most curable forms of cancer, especially if it diagnosed early.
The regimen containing doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) is the common standard of care for the frontline treatment of HL. However, there is no standard of cure in advanced-stage of HL's patients; particularly in our context for several reasons: late diagnosis, frequency of bulky disease, lack of access to autologous stem cell transplantation.

Aims: To assess the poor outcomes and prognosis of adult patients (pts) with high risk advanced stage HL treated by ABVD regimen in first line.
Methods: We present a recent retrospective analysis updated on a period of 04 years (January 2009-december 2012). Adult pts with HL were staged according to the Cotswold's classification and evaluated according to the prognostic's factors of EORTC, IPS and GHSG. High-risk (HR) HL was defined in clinical stage (SC) IIB, III and IV by the presence of 04 involved lymphoid areas, and / or mediastinal mass ratio: MMR≥ 0.45 and / or ≥ 2 extra lymph node sites affected by the disease (for SC IV).
The initial treatment strategy was the ABVD (4-8 cycles) consolidated with radiation in limited stages.
Results: Until December 31, 2012, one hundred twenty six (126) pts with HL have been diagnosed. The median age of all pts was 29.2 years (range, 15-74 years), the sex ratio is 0, 89 (M: 60 / F: 67) and the mean time to diagnosis was 5.4 months (01-36) months. Early stages are 61 (48.4%), and 65 were extended (51.6%).Thirty six pts have a bulky disease (51.6%) including 18 (56%) in stage IIB. At diagnosis advanced-stage IIB (n = 34), III (n = 27) and IV (n = 38) are ninety nine (T = 99); among them 62(62%) pts are HR: IIB= 21 (33.8%), III= 16 (25.8%), and IV= 26 (42%), and 37 are in favorable advanced stages. So 49.2% of the entire series and 62% of the advanced stages IIB, III and IV are HR forms. The primary responses to ABVD protocol in 56 pts evaluated with HR HL (IIB = 20), (III = 14), (IV = 22), and 35 favorable advanced stages (IIB=12), (III=11), (IV=12) are: - Response: in 34 (60.7%) HR pts (II=12, III=09, IV=10), to 29(83%) favorable pts (II=11, III=08, IV=10). - Failure (primary failure + relapses): 22(39.3%) HR patients (II=08, III=05, IV=09), to 06(17%) favorable pts (II=01, III=03, IV=02) (P<0, 03). -Total of 13 HR pts are dead (21%) to 03(08%) favorable advanced stage's pts and a four-year overall survival rates of HR HL and favorable forms are 77% to 91% respectively.
Summary / Conclusion: This study shows several facts: - The LH is common in our region from 30 to 40 pts / year, affects young adults (29.2 years). - High risk advanced disease represents almost half of the series (49.2%), - ABVD protocol provides a response in only 60% with a high failure rate (40%), a four-year overall survival rate of 77% to 89% at five years in the literature see even 96% with the new primary intensification. -Very poor prognosis of HR HL represents clearly an area of unmet medical need, and a prospective study will be launched in comparing BEACOPP to ABVD consolidated with autologous stem cell transplantation.

Myelodysplastic syndromes and bone marrow failure syndromes incl. PNH - Biology

ANALYSIS AND VALIDATION OF THE MIRNA EXPRESSION PROFILE IN PLASMA FROM PATIENTS DIAGNOSED WITH MYELODYSPLASTIC SYNDROME

M Andres-Coduras[1*], F Ramos[2], M Montañés[3], C Pedro[4], M Andrade-Campos[3], M Fuertes[2], R De Paz[5], M Pocovi[6,7], P Giraldo[3,7,8]
[1]Unidad de Investigación Traslacional, Hospital Universitario Miguel Servet, Zaragoza, [2]Servicio de Hematología, Hospital de León-IBIOMED, León, [3]Servicio de Hematología, Hospital Universitario Miguel Servet, Zaragoza, [4]Servicio de Hematología, Hospital del Mar, Barcelona, [5]Servicio de Hematología, Hospital Universitario La Paz, Madrid, [6]Dpto. Bioquímica y Biología Molecular y Celular, Universidad de Zaragoza, [7]Centro de Investigación Biológica en Red de Enfermedades Raras, CIBERER, [8]Unidad de Investigación Traslacional, Instituto Aragonés Ciencias de la Salud, Zaragoza, Spain

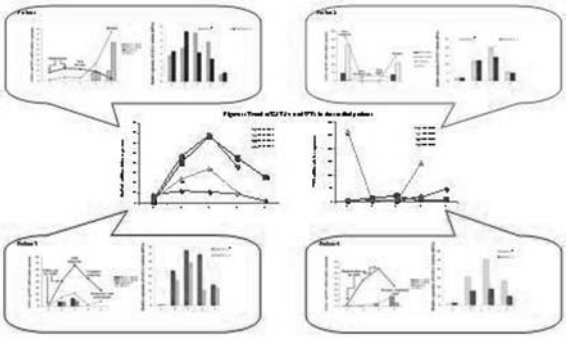
Background: Myelodysplastic syndrome (MDS) is a group of neoplastic disorders characterized by abnormal maturation and differentiation of hematopoietic cells and frequent transformation into acute myeloid leukemia, but current prognostic scores explain only a small fraction of patient evolution variability. The pathogenesis of these complex disorders involves both the stem cells and their interactions with the microenvironment. Morphology is the basis of the MDS diagnosis, but its interpretation is subject to potential inter-observer variability. In a recent study, inter-observer disagreement was observed in 27% of the samples considered suitable for morphological evaluation. In this sense, those categories with unilineage dysplasia were the least reproducible (*Font P et al., Ann Hematol 2013*). New biomarkers might be of help in the diagnostic work-up, pathogenetic understanding as well as in prognostic stratification of MDS patients. Studies are now focused on gaining more knowledge about miRNAs. These small, non-coding RNAs sequences are involved in the regulation of biological processes. Some studies have shown that the miRNAs are stable and in detectable quantities in cell-free plasma (*Mitchell et al. PNAS, 2008*), and their expression in peripheral blood (PB) has been related with various neoplastic conditions including acute leukemia and MDS (*Schotte D et al., Leukemia 2012, Rhyasen GW and Starczynowski DT, Leukemia 2012*). Recently we have described a profile (Aragon miRNA Profile) of 14 miRNAs detected in PB and plasma of MDS patients (patent pending) that was present in higher concentration in MDS as compared to controls. Ten out of fourteen studied miRNAs had similar expression profile in PB and plasma although the increase with respect to controls was higher in plasma.
Aims: The aim of this study is to analyze Aragon miRNA profile in a larger number of plasma samples in order to validate our previous results.
Methods: We have studied a total of 243 patients diagnosed with MDS, 193 were derived from the project INBIOMED HEMA-001/2006 and 50 corresponding to patients diagnosed in the Haematology department of Miguel Servet University Hospital (2008-2011).PB and plasma samples were deposited in the Aragon Biobank. RNA was extracted from PB using Paxgene Blood miRNA kit (PreAnalytix). A miRNA signature in MDS was determined by q-PCR using Megaplex™ Primers AV2.1 and Human Pool B (Applied Biosystems, USA). A total of 754 miRNAs of the currently listed in the Sanger miRBase database were analyzed. 14 differentially expressed miRNAs were selected. To obtain cell-free plasma miRNAs, we used Total RNA Purification Kit (Norgen, Canada). A previous step of cDNA preamplification was performed with Megaplex PreAmp Primers Human Set (Applied Biosystems, USA).
Results: In a previous study, we founded 14 differentially expressed miRNAs in the PB and plasma from 40 MDS patients vs. normal controls. 71.4% of the studied miRNAs had similar expression profile in PB and plasma, but the increase with respect to controls was higher in plasma.The results obtained in the present study, performed with the same procedure in a larger MDS population, will be a test-bed for further developments. Detailed data will be provided during the meeting.
Summary / Conclusion: Aragon miRNA profile in plasma might be of help for the diagnostic work-up, pathogenetic understanding as well as prognostic stratification of MDS patients. Additional information related to specific MDS subsets, response to hypomethylating agents and disease evolution will be needed before its very role in MDS management can be established.

B1427

PROGNOSTIC SIGNIFICANCE OF GATA-1 AND WT1 LEVELS IN PEDIATRIC HEMATOLOGICAL DISORDERS

F Petruzziello[1], R Sessa[2], E Giiovannone[2], M Catania[2], R Parasole[1], G Menna[1*], R Cuccurullo[1], V Poggi[1], P Izzo[2,3], A De Matteo[1], M Grosso[2]
[1]Pediatric Hemato-Oncology, Santobono-Pausilipon Hospital, Naples, Italy, [2]Molecular Medicine and Medical Biotechnology, University of Naples "Federico II", [3]CEINGE - Advanced Biotechnology, Naples, Italy

Background: Acquired mutations in hematopoietic transcription factor GATA-1 were reported in Down Syndrome (DS), Transient Myeloid Disorders and Acute Megakaryoblastic Leukemia (AMkL). These mutations occur in exon 2 and lead to a truncated shorter protein missing the N-terminal transactivation domain (GATA-1s).
Aims: This study was aimed at evaluating *in vivo* e *in vitro* results about the role of GATA-1 isoformson expression levels of specific WT1 isoforms (+/- KTS).
Methods: We monitored the GATA-1, WT1 and their isoforms expression levels in 4 pediatric patients affected by different hematological disorders (1 Acute Lymphoblastic Leukemia (ALL)-DS, 1 AMkL, 1 Acute Myeloid Leukemia (AML)-DS and 1 Myelodisplastic Syndrome (MDS)-DS). The expression levels of both GATA-1 and WT1 isoforms were evaluated to correlate changes to clinical progression of disease. For this purpose, transient transfection assays were performed in human K562 erythroleukaemic cells using constructs for the *wild-type* cDNA sequence of GATA-1 full lenght (GATA-1n) and for the sequence mutated at Tyr63 (Tyr63Stop, GATA-1mut) within eukaryotic expression vector p3XFlag-CMV.
Results: Results showed that GATA-1s was able to induce a more dramatic increase of WT1 expression than GATA-1n. Furthermore, allele-specific amplification of WT1 isoforms (+/- KTS) showed that the mutant construct was able to more dramatically increase +KTS isoform already in presence of low expression levels of GATA-1s protein, whereas the GATA-1n protein, at high expression levels, induced a significantly increase of the –KTS isoform of WT1. Total GATA-1 levels increased and/or remained high in the steady state of the monitoring without clinical worsening and in apparent patients' remission. In these conditions the prevalent GATA-1 transcription variant was GATA-1n for each patient. When GATA-1 expression levels started to decrease was to be considered as a "wake-up call" signal for a subsequent relapse. In order to this dramatic event may happen, we observed that the total GATA-1 decrease was accompanied by a drastic knock-down of GATA-1n variant and imbalance ratio in favor of low levels of GATA-1s transcript. However, although the prognostic significance of how GATA-1 isoform ratio affects the worse overall survival is still unclear because of the limited and heterogeneous sample size, we report that, following total GATA-1 decreased expression, the persistence of GATA-1s transcript, even at low levels, was associated to considerable increase of WT1 expression levels. According to our *in vitro* transfection data, relapse was found associated with a WT1 isoform ratio strongly unbalanced in favor of +KTS (Figure 1).



Summary / Conclusion: We can hypothesize that GATA-1 level and the subsequently variants displacement in favor of GATA-1s could be the trigger for the activation of WT1 expression, particularly of +KTS isoform. GATA-1 and WT1 evaluation has been performed on peripheral blood samples instead of bone marrow samples, as commonly reported. This approach is certainly less invasive and traumatic as compared to bone marrow aspirate, and can reduce monitoring intervals in the course of follow-up. Further studies need to be performed in order to clarify the genetic and epigenetic mechanisms underlying the regulation of GATA-1 isoform ratio responsible of the phase of relapse on a larger cohort of DS and non-DS patients. This would allow to contribute to clarify process of the leukemic transformation and could eventually pave the way to novel therapeutic tools.

B1428

ANALYSIS OF BONE MARROW CD34(+) SUBPOPULATIONS BY FLOW CYTOMETRY IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

N Gardikas[1], E Konsta[1], M Vikentiou[1], V Kapsimali[1], C Kontos[2], E Ioannidou[1], C Oikonomopoulou[1], M Atta[1], N Papanikolaou[1], A Bouhla[1], S Papageorgiou[1], M Stamouli[1], G Dimitriadis[1], V Pappa[1*]
[1]Second Department of Internal Medicine and Research Institute, Attikon University Hospital, [2]Department of Biochemistry and Molecular Biology, University of Athens, Athens, Greece

Background: Myelodysplastic syndromes (MDS) comprise a heterogeneous group of haematopoietic stem cell (HSC) clonal disorders characterized by dysplasia and ineffective haematopoiesis. But while it is assumed that MDS is a "stem cell disease", hard evidence for this claim is still lacking, and stem and progenitor alterations in MDS patients have not yet been defined.
Aims: Aim of the study was to determine the frequency of CD34+ populations (in different maturation stages) as well as CD133 (primitive cell marker) and CD96 (putative marker of myelodysplastic stem cell) expression in CD34+ subpopulations, in patients with MDS.
Methods: Bone marrow specimens of 24 patients with MDS and 6 healthy individuals (as control group) were studied using 5-color multiparameter flow cytometry. Patients were classified according to a) WHO as RCMD (n=10, 42%), RARS (n=1, 4%), RAEB 1 (n=4, 17%), RAEB II (n=7, 29%), del 5q (n=1, 4%) and CMML (n=1, 4%) and b) IPSS as low and intermediate-1 risk group (n=15, 62%) and intermediate-2 and high risk group (n=9, 38%).
CD34+ subpopulations were determined using the primitive cell marker CD90 (CD34+/CD90+ and CD34+CD90-). Our analysis included: a) investigation of the relative frequency of CD34+ subpopulations within each group and b) comparison of the prevalence of different CD34+ subpopulations between different groups.
Results: a) There was a statistically significant prevalence of CD34+CD90- compared to CD34+CD90+ subpopulation within all groups: patients (P<0,001), controls (P=0,027), low and int-1 group (P=0,001), int-2 and high risk (P=0,008), RCMD (P=0,005) and RAEB 2 (P=0,018). The addition of CD133 expression in this analysis did not alter the results. b) 1. Both subpopulations CD34+CD90+ and CD34+CD90- had a significant prevalence in both the high risk vs low risk and high risk vs control groups. 2. The expression of CD34+CD90-CD133+ subpopulation was significantly higher in high risk vs low risk and high risk vs control groups. 3. Although there was no difference in the expression of subpopulations CD34+CD90+ and CD34+CD90- between different group of patients, the co-expression of CD96 differentiated the results as the prevalent subpopulation in the high risk group was CD34+CD90-CD96+ cells and in the low risk group was CD34+CD90+CD96+ cells.
Summary / Conclusion: Even though HSC dysfunction is presumed in MDS, the exact nature of quantitative and qualitative alterations is unknown. In the present study we found that the most prevalent HSC subpopulation with high expression of CD133 and CD96, especially in patients with higher risk MDS, is the most mature CD34+CD90-. It is a challenge to investigate a number of parameters that might reveal that these cells play an important role in MDS pathogenesis.

B1429

COMPOSITION OF BONE MARROW SUBPOPULATIONS ANALYZED BY FLOW CYTOMETRY REVEALS DIFFERENCES BETWEEN PEDIATRIC APLASTIC ANEMIA AND REFRACTORY CYTOPENIA

M Nováková[1*], M Suková[2], T Kalina[2], V Pelková[2], V Campr[3], E Vodičková[4], O Zapletal[5], J Blatný[5], Z Zemanová[6], J Trka[2], J Starý[2], O Hrušák[2], E Mejstříková[2]
[1]2nd Faculty of Medicine, Charles University in Prague, [2]Department of paediatric haematology and oncology, [3]Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague and University Hospital Motol, [4]Department of Clinical hematology, University Hospital Motol, Prague, [5]Department of Clinical Haematology, Children's University Hospital, Brno, [6]Center of Oncocytogenetics, Institute of Clinical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic

Background: Aplastic anemia (AA) is a disease with immunological pathogenesis. Refractory cytopenia of childhood (RCC), the most common subtype of MDS in children, is regarded as a clonal disease. Typically RCC is characterized by hypoplastic bone marrow (BM). Immunological mechanisms play a role in at least part of RCC patients. Evaluation of composition of BM populations by flow cytometry (FC) might be challenging since detailed knowledge about physiological composition in childhood is limited.
Aims: Our aim is to characterize BM by FC in AA and RCC with the focus on T cells and to define reference composition of subpopulations in physiological bone marrow.
Methods: We measured BM samples by FC in 34 AA patients (median age 10.3, 1.1-18y) and 26 RCC patients (median age 11, 4.2-18y) diagnosed in 2005-2013. We analyzed granulocytes, lymphocytes, precursors $CD34^{pos}$, $CD117^{pos}$, B cells including evaluation of immature $CD10^{pos}$ cells, T cells ($CD3^{pos}4^{pos}$, $CD3^{pos}8^{pos}$) including activation status by HLA DR expression. We also analyzed follow-up BM samples to evaluate changes following immunosuppression (IST). We established 2 reference categories: BM samples from patients examined within staging of solid tumor and a healthy donor (group A, 28 patients, median age 2.6, 0-17y) and patients at least 2 years after stem cell transplantation (group B, in total 22 patients, median age 11, 2.6-23y). For the aim of detailed characterization of T cells we introduced new polychromatic panel including markers describing T cell subsets (CD3, CD4, CD8), activation (CD57, HLA DR), cytotoxic function (Granzyme B, Perforin) and distribution from naive to memory stage (CD28, CD27, CD45RA). We measured >300 samples including 6 AA and 5 RCC paired samples before and after IST to evaluate differences in T cell composition.
Mann-Whitney test was used for statistical analyses (P<0.05 for all bellow mentioned results).
Results: Comparing both reference categories, we found higher percentage of lymphocytes and precursors $CD34^{pos}$ and $CD117^{pos}$ in patients in group A. We observed higher percentage of lymphocytes, B cells and precursors in control patients younger than 1 year. Proportion of $CD8^{pos}$ T cells out of all T cells and their activation was higher in patients older than 5 years.
Patients with AA have significantly higher number of lymphocytes compared to RCC and all reference samples. RCC patients have also higher percentage of lymphocytes compared to all reference samples. When RCC was compared to group A only the difference was not significant. Total B cells were significantly decreased in RCC compared to AA and reference group, however in both AA and RCC proportion of immature $CD10^{pos}$ B cells was significantly decreased. Following IST $CD10^{pos}$ B cells tended to increase in the majority of treated patients. Precursors $CD34^{pos}$ and $CD117^{pos}$ were decreased in both AA and RCC, but in AA patients they were significantly lower compared to RCC. T cells were increased in both AA and RCC patients, but significantly higher activation of cytotoxic T cells we observed only in AA. By T cell-oriented panel we found decrease of activated $CD8^{pos}$ T cells together with increase of naive $CD8^{pos}27^{pos}28^{pos}45RA^{pos}$ cells in AA patients with good response to IST.
Summary / Conclusion: We found reproducible differences in composition of BM populations analyzed by FC in AA and RCC patients. Decreased percentage of precursors and increased number of lymphocytes was present in both RCC and AA patients. It is important for analyses of BM composition to define control samples, which match also age characteristics.

PERFORMANCE CHARACTERISTICS OF CONSENSUAL APPROACHES FOR SMALL AND MINOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE DETERMINATION BY FLOW CYTOMETRY

I Marinov[1*], M Kohoutová[1], V Tkáčová[1], A Pešek[1], J Čermák[1], P Cetkovský[1]
[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Comparison of individual approaches for paroxysmal nocturnal hemoglobinuria (PNH) clones evaluation by flow cytometry (FCM) as described in the 2010 international clinical cytometry society (ICCS) guidelines has not been reported in literature.
Aims: To rule out the influence of different consensual approaches and strategies for small and minor PNH clone evaluation by flow cytometry on final results, thus leading to consistant interlaboratory variabilty
Methods: We analyzed the performance characteristics of 4, 5 and 6 color protocols for white blood cell (WBC), one and two color protocols for red blood cell (RBC) evaluation for different target PNH clones and compared results from routine PNH patient analysis.
Results: Coefficient of variation (CV) for precision / reproducibility analysis ranged from 0.67 % / 1.49 % to 2.56 % / 3.09 % for granulocytes, from 0.93 % / 3.09 % to 7.76 % / 12.06 % for monocytes and from 0.41 % / 4.73 % to 6.53 % / 5.1 % for RBCs. Linear regression analysis revealed excellent correlation (r = 0.99 %), Wilcoxon ranks test showed no statistically significant differences (P> 0.05), Bland-Altman analysis demonstrated performance agreement with mean bias ranging from 0.02 to 2.2.
Summary / Conclusion: Our results confirmed very good performance characteristics for precision and reproducibility analysis, excellent correlation and favorable agreement between protocols, underlining the crucial role of optimally selected glycophosphatidylinositol (GPI)-specific reagents and appropriate conjugates and secondary role of the number and type of gating reagents, tubes per test and corresponding gating strategy. With respect to this, reported high interlaboratory variability is considerably related to incorrect performance and /or insufficient experience with PNH testing by flow cytometry.

B1431

DIAGNOSIS AND MONITORING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY MULTIPARAMETER FLOW CYTOMETRY. OPTIMIZATION OF PROTOCOLS BASED ON CD59, CD55 AND FLAER

P Beneit[1*], A Mauricio[1], F Tarín[1], M García[1], E Mora[1], M Fernández[1], S Salazar[1], F De Paz[1], J Verdú[1], D Borrego[2], J Fernández[3], A Acedo[4], J Verdú[1]
[1]Hematology, Hospital General Universitario de Alicante, [2]Hematology, Hospital General Universitario de Elda, [3]Hematology, Hospital Universitario de San Juan, [4]Hematology, Hospital de la Vega Baja, Alicante, Spain

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a clonal disease of stem cells due to a somatic mutation in the PIG-A gene (Phosphatidil inositol glycan class A, cr. Xp22.1).
Aims: 1. Screen our reference population as recommended by Parker et al 2. Investigate the antibodies used for high sensitivity studies. 3. Quantify the size of the PNH clone and provide data of outcome and complications. 4. Monitor the clone and perform the tracing of patients.
Methods: 1. Review of results and clinical data of 457 studies (January 2009-

December 2012) in the reference area that includes different hospitals: Alicante, Andalusia and the Balearic Islands). 2. Study of the discrimination ability of the different antibodies used (FLAER Alexa488, CD24 APC H7, CD55/DAF APC, CD59/MIRL FITC and CD16 V450). 3. Study of sensitivity and specificity of our panels using dilution techniques in peripheral blood and bone marrows of healthy controls. 4. For the high sensitivity study, 100 pathological events are measured on an acquisition of 100,000 events (sensitivity 1/1000).
Results: 1. Detection of 7.7% positive cases (3.5% clinically symptomatic)
2. The detection rate has increased significantly since the use of FLAER, which is higher discriminatory than other antibodies 3. The FLAER express similar intensity in myelocytes, metamyelocytes, granulocytes and monocytes, and discriminates better than CD55 and CD59
Summary / Conclusion: · Approximately, 7-8% of patients, presenting at least one criterion of suspicion, have a detectable PNH clone. The effectiveness of the study is very different according to the clinical criteria considered; systematic screening remains controversial in patients with isolated cytopenias or thrombosis, with no evidence of hemolysis or hemoglobinuria. FLAER increases the sensitivity of the technique and avoids errors arising from the study of immature granulocyte series. FLAER allows the joint analysis of the entire population granulomonocytic in AA or MDS cases with low cellularity. The use of CD55 and CD59 allows to identify better intermediate expression clones and possibly to refine the hemolytic power and thrombotic risk in each individual case. Monitoring is essential in patients with small clones HPN/AA, especially in the regeneration phase (possible recuperation at the expense of PNH clone).

ASSESSMENT OF RESPONSE TO RECOMBINANT ERYTHROPOIETIN IN LOW GRADE MYELODYSPLASTIC SYNDROME
D O'Toole[1*], P Kennedy[1], P Thornton[1], J Quinn[1], P Murphy[1]
[1]Haematology, BEAUMONT HOSPITAL, Dublin, Ireland

Background: Ineffective erythropoiesis is characteristic of patients with low grade myelodysplastic syndrome (MDS), such as refractory cytopenia with multi-lineage dysplasia (RCMD) and refractory cytopenia with multi-lineage dysplasia and ring sideroblasts (RCMD-RS). Such patients may also have functional iron deficiency, contributing to hepcidin suppression and iron overload (Murphy PT et al, BJH, 2009:144;451).
Aims: To assess the effect of recombinant erythropoietin (R-EPO) on measures of ineffective erythropoiesis and iron metabolism in patients with low grade MDS and anaemia.
Methods: In 19 patients with low grade MDS (RAMD, n=15; RSMD, n=4) starting on R-EPO (darbepoetin alfa 150ug SC weekly) for anaemia (haemoglobin (Hb) < 10g/dl), we measured CBC, iron parameters and serum levels of EPO, hepcidin 25, tumour necrosis factor-alpha (TNF), growth differentiation factor-15 (GDF-15) and vascular endothelial growth factor (VEGF) prior to starting R-EPO and 8-12 weeks later.
Results: Pre R-EPO blood results showed a negative correlation between serum EPO and serum GDF-15 (P=0.0039), whilst serum hepcidin levels negatively correlated with serum ferritin levels (P=0.01) and positively with total iron binding capacity (TIBC) (P=0.02). Patients with a satisfactory Hb response to R-EPO (n=12) had pre serum EPO levels significantly lower than non responders (n=7) (P=0.019). Responders also had higher serum GDF-15 levels, although not reaching statistical significance. Comparing blood results pre R-EPO and after 8-12 weeks of R-EPO, no statistical difference was found in iron parameters, hepcidin 25, TNF, GDF-15 and VEGF. Analysis of blood results taken after 8-12 weeks of R-RPO therapy continued to show a negative correlation between serum EPO and serum GDF-15 (P=0.032). In addition, post R-EPO Hb correlated negatively with serum iron (P=0.014), transferrin saturation (P=0.016) and ferritin (P=0.04), whilst R-EPO responders had significantly lower serum iron (P=0.0016), transferrin saturation (P=0.0029) and ferritin (P=0.011) than non responders.
Summary / Conclusion: Our results suggest that MDS patients who respond to R-EPO have more effective erythropoiesis at baseline as evidenced by lower serum EPO levels. The negative correlation between serum EPO and serum GDF-1 is an unexpected finding, given the association between GDF-15 and ineffective erythropoiesis in other blood disorders.
R-EPO responders had significantly lower serum iron, transferrin saturation and ferritin, suggesting that R-EPO is better able to overcome functional iron deficiency in these patients with more efficient utilisation of iron to produce Hb.

ANALYSIS OF VB T CELL REPERTOIRE IN MDS PATIENTS
F Alfinito[1*], A Palatucci[2], O Vitagliano[1], V Rubino[2], G Giagnuolo[1], G Ruggiero[2], G Terrazzano[3]
[1]Medicina Clinica e Chirurgia, [2]Sienze Mediche Traslazionali, University of Naples "Federico II", Napoli, [3]Scienze, Università della Basilicata, Potenza, Italy

Background: Myelo Dysplastic Syndromes (MDS) are clonal disorders characterised by ineffective haematopoiesis and development of Acute Myeloid Leukemia (AML). International Prognostic Scoring Systems (IPSS) define MDS prognostic groups, according with AML risk but a need for improvement in diagnostic/therapeutical procedures is largely recognised. Several data suggest the involvement of immune-selection for the emergence, expansion and dominance of dysplastic clones in a sub-group of MDS. In these patients an altered immune-tolerance control could be involved in abnormal clones selection and in AML progression. We found that Treg levels and CD54 expression on cytotoxic T cells in Bone Marrow (BM) identify a distinct subgroup of MDS patients in which it is possible to hypothesise that defective tolerance control plays a role in the selection of the dysplastic precursors likely fostering their AML progression.
Aims: This study is addressing the hypothesis that BM Treg levels and CD54 expression on CD8 T cells, by us previously associated with the occurrence of immune derangement in MDS, might provide useful tools to validate the occurrence of immune-pathogenesis in a subgroup of patients. These criteria are hypothesised to likely represent valuable predicting elements for clinical response to immune-modulating therapeutical approaches in MDS. In order to investigate on such issue we are focusing the analysis of T cell repertoire in BM and peripheral CD4 and CD8 lymphocytes of the patients, categorised according to IPSS as well as their immunological BM profile.
Methods: Eleven MDS patients, grouped according to IPSS criteria (4 Low; 4 Int-1; 2 Int-2; 1 High) have been further categorised according to their immune profile in BM. In this patients T cell repertoire has been analysed by using flow cytometric VB typing on CD4 and CD8 T lymphocytes. The analysis has been always performed in peripheral blood as well as in BM samples.
Results: Our preliminary data showed in all the Low/Int-1 Risk patients the occurrence of multiple VB expansions in both CD4 and CD8 T lymphocytes. When comparative evaluation of the VB expansions was performed between peripheral blood and BM, only one preferential BM expansion was demonstrated in CD8 effectors in all the patients analysed. This expansion was never accompanied by concomitant skewing of the CD4 population bearing the same VB specificity. None of the Int-2/high Risk patients showed a preferential BM expansion in CD8 effectors in comparison with peripheral blood where multiple VB expansions were observed in CD4 T cells.
Summary / Conclusion: Our preliminary results indicate that peripheral blood/BM comparison of VB repertoire in CD4 and CD8 T cell effectors identifies specific single expansions of CD8 repertoire in Low/Int-1, but not in the Int-2/High MDS patients. Comparative analysis of the results obtained in the patients grouped according to their BM immune-profile (Treg levels and CD54 expression on CD8 T cells) will be further discussed.

Myelodysplastic syndromes and bone marrow failure syndromes incl. PNH - Clinical

PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA CLONE IN APLASTIC ANAEMIA PATIENTS AT THE BEGINNING OF DISEASE AND IN REMISSION

Z Fidarova[1*], E Mikhailova[1], S Lugovskaia[2], E Naumova[2], M Pochtar'[2], I Galceva[3], D Kisilichina[2], I Shitareva[3], LKuzmina[1], E Parovichnikova[1], V Savchenko[3]

[1]chemotherapy of hemoblastoses and bone marrow transplantation, Research Center of Hematology of Russian Ministry of Health, [2]Russian Medical Academy of Postgraduate Education , [3]Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: The first results have been published and they show that the frequency of the Paroxysmal Nocturnal Haemoglobinuria (PNH) clone detection at Aplastic Anaemia (AA) can vary between 30 and 70%, and at that the existence of the minor PNH clone at the patients can be a favorable prognostic index induced by the Immunosuppressive Therapy (IST).
Aims: to detect the PNH clone at AA patients at different stages of desease and to reveal its' influence on the IST effectiveness.
Methods: 36 patients with severe and very severe AA (SAA/VSAA) who received combined IST with antithymocytic globulin (hATG) and cyclosporin A (CsA) have been included into the study. Mediane age - 23 years (16-54). 2 of the patients undergone the allogenic bone marrow transplantation (alloBMT).
All 36 patients were divided into 2 groups. The 1st one included de novo AA patients(n=22); the 2nd group – AA patients in complete remission (CR) after IST (n=14). The median remission duration was 3 years (2-6 y). The results of the de novo AA treatment (1st group) were evaluated at 6 and 12 months from the start of IST. We used the flow cytometry (Becton Dickinson (BD) FACS Canto II and Beckman Coulter (BC) FC 500) to evaluate the PNH clone. Peripheral blood samples were analyzed with antibodies CD45(BD), CD15(BD), CD64(BD), CD235a(BC), GPI-tying antibodies CD59 (Invitrogen), CD14(BC), CD24(BC) and FLAER (Cedarlane). Minor PNH clone was detected when the size of the clone did not exceed 1%.
Results: The PNH clone was found in 13 patients among 22 (59%) from 1st group. The minor clone was found in 3 patients, in 10 patients the clone size is exceed 1%. Median (Me) clone size on the Red Blood Cells (RBC: type II + type III) was 0,9% (0,1-1,5%), Granulocytes (GR) - 11,3% (0,1- 27,6%), Monocytes (Mon)- 23,2% (0,3-97,3%). 6 SAA/VSAA patients (46%) with the PNH clone (n=13), showed a complete remission at 6 months from the therapy beginning; 4 patients (30%), including 3 patients with the minor PNH clone, showed partial remission; in 1 patient remission was not achieved even 12 months of treatment. But regardless CR, PNH clone persisted in all patients. It worth to note, that PNH clone disappeared after allo-BMT (n=2).
Only in 3(33%) of 9 de novo AA patients with no PNH clone partial remission was obtained at 6 months. The other patients were still on the treatment.
In the 2nd group the PNH clone was detected in 10 cases from 14 (71%), only 4 of them had a minor clone. The Me of PNH clone size on RBC -2,4% (0,1 to3,6%), Gr – 74,2% (0,4-81%), Mon - 13,5% (0,1-20%)
Summary / Conclusion: The PNH clone has been detected in more than 50 % of de novo SAA/VSAA patients. The disease was characterized by pancytopenia and aplasia of the bone marrow without visible signs of intravascular hemolysis. In our study we observed the best IST response at 6 months in SAA/VSAA patients with the PNH clone (46% CR), but even in CR PNH clone persisted.

B1435

APPLICATION OF INTERPHASE FLUORESCENCE IN SITU HYBRIDIZATION IN MYELODYSPLASTIC SYNDROMES AND THE ASSOCIATION WITH CLINICAL FEATURES

M Xu[1*], M Hou[1], J Peng[1]
[1]Hematology, Qilu Hospital of Shandong University, JINAN, China

Background: Among patients with primary myelodysplastic syndromes (MDS), about 30-50 % acquired clonal chromosomal abnormalities. The chromosomal abnormalities have prognostic value, can be applied to risk factor calculation. Most of the chromosomal abnormalities are detected by conventional cytogenetic (CC) analysis. However, complex abnormalities were difficult to accurately identify by CC. Presently, multiplex fluorescence *in situ* hybridization (M-FISH), which uses fluorescent probes that bind to those parts of the chromosome with high degree of sequence complementarity to detect and localize the specific DNA sequences alteration, was applied to clarify complex karyotypes and occult defects, such as monosomy7, trisomy8, deletions of the long arm of chromosome 5 or of chromosome 7.
Aims: We performed the clinical trial in 100 cases to investigate the genetic basis in MDS patients and its relationship with clinical features and prognosis of MDS. Differences with two methods, CC and FISH, were determined separately in the abnormalities rate and estimated international prognostic scoring system (IPSS). The findings will provide a rational choice for detection of MDS chromosomal abnormalities.
Methods: All patients (60 males and 40 females aged from 12 to 82 years old) included in this study were diagnosed with MDS or MDS-Acute Myeloid Leukemia (AML), Criteria for diagnosis were made according to French–American–British (FAB) classification and were reviewed for application of World Health Organization (WHO) classification. With the application of sequence-specific DNA probes, interphase fluorescence in situ hybridization (I-FISH), is applied on bone marrow cells to detect del(5q33) (CSF1R EGR1); -5(D5S23,D5S72); 7q31(D7S486, D7S522); 7p11-q11(CSP7); 20q12(D20S108); +8(CSP8) and –Y. Chromosome studies were carried out on bone marrow cells with a Trypsin–Giemsa banding technique. The threshold was established using 10 specimens of health controls. Data were analyzed with Spearman Rank Correlation to evaluate the correlation between positive rate detected with probes and the clinical factors. Paired T test was carried to assess the difference of (IPSS) estimated by I-FISH and CC. (*P 0.05*) All of the patients involved had signed the informed consents.
Results: Chromosomal abnormalities were identified in 27% of with CC, compared to 56% with a method of FISH (*P=0.002*). Of the 56 cases with any abnormal finding, 25 (44.6%) were identified only by FISH. The proportion of IPSS categories also varied with different methods, especially intermediate-1 and -2. CC and FISH calculated the percentage of intermediate-2 as 19.5% and 50.5%, respectively. And there is link between genetic aberration and clinic pathologic characteristic. Correlation analysis indicated del(5q31) and leukopenia were negatively correlated; abnormality in chromosome 7 had relevance with the level of alanine aminotransferase (ALT); del(20q) was related to several clinical features, such as leukopenia, reduced vitamin B12 and ferritin.
Summary / Conclusion: CC plays an important role in the classification of MDS by current World Health Organization criteria. However, it may be limited when insufficient numbers of metaphase cells are obtained or cryptic or complex abnormalities, while FISH is a suitable method to complement the limitation. It is more rapid and sensitive to refine chromosome aberrations in MDS. Some of specific detection for genomic features of MDS was proved to be correlative with its clinic pathologic characteristics and the prognosis, but large-scale and long-term follow-up researches were in need to verify the correlation.

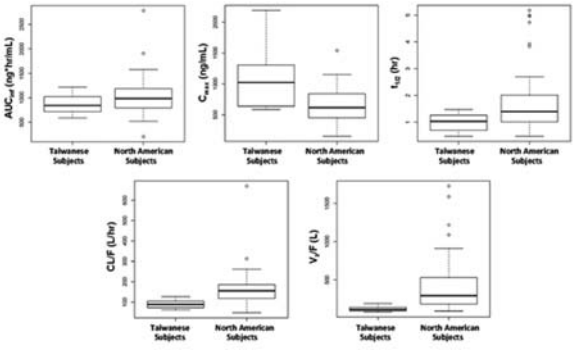
B1436

A PHASE4, OPEN-LABEL STUDY TO EVALUATE THE PHARMACOKINETICS (PK) OF SUBCUTANEOUS (SC) AZACITIDINE IN TAIWANESE SUBJECTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (MDS)

E Laille[1*], W Chou[2], S Yeh[3], Q Dong[1], S Songer[1], C Beach[1]
[1]Celgene Corporation, Summitt, United States, [2]National Taiwan University Hospital, Taipei, [3]China Medical University Hospital, Taichung, Taiwan

Background: PK evaluations of SC azacitidine (AZA) indicate rapid AZA absorption. Mean maximum observed plasma concentration (C_{max}) is 650 ng/mL; median time to C_{max} (T_{max}) is 0.5 hours post-dose; mean area under the plasma concentration-time curve from time zero to infinity ($AUC_{0-\infty}$) is ~1000 ng*hr/mL; mean terminal elimination half-life ($t_{1/2}$) is 1.6 hours, mean apparent clearance (CL/F) is 175 L/hr, and mean apparent volume of distribution (Vd/F) is 410 L (Garcia-Manero, 2011). There is high intersubject variability for all PK parameters. Most AZA PK data have been collected from studies with Caucasian subjects with hematologic malignancies, although a phase I/II study showed the PK profiles of SC AZA in Japanese subjects with MDS and Caucasian subjects were comparable (Uchida, 2011). PK analysis of SC AZA has not been previously performed in Taiwanese subjects with MDS.
Aims: To characterize the steady-state PK of SC AZA during a single treatment cycle in Taiwanese subjects with higher-risk MDS; and to compare AZA PK in these subjects to AZA PK in a historical cohort of primarily Caucasian subjects from North America with MDS, AML, or CMML (Garcia-Manero, 2011).
Methods: Taiwanese subjects received SC AZA 75 mg/m^2/d x 7d. Blood samples were collected prior to dosing on Days5,6, and 7 and post-dose on Day 7 at 0.25, 0.5,1,2,3,4,6, and 8 hrs. In the historical study, North American subjects also received SC AZA 75 mg/m^2/d x 7d; blood samples were collected before dosing on Day 7 and post-dose at 0.25, 0.5,1, 1.5,2, 2.5,3, 3.5,4,6, and 8 hrs. AZA plasma concentrations were determined using a validated high-performance liquid chromatography/tandem mass spectrometric method. Using non-compartmental methods, the following PK parameters were calculated: C_{max}, T_{max}, AUC_{0-t}, $AUC_{0-\infty}$, $t_{1/2}$, CL/F, and Vd/F.
Results: Twelve Taiwanese subjects were studied: 58% were male (n=7); mean±SD age was 58±10 yrs; 11 subjects had IPSS Int-2 or High-risk MDS and 1 subject had IPSS Int-1 risk MDS. In the historical cohort (N=43), 81% were male (n=35), mean age was 69±12 yrs; and 30 subjects had MDS (n=13 IPSS Int-2 or High; n=16 IPSS Low or Int-1; n=1 missing IPSS), 10 had AML, and 3 had CMML. In both Taiwanese and North American subjects, high intersubject variability (large %CV) was observed for AZA exposure. Pre-dose AZA plasma concentrations were below the limit of detection indicating no AZA accumulation following multiple-dose administration. For Taiwanese and North American subjects, mean AZA plasma concentrations vs. time profiles were similar in shape with overall higher concentrations observed in North American subjects, except for C_{max}. AZA was rapidly absorbed reaching median (min, max) T_{max} within 0.25 hr (0.25, 0.50) and 0.50 hr (0.17, 1.00) post-dose, for Taiwanese and North American subjects, respectively. Subsequently, mean concentrations

declined in an apparent multiphasic manner. For $AUC_{0-\infty}$, $t_{1/2}$, CL/F, and Vd/F parameters, the ranges of values observed in the 12 Taiwanese subjects were within the ranges of values observed in North American subjects. C_{max} ranges in Taiwanese and North American subjects differed; however, overall AZA exposure (AUC) was within the same range in both groups.
Summary / Conclusion: The AZA PK profile and all PK parameters obtained in Taiwanese subjects with MDS except C_{max} were within the range of the PK profile and PK parameters obtained from North American subjects with MDS or other hematologic malignancies. Evaluation of the safety and efficacy of SC AZA in Taiwanese subjects is currently underway.



B1437
CIRCULATING FETUIN-A/A2HS-GLYCOPROTEIN LEVELS IN MYELODYSPLASTIC SYNDROME
M Dalamaga[1], A Lekka[2], M Triantafilli[2*], J Chamberland[3], K Karmaniolas[4], A Dionyssiou-Asteriou[1], C Mantzoros[3]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, NIMTS Hospital, Athens, Greece, [3]Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Internal Medicine, NIMTS Hospital, Athens, Greece

Background: Excess weight is now considered to be a risk factor for many types of cancer, including leukemia and lymphoma. Indeed, a strong correlation of excess body weight with insulin resistance (IR), characterized by hyperinsulinemia has been well documented. Also, there is evidence that IR is implicated in several malignancies related to obesity. Fetuin-A, also known as α2HS-glycoprotein, a hormone synthesized mainly in the liver, could cause IR via inhibiting insulin signaling, modulate adipocyte function by downregulating adiponectin expression and interact with various growth factors influencing tumor initiation and progression.
Aims: In thiscase-control study, we explored the potential role of fetuin-A in association with insulin and adiponectin, all potential mediators of the effects of obesity on IR, in relation to MDS risk taking into account body mass index (BMI), height, weight, family history of lymphohematopoietic cancer (LHC) and smoking history.
Methods: Blood samples were collected from 101 cases with incident, histologically confirmed primary MDS, and 101 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004 and 2007. Serum insulin and adiponectin were determined by radioimmunoassay. Serum fetuin-A levels were measured using an enzyme linked immunosorbent assay (Biovendor R&D) with a sensitivity of 0.35 ng/mL. The statistical analysis of the data was performed using IBM-SPSS® version 20 for Windows statistical software package.
Results: MDS patientspresented significantly higher height and weight than control subjects (P<0.001), while differences of BMI were only of borderline significance (P=0.12). Serum fetuin-A and insulin were significantly higher in patients than in control participants (P=0.04 and P=0.005 respectively).Serum fetuin-A levels were not significantly different in MDS subtypes, IPSS categories and karyotype (P>0.05). There was statistically significant evidence that elevated serum fetuin-A levels expressed by control-defined quartiles were associated with increased risk for MDS, before and after adjusting for age, gender, date of diagnosis, BMI, family history of LHC, smoking history, serum insulin and adiponectin (p value for linear trend=0.03). Stratifying by BMI revealed that mainly among overweight/obese subjects, those with elevated fetuin-A levels presented a higher risk of MDS after adjustment with MDS risk factors and hormones (for fetuin-A: OR=1.006, 95% C.I. 0.99-1.013, P=0.07 though not significant at α=0.05).
Summary / Conclusion: The interplay of elevated serum fetuin-A levels, hypoadiponectinemia and hyperinsulinemia is associated with higher risk of MDS particularly amid overweight/obese individuals, a finding with potential preventive and clinical implications. Weight loss and physical activity could decrease fetuin-A attenuating thus IR. Pharmacologic agents such as full and selective PPAR-γ agonists that decrease fetuin-A levels could be at the forefront of future therapeutic modalities for obesity-linked malignancies, including MDS. Additional research is needed to elucidate the mechanisms underlying the associations of fetuin-A and insulin with the risk of myelodysplasia and leukemogenesis.

B1438
STRIKING HEMATOLOGICAL ABNORMALITIES IN PATIENTS WITH MICROCEPHALIC OSTEODYSPLASTIC PRIMORDIAL DWARFISM TYPE II MAY INDICATE A POTENTIAL ROLE OF PERICENTRIN GENE IN HEMATOPOIESIS
S Unal[1*], M Cetin[1], Y Alanay[2], K Boduroglu[2], E Utine[2], E Kilic[2], Y Ozsurekci[1], F Gumruk[1]
[1]Hacettepe University Division of Pediatric Hematology, [2]Hacettepe University Department of Genetics, Ankara, Turkey

Background: Microcephalic osteodysplastic primordial dwarfism (MOPD II) is among the rare etiologies of dwarfism with similarities to Seckel syndrome. Seckel syndrome is well-known to have various associated hematological abnormalities, however the hematological findings of MOPD II patients are very limited.
Aims: To figure out the hematological characteristics of MOPD II patients.
Methods: A series of 8 patients from 7 unrelated families who were diagnosed with MOPD II syndrome by clinical evaluation were further genetically tested for pericentrin mutations. Case 3,5,7 had one visit. The patients were designated to have leukocytosis or thrombocytosis if they had persistently (excluding case3,5,7) high levels for age at multiple visits without any other cause. None of the patients had any symptom or sign of infection at work-up. The cases1,2,4,6 were screened for iron deficiency and were found to have normal iron status. Case 4 was also evaluated with bone marrow aspiration as well in order to understand the etiology of leukocytosis.
Results: All of the patients were found to have pericentrin mutations. Of the 8 patients with MOPD II, the mean age at assesment was 58.0±46.3 months (6-144 months and male:female ratio was 3:5. There was consanguinity between parents in 7 (87.5%) of the patients. Case 1 and 2 were siblings from same parents, whereas other patients were not related.
The hematological evaluation revealed leukocytosis in 6 (75%), thrombocytosis in 7 (87.5%) and anemia in 2 (25%). In 5 patients (62.5%) leukocytosis and thrombocytosis were concomitantly found, whereas in others either one was present. The mean hemoglobin level of the group was 11.8±1.4 g/dl (10-14.2); the mean WBC count and platelet counts were 22.6±10.5 $x10^9$/L (13.1-44.2) and 521.0±133.3 $x10^9$/L (285-668), respectively.
Case4, who had higher leukocyte counts was also evalauted with bone marrow aspiration, which revealed cellular bone marrow with 36% lymphocytes, 24% normoblasts, 12% metamyelocytes, 13% neutrophils, 6% monocytes, 4% eosinophils and 1% stab, with a myeloid/erythroid ratio of 1.08. No blasts were detected in the peripheral blood and the bone marrow aspirate. Immunological status of this patient was also evaluated and no cellular or humoral defects were detected. During the follow-up for 60 months, leukocytosis, thrombocytosis and anemia persisted. Case 6 developed moyamoya disease and recurrent stroke and managed with low molecular weight heparin followed with aspirin prophylaxis.
Summary / Conclusion: MOPD II was mapped to 21q22.3 and biallelic mutations in the pericentrin gene were shown to underlie the etiology. Pericentrin is an integral protein of the centrosome that serves as a multifunctional scaffold for anchoring various proteins and protein complexes.Depletion of PCNT has been shown to cause apoptosis leading to dwarfism in MOPD II, whereas overexpression has been shown to induce cell death in hematopoetic progenitor cells via mitotic defects and anuploidy, in addition to the role of overexpression of pericentrin in solid tumors and AML. The high leukocyte and thrombocyte counts in MOPD II patients may be related to the different functions of pericentrin in various cell types. In conclusion, upto our knowledge and according to the literature overview hematologic abnormalities including leukocytosis, thrombocytosis or both are very initialy being reported in a series of patients as accompanying characteristics of the disease, excluding 2 different previous case reports data giving the platelet and WBC counts of their patients within the report and were also consistent with our findings. This data may help to understand the potential function of pericentrin gene in hematopoietic cell proliferation and differentiation.

B1439
CASE SERIES OF APLASTIC ANEMIA; AN INSTITUTION BASED REVIEW
M Taj[1*], S Shaheen[2], U Zaidi[1], R Qureshi[1], T Shamsi[1]
[1]Department of Haematology & Transplantation, [2]Department of Research, National Institute of Blood Disease & Bone Marow Tansplantation, Karachi, Pakistan

Background: Aplastic Anemia (AA) is one of the frequently encountered Bone Marrow Failure Syndromes in Pakistan. It is idiopathic in more than 80% of cases however the major identifiable causes include drugs, ionizing radiation, chemicals and certain viruses.
Aims: We have performed a prospective data collection of patients suffering

from AA with detailed analysis of their baseline characteristics and same characteristics were compared with the control population of same physical characteristics without AA.
Methods: We designed an extensive database which incorporated all detailed baseline characteristics of patients suffering from AA and certain epidemiological factor exposure prior to the development of AA. These parameters included their socioeconomic details, nature of work, living conditions, exposure to certain known industrial toxic materials. The data was analyzed on SPSS version 17 and frequencies were determined and compared with 150 control population without AA.
Results: From December 2010 till December 2012, we collected detailed data of 153 confirmed cases of Aplastic Anemia. Out of them 105 (68.6%) were male and 48 (31.4%) were females. We also collected 150 control cases with 58 males (50.4%) and 57 females (49.7%). The mean age at the time of presentation was 21 years (range 3-69 years). The urban population constituted 93(60.7%) while rural was 59 (39.3%). Overall 31.3% of patients belonged to Karachi. Mean hemoglobin was 7.73, mean while cell count was 2.23 and mean platelet counts were $14x10^{10}$ at the time of first visit in clinic. Very Severe AA in 22.3%, Severe AA in 43.5% and Non-Severe AA was identified in 13.5%. Chronic use of NSAID could be established in 23.5% of patients with AA while 5.2% in control group. Benzene exposure in 7.8% versus 0.9% of control group, organophosphates in 20.3% while 11.3% in control population. There was no significant difference with excessive use of fluoride, lead containing chemicals, hair dye or microwave oven use. HLA matched Allogenic stem cell transplant was performed in 36(23%) with complete response seen in 21(72%) cases in past two year. 71 (48.4%) continued with supportive care therapy alone and 29 (21.2%) continued Cyclosporin alone or with ATG.
Summary / Conclusion: There probable identifiable risk factors include use of NSAIDS, Benzene and exposure with organophosphorous compounds. The affect need to be further established by serum levels of theses injurious toxins and its in-vitro effect on pleuripotent stem cells and it might contribute in disease prophylaxis in future. The overall mortality can be reduced if HLA identical donor identified (Allogenic transplant outcome 72%) and also with good supportive care if other treatment options utilized.

Background: Thrombotic events (TE) are the most feared complication in paroxysmal nocturnal hemoglobinuria (PNH), accounting from 40 to 67% of the deaths in the pre-eculizumab era. The likelihood of TE in the PNH patient population is up to 62 times higher than in the general population. In PNH, TE often happens despite correct anticoagulation. Eculizumab, a MoAb designed to block complement's C5, has proven to be safe and effective in the prevention of TE in PNH.
Aims: The aims this study were to analyse the number of TE and their complications before and after initiating eculizumab on PNH patients, and its effects on both the number and consequences of TE and the QoL of the patients.
Methods: The study reviews the medical history of a Spanish cohort of 22 patients with medical history of TE caused by PNH and their clinical course before and after receiving eculizumab.
Results: Fourteen men and 8 women, ages between 30 and 72 (mean 52.7, SD 12.1), were included in the study. Eight patients (36.3%) did not have a previous diagnosis of PNH before suffering their 1st TE; average time from diagnosis to 1st TE was 5.9 yrs (SD 5.4, range 0.2 – 15.9). In the other 14 cases (63,6 %) the diagnosis of PNH preceded the 1st TE by 2.2 yrs on average (SD 3.3, range 0.1 – 6). The mean granulocyte clone size at diagnosis (n=13) was 73.1% (SD 21.1, range 35-100). The average number of TE per patient before starting eculizumab was 2.1 (SD 1.3, min=1, max=7). In total, the 22 patients presented 42 TE before eculizumab, despite the fact that all of them were under anticoagulation prophylaxis. The most frequently affected territory was abdominal (18 TE, 42.9%), out of which 9 were Budd-Chiari syndromes, followed by brain (11 TE, 26.2%), lower extremities (9 TE, 21.4%), and atrial, dermal, retinal and pulmonary (1 case each, 2.1%). The TE was venous in 35 occasions (83.3%), and arterial in 7 (16.7%). The mean granulocyte clone size at the time of the 1st TE (n=13) was 78.9% (SD 21.2, range 30-100). Fifteen patients (68.2%) presented a total of 30 serious complications due to TE. Ten patients (45.5%) presented 18 abdominal complications, including hepatomegaly (7), splenomegaly (4), increased liver enzymes (2), jejunectomy (2), cirrhosis (1), ascites (1) and abdominal pain (1). Eight patients (36.4%) presented 9 neurological complications, including hemiplegia (5), hemiparesia (3) and lose of conscience and dysarthria (1). One patient presented papiledema, one varicose veins and one dehiscence of suture in a previous surgery. Two patients died without receiving eculizumab, a 72 year old man after hemiplegic consequences of a sepsis by E. Coli, and a 48 year old woman after a failed allogeneic BMT. Both patients had been under treatment with eculizumab for more than 2 years each with good QoL. The mean follow-up (until February 26, 2013) of the remaining 19 was 3.1 years (SD 1.9, range 0.6 – 8.1). One patient suffered a possible pancreatic micro-thrombosis 15 days after the first infusion of eculizumab, of which the patient recovered well in the next few days. None of the others have had any TE event, and all are well and with good QoL. Eighteen of them are still anticoagulated.
Summary / Conclusion: TE are a severe and recurring complication of PNH. The most frequent territories are abdomen and brain, leading to severe, sometimes life-long sequelae. TE can appear with clones of any size, are difficult to predict and are not adequately prevented with standard anticoagulation. Eculizumab is a safe treatment for PNH that effectively prevents TE and their complications.

B1441
DETECTION OF PNH-CLONE IN PATIENTS WITH DEPRESSION OF HEMOPOIESIS
T Glazanova[1*], Z Chubukina[1], O Rozanova[1], E Shilova[2], S Gritsaev[2], L Bubnova[1]
[1]laboratory of immunohematology, [2]Hematology, Russian research institute of hematology and transfusiology, Saint-Petesburg, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, life-treatening clonal blood disorder. Its immunologic diagnostics attracts more and more attention during the recent years as there appeared standardized flow cytometric protocols using a panel of monoclonal antibodies, and such drug as Eculizumab has been developed. It is known that beside patients with confirmed clinical diagnosis of PNH, cells with PNH-phenotype (PNH-clone) are often revealed in patients with aplastic anemia (AA) and myelodysplastic syndrome (MDS). Nevertheless, the frequency of detection of PNH-clone and its dynamics vary broadly, according to different data.
Aims: to study the frequency of detection of PNH-clone and its size in different groups of patients with blood diseases.
Methods: PNH-cells were revealed using multi-color flow cytometry (FC 500, Beckman Coulter), detecting PNH-clone in granulocytes (FLAER/CD24/CD15/CD45), monocytes (FLAER/CD14/CD64/CD45) and red blood cells (CD235a/CD59), revealing II and III type PNH-RBCs. The corresponding cells lacking expression of listed surface antigens were considered PNH-clone.
Results: During the period from June 2011 to March 2013 in laboratory of immunohematology of Russian Research Institute of hematology and transfusiology we have examined 148 patients in order to reveal PNH-clone. Of them the diagnoses on admission to laboratory were distributed as follows: AA – 69 patients, MDS – 41, suspicion for PNH – 16 patients, other (hypercoagulation, thrombophilia, cytopenia of unknown origin, autoimmune hemolytic anemia) – 22 patients. In total PNH-clone was established in 62 patients (41.8% of cases), among them with PNH diagnosis – 43.8% (7 of 16 examined patients), AA – 63.8% (44 of 69), MDS – 21.9% (9 of 41), other diagnoses – 9.1% (2 of 22). The size of detected PNH-clone varied from 0.01% to 100%. It was less than 1% in 12 (27.3%) patients with AA, 6 (66.7%) – with MDS, 2 (100%) – with other diagnoses. PNH-clone from 1.1 to 10% was observed in 13 (29.5%) patients with AA and in no cases in patients of other groups. PNH-clone sized 10.1-99.9% was detected in 7 (100%) PNH patients, 19 (43.2%) AA patients, 3 (33.3%) MDS patients. It should be noted that in MDS patients its size did not exceed 20%. In examined patients the symptoms of latent intravascular hemolysis (moderately increased LDH, transient hemosiderinuria) usually developed when pathologic clone exceeded 25%. Clinically manifested hemolysis with skin colour changes, darkening of urine and laboratory signs of hemolysis were observed in patients with large PNH-clones, exceeding 80%. The dynamics of PNH-clone was evaluated in 21 patients, studies were performed every 6 months. Gradual increase of PNH-clone was observed in 8 (38.1%) of cases.
Summary / Conclusion: Thus, PNH-clone occurs more frequently in AA than in MDS patients, and its size in MDS is mostly less than 1% and in other cases it does not exceed 20%.

B1442

LENALIDOMIDE (LEN) IN MYELODYSPLASTIC (MDS) DEL(5Q) PATIENTS: A SINGLE INSTITUTION POPULATION-BASED EXPERIENCE

A Pelizzari[1*], E Cerqui[1], F Schieppati[1], E Borlenghi[1], C Pagani[1], D Bellotti[2], G Rossi[1]
[1]Hematology, Spedali Civili, [2]Cytogenetics and Molecular Genetics, University of Brescia, Brescia, Italy

Background: LEN induces red blood cell transfusion independence (TI) and complete cytogenetic response (CCR) in MDS with del (5q). Published results of large multicentre MDS-003 and MDS-004 studies are well known, but only limited information on population-based experience is available.
Aims: To evaluate safety, efficacy and long-term outcome in a strictly consecutive population-based series of MDS pts with anemia and del(5q), treated with LEN at a single Institution.
Methods: All consecutive MDS pts classified according to WHO criteria and IPSS, and treated with LEN at our Institution between July 2007 and February 2013 were analysed. Institutional guidelines include observation until transfusion need, then epoetin (EPO) treatment and LEN for EPO non-responders. Initial LEN doses was 10 mg po days 1-21 on 28-day cycles, without thrombosis primary prophylaxis. Responses were evaluated according to IWG criteria after 4 months. LEN was continued until loss of TI, toxicity, leukemic evolution or death. Bone marrow blasts count and cytogenetic analysis were performed in all responsive cases treated for at least 6 cycles.
Results: Twenty patients were recorded (7,5 % of 264 newly diagnosed MDS). Median age was 75,5 years (range 53-87) female were 65%. WHO categories included unclassificable (2), MDS del(5q) (12), RCMD (2) and RAEB I, RAEB II, RARS and RARS-T (one each). Eighteen cases (90 %) had IPSS Low/Int-1 and bone marrow blast count ≤ 5%. By conventional cytogenetics 5(q-) was isolated in 18 (90 %) and associated with one additional abnormality in 2 [+8 and del(17p)]. Median time from MDS diagnosis was 13,5 months (range 1-87), all patients were transfusion-dependent. Fourteen cases were pre-treated and non-responders to epoetin. Median number of cycles was 6 (range 1-43). Median follow-up was 33 months (1-152) after MDS diagnosis. Among the 18 cases evaluable for erythroid response (2 too early), TI was reached in 15 cases (83 %), haematologic improvement in1, failure in 1; one case refused treatment after 2 cycles. Cytogentic response was evaluated in 9 pts. There were 6 CCR (66 %) and 3 partial response. Haematological toxicity (neutropenia and/or thrombocytopenia WHO grade 3-4) was observed in 55 % of cases. Non haematological toxicity included: thrombosis (3), diarrhea (2), headache, abdominal pain, rash, transaminases increase, fatigue (1 each). It caused LEN discontinuation in 2 cases in TI (cutaneous rash and deep venous thrombosis with pulmonary embolism). The incidence of deep venous thrombosis/pulmonary embolism was higher than expected occurring in 3/20 cases, (15 %), two of whom had haematologic comorbidity as risk factor (asymptomatic multiple myeloma and indolent lymphoma). Two pts with isolated del(5q) evolved to acute myeloid leukemia (AML) during treatment, respectively after 1 and 7 months (the latter while in CCR). The 5-year actuarial risk of progression to AML was 15,6 % (SE ± 13,4). The 5-year overall survival probability was 67,7 % (SE ± 13,8). Causes of death were: congestive hearth failure in one, gallbladder carcinoma in one, infection in one, hemorrhage in one and AML in 2. At present 9 patients are still on treatment after a median of 23,5 months (range 4-68+).
Summary / Conclusion: In a population-based series of MDS del(5q) pts median age was higher than in clinical trials. EPO was ineffective in transfusion dependent pts and is currently avoided at our Centre. LEN confirmed to be effective and manageable. TI was obtained at high frequency and was durable even after LEN interruption. Thrombosis was frequent suggesting that prophylaxis should be considered, at least in pts with other risk factors. LEN did not increase the risk of leukemic evolution. Survival was satisfactory and causes of death weren't treatment related.

B1443

MORPHOLOGICAL FEATURES OF HEMATOPOIESIS IN MDS PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION WITH REDUCED INTENSITY CONDITIONING

V Dvirnyk[1*], L Kuzmina[2], A Kokhno[2], E Glasko[3], E Parovichnikova[2]
[1]Clinical laboratory, [2]Chemotherapy of hemoblastoses and bone marrow transplantation, [3]Pathology department, Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: The use of conditioning regimens with decreased intensity extend the availability of allo-HSCT for elderly MDS patients and MDS patients with comorbidities. However, data on the morphological characteristics of the recovering hematopoietic tissue in MDS patients at different times post-transplant are still uncertain.
Aims: To study morphological features of hematopoiesis in bone marrow aspirates and trephine biopsies of MDS patients taken at different time points after allo-HSCT with reduced intensity conditioning.
Methods: We have analyzed 98 bone marrow aspirates and 94 trephine biopsies from 2 high risk, 3 intermediate-2, 5 intermediate-1 MDS patients before and after1,2,3,6, 12 and 24 months allo-SCT.
Results: Abnormal karyotypes before transplantation were found in 5 patients. Engraftment was achieved in 9 of 10 patients. One patient died of graft failure6,5 month post transplant. Another patient died from a severe infection that developed on the background of the extensive form of chronic GVHD 13 months after allo-HSCT. Rapid recovery of blood parameters after transplantation was noted for the rest of the patients. Threphine biopsies after allo-HSCT indicated hypoplasia of bone marrow with erythroid predominance for majority of patients. However the numbers of megakaryocytes were reduced. Bone marrow cellularity in patients with severe GVHD was not lower compared to those without GVHD. However delayed engraftment in 2 patients with acute GVHD was observed. Focal fibrosis of the stroma, revealed by pre transplant biopsies in 4 patients, persist in 2 of them in the follow-up period. Magaloblasts were found in 6 of 10 patients during early post transplant period. Significant reduction of erithropoiesis was observed later. Granulocytopoiesis was not affected in most of the patients. Dysplastic changes in megakaryocytes persist during all periods of observation in most patients, but were less pronounced compared to the baseline.
Summary / Conclusion: Recovery of hematopoietic tissue after allo-HSCT in MDS patients is similar to that in other hematological malignancies. Hypoplasia of hematopoietic tissue was still detected in the majority of patients after transplantation. However disease-specific signs of dysplasia were significantly reduced.

B1444

AZACYTIDINE THERAPY FOR MDS AND AML PATIENTS: RETROSPECTIVE MULTICENTRE REGIONAL EXPERIENCE IN PATIENTS NOT ENROLLED INTO CLINICAL TRIALS.

M Clavio[1*], S Aquino[1], P Minetto[1], M Bergamaschi[1], L Del Corso[1], E Balleari[1], M Miglino[1], E De Astis[1], L Canepa[1], F Galaverna[1], E Arboscello[1], L Mitscheunig[1], F Guolo[1], G Pastori[1], I Pierri[1], R Ghio[1], D Lovera[1], D Avenoso[1], M Gobbi[1]
[1]Clinical Hematology, IRCCS Ospedale S Martino - IST Genova, Genova, Italy

Background: In higher-risk patients with myelodysplastic syndromes (MDS), the DNA methyltransferase inhibitors produce responses in 20% to 30% of patients and azacitidine (AZA) has demonstrated a survival advantage when compared with conventional therapies. AZA is increasingly used in low-risk patients failing to respond to recombinant human erythropoietin (r-EPO) and in acute myeloid leukaemia patients (AML) with low marrow blast count or considered not fit for intensive chemotherapy.
Aims: We report a retrospective review on AZA treatment of MDS and AML patients in the common clinical practice of an Italian region (Liguria).
Methods: Of 67 patients who started azacitidine therapy only 46 patients received at least 4 courses of therapy, and were therefore considered evaluable for response and included in the study. Median age was 74 years (56-84), male/female ratio was 25/21. Nine patients (19%) had untreated AML with marrow blasts ranging from 25 to 41%. MDS patients had RA or RARS (n.7, 19%), AREB-1 (n. 13, 35%), AREB 2 (n. 15, 40%), other forms (n.2, 5%). In MDS patients the IPSS score was low / int-1 in 18 pts, int-2 / high in 13 pts, not assessed in 7 pts. Twenty-six patients had a transfusion-dependent anaemia and the median number of packed erythrocyte units transfused weekly was 1 (range 1-2). All low and int-1 risk MDS patients had transfusion dependent anaemia and were unresponsive to r-EPO.
Results: After a median of 8 courses (range 4-44) 26 patients (63%) achieved a haematological response (CR in 26%, PR in 24%, HI in6,5%) whereas 20 (43,5%) were unresponsive. According to diagnosis and IPSS score responders were 6 (66,6%) among AML patients (CR1, PR4, HI 1), 10 (55,5%) in low /int-1 risk MDS patients and 7 (54%) among int-2 / high risk MDS patients (CR4, PR 3). Response was achieved after a median of 5 (range 3-6), 3 (range 2-12) and 5 (range 1-12) AZA courses in AML, low/int-1 risk and int-2 / high risk MDS patients, respectively. Grade 1-2 myelotoxicity was commonly observed but no life threatening infections were reported. Eight-teen patients concomitantly received r-EPO therapy. Response lasted a median of 16 months (range 4-40) and median survival was 6 months in AML patients (4-9) and 23 months (6-48) in MDS patients.
Summary / Conclusion: These preliminary data confirm efficacy and feasibility of AZA therapy in the common clinical practice, for both AML and all risk MDS patients.

B1445

CLINICAL FEATURES AND ANALYSIS OF PROGNOSTIC RISK FACTORS OF 124 PATIENTS WITH MYELODYSPLASTIC SYNDROME

Y Lin[1*], C Wu[1]
[1]Dept of Hematology,Union Hospital Affiliated to Fujian Medical University, Fujian Insititute of Hematology, FUZHOU, China

Background: Myelodysplastic syndrome is a malignant clonal disease of hematopoietic stem cells, with the risk of eventually progress to acute leukemia. Large number of foreign clinical data analyzed and summarized the clinical features of MDS. But whether these features of domestic patients equally have, needing clinical data further confirming.
Aims: To gain more the understanding of myelodysplastic syndrome as they

occur in south China, a retrospective clinical analysis was conducted in patients diagnosed as MDS from January 2007 to October 2011 at our hospital Department of hematology.
Methods: Our country reviewers independently examined the bone marrow and peripheral blood smears of all the patients and classify the disease according to the WHO(2008) classification. There were a total of 117 eligible patients.
Results: The median age of the patients was 57.5 years (range17-94). The male:female ratio was 1.8:1. Twenty five percent of the patients were younger than 40 years□57.3% were younger than 60 years. The frequency of the WHO subtypes was RCUD 12.1 % , in which RA was 8.1% , RN 1.6 % , 2.4% in RT , RARS 4%, RCMD 38.7%, RAEB -1 20.2% , RAEB -2 23.4% , the MDS - u 1.6% , 5q - not statistics. Anemia was the most common symptom presenting in 70.3% of the patients. In the 31 patients in whom the cytogenetics in the bone marrow were analysed, 35.3% revealed abnormalities. Of these, trisomy 8 was the most common aberration, and monosomy 7 was the worst prognosis. Transfusions were the main therapeutic modality in 49.2% of the patients. The median survival of patients is 17.9 months. Fourteen point six percent of the patients had progressed to acute myelogenous leukemia (AML) with a median time to disease-progression of 5.6 months. Single factor derived from the KM survival analysis obtained age, gender, LDH , WBC , peripheral primitive cell count , bone marrow blast cell count , Plts , the Plt quality statistically significant .The Cox regression analysis revealed peripheral primitive cell count□the number of bone marrow blasts□LDH * age , and the PLT quality as the parameter significantly associated with survival and disease progression. The establishment of a new prognostic scoring system for domestic is the R- WPSS (domestic) , patients were divided into four groups , namely: the low risk group, risk group, risk group, very high-risk group; median survival times were as follows: 46□36 □12□3 months .
Summary / Conclusion: The median age of our MDS is 57.5 years, and domestic and Asian countries with a median age similar , but smaller than the United States and Europe more than 10 years. The reasons is may biological and environmental factors. Consistent with the proportion of gender of domestic data. The most common for hospitalising with the disease is lung infection (14.5%), chronic diseases are more common in hypertension and diabetes, respectively, 10.4% , 4%. Anemia is the most common symptoms (70.2%) , signs of liver and spleen and lymph nodes are rare. Trisomy 8 was the most common aberration, and monosomy 7 was the worst prognosis. The Cox regression analysis revealed peripheral primitive cell count□the number of bone marrow blasts□LDH * age , and the PLT quality is independent risk factor. The establishment of a new prognostic scoring system for domestic is the R- WPSS (domestic) , patients were divided into four groups , namely: the low risk group, median group, high group, very high-risk group; median survival times were as follows: 46□36□12□3 months.

OVERVIEW OF RUSSIAN PNH REGISTRY

I Lisukov[1*], A Kulagin[1], A Maschan[2], E Shilova[3], K Abdulkadyrov[3], A Zaritskiy[4], V Ivanova[5], Y Bogdanova[6], S Volkova[7], A Gavrilenko[8], T Kaporskaya [9], S Meresiy [10], T Schneider [11], S Yakupova [12], L Anchukova [13], B Bakirov [14], N Kosacheva [15], T Krinitsina [16], V Ustyantseva [17], Y Shatokhin [18], A Rumyantsev[2], B Afanasyev[1]
[1]Hematology & Transplantation, Raisa Gorbacheva Memorial Institute of Children, St Petersburg State Pavlov Medical University , St Petersburg, [2]Federal Research Center of Pediatric Hematology, Oncology & Immunology, Moscow, [3]Russian Research Institute of Hematology & Transfusology, [4]Federal Centers of Heart, Blood & Endocrinology, St Petersburg, [5]SP Botkin Municipal Clinical Hospital, Moscow, [6]Municipal Clinical Hospital #8, Barnaul, [7]Regional Hospital, Nighniy Novgorod, [8]Municipal Hospital #1, Cherepovets, [9]Regional Hospital, Irkutsk, [10]Clinical Medical Sanitary Hospital #1, Perm, [11]Regional Lelingrad Hospital, St Petersburg, [12]Kazan State Medical University, Kazan, [13]Municipal Regional Hospital, Vologda, [14]Bashkirian State Medical University, Ufa, [15]Municipal Regional Hospital, Perm, [16]Republic Clinical Hospital, Petrozavodsk, [17]Russian Railways Clinical Hospital, Chelyabinsk, [18]Rostov State Medical University, Rostov, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disease which can lead to life-threatening complications including thrombotic events (TE), chronic kidney disease (CKD) and pulmonary hypertension. Recently, the international PNH Registry has been established in Russia to assess disease burden and examine the natural history of PNH.
Aims: We aim to update the spectrum and natural history of the disease in Russia according to International PNH Interest Group Classification (Parker C et al, Blood 2005;106:3699-3709).
Methods: The international PNH Registry is a non-interventional, prospective, multicenter, observational study. Study populations: Russian part of international PNH Registry, patients with a confirmed diagnosis of PNH according to international guidelines. Demographics, clinical characteristic and medical history were stratified by PNH clone size and history of bone marrow disorders (BMD).
Results: As of February 2013, the international PNH Registry has enrolled 189 patients from Russia (Table).
Summary / Conclusion: Patients in the international PNH Registry enrolled from Russia represent a broad age range, clone size and degree of hemolysis, two-thirds having a history of BMD. History of TE, CKD and signs of chronic hemolysis were present in patients regardless of PNH clone size. The likelihood of TE was significantly higher in patients with PNH clones ≥20%. Data are essential for the design of treatment trials and for planning services for PNH patients in Russia.

Table. Patient characteristics and symptoms.

Demographics	All patients	Classic PNH	BMD-PNH	BMD-Subclinical PNH
Total patients, n	189	39	97	53
Age at enrollment (years), median	30	35	29	27
Gender female, n (%)	112 (59.3)	28 (71.8)	60 (61.9)	24 (45.3)
Time to diagnosis (months), median	17.3	51.2	10.1	27.9
Clinical characteristics				
Granulocytes clones (%) at enrollment, median	7.4	93.0	16.6	0.2
LDH ratio x ULN at enrollment, mean ± SD, median	2.6 ± 3.2 1.1	6.3 ± 3.5 6.3	2.6 ± 3.1 1.3	0.8 ± 0.2 0.8
History of TE, n (%)	9 (4.8)	4 (10.5)	4 (4.2)	1 (1.9)
CKD at enrollment, n (%)	42 (22.5)	14 (36.8)	16 (16.7)	12 (22.6)
Pulmonary hypertension at enrollment, n (%)	5 (2.7)	3 (7.9)	2 (2.1)	0 (0)
Symptoms stratified by PNH granulocyte clone size				
			<20%	≥20%
Total patients, n			104	80
History of TE at enrollment, n (%)			1 (1.0%)	8 (10%)
CKD at enrollment, n (%)			20 (19.4)	22 (27.5)
Pulmonary hypertension at enrollment, n (%)			0 (0)	5 (6.3)
Lactate Dehydrogenase (LDH) ratio x UNL, mean ± SD (median)			1.1 ± 1.2 (0.8)	4.8 ± 3.8 (4.0)

B1447
ACQUIRED APLASTIC ANEMIA : DIAGNOSTIC AND THERAPEUTIC ASPECTS

H Bellaaj[1*], W Kridis[1], A Chaabouni[1], S Hdiji[1], A Khabir[2], H Rekik[3], M Mdhaffer[1], O Kassar[1], M Ghorbel[1], M Elloumi[1]
[1]Department of hematology , Hedi chaker hospital, [2]Department of pathology, Habib bourguiba hospital, [3]Regional center of blood transfusion, sfax, Tunisia

Background: Aplastic Anemia (AA) is a quantitative marrow failure resulting in pancytopenia. The prognosis depends on the risk of infection and bleeding.Thebone marrow allograftis the best curative treatment. In Tunisia, this technique has been available since 1998 at the National Centre for bone marrow transplantation in Tunis.
Aims: The purpose of our study is to investigate the diagnostic, therapeutic and evolutive characteristics of patients presenting with AA followed in hematology department of Sfax.
Methods: This is a retrospective study concerned with all cases of acquired AA, diagnosed in hematology department of Sfax, during a period of 13 years (between January 1999 and December 2011). The diagnostic confirmation of AA is based on the bone marrow biopsy for all patients. The etiological assessment involved: karyotype on blood and on marrow, liver function tests, viral serology and Ham Dacia test and withflow cytometry. For the severity of the disease we adopted the criteria of Camitta. The proposed treatment was bone marrow allograft (indicated for all patients younger than 45 years with an identical HLA donor), immunosuppressive therapy (cyclosporine+/- antithymocyte globulin: ATG) and / or androgenic and symptomatic treatment.
Results: We collected 92 patients; the mean age was 26 years, ranging from 2 to 87 years. The sex ratio was 1.42%. Sixty-five percent of patients had severe form and 35% moderate form. AA was idiopathic in 78%, post-hepatitic in 16%, toxic in 4% and associated with paroxysmal nocturnal hemoglobinuria in 2%. The allograft was indicated for 55 patients. Thirty-three patients (60%) had a compatible HLA donor. Among them, 82% had a bone marrow allograft. The graft was rejected, due to unfavorable economic conditions in 4 patients and a genetic disease of the donor in one case. In total: 27 among 92 patients were grafted (29%). Thirty seven patients (34%) were treated by immunosuppressive therapy with an objective response up to 37%. Androgen and symptomatic treatment were used respectively in 20and 8 patients (8% and 18% respectively). The 5-year survival was 87% for allograft patients and 36% for patients treated with immunosuppressive therapy.
Summary / Conclusion: The diagnostic and the epidemiological aspects of AA in our series are similar to those seen in the literature (rare disease, young population, predominance of severe and idiopathic forms). Compatible HLA donor was found in 2/3 of cases which is higher than the western series rate, due to the important number of families in our country. Thebone marrow allograftis the potentially curative treatment in our series as well as in the literature. But, objective response was found in 1/3 of our cases after immunosuppressive therapy because of the difficulty of using the ATG in some patients.

B1448

COMBINED OVEREXPRESSION OF WT1 AND BAALC GENES MAY PREDICT AML EVOLUTION IN MDS PATIENTS

M Clavio[1*], M Bergamaschi[1], N Colombo[1], R Grasso[1], L Del Corso[1], S Gandolfo[1], A Bellodi[1], C Ghiggi[1], C Dellepiane[1], L Canepa[1], A Dominietto[1], S Favorini[1], E Arboscello[1], I Pierri[1], L Mitscheunig[1], S Aquino[1], P Minetto[1], E De Astis[1], G Pastori[1], M Miglino[1], M Gobbi[1]
[1]Clinical Hematology, IRCCS Ospedale S Martino - IST Genova, Genova, Italy

Background: Current international Guidelines of Myelodysplastic Syndromes (MDS) indicate that management's strategy of MDS patients should be based on prognostic scoring systems such as the International Prognostic Score System (IPSS). Most used MDS scoring systems do not include biological parameters that are potentially able to influence the clinical course.
Aims: Our goal was to verify if biological markers utilized in acute myeloid leukemia may have any predictive role in high and low risk MDS patients.
Methods: From September 2007 to December 2012 we analyzed 54 MDS patients [40 low-intermediate-1 (LR) and 14 intermediate 2-high IPSS score (HR)] observed in our Hematology department. FLT3 gene ITD, NPM1 gene mutations, WT1 and BAALC expression were evaluated. Abnormal karyotype was observed in 8 cases (3 high and 5 intermediate risk karyotypes). Nineteen patients were treated with azacitidine plus erythropoietin, 2 with chemotherapy , 18 with hematopoietic growth factors only. Three patients underwent allogeneic bone marrow transplantation. The remaining patients received supportive care alone.
Results: A molecular analysis was performed at diagnosis on bone marrow samples in all the patients. No patients showed either FLT3-ITD or NPM mutations. WT1 overexpression was observed in 9 patients (2 LR, 7 HR), BAALC overexpression was present in 15 patients (3 LR, 12 HR). Neither WT1 nor BAALC overexpression were related to cytogenetic abnormalities. We observed a simultaneous overexpression of WT1 and BAALC genes in 8 patients. All these patients had been classified, at diagnosis, as high risk MDS with a IPSS score ≥ 1.5. In all these cases an evolution to acute myeloid leukemia was reported at a median follow up period of 6 months (range 2-9). Among 31 low risk patients only 2 patients evolved to AML. Both these patients had an aspecific diagnostic molecular profile. Three more cases showed an isolated overexpression of WT1 and one of these experienced an evolution. Two are still leukemia free after a follow-up period of 1 year and 5 years respectively. An isolated BAALC overexpression was observed in one patient who had a disease evolution.
Summary / Conclusion: Thank to this analysis we can conclude that the combined more than the isolate overexpression of WT1 and BAALC may be associated to a MDS evolution. The prognostic value of this molecular pattern may overcome that of IPSS score. We suggest that molecular evaluation at diagnosis of MDS should include WT1 and BAALC evaluation whereas there is no reason to perform FLT3 and NPM analysis in this setting.

B1449

RABBIT ANTITHYMOCYTE GLOBULIN IN CHILDHOOD ACQUIRED SEVERE APLASTIC ANEMIA

D Karapinar[1], N Karadas[1], Y Ay[1], M Akin[1], C Balkan[1*], Y Aydinok[1], K Kavakli[1]
[1]Pediatric Hematology, Ege University Children's Hospital, Izmir, Turkey

Background: Acquired severe aplastic anemia (SAA) is a life threatening bone marrow failure characterized by pancytopenia and hypocellular bone marrow. Matched sibling donor is not available for majority of the patients and many children receive immunosuppressive therapy (IST). Although horse anti-thymocyte globulin (ATG) is usually included as a first line treatment, it is not available in Turkey and all the patients received rabbit ATG.
Aims: In this study, we wanted to evaluate the efficacy of rabbit ATG in children with acquired SAA.
Methods: We retrospectively reviewed the medical records of children with SAA who were treated with rabbit ATG, cyclosporine, G-CSF and short term prednisone between 2006 and 2012.
Results: Fifteen children with very SAA (9 boys and 6 girls) aged between 1.5 and 17 years received rabbit ATG as a first line treatment in our institution during six-year period. Only one patient showed partial response and the others failed to achieve any response at3,6,12 months of the first course of IST. Eight patients received second course of ATG. While rabbit ATG was again used at the same dosage in 3 patients, 5 patients received horse ATG. None of these 3 patients showed complete or partial response to the second course of rabbit ATG. Two patients showed partial response to the treatment of horse ATG while the remaining 3 showed no response. Three patients received the third course of rabbit ATG, however they did not show any response. Invasive fungal infection which observed in 60% of the patients was the major reason of death.
Summary / Conclusion: Six-year experience with rabbit ATG has led us to suggest that this option is not proper as the first line treatment in children with very SAA. Fungal infections are very frequent and complete response is very low.

B1450

PROGNOSTIC MARKERS FOR MYELODYSPLASTIC SYNDROME

O Boyko[1*], O Danysh[1], A Lukjanova[1], O Zotova[1], T Horodyska[1], Y Vyhovska[1], Z Maslyak[1], K Kotlyarchuk[1]
[1]SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: Along with certain progress achieved in treatment of myelodysplastic syndrome (MDS) during recent years, issue of accurate prognostic stratification of this disease remains an important task.
Aims: This study was intended to determine clinical parameters, easily accessible, which could be used for evaluation of myelodysplastic syndrome disease course and prognosis of the risk of its transformation into acute leukemia (AL).
Methods: A group of 108 patients with MDS (64 with refractory anemia (RA), 6 – with refractory anemia with ringed sideroblasts (RARS), 28 – with refractory anemia with excess of blasts (RAEB) and 10 – with chronic myelomonocytic leukemia (CMML)) were monitored for their disease course and rate of transformation to acute leukemia. Clinical, morphological, cytogenetic and statistical methods were used within the study.
Results: Among the investigated patients transformation into AL was detected in 28 of the cases. The highest rate of transformation was revealed in CMML and RAEB (40% and 32% respectively) and the lowest – in RA (19%). Retrospective analysis of peripheral blood counts, bone marrow aspirate and cytogenetics in patients with transformation showed that anemia, neutropenia and thrombocytopenia should be considered as prognostically unfavorable. However, the adverse influence on MDS course appeared to depend not only on severity of cytopenia but also on its type (uni-, bi- or trilinear). Accordingly, patients with severe pancytopenia had more aggressive disease course and shorter median time to transformation (8,5±3,65 months), as compared to subjects with bi- or unilinear cytopenia transforming after 13,5±1,45 months and 14,0±2,41 months respectively. Patients whose bone marrow blast counts exceeded 10% (RAEB) developed disease transformation in less than 12 months whereas no dependence between bone marrow blast counts and time to transformation was revealed in RA patients. Another factor to influence disease course prognosis was bone marrow cellularity. The majority of patients who had transformed into AL showed increased (54% of investigated group) and normal (25%) bone marrow cellularity. On the contrary patients with hypoplastic marrow had more favorable disease course and responded well to immunosuppressive treatment with cyclosporine A. This fact could be partially explained by the level of cytokines produced by microenvironment cells and playing important role in disease pathogenesis. In about a half of the patients with disease transformation cytogenetic abnormalities were detected in bone marrow cells already at the first diagnosis of MDS. Leukemia developed faster in these patients as compared to those with normal karyotype. Results of cytogenetics performed at different time points suggested that MDS transformation was preceded by evolvement of new cytogenetic clones, namely additional chromosome8, chromosome 5 deletion and polyploidy, which in turn can also serve as prognostic markers of MDS evolution. Among the investigated patients the disease was more likely to transform in women whereas the very diagnosis of MDS was more frequent in men. Age of more than 60 years can also be considered as prognostically adverse since the rate of MDS transformation in these patients exceeded 65%. Higher frequency of AL development was detected also for transfusion dependent MDS patients.
Summary / Conclusion: Collected data support suggestion that MDS transformation is a multi-step process depending on a number of factors. The obtained results suggest that prognosis of MDS transformation into AL can be influenced not only by laboratory parameters outlined within international prognostic scoring system (IPSS), but also by bone marrow cellularity, age, gender and transfusion dependency status of the patients.

B1451

MONITORING OF THE CYTOGENETIC ALTERATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA/MYELODYSPLASTIC SYNDROME TREATED WITH AZACITIDINE

B De Gusmao[1*], A Campeny[1], E Perez-Persona[1], I Oiartzabal[1], M Ardanaz[1], M Menchaca[1], A Mendizabal[1], J Wong[1], A Pereda[1], J de Castro[1]
[1]Department of Hematology, Hospital Universitario de Álava, Vitoria - Gasteiz, Spain

Background: After the AZA-001 study (Fenoux et.al, ASH/2007) azacitidine has become a standard of treatment for patients with MDS and AML (20-30% blasts in bone marrow) included risk cytogenetic, with higher rates of response and survival. Hellström-Lindberg et.al (ASCO/2008) stated that there is no relationship between pretreatment and worsening of cytogenetics in patients who evolved to AML.
Aims: Determine the effect of treatment with azacitidine (75 mg/m2/day x 5 days) on the cytogenetic alterations and the response according to the IWG (Cheson 2006) in patients with MDS and AML who have received at least 4 cycles of treatment.
Methods: we have reviewed the patients who had received at least 4 cycles of azacitidine in first line, between May 2009 and December 2012. They were

14 patients (9 men / 5 women) with a median age 76.5 years (range 40-84). 7patients with secondary-AML,4 RCMD (3 IPSS low and 1 IPSS intermediate-1), 2 RAEB (1 RAEB and 1 RAEB2, both with IPSS intermediate-2) and 1 patient with CMML-2 (WHO/2008). In the diagnostics, 50% of patients had > 20% of blasts in the bone marrow study. 9 (64.2%) had normal karyotype, 2 (14.2%) complex karyotype, 1 patient with monosomy7, 1 patient with (5) + Trisomy 8 and 1 patient with normal karyotype but with molecular positive AML-ETO study. Bone marrow aspirate with cytological, cytogenetic and molecular studies were made after 4-6 cycles and the disease progression.

Results: Median of 8.5 (range 5-19) cycles of azacitidine administrated, after 4-6 cycles, 85.8% of our patients hadat least stable disease(4 SD; 4 SD with hematologic improviment; 2 CR, 1 CR with molecular persistence and 1 PR). No patient with less than 20% blasts had progressed after the 4-6 cycle and 42.9% of those who had more than 20% blasts to the Diagnostics (AML, WHO 2008) presented cytologic improvement (< 20% blasts) in the reassessment (P<0.035). 57.1% of patients achieved transfusion independence. This wasn´t related to the quality of the response, the number of blasts in the diagnosis (P=0.999) nor to the 4 - 6th month (P=0.999) and neither is related to transfusion independence with survival (P=0,416). To assess cytogenetic in revaluation changes: 1 patient (7.1%) presented a new disturbance in the revaluation after 4-6 cycles, disappearing in the progression of the disease and 2 patients (14.2%) presented new cytogenetic alterations at the time of the progression. All of them without relevance in the progression of the disease. Median overall progression-free survival was 19.1 (95% CI 10,5 – 25,5) months in patients < 20% of blasts to the diagnostic vs 7.1(95% CI2,7 – 9,3) months in patient > 20% blasts in the bone marrow to the diagnostics (P=0.005), undetermined impact on the small subset of patient AML to have < 20% blasts after reassement. Only 1 patient remains in treatment with azacitidine and the treatment has been suspended in 8 (57.1%) patients because of the progression (1 submitted to the allo-BMT program), 3 patients due to the lack of response to the treatment and 2 patientes by éxitus of non-related cause to the disease.

Summary / Conclusion: Our study confirms the low incidence of the appearance of new alterations cytogenetic described by Hellström-Lindberg (ASCO/2008) following use of azacitidine.

Azacitidine 75 mg/m2 x 5 days has a high rate of response (85.6%), with a high rate of progression-free survival, including patients with a high cytogenetic risk and secondary AML similar data from the AZA-001 study.

It has been detected a high rate of transfusion independence (57.1%) independent of the quality of the response to treatment and without impact on progression-free survival.

B1452

SMALL IMPACT OF NEW CYTOGENETIC SCORE SYSTEM FOR MYELODISPLASTIC SYNDROMES ON CLINICAL PRACTICE

M Calbacho[1*], S Gómez-Rojas[1], M Talavera[2], A Vallés[1], I Saavedra[1], J Rodríguez-Gambarte[1], I Lucea[1], J López-Jiménez[1]
[1]Hematology, [2]Cytogenetic, Hospital Ramón y Cajal, Madrid, Spain

Background: A new comprehensive cytogenetic scoring system in myelodysplastic syndromes (MDS) was recently proposed with the major goal of defining the prognostic impact of rare, single cytogenetic abnormalities not included at the current Prognostic Scoring System (IPSS) model.Cytogenetic abnormalities are important in determining prognosis in MDS. 50% of this patients display clonal chromosome abnormalities. The availability of new therapeutic options for low and high risk MDS targeted against entities characterized by specific chromosome abnormalities underlines the important role of cytogenetics for the clinical.

Aims: Analyse differences between former and new cytogenetic classifications in 49 consecutive MDS patients in a single centre from January 2011 to September 2012.

Methods: Bone marrow samples were obtained from 49 consecutive MDS patients. 38 were new diagnoses (78%) and 11 (22%) were patients already under follow up. Sex: Male: 28, female: 21. Median age: 72 years. WHO diagnoses: CMML: 9 (18%), MDS with del5q: 7 (14%), RCUD: 8 (16%), RCMD: 13% (27%), RAEB 1: 4 (8%), RAEB 2: 6 (12%), t-MN: 2 (4%). Cytogenetic study was performed to all marrow aspirates. Results were excluded if less than 20 metaphases were analyzed. FISH analysis for chromosomes5,7,8, 20 were available in 35 patients.

Cytogenetic results were available in 29 (59%) and not available in 20 (41%): normal: 20/29 (69%), abnormal 9/29 (31%). Abnormalities: del5q: 4 (44%), trisomy 8: 3 (33%), trisomy 21:1 (11%), del7q: 1 (11%), complex karyotype: 0.

FISH anylisis: normal: 22/35 (63%), abnormal: 13/35 (37%). Abnormalities: del5q: 7/13 (54%), del7q: 3/13 (23%), trisomy 8: 3/13 (23%).

Results: No differences were found between former cytogenetic risk classification and the new one at any category: Good risk (83% vs 82%), Intermediate risk (10% vs 14%), Poor risk (7% vs 3%). No very good nor very poor patients were detected. Four patients with no previously cytogenetic result available obtained prognostic abnormalities after FISH analysis (20%).

Summary / Conclusion: FISH analysis is able to find prognostic genetic abnormalities in up to 20% of previously not evaluable samples with karyotyping. Overall impact of the new cytogenetic classification is small in daily clinical practice. Molecular testing for relevant mutations in MDS will be probably a more useful tool.

B1453

COMBINED USE OF AZACITIDINE (AZA) & RECOMBINANT HUMAN ERYTHROPOIETIN (RHUEPO) INDUCES RAPID HAEMATOLOGICAL RESPONSE WITHOUT AFFECTING RESPONSE RATE IN HIGHER RISK MDS: RESULTS OF A RETROSPECTIVE STUDY

V Papadopoulos[1], V Papageorgiou[1], A Karagianni[1*], E Georgiou[1], S Effraimidou[1], K Kokoviadou[1], C Kartsios[1], A Kioumi[1]
[1]Hematology Department, Papageorgiou General Hospital, Thessaloniki, Greece

Background: AZA, a DNA hypomethylating agent, provides 50-60% responses in higher-risk MDS after administration of 6 courses of treatment. Recent laboratory data suggests that demethylation with AZA upregulates EPO-receptor mRNA (Wallach, 2009). AZA might also affect several genes involved in cell cycle, metabolism and signal transduction which are down-regulated in bone marrow erythroid cells in MDS patients non-responsive to rHuEPO.

Aims: To evaluate preliminary data for the combined use of AZA and rHuEPO in MDS patients.

Methods: We explored retrospectively the efficacy of the AZA-rHuEPO combination in a small cohort of 10 (M/F: 5/5) patients (pts) with a median age of 75(67-83) years. Diagnosis (WHO classification) was: RAEB-2:6, CMML:2, RAEB-1: 1 and acute myeloid leukemia: 1; IPSS was: int-2 in 8/10 and high in 2/10 pts. Median time from diagnosis was 6(1-31) months. 9/10 pts were transfusion dependent, 8/10 were refractory to previous rHuEPO administration, while 2/10 pts were not previously treated with rHuEPO but their serum EPO levels at diagnosis were >200 U/L. Patients were given AZA at FDA/EMEA-approved schedule (75 mg/m^2/d x7d /4-weekly) initially for 6 courses and continued if response was obtained. rHuEPO (40,000IU/week) was given until achievement of steady Hb level >10.5 g/dL or until AZA discontinuation.

Results: Median follow-up was 21.5 (range 2-45) months. Patients received a median of 12 cycles (range 2-33) of AZA; half the patients received 10 or more courses. The median time on rHuEPO was 20.5 weeks (3.71-34) after AZA start. Best response (IWG 2006 criteria) was CR in 1/10 pts (RAEB-2), marrow CR in 1/10 pts (AML), and stable disease with hematological improvement (HI) in 4/10 pts (RAEB-1:1, RAEB-2:2, CMML: 1) leading to an overall response rate of 60%. Transfusion independence was achieved after a median of 32.5 (range 3-62) days and it lasted for a median time of 10.15 months (range 4-40.8). Three patients (33%) were transfusion independent for more than 2 years. Median progression-free survival (PFS) was 15.3 months for those who responded to AZA therapy versus 4.2 months for the non-responders, P=0.003. Median overall survival (OS) was 29.5 months for responders versus 15.4 months for non-responders, P=0.23. The estimated 2-year OS was 62.5% for responders.

Summary / Conclusion: Our data suggests that the combination of AZA and rHuEPO can produce rapidly a haematological response even in patients previously resistant to rHuEPO. In our cohort, response to AZA was not affected by addition of rHuEPO. This highlights the potential for rHuEPO to be used as supportive treatment in patients treated with AZA in need of transfusions.

B1454

AZACITIDINE: AN ALTERNATIVE TREATMENT REGIMEN FOR ELDERLY HIGH-RISK MYELODYSPLASTIC PATIENTS

R Ramakrishna[1*], W Alexander[1], K Sarathy[1]
[1]Southern Haematology and Cancer Research Institute, Wollongong, Australia

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of disorders that manifest bone marrow failure with risk of life-threatening infections and bleeding. MDS occurs with a frequency of 15-50 new cases per 100,000 per year. Around a third of the patients progress to acute myeloid leukaemia (AML). However, the majority of mortality and morbidity relates to infections and bleeding complications. In the majority of patients, the standard care is supported in the form of blood and platelet transfusions, along with growth factors such as G-CSF and antibiotic therapy. Methyltransferase inhibitors (MTI), such as Azacitidine and related analogues are useful in treating MDS. Potentially reversing slicing of genes, such as CDKN2B by parameter methylation has been shown to occur in MDS and increases risk of disease progression. The MTIs have demethylating properties proven both *in vivo* and vitro and hence are useful in treating patients with MDS. Patients with AML have also been treated with Azacitidine intravenously with varying regimens.

The majority of the toxicity related to Azacitidine was myelosuppression, fatigue, and myalgia, along with gastrointestinal symptoms of nausea and vomiting. Injection site erthyrema is also common. Hence tolerance and compliance are a concern.

Aims: Altering the treatment regime of Azacitidine to improve compliance and reduce adverse events without compromising response rate for elderly patients (65+).

Methods: Sixteen (16) patients were enrolled over an 18 month period, in our study of modified subcutaneous Azacitidine therapy to treat high-risk MDS/AML. Age ranged between 67 and 86 with a median of 77. Follow-up, after the therapy initiation, ranged between 6 months and 36 months. All patients have completed at least a trial of four months of therapy. Azacitidine was given at 75 mgs/m^2, three times per week for two consecutive weeks per month (Monday,

Wednesday, and Friday each week). Myelosuppression, as well as overall tolerance and side effect profile was assessed.
Results: In this cohort, 93.75% (15) showed haematological improvement in at least one cytopenia. Decreased transfusion requirement was seen in 75% (12). No haematological improvement was seen in 6.25% (1). Mean survival at 18 months was 56.25%. There has been no grade II, or III complications. Results are summarised in Figure 1 (to be presented).
Summary / Conclusion: In our experience, Azacitidine therapy given subcutaneously three times per week for 2 weeks each month is extremely well tolerated and has good efficacy in terms of disease control with an overall response rate of 75%, and mean survival at 17 months of 56.25%. This is comparable to results achieved in trials with different regimens[1-2]. Therapy was initiated as an outpatient and did not require regular hospitalisations. Symptomatically, they have been able to cope quite well with no Grade II or III complications and decreased transfusion requirement.

B1455
COMPARATIVE EFFICACY OF HOMOHARRINGTONINE PLUS CYTARABINE AND DECITABINE IN PATIENTS WITH MDS/AML
B Xu[1*], Y Liu[1], F Chen[1], P Shi[1], X Guo[1], J Zha[1], Z Fan[1], F Huang[1], S Zhou[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Myelodysplastic syndrome (MDS) is a malignant hematological disease that comprises a heterogeneous group of clonal hematopoietic stem and progenitor cell disorders, with peripheral cytopenias, bone marrow hypercellularity, high-risk of evolving into acute myeloid leukemia (AML). MDS/AML is a special refractory and palindromic AML characterized by poor therapeutic effects and low complete response rate, as well as high treatment-related complications and mortality. Patients with MDS/AML are often elders and represent more intolerance to routine or intensive chemotherapies. Homoharringtonine, an alkaloid found as the major active component in Chinese plants cephatotaxus fortuneif. , has been widely used in AML since the 1970s in China. Decitabine, a hypomethylating agent, is active and has been approved for the treatment of myelodysplastic syndrome (MDS) in recent years.
Aims: In order to compare the efficacy, toxicity and long-term prognosis of HA (Homoharringtonine plus cytarabine) with Decitabine in MDS/AML.
Methods: A total of 26 MDS/AML patients consisting of 14 males and 12 females were included in this study. They were randomly assigned to receive either HA (HHT 4mg m^{-2} d^{-1} ,d1-3; Ara-C 100 m^{-2} d^{-1}, d1-7) or decitabine (20 mg m^{-2} d^{-1}, d1-5). The effects were evaluated by hazard ratios (HR) for overall survival (OS), progression-free survival (PFS) and freedom from first progression. Relative risks were used to analyse complete response rate, total response rate, treatment-related mortality and adverse events. A Log-rank test was used in survival analysis, and a Chi-square test was performed for other outcomes.
Results: The complete remission (CR) rate in HA arm according to MDS/AML criteria was 33% and 36% in decitabine arm (*P*>0.05). HA group had no lower total response rate than Decitabine group(53% *versus* 64%, *P*>0.05). The freedom from first progression in chemotherapy with HA and decitabine was 20% and 18% (*P*>0.05), respectively. PFS was not statistically longer for two comparators with HR was 0.41 (95% confidence interval (CI) 0.09722 to 1.740).There was no statistical difference in OS between the HA group and decitabine group with HR was 0.799 (95% CI 0.2992 to 2.133); median survival: 300 days vs 291 days (*P*>0.05, 95% confidence interval (CI) 0.6165 to 1.445). The treatment-related mortality was 13% with HA regimen versus 18% with decitabine at 3 weeks (*P*>0.05) and 40% with HA regiment versus 18% with decitabine at 3 months (*P*>0.05). The incidence of haematological toxicities and liver function lesion of WHO grade III or IV were not higher in the HA group than that in the decitabine group (*P*>0.05). The total secondary infection rates in all sections of chemotherapies were 58% and 19% (*P* =0.005) in the two groups, respectively. Secondary infection rate was significantly lower in the decitabine group than that in the HA group.
Summary / Conclusion: This study showed that Homoharringtonine combined with cytarabine regiment in treating MDS/AML had a similar therapeutic effect and long-term benefit with decitabine, both regiments were associated with relatively safe and effective outcomes in MDS/AML patients. However, HA regiment showed a higher risk of secondary infection than decitabine. Longer follow-up and further studies will prospectively evaluate the results of HA regiment versus decitabine in this setting.

B1456
LIPOSOMAL IRON IS BETTER THAN IRON SULFATE IN LOW-RISK MYELODYSPLASTIC SYNDROMES (LR-MDS) WITH MILD ANEMIA. MONOCERNTRIC STUDY.
G Giordano[1*], s vittorio[2], f d'amico[3], a d'aveta [1], m de maria[1], g sticca[1]
[1]oncology, Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [2]catholic university, rome, [3]Foundation "J. Paul II" - Campobasso - Italy, Campobasso, Italy

Background: LR-MDS frequently shows a chronic inflammatory status, ferritin high values and impaired capacity of iron absorption and utilization. Liposome has a described anti-inflammatory effect and transports its content directly in blood, beyond gastric and enteric wall.
Aims: Aim of this study is to verify if liposomal iron support in refractory anemia (RA) and refractory cytopenia with multilineage dysplasia (RCMD) with mild anemia is safe and effective in increasing hemoglobin level.
Methods: In group A 7 patients (5RCMD and 2RA), with normal cytogenetics, M/F:4/3, median age 65 years (R64-75), Hb 10.7 g/dl (R10-11.5), saturation of iron binding capacity > 20%, with a median ferritin level of 480 ng/ml (R380-550), ESR 28 mm/1st hour (R20-32), CRP 6 mg/l (R4-7), normal B12 and folate, received liposomal iron 30 mg/day orally for 3 months.
In group B 7 patients (3RCMD and 4RA), with normal cytogenetics, M/F:5/2, median age 63 years (R62-70), Hb 11 g/dl (R10.8-12), saturation of iron binding capacity > 20%, with a median ferritin level of 430 ng/ml (R370-580), median ESR 30 mm/1st hour (R18-38), median CRP 7 mg/l (R5-7), normal B12 and folate, received support with iron sulfate 105 mg orally/day.
Results: Group A showed a median hemoglobin increase of 1.5 g/dl (R0-2), a ferritin decrease to a median of 160 ng/ml (R 100-250), a ESR decrease to a median value of 15 mm/1st hour (R 8-20) and a median CRP 3 mg/l (R2-5).
In group B no significative increase of hemoglobin or decrease of ferritin, ESR and CRP were recorded. 2 patients showed hepygastralgia, 2 stipsis, 2 diarrohea.
Summary / Conclusion: Liposomial iron is safe, effective, well tolerated, effective in increase hemoglobin level and reduce inflammatory markers in low-risk MDS.

B1457
EXPERIENCE WITH 5-AZACYTIDINE IN EAST KENT: WHEN TO QUIT?
I Dharmasena[1], K Lang[1*], M Mohammed[1], J Lindsay[1], K Saied[1], V Ratnayake[1], C Pocock[1]
[1]Haematology, East Kent Hospital Trust, Canterbury, UK, Canterbury, United Kingdom

Background: 5-Azacytidine is a DNA hypomethylating agent which has recently been licensed for the treatment of high-risk myelodysplastic syndrome. It was subsequently approved by NICE in the UK with a significant financial impact on drug budgets, as its administration is continuous in responding patients until intolerance or loss of response. The recommendation from the manufacturers is for at least six cycles to be administered before stopping for lack of efficacy.
Aims: This analysis was performed to identify non-responders as early as possible to quit unproductive 5-Azacytidine therapy in order to reduce unnecessary expense and visits.
Methods: 26 patients with high-risk MDS were treated with 5-Azacytidine between Jan 2009 and July 2012 in EKHT and respectively analysed. To enter the analysis patients needed to have completed 6 cycles of 5-Azacytidine or suffered disease progression prior to this. The response was assessed according to the IWG criteria for MDS.
Results: Eight out of twenty six patients achieved a major response lasting at least 6 months. Six of these patients achieved a major response prior to commencing cycle 3 and the other two patients, whilst not achieving a major response, had improvement in platelet count. No patient who had failed to show any response prior to the 3rd cycle went on to achieve a major response.
Summary / Conclusion: We conclude that response at the end of the 2nd cycle predicts the long term outcome with 5-Azacytidine therapy in high-risk MDS. As a result of this audit local practice is now as follows: Start 5-Azacytidine at 75mg/m^2 d5+2+2 and assess after two cycles If no response – stop If

responding continue for a further 4 cycles and reassess after cycle 6 If borderline response continue for a further 2 cycles and reassess If patient reaches cycle6, and is still responding, convert to 105mg/m^2 d1-5 (max 200mg)

B1458

LENALIDOMIDE TREATMENT IN 20 PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS). MULTICENTER REGISTRY

B Arrizabalaga[1], R Del Orbe[1*], M Zamora[2], M Ardanaz[3], J Arguiñano[4], M Sirvent[5], L Atucha[6], J Atucha[7], A Insunza[8], C Montes[8], A Campeny[3]
[1]Hematology, Hospital Universitario Cruces, [2]Hematology, University Hospital Cruces , Barakaldo, [3]Hematology, Hospital Universitario de Álava-Txagorritxu, Vitoria-Gasteiz, [4]Hematology, Complejo Hospitalario de Navarra, Pamplona, [5]Hematology, Hospital Universitario Donostia, San Sebastián, [6]Hematology, Hospital Galdakao-Usansolo, Galdakao, [7]Hematology, Hospital Universitario Basurto, Bilbao, [8]Hematology, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Lenalidomide is a drug approved by the FDA for the treatment of low risk MDS with associated 5q deletion and transfusion dependence. In Europe, its approval is being studied by the EMEA and its prescription is usually made respecting the approved indication in the United States. Use of Lenalidomide presents controversial issues in both the timing of its onset, and maintenance if complete remission is achieved.
Aims: To evaluate the use of Lenalidomide in MDS in the clinical practice of several hospitals in our geographic area, in order to analyze the results.
Methods: Between July 2007 and January 2013, we performed a multicentre and retrospective registry, which was carried out in seven hospitals from northern Spain. Data was collected from patients diagnosed with MDS, treated with Lenalidomide. Information for the karyotype at diagnosis and subsequent evaluations was included. Similarly we obtained demographic data, risk stratification, transfusion-dependence and response to treatment.
Demographic data, WHO classification and risk prognosis scores are listed in Table I. Karyotype / cytogenetics: 15/20 patients (75%) had deletion 5q, of which 3 had other abnormalities (2 had the V617F JAK-2 gene mutation and one patient was a carrier of the translocation t (2; 11)(p21: q23)).

Table I.	
Patients	20 (13 female/7 male)
Age	Mean 69.15 (range 50-78)
WHO classification	RARS 4/20 (20%) RCMD 4/20 (20%) RAEB-1 2/20 (10%) RAEB-2 1/20 (5%) MDS 5q deletion 8/20 (40%) Unclassifiable MDS 1/20 (5%)
IPSS	Low-risk 14/20 (70%) Int-1 5/20 (25%) Int-2 1/20 (5%)
WPSS	Very-low risk 8/20 (40%) Low risk 7/20 (35%) Intermediate 3/20 (15%) High risk 1/20 (5%) Very-high risk 1/20 (5%)

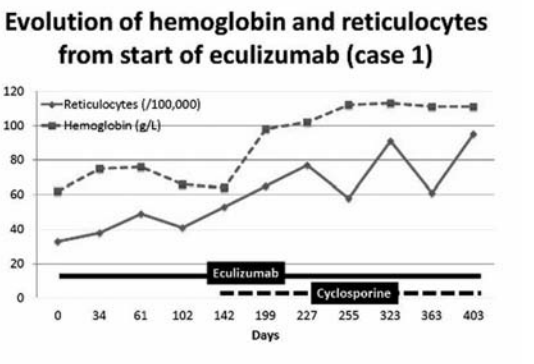
Results: Response to treatment: 65% of the patients (13/20) achieved complete hematological response in a median time of 136 days (31-396), equivalent to 5 treatment cycles of 21 days of Lenalidomide 10mg/day. Of these only one patient had no 5q deletion. In the group of patients showing no hematological response (7/20, 35%), we observed that one of them was the patient presenting a 5q deletion and translocation t (2; 11) (p21: q23), while the rest of the group lacked the 5q deletion. Cytogenetic remission (CyR) was evaluated in 10 patients (50% of cases), noticing that 5 of them (4 with deletion 5q, and 1 non-5q) showed complete CyR (defined as normal karyotype and/or 0% of 5q - by FISH). The average time to reach complete CyR was 304.8 days (range 123-518). In 2 patients, we found partial CyR and 3 patients there was no response, of which 2 showed increased percentage of 5q- clone (90 to 92%, and 32 to 74%). We analyzed the relationship between the percentage of mitosis 5q- and the time required to reach the complete CyR (Pearson correlation). As a result we observed that the higher percetage of the 5q- clone was, the longer it took the patient to reach complete CyR (p: 0.44). Discontinuation of treatment: Lenalidomide was suspended in 11/20 patients (55%): 3 patients due to no answer, 2 patients due to disease progression, 2 patients due to adverse events, and 4 patients due to the physician's decision since they had achieved complete CyR. The 4 latter patients had received Lenalidomide on average 10 cycles (4-24) for 21 days. They presented a disease relapse at a median time of 23 months (10-42). In the bone marrow cytogenetic study, one of them showed clonal evolution towards a complex karyotype, with worse prognosis than prior to treatment. These four patients were resumed on Lenalidomide therapy at the same dose (10 mg/day x 21 days), 2 of them reached CyR again with complete hematological remission at 6 and 9 months respectively, and 2 progressed to acute leukemia.
Summary / Conclusion: Data from this registry intended to be "a snapshot" of clinical practice today and reflect: a) Lenalidomide is sometimes prescribed off-label FDA approval (35% of patients had no transfusion-dependence at baseline). b) Percentages of hematological and cytogenetic response are generally similar to those described in the literature. c) Treatment is interrupted in most of the patients who achieve complete hematological and cytogenetic remission, and relapse is common. d) Progression towards acute myeloid leukemia is observed in 10% of cases. It is essential to carry out controlled clinical trials to assess if the start of Lenalidomide prior to transfusion dependence increases the number of cytogenetic responses and survival and whether the cessation of treatment in patients who achieved cytogenetic remission does not mean a worse prognosis karyotype at relapse.

B1459

RESPONSE TO ECULIZUMAB COMBINED WITH CYCLOSPORINE AFTER FAILURE OF ECULIZUMAB MONOTHERAPY IN 2 PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

M Deldicque[1*], L Knoops[2], E Van Den Neste[1], A Delannoy[3]
[1]Hematology unit, Cliniques universitaires St Luc, Université Catholique de Louvain, [2]Hematology unit, Cliniques universitaires St Luc, Université Catholique de Louvain and de Duve Institute, Brussels, [3]Hematology unit, Hôpital de Jolimont, La Louvière, Belgium

Background: Eculizumab is a monoclonal antibody that inhibits terminal complement activation. In patients with paroxysmal nocturnal hemoglobinuria (PNH), eculizumab stabilizes hemoglobin concentration in the absence of transfusion in half of the patients.
Aims: We hypothesized that in patients who failed on eculizumab, the addition of an immunosuppressive drug could improve the biological and clinical patient's status.
Methods: Here we report on 2 patients who remained transfusion dependent on eculizumab. When eculizumab was given combined to cyclosporine, the first patient became transfusion-independent, while in second patient, the number of packed red cells transfused was cut by half.



Results: Patient1, a 51-year-old man, developed aplastic anemia in October 2008. A small PNH clone (0.6% of granulocytes) without hemolysis was present at diagnosis. The patient eventually developed red cell and platelet transfusion dependence and was treated with rabbit anti-thymocyte globulin (ATG), cyclosporine, and steroids in January 2009. He failed to respond except for an improvement of the neutrophil count. A second course of ATG-cyclosporine was started in May 2009. The patient became transfusion-free and cyclosporine was withheld in February 2010. In May 2011, transfusions were again needed with, in addition, obvious signs of hemolysis and an increasing proportion of granulocytes with PNH phenotype, up to 15%. Eculizumab infusions were started in November 2011 but did not decrease the red cell transfusion rate (10 packs transfused between November 2011 and April 2012). In April 2012, cyclosporine was resumed, in addition to eculizumab. No red cell transfusion was needed since April 2012 (see figure). In January 2013, hemoglobin concentration was 122 g/L with $79x10^9$ platelets/L and $2.75x10^9$ neutrophils/L.

Patient2, was a male aged 74 years in September 2008 when a diagnosis of aplasia was made with 30% of PNH-type neutrophils but without hemolysis. ATG, cyclosporine, and steroids were started in October 2008. Platelet count and hemoglobin concentration improved and transfusion could be omitted until December 2009, when abdominal painful crisis and hemolysis were noted. Cyclosporine was stopped in December 2009 and, as hemolysis was prominent, eculizumab was started in May 2010 but failed to reduce the transfusion rate (2.2 packed red cells monthly). Eculizumab was stopped and cyclosporine was started in November 2010 without any response. Eculizumab was added to cyclosporine in January 2011, which was followed by an improvement of abdominal pain, and by a decrease of the transfusion rate down to 1.5 packs monthly. In January 2013, hemoglobin concentration was 89g/L with $66x10^9$ platelets/L and $2.89x10^9$ neutrophils/L.
Summary / Conclusion: These two cases suggest that in some patients with aplastic anemia evolving to PNH, a poor response to eculizumab can be improved to a large extent by the addition of cyclosporine. The mechanism of the beneficial effect observed when both drugs are combined remains speculative but could conceivably rely on the additive effect of eculizumab on hemolysis and of cyclosporine on aplasia, as suggested by the reticulocyte count rise in case 1 (figure) after cyclosporine was started.

B1460
EFFICACY OF ERYTHROPOIESIS-STIMULATING AGENTS IN ANEMIC PATIENTS WITH MYELODYSPLASTIC SYNDROME
N Romanenko[1*], S Tiranova[1], S Gritsaev[1], S Bessmeltsev[1], K Abdulkadyrov[1]
[1]Hematology, Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background: Anemia in Myelodysplastic Syndrome (MDS) patients is the most frequent symptom and can be observed above 85% patients. Anemia decrease survival rate and overall quality of life. Red blood cell (RBC) transfusions are routinely used to treat anemia. However numerous RBC transfusions may cause iron overload and hemosiderosis. While erythropoiesis-stimulating agents (ESA) treatment has been shown significantly to increase hemoglobin concentration, reduce transfusion dependency, improve overall survival and quality of life.
Aims: To study efficacy ESA in anemic patients with MDS and find out the correlation between positive response to ESA and initial serum erythropoietin (SE).
Methods: The investigational group of patients (n=42) were diagnosed myelodysplastic/ myeloproliferative neoplasms (by WHO classification) and concluded patients only with refractory anemia: RA (n=18), RCMD (n=2), RARS (n=6), del(5q) (n=4), RAEB-1 (n=5) and RAEB-2 (n=4), chronic myelomonocytic leukemia (CMML) (n=3). All patients were determined anemia (Hb concentration 3.5-10.0 g/dL). The median age was 70.0 years (range 52-88). RBC transfusions were administrated to the patients whose Hb concentration was below 8.0 g/dL, to increasing up to 8.5-9.9 g/dL. Transfusion dependency showed 22 (52.4%) patients, they were received 4.0±1.2 (2-7) RBC units every 8 weeks. ESA were administrated to patients subcutaneously: epoietin alpha (n=17) and epoietin beta (n=14) were injected 150 IU/kg three times a week, darbepoietin alpha (n=11) – 500 µg every three weeks. The target Hb concentration was 11 g/dL. Erythroid response (ER) rate was estimated by IWG 2006 criteria as major and minor ER. One group of MDS patients (with RAEB-1, RAEB-2 and CMML) were administrated ESA and chemotherapy (Decitabine, Cytarabine, Hydroxyurea) but another group (with RA, RCMD, RARS, del(5q) received ESA only.
Results: The overall ER rate was 15 of 42 (35.7%) in ESA patients. Major ER showed 11 patients (26.2%): 6 patients increased Hb concentration >2 g/dL (no-RBC transfusion) and 5 patients stopped RBC transfusions. Minor ER was observed in 4 patients (9.5%): 2 ones reduced RBC transfusions more than 50% and 2 patients increased Hb at 1.0 and 1.6 g/dL. On the whole in different groups of patients positive ER (major + minor) vs no-ER was ascertained following: RA 5/13, RCMD 1/1, RARS 3/3, del(5q) 0/4, RAEB-1 3/2 and RAEB-2 2/2, CMML 1/2. ESA treatment was 4-8 months. During this time Hb level increased from 7.9±1.1 g/dL to 10.4±1.1 g/dL ($P<0.05$) in the major ER group patients, from 8.5±1.0 g/dL to 9.7±1.2 g/dL in the minor ER patients and from 7.3±1.8 g/dL to 8.7±1.2 g/dL in the no-ER patients. Even though Hb concentration increased in the no-ER group of patients but the reason of this situation was connected with regular RBC transfusions. In a small group MDS patients we determined negative correlation between positive response and initial level of SE ($r=-0,57$; $P<0,05$; n=17). 6 (60%) patients showed positive ER with SE <200 IU/L (26-180 IU/L), and none positive ER were observed in patients with SE >500 IU/L (540-970 IU/L).
Summary / Conclusion: The study was shown that ESA is effective at increasing Hb concentration, reducing RBC transfusion dependency in MDS patients with anemia. Initial level of SE (<200 IU/L) may be used as prognosis of positive response to ESA.

B1461
DELETION 5Q MYELODYSPLASTIC SYNDROMES (MDS) TREATMENT AND DIAGNOSTIC PATTERNS IN MEXICO: RESULTS FROM A PHYSICIAN SURVEY
C Hernández-Pérez[1], J Kassack-Ipiña[2], M Soriano[3*], R Arnold[4], D Mahmoud[5]
[1]Centro Médico Nacional Siglo XXI, [2]Hospital General de México, [3]IMS Health, Mexico City, Mexico, [4]HEOR, IMS Health, New York, [5]Celgene Corporation, Summit NJ, United States

Background: Deletion of the long arm of chromosome 5 (5q) is the most common chromosomal abnormality seen in MDS; however, there is little information about treatment and diagnostic patterns for this disease, especially in Latin America.
Aims: This study aimed to understand the real-life approach to treatment and diagnosis in Mexico in 2012.
Methods: Overall clinical practice for management of del(5q) MDS was investigated through a physician face-to-face survey. Eligible participants were hematologists and/or hemato-oncologists with at least 5 years of clinical experience treating patients with MDS. 10 physicians (90% hematologists; 10% hemato-oncologists) practicing in one of 5 major public hospitals in Mexico City (IMSS, ISSSTE or MoH) and/or two private hospitals answered the questionnaire.
Results: Significant differences were found in treatment patterns when comparing public and private healthcare physician responses. The patient flow in the public practice starts at Family Medicine Units, which care for basic health issues, as well as in second level hospitals and centers that tend to basic specialties before being referred to a hematologist in third-level high-specialty hospitals. Moreover, these patients arrive in a more advanced stage of the disease than those in private practice. The only way to diagnose del(5q) is through karyotyping; however, there are several important challenges, including a) lack of expertise in performing karyotyping as well as diagnosis; b) karyotyping for del(5q) is not covered by the major social security system, IMSS, which covers 43% of the population; c) most performed tests are paid out-of-pocket and, considering that about half of the population is considered to have income below the poverty line, karyotyping is expensive; and, d) there is a lack of good quality laboratory testing facilities for performance of karyotyping for del(5q) and the majority are located in 3 major cities (Monterrey, Guadalajara and Mexico City), making access difficult for ~80% of the population. Likewise, since most treatment centers are also located in major cities, patients must travel from other parts of the country to get diagnosed and treated. Physicians report that most MDS patients receive treatment for anemia prior to referral; moreover, they acknowledge lenalidomide as the best treatment option for MDS del(5q). However, due to its high cost and restricted availability, they use whatever is readily available at the institution. Thalidomide is used in 1st line treatment, cyclosporine and prednisone as 2nd line and hypomethylating drugs, such as azacitadine or bone marrow transplant as 3rd line. Additionally, due to misdiagnosis and/or co-morbidities, patients are treated with erythropoietin (EPO) (for anemia), granulocytic colony stimulating factors (for leucopenia), platelet agonists or transfusions (for thrombocytopenia), and iron chelators (for iron excess due to transfusions).
Summary / Conclusion: In order to have appropriate del(5q) MDS diagnosis and treatment, following accepted treatment guidelines in Mexico, there is a clear opportunity to increase continuous medical education on the disease and diagnosis as well as training to spur more highly qualified geneticists for MDS in the country. Moreover, there is a need to have more reference centers and genetic testing laboratories and greater availability of del(5q) karyotype testing in the public sector. In addition, improving access to novel drugs, such as lenalidomide, will expand the treatment options indicated for del(5q) MDS in Mexico.

B1462
A RETROSPECTIVE REVIEW OF THE TREATMENT OF APLASTIC ANEMIA
G Gaman[1*], A Gaman[2]
[1]Hematology, [2]Pathophysiology, Hematology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: Introduction: Aplastic anemia is a syndrome of bone marow failure (pancytopenia and marow hypoplasia). However, current therapies (bone marow transplantation, immunosuppresive therapy with cyclosporine and antilimfocyte or antithymocite globuline) are curative.
Aims: Aims: The primary objective was to review the management of treatment for severe aplastic anemia at patients in order to elucidate differences in treatments and review the mortality and morbidity which relate to the variation of treatment.
Methods: Methods: We treated 36 patients in the Clinic of Hematology of Craiova for aplastic anemia (both severe and moderate) over a period of 16 years. A total of 36 patients of aplastic anemia were treated in our institution from 1997 to february 2013. Thus, a total a of 36 patients were included in the analysis.
Results: Of the total of reviewed patients, 21 were male and 15 were female; The mean age at diagnosis was of 46±2 ,4 years. Nine patients (25%) of patients had severe aplastic anemia, 25 patients (69,5%) had severe anemia

and two (5,05%) patients had moderate aplastic anemia. Four patients (9%) developed aplastic anemia in the setting of hepatitis (B2 patients and C2 patients) and 4 patients (9%) were diagnosed with toxic aplastic anemia; 89,9% of patients were treated with cyclosporine and ATG or ALG and had a complete response.The average time to C.R. was of 23±11 months. Average duration of treatment was of 12±10 months. Three patients died: one from complications unrelated to aplastic anemia and two related to a second neoplasm (unrelated to treatment). The average time to transfusion independence for all patients was of 8±8 months. The time to transfusion independence was associated with immunossupresive failure (P=0,001). Patients who did not respond to treatment had an average time to transfusion independence of 15±12 months as compared to those who were complete responders and who had an average time to transfusion independence 2±2 months. Additionlly, there was an association between immunosuppresive failure and cyclosporin levels (P=0,002). There was a non-significant association between immunosupressive failure and bone marrow cellularity (P=0,02). Other 4 patients had evidence of a cytogenetic abnormality (iso-17 q, del 16 q, 5q), but never progressed to LAM, MDS or myeloproliferative neoplasms.

Summary / Conclusion: With immunosupressives regimens, aplastic anemia is currative in the majority of cases. For patients with confirmed clonal disease, it is possible that immunosupressive failure and the ultimate development of MDS, PNH or LAM are related.

B1463

LONG TERM AZACYTIDINE THERAPY IN RESPONDING MDS IS FEASIBLE AND PROLONGS THEAREPEUTIC BENEFIT: ANALYSIS IN 18 ELDERLY PATIENTS

E Sala[1*], C Messina[1], F Giglio[1], M Tassara[1], F Pavesi[1], E Guggiari[1], S Marktel[1], F Ciceri[1], C Corti[1], M Carrabba[1], M Bernardi[1]
[1]Hematology and Bone Marrow Transplantation, San Raffaele Scientific Institute, Milan, Italy

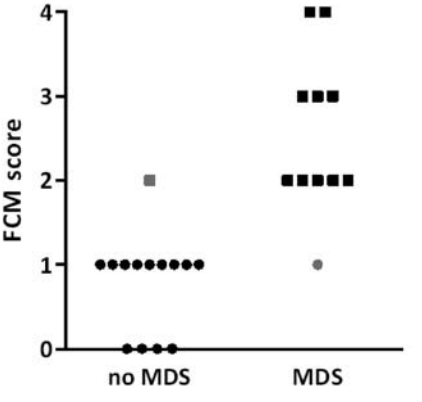
Background: The only potentially curative treatment for Myelodisplastic Syndromes (MDS) is allogeneic stem cell transplantation (allo-SCT). Nevertheless, MDS is more frequent in elderly patients (pts). The majority of these pts are not candidate for transplant. Azacytidine (AZA) compared with conventional supportive care may improve quality of life and long-term outcome of higher-risk (HR) MDS (IPSS Int-2 or high) and is therefore the reference frontline therapy of pts ineligible for allo-SCT. No indications have been established regarding how long AZA treatment should be continued. Pts responding to AZA should continue the treatment until relapse. Outcome after AZA failure is poor. Rapid loss of response to AZA has been observed in case of inter-cycle interval prolongation or withdrawal of treatment.
Aims: To assess long term tolerability to AZA in HR MDS/AML pts who responded to treatment and underwent more than 6 cycles of therapy.
Methods: We retrospectively evaluated the tolerability profile of AZA in a series of 18 consecutive pts treated at our Institute from 11/2010 to 2/2013. We used the approved schedule of AZA 75 mg/m(2)/d subcutaneously for days 1-7 of every 28-day cycle. To assess treatment related toxicities weekly blood examinations and clinical monitoring were performed. After the first 6 cycles a bone marrow evaluation was also planned in order to assess response.
Results: Between 11/2010 and 2/2013 we administered AZA to 18 pts (**table 1**: pts' characteristics). 9/18 pts (5 HR MDS, 4 AML with <30% of blasts) received more than 6 cycles, median number of cycles being 13 (range 8-18); after VI cycles 6/9 pts were in Partial Response (PR), while 3/9 pts in Stable Disease (SD). All 9 pts continued with further cycles. After a follow up (fu) of 366 days (median, range 231-637), 7/9 pts are alive, still responding to AZA, 2/9 died of disease progression. In this series of pts, we documented a good profile of tolerability to AZA, maintained during all cycles. As it has been previously reported, the most frequent adverse event was gastrointestinal (GI) constipation (no grade III-IV severity). We also observed neutropenia e thrombocytopenia of grade III-IV (5/9 pts). In order to maintain the correct cycle timing, we decided as our policy to administer AZA despite the detection of neutrophil values <1000/mmc (but >500/mmc). All neutropenic pts received anti-bacterial, anti-fungal and anti-viral prophylaxis. During fu the incidence of severe infectious events leading to hospitalization was low: only two cases of febrile neutropenia were observed and both cases were successfully treated with large spectrum anti-microbial therapy.
Summary / Conclusion: In HR MDS pts, AZA improves survival vs conventional care regimens. AZA treatment is associated with delayed disease progression, reduced transfusion requirements and enhanced quality of life and it is the standard of care for pts with HR MDS ineligible for allo-SCT. The likelihood of having a sustained response to AZA is increased by maintaining a correct cycle-timing and maximizing treatment duration. Our preliminary data suggest that AZA is well tolerated even after several cycles: we observed a low percentage of severe adverse events, especially infectious ones despite the occurrence of severe neutropenia. Our data support AZA administration until disease progression. The favorable toxicity profile of the drug even in presence of prolonged neutropenia allows the maintenance of a correct interval between consecutive cycles, thus maximizing the therapeutic potentialities of this hypomethylating agent.

B1464

EVALUATION OF FLOW CYTOMETRIC SCORE FOR THE DIAGNOSIS OF LOW-GRADE MYELODYSPLASTIC SYNDROMES

M Heron[1*], L Bakker[1], W Posthuma[2], R Brouwer[2], F Smedts[3], M Batstra[1]
[1]Medical Laboratories, Department of Immunology, [2]Department of Internal Medicine, [3]Department of Pathology, Reinier de Graaf Hospital, Delft, Netherlands

Background: The diagnosis of myelodysplastic syndromes (MDS) is not always straightforward when patients lack specific diagnostic markers, such as clonal cytogenetic abnormalities and/or ringsideroblasts. Recently, a flow cytometric score (FCM score) has been developed and validated to be able to discriminate low-grade MDS from non-clonal cytopenias (1).
Aims: We aimed to test the applicability of the FCM score in our hospital population.
Methods: Immunophenotypic data generated in the diagnostic work-up of bone marrow samples from patients suspected of having MDS in 2012 were retrospectively analyzed. The flow cytometric algorithm as proposed by Della Porte et al (1) was used to determine an FCM score. The FCM score was composed of four cardinal parameters: CD34+ myeloblast-related and B-progenitor-related cluster size, myeloblast CD45 expression and granulocyte side scatter value. An FCM score of 2 or more was considered suggestive for the diagnosis of MDS.
Results: A correct diagnosis of MDS was formulated in 10/11 cases (sensitivity 91%), while 1 false-positive result was noted among 14 control patients (specificity 93%) (Figure 1). Eighty percent (4/5) patients without specific markers of dysplasia (ring sideroblasts and/or clonal cytogenetic abnormalities) were correctly classified. The positive likelihood ratio of the flow cytometric score was 12.7.



Summary / Conclusion: The evaluation of the proposed FCM score in low-grade MDS showed a high sensitivy and specificity, and a clinical important positive likelihood ratio. This study confirms the applicability of the described FCM score in our hospital population and may help to establish the diagnosis of myelodysplastic syndrome, especially when morphology and cytogenetics are indeterminate. However, the relatively low number of patients included in the analysis warrants further experience with the use of the FCM score in the diagnostic work-up of patients suspected of having MDS.

B1465

A NEW CASE OF REFRACTORY ANEMIA WITH RING SIDEROBLASTS AND THROMBOCYTOSIS SF3B1 AND JAK2 V617F POSITIVE, RESPONDING TO LENALIDOMIDE MONOTHERAPY.

G Georgiou[1*], M Francesci[2], L Benusiglio[3], P Menoud[2], P Beris[1]
[1]Hematology, Unilabs - Switzerland, Coppet, [2]Molecular biology, Unilabs - Switzerland, Lausanne, [3]Internal medicine, Private practice, Geneva, Switzerland

Background: Refractory anemia with ring sideroblasts has recently been associated with SF3B1 mutations in more than 60-80% of cases according to the published series. The revised WHO classification of hematopoietic tumors introduced the new category myelodysplastic/myeloproliferative neoplasms (MDS/MPD). Refractory anemia with ring sideroblasts associated with marked

thrombocytosis (RARS-TE) is the best characterised hematologic entity in this category of MDS/MPD. Besides the SF3B1mutation more than 50% of cases carry also the JAK2 V617F or MPL mutations. Gerwin Huls et al (Blood 2010; 116: 180-182) reported two such cases responding to lenalidomide single agent treatment. Both patients became transfusion independent and one attained complete molecular remission.
Aims: We report another case of refractory anemia with ring sideroblasts and thrombocytosis positive for SF3B1 and JAK2 V617F mutations, who was successfully treated by lenalidomide. We present clinical, haematological data and molecular biology markers at diagnosis and after four months treatment.
Methods: 65 years old male patient from Spain. At diagnosis Hb: 98 g/L, MCV 108 fl, WBC 6 G/L with 66% neutrophils, Plt: 400 G/L. Four months later Hb 92 g/L, WBC4,9 G/L, reticulocytes 68 G/L, Plt 465 G/L. Bone marrow aspiration with iron staining was performed. Caryotype (G-banding) was determined in culture of bone marrow unstimulated and GM-CSF and G-CSF stimulated cells. RNA and DNA was extracted from peripheral blood and the mutations of the gene SF3B1 and JAK2 V617F were looked by PCR and sequencing and pyrosequencing respectively. JAK2 mutation analysis was repeated 4 months after initiating lenalidomide treatment.
Results: Bone marrow was hypercellular (70-75%) with marked dyserythropoiesis and dysmegakaryopoiesis. Blasts cells were less than 2%. 75% of erythroblasts were ring sideroblasts upon iron staining. Caryotype was normal, 46XY. Serum iron 39,6 µmol/L with 82% of transferrin saturation, ferritin 536 µg/L. JAK2 V617F mutation was present (30% by pyrosequencing) and we also found the K700E mutation of the gene SF3B1 (PCR and direct sequencing) in heterozygous state. On September 2012 we started treatment with lenalidomide 5mg per day, 21 days out of 28 per cycle. Beginning cycle2, lenalidomide was increased to 10mg per day 3 weeks out of 4. An hemogramme done after 4 cycles, gave the following results: Hb 121 g/L, MCV 102 fl, reticulocytes 86 G/L, WBC4,7 G/L, Plt 228 G/L. JAK2 V617F mutation analysis at that point was repeated and showed no mutation (by pyrosequencing). Lenalidomide is tollerated very well with no side effects particularly with no clinical sign of polyneuropathy.
Summary / Conclusion: This patient satisfies all WHO criteria for the diagnosis of RARS-TE. He presented a specific mutation for sideroblastic anemia and was JAK2 V617F positive. Treatement with lenalinomide was motivated because of deterioration of anemia. The response to the treatment is evident with a gain of more than 29 g/L of Hb, correction of platelet number and the disapperance of JAK2 V617F mutated clone. Our case confirms the two previous cases presented by Gerwin Huls et al, particularly regarding anemia improvement, correction of thrombocytopenia and complete molecular response concerning JAK2. Furthermore our results agree with the rapid effect of lenalidomide. In our opinion these three cases consist a strong argument to perform a multicenter International prospective clinical study on the effect of lenalidomide in cases with RARS-TE.

B1466
OUTCOME OF 5-AZACITIDINE AND DECITABINE TREATMENT IN ELDERLY PATIENTS WITH MYELODYSPLASTIC SYNDROME
S Nam[1*], T Lim[1], B Kim[1]
[1]Division of Hematology-Oncology, Department of Internal Medicine, VHS medical center, Seoul, Korea, Republic Of

Background: Myelodysplastic syndrome (MDS) are heterogenous group of hematologic disorders broadly characterized by cytopenias associated with a dysmorphic and usually cellular bone marrow, and by consequent ineffective blood cell production. For patients with MDS an epigenetic therapy with hypomethylating agents is considered standard of care.
Aims: We evaluated the outcome of 5-Azacitidine and Decitabine treatment in elderly patients with myelodysplastic syndrome in our veterans hospital.
Methods: For analysis, patients were included if they were ≥ 60 years, had morphological evidence of MDS per bone marrow examination at the time of diagnosis and were treated with either hypomethylating agent, 5-azacitidine and decitabine. The patients received 5-azacitidine 75mg/m2, d1-7 or decitabine 20mg/m2, d1-5 at four weeks interval. The primary end point was overall response rate.
Results: A total of 27 patients were analyzed. Median age was 68 years (range 61-81 years). 10(37%) patients had received 5-azacitidine and 17(63%) patients had received decitabine. The International Prognostic Scoring System risk category was Intermediate-2/High in 44%. A median of 5 courses (range 1-16) were delivered and 56%(15/27) patients were treated 4 cycles over. The overall response rate was 59%. Patients who showed response (CR+PR+HI) had significantly longer overall survival than those who did not (30 months vs 5months, P=0.01). With a median follow-up duration of 12 months, median overall survival was 14.7 months. The difference in overall survival was evident in the Intermediate-2/High risk group but not in the Intermediate-1 risk group. However, the difference between 5-azacitidine and decitabine group was not stastically significant.
Summary / Conclusion: In our study, both 5-azacitidine and decitabine were feasible and effective in elderly patients with myelodysplastic syndrome. The overall survival was significantly longer in patients showing response. There were needed additional large-scale prospective studies.

B1467
MELATHONIN PLUS DANAZOLE, PREDNISONE AND ERYTHROPOIETIN ALPHA IS EFFECTIVE IN TREATMENT OF MYELODYSPLASTIC SYNDROMES WITH ANEMIA AND THROMBOCYTOPENIA.
G Giordano[1*], f d'amico[2], a d'aveta [1], m de maria[1], p nicola[3], p mondello[4], c sansò[5], g sticca[1]
[1]oncology, [2]Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [3]chieti university, chieti, [4]oncology, policlinico "g martino", messina, [5]catholic university, rome, Italy

Background: Melathonin was reported effective in some cases of ITP because of its thrombopoietic effect.
Aims: Aim of this study is to verify if danazole, prednisone, melathonin and erythropoietin alpha is effective and safe in patients with refractory cytopenia with multilineage dysplasia (RCMD) with anemia and thrombocytopenia.
Methods: This study is a multicentric study.
20 patients with RCMD with IPSS intermediate or low showed anemia and thrombocytopenia. Cytogenetics was normal in 15 patients and not evaluable in 5 patients. In group A 10 patients received orally danazole 200 mg/day, prednisone 25 mg/day, melathonin 60 mg/day, B12 400 mg/day, calcium levofolinate 7.5 mg/day, liposomal iron 30 mg/day, erythropoietin alpha 40000 IU subcutaneous weekly (5 originator and 5 biosimilar) for at least 3 months. In group B 10 patients received the same treatment except melathonin. In group B 7 patients received originator erythropoietin alpha and 3 biosimilar. In group A M/F was 6/4, median age was 68 years (R62-80), median follow-up was 4 months (R2-6), median Hb 9 g/dl (R8.5-10), median PLT count 40000/mcl (R30000-50000). In group B M/F was 5/5, median age was 66 years (R60-84), median follow-up was 3 months (R2-5), median Hb 8.7 g/dl (R8-9.5), median PLT count 27000/mcl (R20000-45000).
Results: In group A median platelet count after treatment was 55000/mcl (R40000-60000), median Hb 10 g/dl (R9-11). In group B median platelet count after treatment was 38000/mcl (R25000-50000), median Hb 10.2 g/dl (R9-10.5). In group A the 5 patients receiving biosimilar erythropoietin alpha showed a median platelet count of 55000/mcl vs a median platelet count of 40000/mcl in patients receiving originator molecule. No side effects were noted in the two group.
Summary / Conclusion: Melathonin, danazole, prednisone and erythropoietin alpha is safe and effective in RCMD with anemia and thrombocytopenia.

B1468
CLINICAL ANALYSIS OF 24 PATIENTS WITH SEVERE APLASTIC ANEMIA AND VERY SEVERE APLASTIC ANEMIA TREATED WITH ANTITHYMOCYTE GLOBULIN(ATG) COMBINED WITH CYCLOSPORINE
Y Yan[1], L Wei[1*], G Sujun[1], F Hongqiong[1]
[1]Department of Haematology and oncology, First Hospital of Jilin University Changchun China, changchun jilin province, China

Background: Severe aplastic anemia(SAA) and very severe aplastic anemia(VSAA) are serious hematopoietic disease,most of the patients would die within 6-12 months if they couldn't receive effective treatment. If the patient is younger than 40 years old and has a histocompatible sibling donor,the first choice is hematopoietic stem cell transplantation (HSCT);but If the patient is older than 40 years old and has no histocompatible sibling donor, Immunusuppressive therapy (IST) is a key treatment strategy ,the standard IST is antithymocyte globuline (ATG) plus cyclosporine A (CsA). Because the majority of patients have no histocompatible sibling donor. so IST is a key treatment strategy to the patients.
Aims: Here we summarized the recent therapeutic effect and adverse reaction of treatment with ATG plus CsA in 24 patients with SAA and VSAA as follows.
Methods: There are 13 patients with SAA and 11 patients with VSAA including 10 male and 14 female ranged from 6 to 63 years old median age was 18 years. All the patients were treated with rabbit ATG from France at a dose of 3-5mg/kg/day for 5 days, and received the CsA a week later at a initial dose of 3-5mg/kg/day, then adjusted the dose of CsA according to the blood concentration and reduced the dose after one year gradually.we also treated the patients with the hematopoietic stimulating factors(eg.G-CSF,L-11,EPO) after the ATG treatment. We strengthened the anti-infective therapy within 2 months after ATG treatment , And we emphasized the erythrocyte suspension and platelet infusion.
Results: We evaluate the effects according to the Camitta criteria 4 months after the ATG treatment, 6 patients achieved CR,12 PR,the other 6 patients had no response,the overall response rate is 75%, during the treatment,22 patients suffered from Varying degree of inflammation, including 10 sepsis 4 of them whose history was longer than 6 months died early,We haven't found MDS or PNH evolution for 2 years.
Summary / Conclusion: ATG plus CsA is an effective treatment for SAA and VSAA,we can overcome the severe infections and allergic reactions.

B1469

EFFICACY AND TOLERABLITY OF AZACITIDINE TREATMENT IN PATIENTS WITH MDS, AML AND CMML

A Biedma[1*], C Avellaneda[2], J Berruga[1], D Tallón[2], C Ferrer[1], M Anguita[2]
[1]Hematology, Hospital San Juan de la Cruz., [2]Hematology, H San Agustín , Jaén, Spain

Background: Azacitidine (AZA) is a hypomethylating agent approved for the treatment of adults patients (pts) who are not eligible for haematopoietic stem cell transplantation with: Int-2 and high-risk myelodysplastic syndromes (MDS) according to the International Prognostic Scoring System (IPSS); chronic myelomonocytic leukemia (CMML) with 10-29% marrow blasts without myeloproliferative disorder, and acute myeloid leukaemia (AML) with 20-30% blasts and multi-lineage dysplasia, according to World Health Organization (WHO) classification (1). AZA efficacy has been firmly established in higher risk MDS patients; however, in CMML its efficacy remains uncertain (< 10 patients have been treated in the AZA trials) (2). Regarding AZA efficacy in AML, an AZA-001 trial sub-analysis showed that AZA significantly prolonged overall survival (OS) vs. conventional care regimens (CCRs) in 113 patients with WHO-classified AML and 20 – 30% BM blasts (3)
Aims: We describe the clinical experience with azacitidine in patients with MDS, AML and CMML with safety data included.
Methods: Multicenter, observational, post market, retrospective study in the AZA indicated population (patients with MDS, AML and CMML) treated with AZA (≥ 3 months) before September 2011.
Results: Twenty one patients were included (intent to treat population). AZA treatment was administrated in 5-2-2 and 7 days schedules in 15 (66.7%) and 6 patients (28.6%), respectively (11.7 cycles; mean); with concomitant G-CSF in 18 pts. Six (28.6%) patient continued with the AZA treatment; 11 pts (52.4%) achieved transfusional independence (TI) (mean: 33.9 weeks), and 3 maintained it at the end of the study. Thirteen (61.9%), 10 (47.6%), 7 (33.3%), 7 (33.3%) and 2 (9.52%) patients, achieved erytroid, plateled, granulocytic and morphological medullar response, respectively at a mean of 5.08, 5.80, 3.29, 5.29 and 3 cycles. The best response to AZA treatment was complete response (CR) in 4 patients (19%), partial response (PR) in 3 (14.3%) and stable disease (SD) in 10 (47.6%). Overall response rate (ORR) (RC+RP+EE)= 17 patients (81%). The median overall survival (OS) was 612 days (20.4 months) (95% CI 233 – 800). At the end of study 7 patients (33.3%) remained alive with none exitus related with AZA treatment. Adverse event (AE) was reported in 13 patients, among them 11 required dose reduction/withdrawal treatment. The AE included: Grade2-4 neutropenia (n=12), Grade 3-4 thrombocytopenia (n=2), Grade 3 cytopenia (1), Grade 2 injection site reaction (n= 1), Grade 1 polycythemia (n=1) and Grade 3 digestive toxicity (n=1).

Summary / Conclusion: The current results of our study showed that azacitidine treatment of patients with MDS, CMML and AML is effective with an ORR of 81%. The therapy was well tolerated with cytopenia as more commonly reported haematological adverse event and digestive toxicity and injection site reaction as nonhaematological events. In conclusion azacitidina is effective and safety in the treatment of these patients.

B1470

INTESTINAL ANGIODYSPLASIAS AND MYELOSYPPRESSION: 3 CASE REPORTS- THE ROLE OF LONG ACTING OCTREOTIDE

I Prousanidis[1*], A Agorastos[2], M Charalampidis[3], AGiannopoulos[3], P Gkika[3], V Zioganas[4], P Kiryttopoulos[3]
[1]1st Propaedeutic Internal Medicine Dpt, AHEPA Univesrity General Hospital of Thessaloniki, [2]internal medicine, Cancer Hospital of Thessaloniki"Theagenio" , Thessaloniki, [3]Internal medicine, General Hospital of Veria, Veria, [4]Gastroenterology, Hippokration General Hospital , Thessaloniki, Greece

Background: Vascular malformations of the gastrointestinal tract are one not so common cause for gastrointestinal bleeding and iron deficiency anemia. The co – existence of myelodysplastic syndrome in cases like these has been registered, leading the patients to be treated independently for the 2 co – existing diseases.
Aims: Our goal was to investigate the possibility of correlation between the gastrointestinal and the hematological condition of such patients. We took under consideration the new data of international literature, where the role of certain cytokines – that are produced from the intestinal vascular malformations – on the suppression of the bone marrow, is suggested.
Methods: 3 patients, all 3 above the age of 65, were treated with blood transfusions and iron supplementation for a period of at least two years for iron deficiency anemia due to gastrointestinal bleeding, which was provoked by angiodysplasias of the small intestine (as were diagnosed after a thorough endoscopic approach and the use of wireless video capsule). At the same time, these 3 patients were treated with erythropoietin, since they were thought to suffer from myelodysplastic syndrome. With the beginning of the second year of treatment, therapy on all 3 patients seemed to fail and the results of the bone marrow biopsy were reconsidered. We found out that at all 3 patients, myelodysplastic syndrome was not a definite diagnosis because the histology report concluded that the findings were not compatible with any certain type of myelodysplastic syndrome but merely with myelosuppression. Having in mind the suggested in such cases thalidomide and octreotide therapeutic approach, we started treating the patients with long-acting octreotide, in a dosage of 20 mg, given intragluteally at 4 – week intervals for at least one year.
Results: The hemoglobin levels, blood transfusions, iron supplementation, hospitalizations and the need for erythropoietin on all 3 patients were monitored during the period of their octreotide treatment. The results were satisfactory, since all 3 of them maintained an Hb level above 9mg/dl without being submitted to their previous treatments.
Summary / Conclusion: The suppressive role of intestinal vascular malformations via cytokines on the bone marrow productive procedure is a topic with great interest and prospective. The identity and role of intermediate cytokines is discussed and the benefit deriving from the usage of long acting octreotide,as well as thalidomide, is yet to be proved.

B1471

CLINICAL TRIAL OF PROPHYLACTIC ANTIFUNGAL AND ANTIVIRAL THERAPY IN SAA/VSAA PATIENTS UNDERGOING IMMUNOSUPPRESSIVE THERAPY

H Chang[1*], Y Jia[1], J Li[1], J Liu[1], J Yang[1], H Ma[1]
[1]WestChina Hospital, Sichuan University, Chengdu, China

Background: Persistent neutropenia associatedInvasive fungal infections predominantly with aspergillus, and bacterial infections are a major cause of death in patients with SAA.Patients of SAA/VSAA undergoing immunosuppressive therapyare also susceptible to viral infections. In multivariate analysis, younger age, absolute neutrophil count > 200 cells/μL before IST, absence of IFIs, and use of voriconazole were independently predictive of survival .
Aims: The aim of this study was to investigate the effects of prophylactic antifungal and antiviral therapy in SAA/VSAApatients undergoing IST .
Methods: 26 patients with SAA/VSAAundergoing IST were evaluated. The patients were divided into two groups. We reviewed the records of 14 patients (group1, non- prophylactic group) with SAA/VSAA admitted to our Hematology department from 2005 to 2012 who received immunosuppressive therapy (IST) without prophylacticanti-infective therapy. 12 patients (group2, prophylactic group) undergoing IST during April 2012- February 2013 with prophylactic antifungals , antiviralstherapy, Valaciclovia 0.3 po bid plus Micafungin 50mg intravenously qd.
Results: In 12 patients of prophylactic group , 8 were response to IST, 4(33.3%) were found neutropenic febrile (1 patient wasserum sickness, 1 patient with bacterial infection, 2 patients with bacterial and fungal infections and serum sickness). In 14 patients of non- prophylactic group , 10 were response to IST , but had longer hospitalized time than prophylactic group, 13(92.8%) patients

occurred neutropenic febrile (each patient developed 1 or more febrile episodes) (2 patients were associated with serum sickness, 3 patients with bacterial infection, 7 patients with clinically documented bacterial and fungal infections,1 patient with bacterial and viral infections).
Summary / Conclusion: Our study showed thatprophylactic antifungals , antivirals treatment is very imperative. Prophylactic antifungal and antiviral therapy is effective in reduce neutropenic febrileand hospitalized timefor SAA/VSAA patients undergoing immunosuppressive therapy.

B1472
SUCCESSFULL AZACITIDINE BASED TREATMENT OF THERAPY RELATED MYELODYSPLASTIC SYNDROME WITH NORMAL KARYOTYPE OCCURRED AFTER ACUTE MYELOID LEUKEMIA
F Saltarelli[1*], C Tatarelli[1], V Naso[1], M Spiriti[1], M Bianchi[1], E Conte[1], A Ferrari[1]
[1]Hematology, S.Andrea Hospital, "Sapienza" University, Rome, Rome, Italy

Background: Therapy-related myelodysplasia (t-MDS) occurs as a complication of cytotoxic treatment given for cancer. Typically at presentation chromosomes abnormalities and/or complex karyotype are present. Standard chemotherapy is often not effective with very low complete remission rates so prognosis remains poor.
Aims: Azacitidine is an hypomethylating drug that showed to be effective in MDS. We describe here 3 patients with t-MDS secondary to chemotherapy for de novo acute myeloid leukemia (AML), successfully treated with Azacitidine.
Methods: Between April 2011 and November 2012 we observed in our centre 2 women and one man previously successfully treated for AML (M2,M2 NPM+, and M5) who were then diagnosed with MDS, defined by blast count <20% and typical cytological morphology in bone marrow aspirate. Patient 1 was a 48 years-old lady diagnosed in March 2011 with RAEB-1, not transfusion dependent and with 2 cytopenias. Patient 2 was a 74 years-old lady diagnosed in February 2012 with RAEB-1 but with a mild anemia; patient 3 was a 64 years-old man presented in February 2012 with RCMD was transfusion dependent for Red blood Cells and Platelets. All patients were Intermediate-1 and Intermediate according to IPSS and WPSS scores respectively. Karyotype was evaluable in all patients and was normal. t-MDS occurred after 44 months of complete remission (CR) for patient1, after 22 months from 2nd CR for patient 2 and after a 8 months CR for patient 3. Azacitidine was started at a median of 1 month from t-MDS diagnosis at the dose of 75 mg/sqm daily for 7 days every 4 weeks. A median of 9 courses were administered (range 7-15). Response was assessed according to the International Working Group criteria.
Results: Patient 1 received 15 courses of azacitidine and after obtaining complete remission underwent allogenic stem cell transplantation. Patient 2 received 9 courses of azacitidine achieving complete remission and she is still on treatment. Patient 3 achieved stable disease with persisting severe thrombocytopenia and anemia after 7 courses of azacitidine but died because of hemorraghic stroke. Therapy was generally well tolerated except for patient 3 who experienced several grade 2- 3 infective episodes . Median overall survival of t-MDS patients was 12 months (range 6-22)
Summary / Conclusion: Currently there is no standard treatment for patients wit t-MDS. In our small experience, azacitidine given upfront showed to be effective improving overall survival with an accetable toxicity profile. Further studies are needed to confirm these results.

B1473
RAPID HAEMATOLOGICAL RESPONSE WITH 5-AZACYTIDINE IN HIGH RISK MYELODYSPLASTIC SYNDROME
J Roy[1], S Weston-Smith[1], S Sahu[1], R Grace[1], E Dimitriadou[2], A Nikolova[1], A Rumbold[1], S Gupta[1*]
[1]Haematology, East Sussex Healthcare, East Sussex, [2]Haematology, Maidstone and Tunbridge wells Hospital, Maidstone , Kent , United Kingdom

Background: High risk myelodysplastic syndrome (IPSS intermediate 2 and above) and CMMLII have poor prognosis. Median survival with best supportive care is less than one year. 5-azacytadine has significantly changed the median survival in these patients. Median cycles to complete haematological response has been 4 cycles.
Aims: We report two patients who achieved complete haematological response just after one cycle of azacytidine. It is not commonly seen that patients acheive such rapid response.
Methods: 67 years old male patients presented with Hb-7gm/dl, WBC-54X10^9 /L and platelets-17x10^9 /L. Peripheral monocyte count was 5.5x10^9 /L. Bone marrow showed Chronic myeloonocytic leukaemia (CMMLII) with 11% promocytes and blasts. Karyotype was normal with FISH for chromosome 5 and 7 being negative. He was requiring 2 units RBC support every 2 weeks, and one pool of platelets every week for past 2 months before starting 5 Azacytidine. He had splenomegaly of 10cm below the costal margin. He was started on 5-azcytidine with the standard dose of 75mg/m^2 for 7 days .2 weeks after the last day of 5 –Azacytidine, his haemoglobin rose to 9gm/dl and platelets improved to 33x10^9/Lwithout any transfusion support. White cell count started to reduce and neutrophils normalized. Just before starting the second cycle he achieved complete haematological remission and transfusion independence. He continued to receive further 3 cycles before bone marrow which revealed 4 % blasts and continuing tri-lineage dysplasia He has completed 9 cycles of Azacytidine and continues to be in complete haematological remission. Second patient is a 79 years old male who presented in 2011 with isolated thrombocytopenia of 40 X109 /L and normal haemoglobin and white cell count. Bone marrow revealed MDS RCMD with 3 % blasts. He had complex cytogenetics with deletion5,-22, +22, deletion 20, +marker. He chose to remain on watch and wait initially. 5 months later he was admitted through the accident and emergency department with septicaemia and swollen joints. Blood test: Hb-7.9 gm/dl, WBC-1.3xX10^9 /L, Neutrophils-0.4x10^9 /L, Platelets-20x10^9 /L. Repeat bone marrow after sepsis revealed RAEB II with 17% blasts with same complex cytogenetics abnormality as presentation. He was started on Azacytidine of 75mg/m2 for 7 days. Immediately after completing the drug he was again admitted with second episode of sever sepsis and sever pancytopenia. As he recovered from sepsis his counts recovered and he achieved complete normal blood counts with Hb-14.5gm/dl, WBC 6.8x10^9 /L, neutrophils 2.5x10^9 /L and platelets 340x10^9 /L. Patient refused to have any more chemotherapy and further tests thinking he has been cured. His last blood test in January 2013 which was3 months after last dose of Azacytidine still shows complete haematological remission
Results: We have reported that both patients acheived complete haematolgical response just after one cycle of azacytidine. In one patient we could document bome marrow dysplastic remmission also but the otherpatient unfortunately declined further investigation and treatment.
Summary / Conclusion: Azacytidine treatment results in significantly higher response rates, improved quality of life, reduced risk of leukaemic transformation, and improved survival compared with supportive care. Complete haematological repose just after one cycle is not common. It has not been reported till date in the literature. Early platelet response has been a marker of long term survival and long progression free survival. It would be interesting to see if very rapid response in haemoglobin and white cell, just after one cycle could also translates in to long progression free survival

B1474
A RARE DISEASE IN CHILDHOOD: PNH AND ITS TREATMENT WITH ECULIZUMAB
G Aydogan[1*], D Tugcu[1], A Akcay[1], N Ayaz[1], G Keskindemirci[1], Z Salcioglu[1], F Akici[1], M Demirkaya[1], M Gokce[1], H Sen[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired syndrome in which glycosyl phosphatidylinositol–anchored proteins (GPI-AP) are deficient on the surfaces of blood cells. PNH can present at any age, most commonly between 20 and 50 years. It is extremely rare in childhood and adolescence. Only 70 well-documented pediatric cases of PNH could be retrieved from the literature and most of these have arisen in a previous setting of bone marrow failure. There are few pediatric case reports presented with reccurrent hemolytic episodes. Treatment is mainly supportive in the form of folic acid, iron supplements, and blood transfusions of filtered red cells when ever necessary. Hematopoietic stem cell transplantation is the only curative option for patients with PNH. A novel alternative treatment option for adult patients with PNH includes the humanized monoclonal antibody eculizumab.
Aims: Eculizumab is not licensed for use in patients <18 years of age. The experience regarding to the use of eculizumab therapy under 18 years is lacking. So, we find it significant to share our experience regarding to the use of eculizumab for a 10 year old patient that was diagnosed as PNH at 4.5 years of age and have been managed successful by eculizumab for more than one year in Kanuni Sultan Süleyman Education and Research Hospital.
Methods: The diagnosis of the patient was made at 2007 with immunphenotyping and then verified with FLAER method.She had been given blood transfusions, hyperhydration therapy, low-dose oral prednisolone continuously at the beginning and then during hemolytic attacks.During follow-up, attacks had become more frequent and recur at 2-3 weeks intervals.With the informed consent of the family, eculizumab therapy was commenced. The dose of eculizumab was set according to the weight of the child as 600 mg/week for 4 week, then 900 mg/every other week parenterally.
Results: After introduction of eculizumab both the frequency and the severity of the attacks had declined significantly. She has been under eculizumab therapy for more then one year without any considerable advers effect.
Summary / Conclusion: Depending on our experience; we can say that, like in adults, eculizumab may have a substantial role in controlling hemolytic episodes and preventing thrombotic complications and improving quality of life in children

Myeloma and other monoclonal gammopathies - Biology

THE NOVEL PAN-HDAC INHIBITOR, CKD-581 ENHANCES THE ANTI-MYELOMA EFFECTS OF BORTEZOMIB

C Lee[1], S Beom[2*], K Ahn[1], W Jung[1], Y Koh[2], J Kim[2], H Lee[3], J Kwon[2], H Kim[4], H Yoon[5], I Kim[2], M Kim[6], B Kim[1,2], S Yoon[1,2,7]
[1]Cancer Research Institute, College of Medicine, Seoul National University, [2]Internal Medicine, Seoul National University Hospital, Seoul, [3]Internal Medicine, Dongguk University Medical Center, Goyang, [4]Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, [5]Internal Medicine, College of Medicine, Kyunghee University, [6]CKD Research Institute, Chong Kun Dang Pharmaceuticals, [7]Clinical Research Institute, College of Medicine, Seoul National University, Seoul, Korea, Republic Of

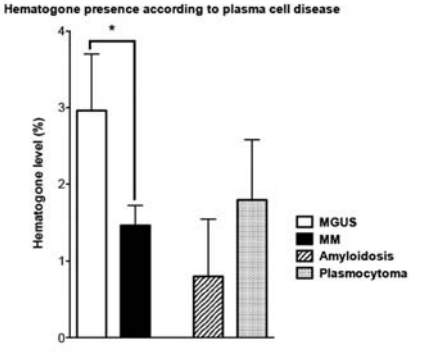
Background: Despite recent advances in myeloma treatment with the advent of new targeted agents such as bortezomib, thalidomide and lenalidomide, multiple myeloma (MM) still remains incurable. To improve clinical outcome of MM patients, many studies have been trying to develop novel targeted drugs.
Aims: We wanted to examine the efficacy of CKD-581, a novel HDAC inhibitor, either alone or combined with bortezomib in MM.
Methods: Antimyeloma effect of CKD-581 was tested in 6 commercial MM cell lines, either alone or combined with bortezomib. The same experiment was done with the presence of bone marrow stromal cells. We also examined the effect of CKD-581, either alone or combined with bortezomib in an animal model and freshly isolated MM cells from MM patients' bone marrow. For an animal study, we used NRG(RAG2−/−gc−/−) mice that were injected with MM cells via tail vein.
Results: CKD-581 had a potent anti-myeloma effect in 6 MM cell lines. At the molecular level, CKD-581 caused accumulation of acetylation of histones and activated cleavage of PARP and caspase 3 in MM cells. In combination with bortezomib, CKD-581 synergistically increased bortezomib-mediated apoptosis in MM cells. In addition, this synergistic effect was maintained despite co-culture with bone marrow stromal cells (BMSCs). Mice treated with CKD-581 alone and CKD-581 combined with bortezomib survived longer than non-treated controls, with the longest survival in combination arm. MM cells were not detected in bone marrow of treated mice. In *ex vivo* study, CD138+ cells decreased significantly when cells were treated with CDK-581 alone and CKD-581 combined with bortezomib.
Summary / Conclusion: Our data indicated that CKD-581 had apoptotic effects in MM and it showed synergism with bortezomib.

B1476

IMMUNOPHENOTYPIC ANALYSIS OF BONE MARROW B LYMPHOCYTE PRECURSORS (HEMATOGONES) IN PLASMA CELL DISORDERS: A NEW MARKER OF DISEASE?

Q Cabrera[1*], S Chantepie[1], J Mear[1], V Salaun[2], F Truquet[2], A Gac[1], O Reman[1], X Troussard[1], M Macro[1]
[1]Service d'hématologie clinique, [2]Service d'hématologie biologique, CHU de Caen, Caen, France

Background: Hematogones (HGs) are normal B-cell precursors present in bone marrow, including pro-B, pre-B and immature B cells, and characterized by phenotypic co-expression of CD19 and CD10, and the acquisition of CD20. HGs level in bone marrow aspirates is inversely correlated with age, but can be increased after chemotherapy or stem cell transplantation. This increase may reflect B cell reconstitution. Recent studies suggested that HGs level in bone marrow was statistically correlated with favorable outcome in acute myeloid leukemia and allogeneic hematopoietic stem cell transplantation. However, no data exist on the presence of these B-cell precursors in patients with plasma cell disorders.



Aims: Our goal was to describe the HGs level in plasma cell disorders, and to determine any correlation with plasma cell infiltration or disease activity.
Methods: We analyzed by cytology and flow cytometry cells obtained from bone marrow aspiration in 73 patients at the time of diagnosis for plasma cell diseases: monoclonal gammopathy of undetermined significance (MGUS, n=16), multiple myeloma (MM, n=48), AL amyloidosis (n=6) and isolated plasmocytoma (n=3). HGs were isolated as CD10+/CD19+ CD45low and CD20+ cells by flow cytometry with a 4-colour combination. The data were visualized using a plot of side scatter scale versus CD45 staining. The sensitivity cut-off was 0.01% of the total number of nucleated cells. Plasma cells were analyzed using a CD38/CD138 plot and for CD19, CD20, CD56, CD117, CD33 and CD28 expression.
Results: The mean age of the 73 patients was 64.8 years old. Sixty-two patients (84%) had detectable HGs in the bone marrow. The median and mean percentages of total HGs were 2.04% and 1.81% (0-10%) respectively. The mean level of HGs was similar in both men and women (1.80%). The percentage of HGs was not correlated with age, and high values have been observed in very old patients (4.6% in a 89 years old patient for example). The percentage of HGs was inversely correlated with plasma cell infiltration, as assessed by both flow cytometry and cytology (P=0.0089 and P=0.0126, respectively). Moreover, the percentage of bone marrow HGs was significantly lower in multiple myeloma patients (smoldering and/or active myeloma) than in monoclonal gammopathy of undetermined significance (P=0.04, figure 1). There was no correlation between HGs level and the expression of CD56, CD117, CD28, CD33 or beta2-microglobinemia at diagnosis.
Summary / Conclusion: At our knowledge, this is the first study to show HGs presence in plasma cell disorders. Our results demonstrate that B-cell precursors could be identified in the majority of patient with monoclonal protein. Moreover, we found that the percentage of HGs was inversely correlated with plasma cell infiltration and disease activity. More data and a longer follow-up of our patients are needed to determine the prognostic impact, in MGUS and multiple myeloma progression and survival.

B1477

POTENTIAL ROLE OF PPAR-G AND HMOX1 IN MULTIPLE MYELOMA (MM) CELL DEATH

D Tibullo[1*], C Conticello[1], C Giallongo[1], P La Cava[1], N Parrinello[1], A Romano[1], A Chiarenza[1], G Palumbo[1], F Di Raimondo[1]
[1]clinical and molecular Biomedicine, Section of hematology, Ospedale Ferrarotto, university of Catania, catania, Italy

Background: Peroxisome proliferator-activated receptor γ (PPAR-γ) is a multifunctional transcription factor that regulates immune and inflammatory responses. It has been previously shown that normal and malignant B cells, including multiple myeloma, express PPAR-γ but its physiological role remains unknown. Moreover, while certain PPAR-γ ligands can induce apoptosis of multiple myeloma cells and PPAR- γ over-expression decreases MM cell growth, silencing PPAR-γ expression by RNAi increases survival of B lymphoma cells (Garcia Bates Clin Can Res 2009). Heme Oxygenase 1 (HO1) is a microsomal enzyme that catalyzes the degradation of heme into carbon monoxide, biliverdin and ferrous iron. It plays a pivotal role in inflammation, oxidation and apoptosis. It is able to regulate PPAR-γ by enhance its expression as well as different PPAR-γ agonists upregulates HO1 via a PPAR-g dependent-pathway. Moreover, it has been recently described that Bortezomib is able to increase HO1 expression (Barrera, Cell Cycle 2012).
Aims: The aim of this study was to evaluate the correlation between Bortezomib, HO1 and PPAR-γ in multiple myeloma cells.
Methods: Three human multiple myeloma cell lines (ARH77, U266, SKMM1) were incubated with rosiglitazone (1μM, 72h), a synthetic agonist of PPAR-γ currentlyused to treat type 2 diabetes, and with Bortezomib (10nM, 24 h). Cell viability was evaluated by flow cytometer (Becton-Dickinson, San Jose, CA, USA) with annexin V and 7-Aminoactinomycin D (*7-AAD*) assay. Real-time PCR (7900 Fast Real Time PCR Applied Biosystems) was used to analyze PPAR-γ and HO1. HO1 enzymatic activity was evaluated by a colorimetric assay.
Results: Rosiglitazone was able to induce apoptosis in human multiple myeloma cells (apoptotic cells 48%±9,3 vs 35%±7 of control) and a relevant increase of PPAR-γ (30 folds) and HO1 (12 folds) expression. Bortezomib, as expected, was able to decrease cell viability of about 50% and, more notably, was able to increase HO1 protein and mRNA expression (40 fold) and PPAR-γ expression (16 folds). We have also treated myeloma cells with Bortezomib plus or not an inducer (Hemin 10uM) or an inhibitor (Tin, Sn-Mesoprotoporphyrin, 10uM) of HO1 enzyme activity. The treatment with Hemin and Tin alone did not change cell viability whereas combination of Bortezomib with Hemin induced higher mortality levels than Bortezomib alone and, in contrast, Bortezomib plus Tin induced a reduced cell mortality.
Summary / Conclusion: Our results indicate that the antidiabetic drug rosiglitazone, a PPAR-γ activator, and proteasome inhibitor Bortezomib are able to induce apoptosis, HO1 and PPAR-γ expression in multiple myeloma cells. In addition, HO1 expression is induced by Hemin that enhances the pro-apoptotic activity of Bortezomib, suggesting a potential role of peroxisome proliferator-activated receptor γ and HO1 in multiple myeloma-drug induced cell death

B1478

INFLAMMATORY MONOCYTES ARE INCREASED IN MM AND CORRELATED TO EXTENSION OF BONE DISEASE

N Parrinello[1], A Romano[1*], P La Cava[1], A Chiarenza[1], A Triolo[1], C Conticello[1], G Rizzo[1], M Cavalli[1], G Palumbo[1], F Di Raimondo[1]
[1]Division of Hematology, Ospedale Ferrarotto, Catania, Italy

Background: The immune function in MM is impaired consequently to an immunologically hostile microenvironment and cellular defects, differently from MGUS. Inflammatory CD14+/CD16+ monocytes (IM) have a wide range of chemokine pathways for recruitment into tumour microenvironment, in which they differentiate into macrophages or alternatively in dendritic cells and as shown exclusively in mouse model they might enhance oxidative stress and endothelial dysfunction. In mouse model increased levels of sIL-2R induce expansion of IM. Activin-A is potently up-regulated in monocytes as well as stromal fibroblasts by cognate interaction with activated T cells in the bone marrow milieu and plays a functional role in the suppression of inflammation.
Aims: Evaluation of IM in patients with advanced bone disease.
Methods: In a cohort of 40 newly diagnosed MM , 30 MGUS and 20 Healthy subjects, we evaluated in peripheral blood the absolute count of monocytes and their phagocytic activity and IM by flow cytometry. Circulating levels of Activin A, sCD44 and sIL-2-R were detected by a commercially available ELISA kit in sera of 20 newly diagnosed MM, 20 MGUS and compared to 10 healthy subjects matched for age and sex.
Results: Even though absolute count of monocytes was similar between healthy subjects vs MGUS vs MM, they have a reduced phagocytosis (90.6±3.3 vs 80.6±4.7vs 71.2±2.2). IM in MM were higher than in MGUS or healthy subjects (respectively, mean 51.39±4.47/mmc vs 48.32±7.82/mmc vs mean 37.75±3.45/mmc, P=0.027). Absolute count of MI was positively correlated with presence and extension of osteolytic MM-related bone disease (evaluated at MRI) and cytogenetics risk (according to Mayo criteria).
MM patients with bone disease exhibited an increased amount of circulating Activin A (260.8±29.24 ng/mL) compared to MGUS (189.5±32.43 ng/mL) and healthy subjects (mean 62.18±8.83 ng/mL) (P<0.0001, one way ANOVA). Among MM patients, Activin A was significantly increased in presence of osteolytic lesions (280.4±26.82 vs 173.5±24.15 , P=0.014, unpaired T test). In MM sCD44 and sIL-2R were increased when compared to healthy subjects (respectively mean 6.4±0.4 vs 3.4±0.5 ng/mL vs , P=0.02 and 2.1±0.2 vs 1.2±0.01 ng/mL vs , P=0.02).
Summary / Conclusion: Taken together, our findings suggest a role for MI MM contributing to osteolysis and aggressive disease.

B1480

INCREASED SERUM LEVELS OF MIP-1ALPHA CORRELATE WITH BONE DISEASE AND ANGIOGENIC CYTOKINES IN MULTIPLE MYELOMA PATIENTS

G Tsirakis[1*], C Pappa[2], A Boula[2], A Kolovou[3], C Vasilokonstantaki [4], M Alexandrakis[1]
[1]Hematology, University Hospital of Heraklion, [2]Hematology, Venizelion General Hospital of Heraklion, Heraklion, [3]Hematology, General Hospital of Chania, Chania, [4]Hematology Laboratory, University Hospital of Heraklion, Heraklion, Greece

Background: Many cytokines possess multiple roles in the pathogenesis of multiple myeloma. Macrophage inflammatory protein-1alpha (MIP-1alpha) is an osteoclast activating factor with a major role in myeloma bone disease.
Aims: The aim of the study was to examine the participation of MIP-1alpha in the angiogenic process of the disease, by correlating its levels with major angiogenic factors, such as basic-fibroblast growth factor (bFGF), hepatocyte growth factor (HGF) and interleukin-18 (IL-18).
Methods: Fifty-six newly diagnosed myeloma patients (30 male and 26 female; median age 66 years, range 40-84 years) were enrolled in the study. The types of monoclonal proteins were: IgG for 34 patients, IgA for 16 patients and light chain disease for 6 patients. According to international staging system, 16 were in stage I, 19 in stage II and 21 in stage III of the disease. Bone involvement was graded according to standard X-ray evaluation, into four scores: grade 0, with no lesions (16 patients), grade1, with involvement of one bone or with diffuse osteoporosis (10 patients), grade2, with more than one but less than four bone lesions (10 patients) and grade3, with more than four lesions or presence of bone fracture (20 patients). Twenty-five, age and sex matched, healthy volunteers were used as controls.
Serum samples were collected from all subjects, stored at -70^{o}C, and assayed at the end of the study. Serum levels of the MIP-1alpha, IL-18, bFGF and HGF were measured by ELISA, according to manufactures' instructions.
Results: All analyzed parameters were found higher in myeloma patients (P<0.001 for all cases). They were all also increasing levels with the advance of the disease (P<0.001 for all cases). Similarly with disease staging, all of them were higher while bone involvement was progressing (P<0.04 for MIP-1alpha, P<0.001 for other cases). In the group of myeloma patients, serum levels of MIP-1alpha correlated positively with IL-18 (r=0.596), b-FGF (r=0.509) and HGF (r=0.424). Furthermore, IL-18 correlated positively with b-FGF and HGF (r=0.676 and r=0.511 respectively), while b-FGF correlated positively with HGF (r=0.508) (P<0.001 for all cases).
Summary / Conclusion: MIP-1alpha seems to be a predominant factor responsible for the enhancement of bone resorption and increased angiogenesis. The positive correlation between MIP-1alpha and the angiogenic chemoattractants supports the involvement of these factors in the biology of myeloma cell growth. Moreover, they could be used as possible therapeutic targets as well as markers of disease activity.

B1481

EPILEPSY DOSES OF VALPROATE COMBINED WITH THE ANTI-HELMINTHIC, NICLOSAMIDE, SYNERGISTICALLY KILL MYELOMA CELLS: A POTENT NEW ANTI-MYELOMA DRUG COMBINATION.

L Ferretti[1*], S Raffles[2], H Giles[1], M Jankute[1], B Merrick[2], C Bunce[1], M Drayson[2], F Khanim[1]
[1]School of Biosciences, [2]Medical School , The University of Birmingham, Birmingham, United Kingdom

Background: Multiple myeloma (MM) is a plasma cell neoplasm which is characterized by a clinical course of remission and relapse. Progressions in its treatment have largely focused on developing novel agents; however, drug redeployment offers an inexpensive and efficacious strategy for identifying new therapeutic options with minimal adverse effects. Using a drug-redeployment screening strategy, we identified and have shown that the anti-helminthic niclosamide is an effective anti-myeloma agent that targets the mitochondrial respiratory chain inducing production of mitochondrial superoxide (mitosox) and triggering apoptosis and autophagy. Rescreening of the library with low dose niclosamide identified valproate, an anti-epileptic and Histone Deacetylase Inhibitor (HDI), as potentiating cell killing. Here we show that valproate used at anti-epilepsy doses has little or no activity alone, but in combination with niclosamide, demonstrates potent synergistic anti-myeloma activity. Our data shows that this synergy arises through enhanced production of oxidative stress, reduction of antioxidative responses and modulation of acetylation state of non-histone proteins.
Aims: The aim of this project is to identify redeployed drug combinations with anti-myeloma activity that will offer therapeutic hope for relapsed/refractory myeloma patients.
Methods: Cell viability, cell death and reactive oxygen species (ROS) production was measured using flow cytometry. N-acetylcysteine (NAC) was used to modulate ROS levels. Molecular, cellular and biochemical studies were performed to measure Superoxide dismutase (SOD) activity, changes in gene expression and protein levels. Acetylation state and levels of proteins were assessed using proteomics approaches.
Results: Cross-titrations of niclosamide and valproate demonstrated synergistic killing of MM cell lines associated with both apoptosis and autophagy. We have shown previously that niclosamide induces mitochondrial superoxide (mitosox) in MM cell lines. Here we show that valproate induced production of non-mitosox ROS, alone and in combination with niclosamide treatment whilst also potentiating production of mitosox in the combination treatment. The role of oxidative stress was verified with the antioxidant N-acetylcysteine partially rescuing MM cell lines from cell death induced by the drug combination. The increase in mitosox production correlated with decreased mitochondrial SOD (SOD2) activity, whereas activity of the cytosolic SODs (SOD1, SOD3) was unaffected. Although we did observe perturbations in sirtuin gene expression and in mitochondrial genes, these together with the changes observed in SOD2 mRNA or protein levels did not explain the enhanced oxidative stress levels in the combination treatment. Since many non-histone proteins have been shown to be regulated by acetylation, we have performed an acetylome analysis using tandem mass-tagging (TMT) and mass spectrometry to dissect the role of low dose valproate on protein acetylation in myeloma cells. Preliminary data demonstrates changes in SOD2 acetylation, a modification that regulates SOD2 activity.
Summary / Conclusion: We have successfully identified a redeployed drug combination with anti-myeloma activity using small scale screening of a drug library. The combination of valproate and niclosamide (VaN) demonstrated potent synergistic anti-myeloma activity. Importantly, the concentrations of both agents used are clinically achievable, safe and affordable which will expedite progression of VaN therapy to phase I/II clinical trials.

B1482

TRANSLOCATION T(14;16): FREQUENCY AND SIGNIFICANCE IN PATIENTS WITH MULTIPLE MYELOMA

P Mičková[1*], J Balcárková[1], T Pika[2], M Holzerová[1], K Nevimová[1], V Ščudla[2], K Indrák[1], M Jarošová[1]
[1]Department of Hemato-Oncology, Faculty of Medicine and Dentistry , [2]Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacký University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic

Background: Together with translocations t(4;14) and t(14;20) and deletion of the TP53 gene, translocation t(14;16) is a high-risk cytogenetic aberration in patients with multiple myeloma (MM). Translocation t(14;16) with subsequent

increased expression of the *MAF* proto-oncogene and deregulation of the *WWOX/FOR* gene are associated with an aggressive course of the disease, decreased sensitivity or resistance to chemotherapy and early progression/relapse of the disease. Due to its very low incidence in MM patients (2-10%), the significance of t(14;16) has not been fully elucidated.
Aims: The goals were to determine the frequency of translocation t(14;16) and to analyze cytogenetic, molecular cytogenetic and clinical data in a group of patients with MM or monoclonal gammopathy of undetermined significance (MGUS) diagnosed and treated at the Department of Internal Medicine III and cytogenetically investigated at the Department of Hemato-Oncology, University Hospital Olomouc in 2000-2013.
Methods: In all MM or MGUS patients, bone marrow was tested by conventional cytogenetic methods and FISH with locus-specific, centromeric, whole chromosome and BAC probes; one patients was investigated using mFISH and arrayCGH.
Results: Translocation t(14;16) was found in 10 (2.9%) out of a total of 339 patients investigated for *IgH* gene rearrangement. The group of 10 patients comprised 5 males and 5 females with a median age of 67 years. The only monoclonal immunoglobulin isotype detected in the patients' blood serum was the IgG isotype; in two patients, a Bence Jones protein was detected. The ratio of kappa to lambda free light chains was 5:5. Using the Durie-Salmon staging system, clinical stage I was found in 2 patients and stages II and III in 3 and 5 patients, respectively. Significant renal insufficiency was observed in 3 patients. Cytogenetic and molecular cytogenetic assays revealed other additional changes in all 10 patients with s t(14;16): deletion of the RB1 gene (7 patients), trisomy or tetrasomy of chromosome 15 (7 patients) and structural and numerical aberrations of chromosome 8 (7 patients). To determine the frequently altered regions of chromosomes 8p and 8q, BAC-specific probes were used as follows: 8p23.1 (RP11-589N15), 8p21.3 (RP11-177H13), 8q24.21 (*MYC* FISH DNA probe), 8q24.3 (RP11-639O3), RP11-639O3 (8q24.3) and a chromosome 8 centromere probe. The most frequently detected chromosome 8 aberration was deletion of the short arm region (8p21.3).
Summary / Conclusion: Cytogenetic and molecular cytogenetic analysis of 339 patients with MM or MGUS confirmed a low incidence of t(14;16) (2.9%). In no patient, this was the only aberrations; it was a part of complex changes in 9 out of 10 patients. Recurrent aberrations in the complex karyotype of patients with t(14;16) were aberrations of chromosomes 13, 15 and 8. Out of 10 patients, only 2 are alive, with the OS rates of 5 and 20 months, confirming the adverse prognostic significance of this aberration in this small group of patients.

Supported by Palacký University student research grant no. LF-2013-004

B1483

THE RELATIONSHIP OF MYELOMA CELLS, STROMAL CELLS AND MONOCYTES UNDER BONE MARROW MICROENVIRONMENT

H Ikeda[1*], Y Aoki[1], T Hayashi[1], T Ishida[1], Y Shinomura[1]
[1]First department of internal medicine, Sapporo medical university, Sapporo, Japan

Background: Multiple myeloma (MM) is a disease characterized by clonal B-cell tumors of slowly proliferating plasma cells within the bone marrow. The current data on MM disease progression indicate thatbone marrow microenvironment plays crucial role in pathogenesis of MM. Myeloma cells contacts with bone marrow stromal cells (BMSCs), which secrete factors/cytokines, promoting tumor cell growth and survival. Paracrine secretion of cytokines such as interleukin-6 (IL-6), insulin-like growth factor-1, and inflammatory protein-1a in BMSCs promotes multiple myeloma cell proliferation and protects against drug-induced cytotoxicity. These cytokines provide stimulatory signals for multiple myeloma growth and survival.
Myeloma is closely associated with lytic bone disease, the most debilitating manifestation of the malignancy, found in 40-75% of patients. Disease-related skeletal complications in MM patients result in significant morbidity due to pain, pathologic fractures and spinal cord compression. The BM microenvironment creates a supportive niche for myeloma cell growth. Osteoclasts and BMSCs, along with extracellular matrix and cytokines stimulate tumor cell proliferation and confer chemoresistance. Therefore, dynamic reciprocal interactions among myeloma cells, osteoclasts, osteoblasts, and BMSCsimpact both the establishment and progression of MM.
In current study, monocyte can directly promote osteogenic differentiation of BMSCs through cell contact interactions and production of osteogenic factors. This mechanism is mediated by the activation of STAT3 signaling pathway in the mesechymal stem cells that leads to the upregulation of Osteoblasts-associated genes such as Runx2 and alkaline phosphatase (ALP), and the down-regulation of inhibitors such as DKK1 to drive the differentiation of mesechymal stem cells into osteoblasts.
Aims: The aim of this study is to expose a role of monocytes that supports myeloma cells in BM microenvironment.
Methods: The growth inhibitory effect of MM cell lines, monocytes and BMSCs was assessed by measuring 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrasodium bromide (MTT) dye absorbance.
To evaluate growth stimulation and signaling in MM cells, MM cells were cultured in BMSC coated 96-well plates in the presence or absence of monocyte. DNA synthesis was measured by [3H]-thymidine uptake, with [3H]-thymidine added during the last 8 h of 48 h cultures. All experiments were performed in quadruplicate.
Results: we observed increased proliferation of MM cell lines in the presence of either BM stromal cells or monocytes compared to cell line-only control. Furthermore, the co-culture of BM stromal cells plus monocytes induced the greatest degree of proliferation of myeloma cells. In addition to increased proliferation, BMSCs and monocytes decreased the rate of apoptosis of myeloma cells.
Summary / Conclusion: Our results therefore suggest that highlights the role of monocyte as an important component of the BM microenvironment.

B1484

BORTEZOMIB UPREGULATES OSTERIX AND OSTEOCALCIN IN OSTEOBLASTS AND REDUCED MYELOMA-INDUCED APOPTOSIS

Q Bai[1*]
[1]Hematology, Xijing Hospital, Fourth Military Medical University, Xi'an, China

Background: Multiple myeloma is the disease with the highest incidence of bone involvement among the malignant diseases. Complex interactions between myeloma cells and bone marrow stroma cellspromote osteoclastic bone resorption and suppress osteoblast activity, there is uncoupled or severely imbalanced bone remodeling with increased bone resorption and decreased or absent bone formation. Bisphosphonates are specific inhibitors of osteoclast activity. They reduce bone breakdown but do not restore bone formation.Clinical data indicate that Bortezomib has potential to regulate bone turnover and increase serum alkaline phosphatase and osteocalcin concentrations.The underlying mechanisms of Bortezomib's action on osteoblasts proliferation and apoptosis remain to be clarified. We therefore investigated roles of Bortezomib on cultured osteoblast in the present study.
Aims: To explore Bortezomib's effects on osteoblasts in the presence of myeloma cells and culture supernatants.
Methods: To mimic the microenviroment of osteoblasts in myeloma bone disease, the mouse calvaria-derived MC-3T3E1 osteoblast cells were cocultured with RPMI8226 myeloma cells and the supernatants. Cell proliferation and apoptosis were evaluated by MTT assay and flow cytometry respectively. Formation of mineralized nodules was calculated by alizarin red staining. RT-PCR and Wstern blot were employed to access expressions of Runx2/cbfa1, osteocalcin (OCN) and osterix (OSX).
Results: MTT results showed Bortezomib dose-dependently inhibited MC-3T3E1 cells growth with an IC50 of 38.1 nM at 48 h. Bortezomib lower than 5 nM was tolerable and non-toxic to both MC-3T3E1 and RPMI8226 cells. MC-3T3E1 cells cocultured with RPMI8226 cells or supernatants underwent extensive apoptosis while 5 nM Bortezomib significantly attenuated apoptosis in conditioned culture. OSX and OCN at mRNA and protein levels markedly increased as response to 5 nM Bortezomib. However, no significant changes were observed in Runx2/cbfa1 expressions and mineralized nodules formation.
Summary / Conclusion: Bortezomib at low concentrations prevented apoptosis and protected osteoblasts in myeloma bone disease. These effects might be mediated by the activation of OSX and OCN through a Runx2/cbfa1-independent mechanism.

B1485

ANALYSIS OF B-CELLS AND PLASMA CELLS IN MONOCLONAL GAMMOPATHIES

P Všianská[1,2*], L Říhová[1,2], T Varmužová[1,2], R Suská[1], M Penka[1], R Hájek[1,2]
[1]Dept. of Clinical Haematology, University Hospital Brno, [2]Babak Myeloma Group by Dept. of Pathological Physiology, Faculty of Medicine, Masaryk University Brno, Brno, Czech Republic

Background: Monoclonal gammopathy of undetermined significance (MGUS) is non-malignant disease, which can progress into malignant form-multiple myeloma (MM). MM is characterized by the presence of clonal plasma cells (PC) arising from malignant transformed B-cells. It is still not clear which stage of B-cell differentiation is responsible for the development of MM and for eventual relapse after treatment, so nowadays there is an effort to identify the source of myeloma-initiating cells.
Aims: Analysis of the phenotypic profile and enumeration of B and PC subpopulations in monoclonal gammopathy patients.
Methods: Total of 38 newly diagnosed MM patients, 18 MGUS patients and 18 controls without MM were analysed. There were identified $CD19^+$ cells in peripheral blood (PB) or bone marrow (BM) and surface expression of CD38, CD45, IgD, CD24, CD20, CD138, CD19, CD27 and IgM was studied by 8-color flow cytometry. The enumeration of transitional, naive, preGC and memory B-cells (with/without isotype switched), switched $CD27^-$ B-cells and plasmablasts was done in PB. Moreover, immature B-cells and normal/abnormal PCs were detected in BM. Comparison of MM samples with controls and MGUS samples was done.
Results: There was found significantly lower % of the total $CD19^+$ cells in MM than in control samples for both PB [3.9% (0.4-8.9) vs. 6.8% (3.8-12.2), $P<0.005$] and BM [4.2% (0.6-50.9) vs. 11.3% (3.5-20.9), $P<0.05$]. Moreover in

BM the decrease of CD19+ cells in MM was significant also compared with MGUS [7.9% (3.9-21.1), P<0.005]. In PB, transitional B-cells were reduced in MM when compared with controls [0.9% (0.0-12.2) vs. 2.5% (0.8-5.8), P<0,05], while reduction of naive B cells in MM was significant compared with both controls [36.4% (2.4-70.9) vs. 56.0% (45.2-70.6), P<0.01] and MGUS [56.7% (7.7-77.2), P<0.05]. On the contrary, switched memory B-cells were increased in MM compared with controls [20.5% (4.9-67.2) vs. 12.5% (6.5-17.1), P<0.01] and MGUS [11.3% (4.2-41.3), P<0.01]. In comarison with controls, higher number of CD27- switched B-cells was found in MM [10.0% (2.6-38.0) vs. 5.2% (2.4-9.0), P<0.01], as well as preGC B-cells were increased in MM compared with controls [0.7% (0.0-2.4) vs. 0.3% (0.0-0.8), P<0.01]. No difference was found when compared plasmablasts in all three groups. In BM there were found similar results as reduction of naive B-cells in MM compared with controls [37.0% (0.6-67.9) vs. 48.0% (27.3-86.3), P=0.05] and MGUS [50.1% (13.8-74.9), P<0.05], as well as increase of switched memory B-cells in MM compared to both controls [14.0% (1.4-41.3) vs. 5.7% (1.7-11.5), P<0.05] and MGUS [6.0% (0.5-21.3), P<0.05] and increase of CD27- switched B-cells in MM compared with controls [8.1% (1.3-96.4) vs. 5.9% (1.4-13.7), P<0.01]. In contrast to PB, plasmablasts in BM were increased in MM compared with MGUS [2.6% (0.1-18.0) vs. 1.2% (0.4-31.6), P<0.05]. As expected, higher % of PC was found in MM mostly with abnormal phenotype CD19- compared with both MGUS and controls (P<0.005).

Summary / Conclusion: Polychromatic flow cytometry is capable to identify minimum of 10 B-cell and PC subpopulations. Reduction of CD19+ cells in MM should be mediated by an increased number of abnormal PCs. The enhancement of isotype-switched memory CD27+ and isotype-switched CD27- B-cell subpopulations in MM patients suggests that some of these could be a potential source of myeloma-initiating cells. Analysis on DNA level will be done.

Supported by MSM0021622434, IGA NT12425 and GACR P304/10/1395 grants.

B1486

SPHINGOSINE KINASE 2 IS OVEREXPRESSED IN PATIENTS AFFECTED BY MULTIPLE MYELOMA

G Barra[1*], C Cerchione[2], E Madonna[2], G Pasquale[1], A Sementa[3], F Pane[2], L Catalano[2], R De Palma[1]

[1]Clinical & Experimental Medicine, Second University of Naples, [2]Hematology & BMT, Federico II University, Napoli, [3]Ematologia e TMO, Azienda Ospedaliera SG Moscati, Avellino, Italy

Background: Sphingosine-1-phosphate (S1P) is a bioactive sphingolipid generated upon phosphorylation of Sphingosine by two kinases, Sphingosine Kinase 1(SHPK1) and 2 (SHPK2). S1P was first characterized for its role in controlling apoptosis-survival balance, however in the last years many data showed that this molecule has a peculiar role in embryology and maturation of vascular compartment, trafficking and function of cell of the immune system, inflammation, cell transformation. SHPK1 is found in the cytosol while SHPK2 is found mainly in the nucleus. SHPK2 seems to be able to affect gene transcription. It is now accepted that these two kinases may have different role in cell functions. Recent findings suggest that these two kinases may play an important role in the growth and behaviour of cancer cells. There are no data concerning the expression of SHPK1 and SHPK2 in MM.

Aims: The aims of this work was to assess the expression of SHPK1 and SHPK2 in bone marrow of patients affected by Multiple Myeloma (MM).

Methods: We analyzed the bone marrow of fourteen individuals who underwent bone marrow biopsy for diagnostic purposes. Six individuals had MM at the first diagnosis, one individual had MM and was at that moment in remission after chemotherapy, two individuals were found to be normal, five individuals had other hematological malignancies (ALL, AML, CML, CLL). cDNA was prepared acording to standard protocols and quantitative PCR was performed using validated specific primer for SHPK1 and SHPK2 using a 7500 Thermal Cycler. The results were analyzed using a dedicated software.

Results: We found that SHPK2 was overexpressed in marrow of MM patients (P<0.001) when compared to normal marrow and to other hematological malignancies (P<0.05). Intriguingly, the patients with MM in remission showed levels of SHPK2 comparable to normal marrow. Same levels of SHPK1 were measured in normal individuals and in patients regardless of the disease.

Summary / Conclusion: These preliminary data indicate that SHPK2 is highly expressed in bone marrow of MM patients. SHPK1 was found to be expressed always at similar levels in normal individuals, individuals with MM or other hematological malignancies. Therefore, it is likely that the role of SHPK2 in MM is not, or not only, linked to phosphorylation of sphingosine. It is possible to speculate that here SPHK2 has a function due to its capacity to control gene transcription. More data are needed to confirm these results and to understand the meaning of the expression of this kinase in MM. However, these data may lead to new therapeutical approaches in MM through specific targeting of SPHK2.

B1487

ESTABLISHMENT OF A BORTEZOMIB-RESISTANT CELL LINE KM3/BTZ

P Yedi[1*], W Luqun[1]

[1]Department of Hematology, Qilu Hospital of Shandong University, Jinan, China

Background: Multiple myeloma is an incurable plasma cell malignant disease.As the first generation proteasome inhibitor,bortezomib already displays significant single-agent anti-tumor activity in the treatment of MM.However,drug-resistance has been a major challenge.So,we will establish the cell line resistant in bortezomib,and investigate its biological characteristics and mechanisms of drug-resistant in MM preliminarily.

Aims: To establish a bortezomib-resistant cell line KM3/BTZ of human multiple myeloma (MM) and investigate its biological characteristics and mechanisms of drug-resistant in MM preliminarily.

Methods: The KM3 cell line was exposured to bortezomib at increasing doses to obtain a stable bortezomib-resistant KM3/BTZ in vitro. The growth curve was drawn and the doubling time was counted. MTT assay was used to evaluate the sensitivity of drug resistance. The expression of MDR-1 mRNA was determined by RT-PCR in KM3 and KM3/BTZ cell lines.

Results: The KM3/BTZ cell line resistant to bortezomib was established successfully with the resistance index of 19.7 (KM3/BTZ to KM3). Compared with the parent cells, KM3/BTZ exhibited a significant longer doubling time (p□0.05) .The expression of MDR-1 mRNA was not observed in either resistant or parent cells.

Summary / Conclusion: We have successfully established bortezomib resistance cell line KM3/BTZ and its drug-resistant character is stable. The KM3/BTZ cell line might serve as an ideal model to explore the drug-resistance mechanisms and to reverse the drug resistance.

B1488

IMPACT OF P53 PERCENTAGE IN SURVIVAL OF PATIENTS DIAGNOSED OF MULTIPLE MYELOMA

B Zamarreño[1*], M Alvarez[1], A Cabrera[1], M Angel P Alvarez[1], H Henriquez[1], N Cruz[1], J Brito[1], T Labarta[1], M Bello[2]

[1]Hematology , [2]University Hospital Doctor Negrin, las Palmas de gran Canaria, Spain

Background: The natural history of multiple myeloma (MM) is highly variable despite the homogenous morphologic appereance of malignant plasma cells. Clinical outcome for MM appears to be defined by genetic events. Genetically high risk disease is defined as any of the following, t(4;14), t(14;16), t(14;20) deletion 17p by FISH, or deletion chromosome 13 or hypodiploidy by conventional metaphase cyogenetics. Chromosome 17p13 deletion seems to be an independent prognostic factor and also a progression marker.

Aims: To retrospectively investigate the prognostic impact of p53 on the outcome of newly diagnosed MM.

Methods: We analyzed the impact of p53 mutation in a series of patients who were diagnosed of MM since the year 2010. A series of 12 patients was analyzed: 6 male and 6 female. Median age at diagnosis was 63.16. We performed a comprehensive stratification of the disease, using the Durie Salmon staging system and the ISS. Fluorescence in situ hybridization (FISH) analysis identified genetic abnormalities such as +14 in 1 patient, t(4;14) in2, rearranged IgH in3, while the rest of our patients (6) only showed chromosome 17p13 deletion. 5 out of the 12 patients were included in the VISTA study, the other 7 patients were treated using a combination of Bortezomib-Dexamethasone. We show a table with our patients prognostic factors in Figure 1.

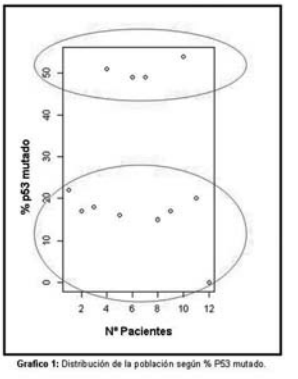


Grafico 1: Distribución de la población según % P53 mutado.

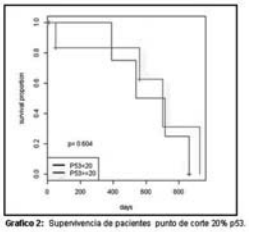

Grafico 2: Supervivencia de pacientes punto de corte 20% p53.

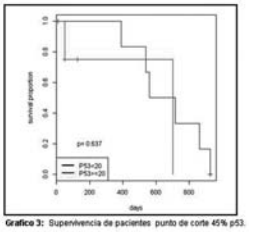

Grafico 3: Supervivencia de pacientes punto de corte 45% p53.

Results: Two patients died in the first two years because of MM progression, one of them within the first month presenting central nervous system (CNS) involvement. 1 patient died after 4 m. because of refractory disease and 3 patients died the first month after diagnosed; 2 of septic shock and the other because of rapid progression. 4 patients are receiving maintenance chemotherapy, 1 has relapsed, and 2 patients are not taking any medication, being closely followed on their disease evolution. The presence of mutated p53 in the medical literature in MM has been related with CNS involvement and bad response to conventional treatment, including autologous hematopoietic stem cell transplantation. It is well known that mutated p53 worsens the prognosis in patients diagnosed with MM, though there is still a controversy about wether the percentage of p53 mutated cells is important in these patients progress. Since we were looking for a cut-off point to predict a worse prognosis, we divided the sample (graph 1) into two different groups, establishing a cut-off point of 20 % and 45 % to evaluate the survival. Even though our sample has a small number of patients and we could not find any statistically significant difference using both cut-off point of 20 % (graph 2) and 45 % (graph 3); out of the 5 deceased patients, two presented a mutated p53 under 20 %; 3 of them over 45%. One out of the 3 patients that presented a p53 over 45 %, showed another cytogenetic alteration that is related to bad prognosis t(4;14); leaving the rest only to present p53 mutation as the isolated prognostic marker. Though our results have not been statistically significant, in our group of patients, those who showed a p53 mutation over 45 % turned out to have decreased OS because of a rapid disease progression. We could consider the high percentage, over 45, of mutated p53 as an independent bad prognostic factor.

Summary / Conclusion: Even though we present here a very small sample, the poor prognosis of the chromosome 17p13 deletion is obvious, with the following survival graphics.Since there are no studies about the importance of percentage of mutated p53 cells in MM and its relation with other prognostic factors, we suggest that studies with bigger samples are needed.

B1489

CYTOTOXIC EFFECTS OF APIGENIN ON MULTIPLE MYELOMA CELLS

Y Baran[1*], S Yilmaz1, Z Cincin[2], I Kozanoglu[3], B Cakmakoglu[2], H Ozdogu[3]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, Izmir, [2]Department of Molecular Medicine, Istanbul University, Institute of Experimental Medical Research, ISTANBUL, [3]Department of Hematology, Baskent University, Adana Teaching and Medical Research Center, Adana, Turkey

Background: Apigenin, a common plant flavonoid, has been reported to suppress the proliferation of prostate, breast cancer and various types of leukemic cells. It also inhibits cell cycle progression and induces apoptosis. Apigenin triggers its anti-carcinogenic effects by inducing modulation of several kinase activities, inhibition of NF-KB and proteosomal activation and proteosomal degradation of Her2/neu proteins. Multiple myeloma is the second most common hematologic cancer. However, an approach that can cure multiple myeloma completely via current approach is not achieved yet.

Aims: The purpose of this study is to determine the cytotoxic and apoptotic effects of Apigenin on U266 Multiple Myeloma cells.

Methods: Time-dependent antiproliferative effect of Apigenin was determined by MTT cell proliferation test. Apoptotic effects of Apigenin was determined by changes in activity of caspase-3, loss of mitochondrial membrane potential and localization of phosphatidylserine on plasma membrane (Anexin-V by flow cytometry).

Results: The results demonstrated that Apigenin has time and dose-dependent anti-proliferative effect on U266 Multiple Myeloma cells. IC50 values obtained for Apigenin at 48- and 72 hours on U266 Multiple Myeloma cells were 36.6- and 31.4 μM, respectively. It was shown that caspase-3 enzyme activity was increased 164- and 186% in response to 30-, and 40 μM Apigenin, respectively. There were 21.5-, 36.7-, and 63% of the cells in apoptosis in response to 20-, 30-, and 40 μM Apigenin, respectively. As compared to control group, there were 69- and 162% increases in loss of mitochondrial membrane potential of U266 cells exposed to 20-, and 30 μM Apigenin.

Summary / Conclusion: In conclusion, all these results showed for the first time that Apigenin has anti-proliferative and apoptotic effects on multiple myeloma cells in a dose-dependent manner.

B1490

TREND ANALYSIS OF P53 AND AMPLIFICATION OF CYCLIN D1 GENE IN MULTIPLE MYELOMA AFTER BORTEZOMIB AND DOUBLE AUTOLOGOUS STEM CELL TRANSPLANTATION

A Fiorini[1*], P Falcucci[2], A Carpaneto[3], M Montanaro[3], R Ottaviani[4]
[1]hematology, ospedale s.anna, ronciglione-viterbo, [2]hematology, ospedale s.anna , [3]ospedale s.anna, ronciglione, [4]cytogenetics department, ospedale belcolle , viterbo, Italy

Background: In patients with multiple myeloma (MM) risk stratification by chromosomal abnormalities may enable a more rational selection of therapeuthic approaches. Patients presenting with del (17p) are known to have a short event-free survival (EFS) and overall survival (OS); patients with t(11;14) and amplification of cyclin D1 have relatively favorable prognosis; instead patients with up-regulation of cyclin D1 independently of a t(11;14) have indefinite prognosis. Some data suggest that Bortezomib-based treatment is able to improve outcome in patients with MM, including patients with high-risk chromosomal aberrations, while double autologous transplantation can not overcome the poor prognosis of high-risk cytogenetics.

Aims: We evaluated the correlation between bone marrow FISH analysis changing (from the diagnosis to the consolidation therapy) and response to therapy after induction therapy, first and second autotransplantation.

Methods: A female patient 58 years old was diagnosed with Multiple Myeloma IgG/K, Durie&Salomon stadium III, ISS 2. She underwent to 7 cycles of VTD (Bortezomib, Thalidomide, Dexametasone) and then she received double autologous stem cell transplantation. Fish analysis was performed on bone marrow sample of patient at diagnosis, after 7 cycles of Bortezomib-Thalidomide-dexametasone, after I and II autologous transplantation. We performed bone marrow biopsy and laboratory test at the same time of FISH analysis. Patient underwent also to MR whole body and CT scan of bone to assess the response to therapy.

Results: Our patient achieved a poor partial response after 7 VTD cycles; after the first auto-transplantation she achieved a good partial response which was confirmed after the second one. FISH analysis at diagnosis showed the presence of p53 in 4.6% of analysed nucleus and the amplification of D1 cyclin in 20.7% of nucleus; after induction therapy (7 VTD) p53 was in 15.5% of nucleus and amplification of D1 cyclin in 3.3%. After the first autotransplantation p53 was in 11.4% of nucleus and amplification of D1 cyclin in 2.5%; after the second transplantation percentage of p53 and D1 cyclin were respectively 4.4% and 0. FISH analysis at diagnosis showed the presence of p53 in 4.6% of analysed nucleus and the amplification of D1 cyclin in 20.7% of nucleus; after induction therapy (7 VTD) p53 was in 15.5% of nucleus and amplification of D1 cyclin in 3.3%. After the first autotransplantation p53 was in 11.4% of nucleus and amplification of D1 cyclin in 2.5%; after the second transplantation percentage of p53 and D1 cyclin were respectively 4.4% and 0.

Summary / Conclusion: Our data show a better response to therapy at the same time of reduction of p53 after double autologous stem cell transplantation and not after bortezomib-based induction therapy. We suggest that double autotranplantation after high-dose chemotherapy in high-risk multiple myeloma can still have a role for treatment of high-risk multiple myeloma in the present. The prognostic role of amplification of D1 cyclin indipendently of a t(11;14) in not so clear nowday. Our patient is now receiving consolidation therapy with Bortezomib-Thalidomide-Dexametasone and she will undergo to a new FISH analysis at the end of the second course of consolidation.

B1491

PROGNOSTIC VALUE OF 13Q14 DELETION AND IGH REARRANGEMENT BY INTERPHASE FISH IN EGYPTIAN MULTIPLE MYELOMA PATIENTS

M Moussa[1*], R Ali[2]
[1]Internal Medicine and Hematology, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Multiple myeloma (MM) is a clonal bone marrow disease characterized by the neoplastic transformation of differentiated B cells with the accumulation of malignant plasma cells in the bone marrow compartment. In Egypt, its extrapolated prevalence is 17,630/76,117,421 with annual rate around4,085/76,117,421. Chromosomal aberrations in MM are typically complex and represent a hallmark of the disease, the most frequent structural aberrations are 13q14 deletion detected in 33-50% of the cases and 14q32 IgH rearrangement detected in 60-70% of the cases with t(11;14) (q13;q32) being the most frequently detected 14q32 translocation seen in 15% of these patients.

Aims: To detect both 13q14 deletion and 14q32 IgH rearrangement by I-FISH on 100 newly diagnosed Egyptian myeloma patients and their relation to patients outcome and prognosis .

Methods: Patients were subjected to complete history, clinical examination and laboratory. Also we tested the expression of 13q14 deletion by LSI D13S319 probe assay and 14q32 IgH rearrangement by IGH dual color FISH break apart assay on bone marrow samples collected from the patients at diagnosis (before starting therapy). Staging and follow up of patients were carried out to detect the outcome of the disease.

Results: we found that 65% of the examined myeloma patients showed genetic aberrations (13q14 deletion, 14q32 IgH rearrangement or both) by I-FISH. Of which, 40% were positive only for 13q14 deletion, 20% were positive only for 14q32 IgH rearrangement and only 5% was positive for both aberrations.
13q14 deletion was associated with more patients being resistant to chemotherapy or dying indicating its poor impact on patients' prognosis, whereas 14q32 IgH rearrangement was associated with more patients in remission indicating its good impact on patients' prognosis. Comparing myeloma patients who went into remission to those who died or were resistant to chemotherapy revealed highly statistical significance (p value ≤ 0.001) as regards to their serum Calcium, Albumin, B2 microglobulin and bone marrow clonal plasma cell levels with p values (0.0009,0.0001,0.0001 and 0.0001 respectively). Moreover, there was a statistical significance (p value ≤ 0.05) found in these patients as regards to their total protein and serum M-component with p values (0.0288 and 0.0182 respectively).

Summary / Conclusion: 13q14 deletion detected by LSI D13S319 FISH probe in myeloma patients was seen in 40% of the studied cases and was associated with patients being resistant to chemotherapy or dying. Whereas, 14q32 IgH rearrangement detected by IGH dual color break apart FISH assay in these patients was seen in 20% of the studied cases and was associated with patients in remission.

Myeloma and other monoclonal gammopathies - Clinical

B1492

ROLE OF 18 F-FDG PET/CT IN THE ASSESSMENT OF PATIENTS WITH SMOLDERING MULTIPLE MYELOMA

T Za[1*], E Rossi[1], C Caldarella[2], A Ciminello[1], S Betti[1], L Fianchi[1], V Rufini[2], G Leone[1], A Giordano[2], V De Stefano[1]
[1]Institute of Hematology, [2]Institute of Nuclear Medicine, Catholic University, Roma, Italy

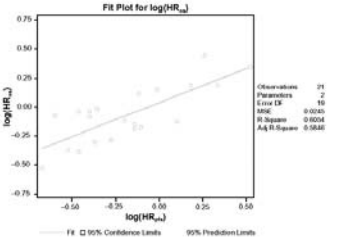
Background: Smoldering multiple myeloma (SMM) is a proliferative plasma-cell disorder without organ damages (defined as presence of hypercalcemia and/or renal insufficiency and/or anemia, and/or lytic bone lesions, CRAB), and without need to treat. Whole body X-ray (WBXR) and magnetic resonance imaging (MRI) are the cornerstone imaging procedures in the initial staging.
Aims: The aim of the study was to determine the role of ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET) / computed tomography (CT) for the assessment of bone disease in patients with SMM without lytic lesions in standard imaging.
Methods: The study population consisted of 46 patients (M/F 23/23) with diagnosis of SMM referred at our institution from February 2008 to December 2012; the median age was 67.5 years (range 39-88). Diagnosis of SMM was established according to the criteria of the International Myeloma Working Group. In particular, SMM was characterized by the presence of a monoclonal component (MC) of >3 g/dL and/or bone marrow plasma cell infiltration of >10%, and/or the presence of Bence-Jones proteinuria >1 g/dL in the absence of end-organ damage (CRAB). The MC components were as follows: IgGκ in 26 patients, IgGλ in7, IgAk in7, IgAλ in4, light chain λ in 1 and biclonal in 1. All patients performed PET/CT at our institution at the time of diagnosis together with WBXR and MRI of the spine and pelvis; the exam was repeated in 13 patients during follow-up (median 11.5 months, range 5-31). No patient received chemotherapy. Three authors (TZ,ER,VDS), blinded to each other, classified like "advantageous" or "not-advantageous" the use of PET/CT imaging for the overall management of the patients. Criteria of judgement were the influence of PET/CT in the identification of evolution to SMM to a symptomatic form to be treated, the confirmation of no evolution, the identification of other neoplastic diseases.
Results: In 12 cases PET/CT detected focal increased FDG uptake at diagnosis and upstaged the disease (26%). All the abnormal areas corresponded to bone lesions later identified by MRI (n=10) or TC (n=2) (100% sensitivity); in 1 patient bone lesion was also confirmed by a a novel detailed X-ray. In 3 patients the bone lesions were found outside the spine or the pelvis. In 2 additional cases PET/TC detected synchronous solid neoplasms (renal and prostatic). In 4 of the remaining 32 cases (25%) without FDG uptake at diagnosis, PET/CT allowed to classify as osteoporosis some doubtful lesions at standard imaging. In three cases PET/CT was considered falsely negative for bone lesions (91% specificity). In 1 cuneiform vertebra bone biopsy showed plasmocytoma; in 2 cases bone lesions detectable at MRI developed during the follow-up in X-rays areas suspected at diagnosis but PET/CT-negative. During the follow-up, PET/CT revealed evolution of disease in 4 of 13 patients (30.7%). PET/CT was considered advantageous in 14 SMM patients (30.4%), because of upstaging of MM (n=12) or detection of another neoplasm (n=2); notably, in all the upstaged patients the bone lesions were not identified by first WBXR and were outside the areas explored by first MRI in 3 patients (6.5% of the overall cohort and 25% of the PET/CT-positive patients).
Summary / Conclusion: PET/CT can upstage SMM at diagnosis or during the follow-up in at least one-quarter of cases and should be included in the imaging work-up of the patients with SMM.

B1493

INVESTIGATION OF THE RELATIONSHIP BETWEEN TREATMENT EFFECTS ON PROGRESSION FREE SURVIVAL AND OVERALL SURVIVAL IN CLINICAL TRIALS OF MULTIPLE MYELOMA BASED ON PUBLISHED LITERATURE

S Cartier[1*], B Zang[2], V Rosen[1], V Zarotsky[1], J Bartlett[2], P Mukhopadhyay[3], S Wagner[2], Y Su[2]
[1]OptumInsight, Inc., Burlington, Canada, [2]Bristol-Myers Squibb, Princeton, [3]Bristol-Myers Squibb, Wallingford, United States

Background: A primary goal in the development of new oncology therapies is to improve overall survival (OS). In recent years, advances in the treatment of multiple myeloma (MM) have led to improvements in OS. However, with improved treatment options and multiple rounds of therapy it is becoming an increasing challenge to demonstrate OS improvements in the context of clinical trials. Thus, progression free survival (PFS) is seen as an important surrogate marker for OS. However, a clear relationship between PFS and OS in patients with MM has yet to be established.
Aims: Use published literature to test the hypothesis that treatment effects on PFS are positively associated with treatment effects on OS in MM.
Methods: An initial systematic literature review of MM identified 13 studies published between 2002 and March 2012 that reported hazard ratios (HRs) for the effects of treatment on PFS and separately on OS. The literature review and subsequent analysis were updated with HRs identified for 4 additional studies. Patients in 16 of the studies received first-line treatment (13 investigating induction and 3 maintenance), only 1 study was in the relapsed/refractory setting. The Pearson correlation coefficient (r) was used to estimate the relationship between the reported HRs (HR_{PFS} and HR_{OS}), and the log-transformed HRs ($\log(HR_{PFS})$ and $\log(HR_{OS})$). The log transformation was conducted to minimize the non-linearity between the two HR distributions and allow for values between positive and negative infinity. R^2 values were estimated from linear regression models of the HR and the log(HR) relationships, with 95% Confidence Intervals around the R^2 values estimated using Olkin and Finn's approximation of the standard error and Student's T distribution. Sensitivity analyses included the estimation of two weighted regression models to investigate the robustness of the R^2 estimates. One method weighted studies by sample size, and the second weighting method utilized the geometric mean of the variance of the HRs to account for the multi-directional error around the two HRs. The subgroup of studies investigating treatment effects for induction in newly treated MM patients was also investigated.
Results: Pearson r estimates for the treatment effects on PFS and OS showed a positive relationship between HR_{PFS} and HR_{OS} r=0.799(CI: 0.55-0.91; P<0.0001), and between $\log(HR_{PFS})$ and $\log(HR_{OS})$ r=0.778 (CI:0.51-0.90; P=0.0014). Linear regression models reflected that the treatment effect on PFS was significantly associated with the treatment effect on OS, and produced R^2 values of 0.638 (CI: 0.41-0.86) for the regression of HR_{OS} on HR_{PFS} and R^2 values of 0.605 (CI: 0.37-84) for the regression of $\log(HR_{OS})$ on $\log(HR_{PFS})$. (Figure 1) The sensitivity analysis results for the Pearson r estimates were generally consistent, ranging from 0.65 to 0.82. The weighted regression models produced extremes for the R^2 estimates ranging from 0.42 to 0.67; the lower R^2 values resulting from the weighting by geometric mean. The subgroup analysis of studies investigating treatment for induction produced similar values to that of the base case analysis, r=0.804 for $\log(HR_{OS})$ on $\log(HR_{PFS})$ and the R^2=0.65.



Summary / Conclusion: This analysis based on published data indicates that the treatment effects on PFS are positively associated with treatment effects on OS among patients with MM. Although this empirical evidence has shown a positive association, further investigation involving patient-level data are necessary to confirm PFS as a valid surrogate for OS.

B1494

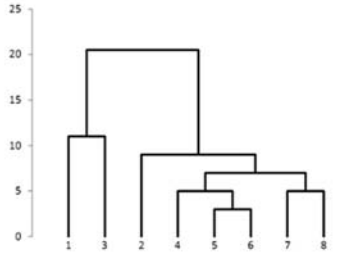
C-MYC GENE RELATED ABNORMALITY AND ADDITIONAL CHROMOSOME 8 WERE UNIQUE CYTOGENETIC ABERRATION IN MULTIPLE MYELOMA

N Sekiguchi[1*], N Takezako[1], M Wagatsuma[2], K Midorikawa[2], T Hagino[1], S Noto[1], K Yamada[2], A Miwa[3]
[1]Divison of Hematology, [2]Division of laboratoy and patology, National Hospital Organization Disaster Medical Center, Tachikawa, [3]Division of Hematology, National Center for Global Health and Medicine , Shinjuku, Japan

Background: Multiple myeloma (MM) is characterized by a significant heterogeneity and has multi-step genetic abnormalities. Worse prognostic factors (WPF) have been reported including non-hyperdiploidy (N-HD), and IgH/FGFR3, del17p, IgH/MAF1 by fluorescence *in-situ* hybridization (FISH) analysis.IgH/c-Myc has been widely accepted WPF in lymphoma, although the abnormality has not been fully studied in MM. Additional chromosome 8 was reported in WPF in 1990's. However, it has not been evaluated in the novel agent era.
Aims: To evaluate that c-Myc gene related abnormalities and additional chromosome 8 affected the prognosis.
Methods: Patients who were newly diagnosed with MM (NDMM) at the National Hospital Organization Disaster Medical Center (DMC) between June 2008 and June 2011 were enrolled in this study. As an initial therapy, cases received bortezomib and dexamethasone (BD) therapy was only evaluated. The Institutional Review Board of DMC approved this study, which was performed in accordance with the Declaration of Helsinki. Diagnostic criteria of MM in this study were according to the International Myeloma Working Group criteria. We

performed FISH analysis to detect major cytogenetic abnormalities including del13q, IgH/Bcl1, IgH/FGFR3, del 17p, and IgH/c-Myc. To clarify genetic aberrations, we additionally performed c-Myc translocation. All probe sets were from Abbott Laboratories. In the present study, WPF was defined as having at least one of following present; N-HD, IgH/FGFR3, and del 17p.Furthermore, to clarify the similarity of each aberrations, we performed hierarchical clustering analysis using Ward's method.

Results: Forty cases received BD therapy. The number of best response was as follows; sCR, CR, VGPR, PR, SD, and PD were1, 0, 12, 11, 15, and1, respectively. Fifteen cases had WPF. The number of IgH/c-Myc, c-Myc translocation (not with IgH), c-Myc gene amplification (GA), and additional chromosome 8 were2,1,5, and2, respectively. At the median follow-up duration was 399 days, fourteen cases were defined as relapsed or refractory MM (RRMM). Among 14 RRMM, 7 cases were available with cytogenetic results both at diagnosis and relapse. As additional aberrations, 3 of 7 cases gained WPF. In total, 8 of 12 cases had WPF in RRMM. On the other hand, 4 of 7 cases obtained additional chromosome8, and 2 of 7 cases gained c-Myc GA. In total, the number of IgH/c-Myc, c-Myc GA, and additional chromosome 8 were2,7, and 6 cases, and these aberrations were recognized in12 out of 14 RRMM. Hierarchical clustering analysis revealed del13q and IgH/FGFR3 made a cluster. Not only IgH/Bcl1, del17p, but also IgH/c-Myc and c-Myc gene translocation (not with IgH) were similar elements, and c-Myc GA and additional chromosome 8 genetic aberration were occurring closely together (See Image).



1; del13q, 2; IgH/Bcl1, 3; IgH/FGFR3, 4; del17p, 5; IgH/c-Myc, 6; c-Myc translocation (not with IgH), 7; c-Myc gene amplification, 8; additional chromosome 8

Summary / Conclusion: To the best of our knowledge, this is the first report focusing on c-Myc gene related abnormalities and additional chromosome 8 in NDMM and RRMM in the era of novel agents, and these aberrations might contribute to worse prognosis. In addition, hierarchical clustering analysis revealed that c-Myc gene related aberration and additional chromosome 8 were similar clusters in cytogenetic aberration.

B1495

PLASMA CELL PROLIFERATION FRACTION AND THE RISK OF PROGRESSION FROM SMOLDERING MULTIPLE MYELOMA (SMM) TO MULTIPLE MYELOMA (MM)

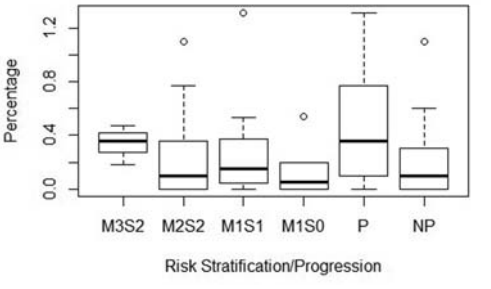
E Manasanch#[1*], E Jordan#[2], N Korde[1], N Tageja[1], M Bhutani[1], M Kwok[1], A Flanders[1], G Carter[3], M Mulquin[1], D Zuchlinski[1], S Steinberg[4], K Calvo[5], I Maric[5], M Roschewski[1], O Landgren*[1], R Braylan*[2]
[1]Multiple Myeloma Section, [2]Laboratory Medicine, [3]National Cancer Institute/National Institutes of Health, Bethesda, United States, [4]Biostatistics, [5]Laboratory of Pathology, National Cancer Institute/National Institutes of Health, Bethesda, United States
#contributed equally
**contributed equally*

Background: Increased plasma cell proliferation has been reported to be an adverse prognostic factor in patients with newly diagnosed MM; however, most previous studies were performed on marrow aspirates (which may not be fully representative of the marrow cellular content) and using assays that are either complex or lack plasma cell specificity. Furthermore, there is limited information on the significance of plasma cell proliferation in the setting of myeloma precursor disease. Using a double immunostaining technique with antibodies against Ki-67 and CD138, applied directly on bone marrow biopsy sections, we prospectively assessed the impact of plasma cell proliferation on patients with SMM who were low, intermediate and high risk for progression to MM based on previously published Mayo Clinic and PETHEMA group criteria.

Aims: To prospectively evaluate the significance of plasma cell proliferation in the progression of SMM to MM.

Methods: As per study protocol, 50 patients with SMM underwent a bone marrow biopsy and were classified according to risk of progression: 3 were high risk by both criteria (M3S2), 22 intermediate risk per Mayo and high risk per PETHEMA (M2S2), 15 intermediate risk by both systems (M1S1) and 10 were intermediate risk per Mayo and low risk per PETHEMA (M1S0). Bone marrow histological sections from each patient were doubled stained with antibodies against CD138/Syndecan (Cell Marque) and Ki-67 (Ventana) using an automated stainer (Ventana Benchmark ULTRA) and the plasma cell proliferation fraction was calculated in each case as the percentage of plasma cells (identified by the CD138 antibody) expressing Ki-67 (1056±139 plasma cells counted/slide). Descriptive statistics were used to analyze the basic features of the data in the study. The Wilcoxon signed ranked test was used to test for differences in the median percentage values of Ki67 staining between groups and in the percentage of positive Ki-67/CD138 stained cells among progressors and non-progressors to MM. An alpha error of <0.05 was considered to be significant.

Results: The median plasma cell proliferation fraction was 0.36% (0.18% - 0.47%) for M3S2, 0.1% (0% - 1.1%) for M2S2, 0.15% (0% - 1.3%) for M1S1 and 0.05% (0% - 0.54%) for M1S0 patients. Thus, the M3S2 patients had the highest median Ki-67 percentage, however this did not reach statistical significance when compared to groups considered at lower risk of progression by Mayo and PETHEMA prediction models, respectively. After a median follow up of 24 months (range 17-30 months), 9 of the 50 patients had progressed to MM (median time to progression 8 months): 3/3 (100%) in the M3S2 group, 4/22 (18%) in the M2S2, 2/15 (14%) in the M1S1 and 0/10 (0%) in the M1S0 group. The median percentage of positive Ki-67 stained plasma cells in patients that progressed (n=9) was 0.36% (0% - 1.3%) versus 0.1% (0% - 1.1%) in non progressors (P>0.05) (Figure 1. Percentage of Ki-67 positive plasma cells by risk stratification and progression to MM. P=progressors, NP=nonprogressors).



Summary / Conclusion: Based on prospectively evaluated SMM patients, we found the percentage of Ki-67 positive plasma cells to be less than 1% in 48/50 (96%) of patients. The plasma cell proliferation fraction using a double immunostaining technique on core biopsies demonstrated a trend towards progression to MM that did not reach statistical significance. This may be, at least, partly explained by the low numbers in the M3S2 (n=3) and progressor (n=9) subgroups. Per study protocol, continued comparison between groups is ongoing.

B1496

DOMESTIC SUBCUTANEOUS SELF-INJECTION OF BORTEZOMIB IN MULTIPLE MYELOMA

C Cerchione[1,1*], E Madonna[1], R Fabbricini[1], L Marano[1], N Pugliese[1], S Avilia[1], G Cerciello[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Bortezomib-based therapies are suggested as standards of care in management of patients with newly diagnosed and relapsed multiple myeloma. The recommended dose and schedule of Bortezomib is 1.3 mg/mq administred on days1,4,8, and 11 of 21-day cycles, a regimen active and well tolerated. Subcutaneous administration of bortezomib could be a good option for patients, particularly those with poor venous access.

Aims: We know that home intravenous administration of bortezomib is feasible to adequately informed patients, because we have recently demonstrated that a solution of bortezomib powder in normal saline stored at 4°C remains stable for nearly one month.

Since 2009, in our unit all patients requiring bortezomib for the treatment of multiple myeloma perform intravenous injection of the drug at home, after having been supplied with the exact dose in saline solution, in ready-to-use plastic syringes, appropriately prepared
under hood in sterile conditions. This procedure reduces the time spent by patients in hospital, improving convenience for patients and physicians. How-

ever, in some patients venous access may be difficult or sometimes unfeasible. As the drug is not histotoxic, subcutaneous administration is feasible, and this possibility is particularly attractive in domestic settings.
Methods: We have verified in 97 patients the safety and efficacy of subcutaneous injections
of bortezomib at the same dose as i.v. administrations (1mg/sm, days1,4,8,11), but dissolved in smaller saline volume (max. 1ml), in association with oral dexamethasone 20mg/dd. 1-2,4-5, 8-9, 11-12, in patients affected by multiple myeloma, with poor venous access.
In particular, the efficacy, evaluated as reduction of the monoclonal component during the i.v. period vs. the s.c. period was performed in a subgroup of 12 patients.
Results: Results indicated an equivalence between the two administration modalities, according to other larger controlled studies.
Based on these reports, 97 patients, requiring Bortezomib as part of anti Myeloma regimens, have been systematically treated by subcutaneous injections, performed at home.
No significant side effects have been reported so far. In particular, in 12 of them we have evaluated an equivalence between the subcutaneous and intravenous administration, according to other controlled studies.
Summary / Conclusion: The possibility to perform an antineoplastic regimen at home is particularly well accepted by all patients affected by multiple myeloma, with an achievement of a very good quality of life.

B1497

BORTEZOMIB (BTZ) RETREATMENT FOR RELAPSED/REFRACTORY (REL/REF) MULTIPLE MYELOMA (MM) IN REAL-WORLD MEDICAL PRACTICE: FINAL DATA FROM THE INTERNATIONAL, NON-INTERVENTIONAL, OBSERVATIONAL EVOBS STUDY

C Hulin[1*], J de la Rubia[2], M Dimopoulos[3], E Terpos[3], E Katodritou[4], V Hungria[5], H De Samblanx[6], A Stoppa[7], D Sargin[8], A Sioni[3], J Diels [9], R Olie [10], O Chirita [11], D Robinson Jr [12], A Potamianou [13], H van de Velde [9], M Delforge [14]
[1]Service d'Hematologie , Centre Hospitalier Universitaire de Nancy-Brabois, Vandoeuvre, France, [2]Hematology, La Fe Hospital, Valencia, Spain, [3]Clinical Therapeutics, University of Athens School of Medicine, Alexandra General Hospital, Athens, [4]Hematology, Theagenion Cancer Centre, Thessaloniki, Greece, [5]Centro de Estudos do Hemocentro da Santa Casa de São Paulo, São Paulo, Brazil, [6]ZNA Middelheim, Antwerp, Belgium, [7]Institut Paoli-Calmettes, Marseilles, France, [8]Istanbul University, Istanbul, Turkey, [9]Janssen R&D, Beerse, Belgium, [10]Janssen-Cilag AG, Baar, Switzerland, [11]Janssen-Cilag UK, High Wycombe, United Kingdom, [12]Janssen Global Services, Raritan, United States, [13]Janssen Pharmaceutica, Athens, Greece, [14]Hematology, University Hospital Leuven, Leuven, Belgium

Background: MM typically follows a relapsing course, with many patients (pts) requiring multiple lines of therapy. Previous studies have shown that Btz retreatment is effective in rel/ref MM; however, the efficacy and safety of Btz for rel/ref MM in everyday medical practice has rarely been studied prospectively, including its use in retreatment.
Aims: eVOBS is an observational study designed to prospectively assess Btz-based therapies for pts with MM in everydaypractice. Final data in pts receiving Btz retreatment for relapsing disease during eVOBS are reported.
Methods: Consenting adults scheduled to receive Btz for MM were enrolled at clinics in Belgium, Brazil, Canada, France, Greece, Spain, Sweden, and Turkey. Pts were also enrolled in Russia but are not included here; these data were presented at EHA 2012 (Abdulkadyrov et al, abs #1507). Therapies received in the 1 yr prior to pts' initial Btz were recorded retrospectively. Prospective observational data were collected over 3 yrs after Btz initiation, including data on subsequent Btz retreatments for relapsing disease received during this period. Data were electronically captured at baseline, after every Btz cycle, and every 12 wks after discontinuation or progression. Responses were investigator-assessed per EBMT, SWOG, M-protein reduction, or other (not specified) criteria. Adverse events (AEs) were graded per NCI-CTCAE v3.0.
Results: 96 of 873 pts enrolled to eVOBS received Btz as first retreatment for progressive disease during the prospective observation period. Median follow-up from start of retreatment was 11 mos. Median age was 62 yrs (range 34–80), 53% were male, 19%/58% had stage II/III disease (Durie-Salmon or ISS), and median number of prior therapies at initial Btz and retreatment was 2 and3, respectively. 30%/46% of pts initiated retreatment as 3rd/4th line therapy. 41% of pts initiated Btz retreatment in combination with dexamethasone, 21% had Btz monotherapy, 20% Btz in combination with lenalidomide, and 6% Btz with thalidomide, compared to 53%, 20%, 2%, and 7%, respectively, at initial Btz. Pts received a median of 6 Btz cycles at initial treatment and 4 at retreatment. 70% of pts started Btz at 1.3 mg/m^2 and 22% at ≤1.0 mg/m^2, vs 89% and 8% at initial Btz. ≥PR rate was 86% at initial Btz, including 49% CR/nCR (vs 69% and 37% for all 873 eVOBS pts). ≥PR rate at retreatment was 46%, including 15% CR/nCR. Median time to ≥PR was 68 days at initial Btz and 59 days at retreatment. ≥PR rate at retreatment was 68% vs 39% vs 20% in pts who had CR/nCR vs PR vs ≤MR at initial Btz (P=0.0022), and was 70% vs 48% vs 39% in pts with 1–2 vs 3 vs ≥4 prior therapies at retreatment (P=0.055). Median TTP/PFS with initial Btz was 11.4 mos (95% CI: 9.9–12.6) and median PFS from start of retreatment was 6.9 mos (95% CI: 4.6–8.2); median OS from start of retreatment was 17.6 mos (95% CI: 14.4–23.5). PFS and OS after retreatment were numerically longer in pts achieving CR/nCR vs PR vs ≤MR. Number of prior therapies at retreatment did not affect PFS; however, there was a trend towards longer OS in pts with fewer prior therapies. Discontinuations under Btz retreatment were mostly due to disease progression (34%), treatment completion (19%), and AEs (19%), compared to 16%, 34%, and 21% at initial Btz. PN during Btz retreatment occurred in 77% of pts, including 21% grade 3/4.
Summary / Conclusion: These data suggest that, in everyday medical practice, Btz retreatment is effective and tolerable in rel/ref MM, with approximately half of pts who responded to initial Btz achieving ≥PR at retreatment.

B1498

ELIMINATING THE NEED FOR 24-HOUR URINE STUDIES IN PHASE I MYELOMA PATIENTS

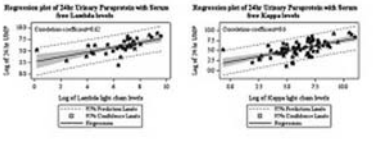
N Shah[1], J Kaufman[1], A Langston[1], E Waller[1], L Boise[1], R Harvey[1], S Lonial[1], A Nooka[1*]
[1]Department of Hematology and Oncology, Winship Cancer Institute, Atlanta, United States

Background: Standard evaluation in myeloma patients for paraprotein estimation includes testing serum protein electrophoresis (SPEP), serum immunofixation (SIFE), serum free light chain (SFLC) ratio, and 24-hour urine collection for urine protein electrophoresis (UPEP) and urine immunofixation (UIFE). 24-hour urine collection is a cumbersome process. Prior studies evaluating SFLC ratio and SIFE/SPEP as substitute for 24-hour urine estimation of paraprotein have major limitations. Few studies included patients with a wide spectrum of plasma cell dyscrasias and others have included both newly diagnosed and relapsed/refractory myeloma patients making the conclusions uninterpretable. There are no prior studies examining the question in a homogenous patient population.
Aims: The aims of current study are to evaluate if SFLC ratio and SIFE/SPEP can substitute for 24-hour urine collection in a homogenous population of advanced myeloma patients enrolling in phase I trials, where a shift in secretion from intact immunoglobulin to SFLC, described as 'free light chain escape' is often observed.
Methods: We analyzed 116 patients that underwent pre-trial staging with SPEP, SIFE, SFLC ratios, UPEP and UIFE prior to enrollment in phase I trials between August 2006 and December 2012. Initially, we evaluated the sensitivity of testing SFLC ratios, SPEP and SIFE compared to UIFE. Subsequently, we assessed the linear relationship between SFLC dichotomized by abnormal ratio (<0.26 or >1.65) vs. 24-hr paraproteinuria to assess correlation. SAS 9.3 version was used for analysis
Results: The sensitivities of SPEP, SIFE and abnormal SFLC ratio assays were 77%, 95% and 96%, respectively, compared to sensitivity of 100% by UIFE. The sensitivity of SFLC+SPEP or SFLC+SIFE increased to 100% enabling detection of paraprotein in all patients (Table 1). In our second analysis, the quantification of SFLC correlated with 24-hr urinary paraprotein estimation. With every log increase in lambda and kappa light chains, 24-hr urinary paraprotein log increased by 0.52 times (P<0.0001) and 0.53 times (P<0.0001); correlation coefficients 0.62 and 0.6, respectively (Figure 1).

Table 1. Sensitivities of Urine IFE, SIFE, SPEP, SFLC ratio in phase I myeloma patients

Laboratory test	No. (% abnormal)
UIFE	116 (100)
SPEP	89 (76.73)
SIFE	110 (94.83)
Abnormal SFLC ratio	111 (95.69)
Serum IFE + abnormal SFLC ratio	116 (100)
Serum PEP + abnormal SFLC Ratio	116(100)

Figure 1. Correlation between 24-hr paraproteinuria and abnormal SFLC



Summary / Conclusion: In advanced myeloma patients in phase I trials, SFLC ratio in combination with SPEP or SIFE detected monoclonal paraprotein in 100% of patients. In addition, there was a linear correlation of SFLC with 24-hr urinary paraprotein estimation, questioning the need for the burdensome 24-hour collection. Further studies to monitor SFLC ratios and 24-hour urine continuously over a period of time may completely eliminate this cumbersome test in advanced myeloma patients.

B1499

CONTRIBUTION OF DIFFUSION AND ADC SEQUENCES IN WHOLE BODY MRI FOR MYELOMA STAGING

S Auger[1,2*], C Exbrayat[1], E Decoux[3], S Aufort[3], C Plassot[2], D Donadio[1], S Merigeaud[3]

[1]hematology, Clinique du Parc, CASTELNAU-LE LEZ, [2]biostatistic, IURC INSERM EA 2415, Montpellier, [3]Radiology and physiotherapy center, Clinique du Parc, CASTELNAU-LE LEZ, France

Background: Treatment of Multiple myeloma (MM) is based on CRAB criteria including bone lesions. Prognostic criteria include Durie Salmon stage (DSS) based on radiography to detect bone lesions. With the advance in imaging, a new scoring was described: Durie Salmon stage PLUS (DSS+) where bone lesions are revealed by MRI or 18F-FDG PET/CT. This score includes 4 stages: IA (single focal lesion (FL) = plasmacytoma), IB (less than 5 FL or mild diffuse disease), II (5 to 20 FL or moderate diffuse disease) and III (more than 20 FL or severe diffuse disease).

Some studies have demonstrated the superiority of PET/CT compared to conventional MRI of the spine and pelvis (SP-MRI).The whole-body MRI with diffusion weighted imaging (WB-MRI) and ADC (apparent diffusion coefficient) mapping (DWI-MRI) seems to modify these arguments allowing to explore extraspinal bone and extraosseous lesions. The use of diffusion may improve sensibility and ADC mapping could avoid false positive. WB-MRI has a very low cost, high acceptability and lasts about 30 minutes with no radiation

Aims: To highlight the additive value of WB-MRI with diffusion and ADC compared to simple SP-MRI in one hand, and compared to WB-MRI with diffusion without ADC, in a second hand

Methods: 22 myeloma patients (median age 67 years, sex-ratio 0.6) were staged on DSS at diagnosis. Then, patients were classified before treatment by DSS+ with SP-MRI, DSS+ with WB-MRI and diffusion , DSS+ with WB-MRI combining diffusion and ADC. We used a 1.5T MRI system (Area, Siemens) to explore the spine with sagittal T1-weighted and coronal STIR sequences. The same coronal STIR sequence covered also the whole body from vertex to the middle thigh associated with axial diffusion-weighted images (two b-values, 50-800 s/mm2 with an axial ADC mapping).

Bone marrow infiltration (BI) pattern and the number of FL were assessed with the different imaging techniques by two radiologists. The staging levels of four systems (DSS, DSS+ SP-MRI, DSS+ WB-MRI with diffusion and DSS+ WB-MRI with both diffusion and ADC) were compared

Results: Among the 22 patients, 5 were classified in DSS I, 3 in DSS II and 14 in DSS III.

There were differences of concordance between DSS and DDS+ depending on the MRI protocol. Patients would have been staged differently according to DSS or DSS+ using: - SP-MRI: 14 of 22 patients (63%) (2 patients DSS I upstaged in DSS+ III, 11 patients down staged (Fleiss Weighted Kappa (FWK) 0.16 (95IC -0.19;0.51)) - WB-MRI with diffusion: 8 patients (36%) (1 patient DSS I upstaged, 7 down staged) (FWK 0.62 (95IC 035, 0.89) - WB-MRI with diffusion and ADC: 6 patients (27%) (FWK 0.63 (95IC 0.32;0.94) 9 patients were staged differently with DSS+ by SP-MRI and WB-MRI with diffusion: 2 were down staged and 7 upstaged. DWI-MRI showed 50 more FL than SP-MRI, including 8 sequelae lesions identified by ADC. DWI-MRI identified 2 extra medullary lesions. BI was upstaged for 8 patients, and down staged for 3 patients with diffusion sequence and ADC. For one patient, WB-MRI allowed to perform preventive femoral nailing on a bone lesion with cortical rupture. Three patients wouldn't have been treated without the discovery of bone lesions on MRI.

Summary / Conclusion: Compared to SP-MRI, WB-MRI detects extraspine and extraosseous lesion. DWI-MRI increases the number of visible lesions and therefore the sensitivity of WB-MRI. ADC improves the specificity distinguishing non-active lesions. Concordance between DSS and DSS+ is poor, each system providing different information, but diffusion and ADC in WB-MRI improve this concordance compared to classical SP-MRI

B1500

SUBCUTANEOUS ADMINISTRATION OF BORTEZOMIB REDUCES ADVERSE EVENTS

C Martinez-Losada[1*], M Llamas-Poyato[1], G Rodriguez-Garcia[1], C Garzas[2], D Buenasmañanas[1], E Garcia[1], C Chic[1], M Alvarez[1]

[1]Hematology, [2]Farmacology, HOSPITAL UNIVERSITARIO REINA SOFIA, CORDOBA, Spain

Background: Bortezomib-based therapies are suggested as standards for patients with newly diagnosed and relapsed multiple myeloma. Until September 2012 the approved dose of bortezomib was 1.3 mg/m2 administered as a bolus intravenous (IV). This regimen is active and well tolerated in most patients. However, many of them usually develop adverse events (AE) short-medium term. As an alternative to the IV administration, subcutaneous (SC) administration of bortezomib is a good choice. It has been shown that SC bortezomib provides equal efficacy to IV bortezomib.

Aims: In this study, we compared adverse events of subcutaneous versus intravenous bortezomib.

Methods: We analyzed 78 patients diagnosed and treated in our Hospital from May 2007 to December 2012. None of them had received bortezomib previously. Bortezomib was administered as a part of a chemotherapy regimen: MPV, VD, VTD and VCD. 42 men and 36 women were included, with a median age at diagnosis of 69 years (43-82 years), 76 multiple myelomas (BJ 10, IgA 21, IgG 44) and 2 plasmacytomas. The route of administration was SC in 45 patients (57.7%) and IV in 33 patients (42.3%). 368 IV injections of bortezomib and 702 SC injections were administered.

Results: 31 (93.9%) of 33 patients, who received IV bortezomib, developed AE whereas 35 (77.8%) of 45 patients, who received SC bortezomib, developed AE. In patients with IV bortezomib, 33.3% of the AE appeared in the first cycle, while in patients with SC bortezomib only appeared 21.3%. The most common AE of IV bortezomib were gastrointestinal (GI) (30.5%), nervous system (NS) (29.1%), infectious (14.2%) inespecific (19.9%), hematological (5%) and cardiac (1.4%) disorders while in patients who received SC bortezomib were GI (23.4%), NS (22.7%), infectious (18.4%), inespecific (24.8%), hematologic (5.6%), skin (3.5%) and cardiac (1.4%) disorders (Table 1). If we compare the incidence of AE by route of administration with respect to total number of injections administered: 43 GI disorders in IV bortezomib vs 33 in SC ($p < 0.01$), 9 bacterial infections in IV vs 7 in SC (P=0.06) and 41 NS disorders in IV vs 32 in SC ($p < 0.01$) were reported. Peripheral neuropathy was reported in 23,4% of patients who received IV bortezomib (grade 1-2: 66.7%, grade 3-4: 33.3%) and in 17% of patients who received SC bortezomib (grade 1-2 : 70.8%, grade 3-4: 29.2%). The AE presented by treatment scheme of VD, MPV, VTD, VCD were respectively: cardiac (1%,2%,0%,0%), infectious (21.8%,13.7%, 7.7%, 13.3%); hematologic (2%,8.5%,0%,0%), inespecific (18.8%,22%,46.2%,26.7%), GI (26.7%,27.5%,15.4%,33.3%), NS (29.7%,23.5%,23.1,26.7%). Skin disorders in MPV and VTD 2.6% vs 7.7% respectively. 3-4 grades AE in those receiving IV bortezomib were NS (44%), hematologic (28%), infectious (24%) and GI (4%), while those receiving SC bortezomib grades 3-4 AE were NS (33.3%), infectious (33.4%), hematologic (28.6%) and GI (4.8%). If we compare the incidence of ≥ 3 AE per patient according to the route of administration, we only found statistical significance in peripheral neuropathy: 11 events in IV vs 7 events in SC (P=0.03). Patients who received IV bortezomib had to temporarily stop treatment in 24 cases (17%) and decrease the dose in 26 cases (18.5%), whereas patients receiving SC bortezomib treatment was discontinued in 8 cases (5.7%) and the dose was decreased in 7 cases (5%).

Summary / Conclusion: Patients receiving SC bortezomib have fewer AE and interruptions of treatment, getting safer administration of bortezomib and improving treatment adherence.

	IV Bortezomib		SC Bortezomib	
Adverse effects	**All grades**	**Grade≥3**	**All grades**	**Grade≥3**

B1501

COMORBIDITY IMPACT SURVIVAL IN MULTIPLE MYELOMA. A SINGLE INSTITUTION STUDY DEALING WITH VALIDATION OF ACE-27 SCORE

S Molica[1*], E Piro[2], M Kropp[3], M Lentini[3]

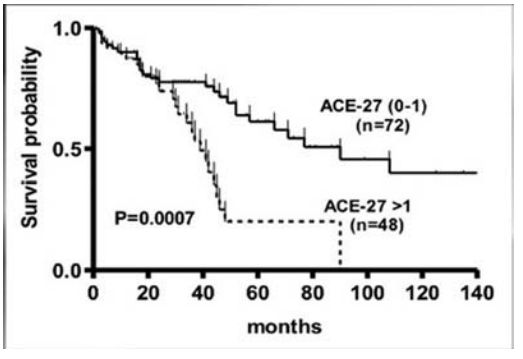
[1]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catazaro, [2]Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy, [3]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: Comorbidities increase in prevalence with age, but their impact on survival in patients with multiple myeloma (MM) is not known. The purpose of this study was to examine the impact of comorbidities on survival in multiple myeloma.

Aims: All patients (pts) with MM diagnosed and treated at the Department of Hematology-Oncology of Catanzaro General Hospital (Italy) from 2000 to 2010 were included in an observational database. The study was evaluated and approved by the local ethical committee.

Methods: Comorbidities were retrospectively graded as None (score=0), Mild (score=1), Moderate (score=2) or Severe (score=3) using the ACE-27 comorbidity index [Piccirillo et al. J Reg Mgmt 1999]. The primary endpoint was overall survival (OS), calculated from the date of diagnosis and censored at the time of last follow-up.

Results: 120 patients were identified in the database. Median age of patients was 69 years (range 41-86 years); 64 were male, 56 were female. Based on the ACE-27 comorbidity index, 24 pts (20%) had no comorbid medical conditions (score=0), 49 (40.8%) had mild comorbidities (score=1), 27 (22.5%) had moderate comorbidities (score=2), 20 (16.6%) had severe comorbidities (score=3). After a median follow-up time of 39 months (range, 2-160 months)53 patients died while median OS was 52 months. Survival curves by comorbidity category are presented in figure 1. As shown, median survival of patients with ACE-27 comorbidity index 0-1 was 90 months therefore significantly longer than median survival of patients with ACE-27 comorbidity index >1 (39 months)(HR=0.421;95% CI, 0.175-0.625; P=0.0007). As expected patients with ACE-27 comorbidity index 0-1were significantly younger than patients with ACE-27 comorbidity index >1 (67 yrs *vs* 70 yrs; P=0.04) whereas no association could be found between the degree of comorbidity and international staging system (ISS)(P=0.130). Finally, ACE-27 comorbidity index impacted therapeutic decisions. As matter of fact, patients with score index >1 less frequently underwent autologous bone transplantation (P=0.02).



Summary / Conclusion: The presence and severity of comorbidities confer a poorer prognosis to patients with MM. Further study is needed to determine to what extent comorbidities directly impact survival versus impacting therapeutic decision-making and tolerance of therapy.

B1502

EXPLORATION AND QUANTIFICATION OF THE DETERMINANTS OF BASELINE HEALTH-RELATED QUALITY OF LIFE (HRQOL) FOR PATIENTS IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

C Kyriakou[1,2*], M Petrucci[3], M Welslau[4], X Leleu[5], I Vande Broek[6], P Bacon[7], P Lewis[8], H Gilet [9], B Arnould [9], P Murphy [10]
[1]Northwick Park Hospital, [2]Royal Free hospital, London, United Kingdom, [3] Department of Cellular Biotechnology and Hematology, Division of Hematology,, Sapienza University of Rome , Rome, Italy, [4]Studienzentrum Hämatologie, Aschaffenburg, Germany, [5]CHRU-Hôpital Huriez, Lille, France, [6]AZ Nikolaas, Sint-Niklaas, Belgium, [7]Celgene International Sarl, Boudry, Switzerland, [8]Celgene GmbH, Munich, Germany, [9]MAPI Consultancy, Lyon, France, [10]Beaumont Hospital, Dublin, Ireland

Background: With the increased use of novel therapeutic agents and extended life expectancy of multiple myeloma (MM) patients, aspects of Health-Related Quality of Life (HRQoL) of these patients are gaining considerable importance. This is particularly so when considering the relapsed/refractory multiple myeloma (RRMM) setting.
Aims: To explore and quantify the baseline determinants of HRQoL in MM patients starting 2nd or 3rd line treatment.
Methods: A European, multicenter, observational study was conducted in RRMM patients starting 2nd or 3rd line treatment. Patients were asked to complete three EORTC questionnaires: 1) Quality-of-Life Core Questionnaire (QLQ-C30) including 15 domains (*Global Health Status/QoL, Physical, Role, Emotional, Cognitive and Social Functioning; Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea* and *Financial Difficulties*); 2) The EORTC QLQ-Multiple Myeloma (QLQ-MY20) including four domains (*Disease Symptoms, Side Effects of Treatment, Body Image* and *Future Perspective*); and 3) The EORTC QLQ-Chemotherapy-Induced Peripheral Neuropathy (QLQ-CIPN20) including three domains (*Sensory scale, Motor scale* and *Autonomic scale*). All EORTC questionnaires were adjusted according to robust international standards to be completed by physicians. Multivariate linear regressions were performed to explain the determinants of baseline HRQoL scores for MM patients starting 2nd or 3rd line treatment. All baseline EORTC scores were used as dependent variables; patients' socio-demographics, disease characteristics and treatment regimens were identified as explanatory variables via univariate testing.
Results: As of Dec 2012, 155 patients (mean age=69; 52.0% male) were enrolled in the study and included in this interim analysis, with an average time since diagnosis of 3 years. At baseline, 14.2% of patients were ECOG ≥2 in terms of their performance status. A total of 87.7% of patients started 2nd line treatment and 12.3% of patients started 3rd line treatment. A total of 33.5% of patients had been treated with prednisone and 40.0% of patients had been treated with bortezomib in their 1st line treatment. Among patients who started 3rd line treatment, all had been treated with prednisone and 52.6% had been treated with bortezomib. The majority of EORTC questionnaires were completed at baseline by physicians (n=152; 98.1%) and patients (n=151; 97.4%). Multivariate linear regression results indicate that some covariates appeared regularly as factors explaining MM patients' HRQoL (from the 7 functioning scores and Global Health Status/QoL), as well as patients' symptoms and side effects (from 17 symptom and side effect scores). Those most frequently showing statistically significant association with worse scores were: poorer baseline ECOG performance status (12 times), previous prednisone intake (10 times), presence of chronic heart failure (4 times), country (3 times) and cumulative dosage of prior bortezomib treatment (3 times) (Table 1).

Table 1: Statistically significant (p<0.05) covariates determining HRQoL per EORTC domain

EORTC questionnaires	Domains	Statistically significant covariates*				
		ECOG performance	Prednisone	Chronic heart failure	Cumulative bortezomib dosage**	Country

Summary / Conclusion: At the initiation of 2nd or 3rd line treatment, MM patients previously treated with prednisone showed worse scores than other patients on many domains of QLQ questionnaires. Similarly, a poorer ECOG performance status was associated with worse scores in the majority of QLQ domains. Among other factors found to be repeatedly associated with worse scores, the prominent ones were country, chronic heart failure and cumulative dosage of prior bortezomib treatment.

B1503

ALLOGENEIC STEM-CELL TRANSPLANTATION IN MULTIPLE MYELOMA IN REAL PRACTICE: LONG-TERM RESULTS FROM A SINGLE INSTITUTION.

R Jiménez[1*], L Rosiñol[1], M Rovira[1], F Fernández-Avilés[1], C Martinez[1], G Gutierrez[1], M Suarez[1], C Fernandez-Larrea[1], Á Urbano[1], J Bladé[1]
[1]Hospital Clinic , Barcelona, Spain

Background: Allogeneic stem-cell transplantation with myeloablative conditioning (MAC) in multiple myeloma (MM) is associated with a high transplant-relat-

ed mortality (TRM) with a 15% of long-term survivors. Allogeneic transplantation with reduced-intensity conditioning (alloRIC) results in a lower TRM with a higher relapse rate. When used in first line in a tandem transplant approach (auto/alloRIC), the incidence of acute graft-versus host disease (aGvHD) grade II-IV reported ranges between 20-43%, chronic GvHD between 50-75% and the TRM between 10-15%. The reported PFS was 25% beyond 7 years. Because of this high morbimortality and the higher rate of relapse, the role of allogeneic transplantation in MM remains controversial, especially as part of the frontlline therapy.

Aims: To analyze the results of allogeneic transplantation in patients with MM outside clinical trials at our institution over a period of 27 years.

Methods: : Between Feb 1986 and April 2009, 23 patients (17 M, 6 F, median age 41 –range 21-52 -) received a MAC from an HLA identical sibling donor. Disease status at the time of transplant was first response in 12 patients (53%) (3 CR, 9 PR), sensitive relapse in 3 (13%) (all PR) and refractory disease in 8 (35%). Conditioning regimen was heterogeneous (6 Cyclo/TBI, 2 Bu/cyclo, 3 BCNU/Mel/Cyclo/TBI, 4 Cyclo/Mel/TBI, 5 Mel/TBI, 2 Bu/Mel). GvHD prophylaxis consisted on cyclosporine/MTX (10), cyclosporine/PDN (8), cyclosporine (2) or other (3). Between April 2001 and Aug 2012, 31 patients (18 M, 13F, median age 48 –range 25-64) received an alloRIC: 25 of them (80%) from an identical sibling donor and 6 (20%) from an unrelated donor. Seven patients (13%) who did not achieve a CR after front-line autologous transplant received an alloRIC in a tandem strategy. 17 (31%) were in sensitive relapse (first relapse 14, second relapse 3). Seven patients (13%) had refractory disease at the time of alloRIC. Conditioning regimen consisted on Fluda/Mel (26 patients), Flu/TBI (3) and Fluda/Mel/bortezomib (2). GVHD prophylaxis consisted on cyclosporine/MTX (6) or cyclosporine/MMF (25). All patients in the alloRIC group had received a prior single autologous transplant.

Results: On an intention-to-treat analysis, the CR rate after MAC was 35%. The incidence of aGvHD grade II-IV and III-IV were 48% and 39%, respectively. The TRM at any time was 56%. The causes of death were GvHD in 7 patients, infection not related to GvHD in 5 patients and VOD in 1 patient. The relapse rate was 30%.There are 3 patients that remain in continued CR at 13, 23 and 27 years beyond transplantation. With alloRIC the CR rate was 45%. The incidence of aGvHD grade II-IV and III-IV were 55% and 22%, respectively. Nine patients develop chronic GvHD. The TRM at any time was 29% and the causes of death were GVHD in 7 patients and pulmonary hemorrhage and post-transplant lymphoma one patient each. Nine patients remain alive in continued CR from 5 months to 9 years of follow-up. After a median follow-up of 36.4 months, the median PFS was not significantly different between MAC and alloRIC and there was a trend towards a longer overall survival in the alloRIC group (4.6 vs 35 months, P=0.05).

Summary / Conclusion: Although a small fraction of patients with MM can be cured with MAC allogeneic transplantation, this procedure is associated with an extremely high TRM. Unfortunately, alloRIC was also associated with a high incidence of severe aGVHD resulting in a high TRM leading to a short PFS. New approaches aimed at decreasing the incidence of aGVHD are crucial.

B1504

BORTEZOMIB-BASED THERAPIES FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA IN REAL-WORLD MEDICAL PRACTICE: FINAL DATA FROM THE INTERNATIONAL, OBSERVATIONAL EVOBS STUDY

Background: The efficacy of bortezomib-based therapies in patients with multiple myeloma (MM) has been demonstrated in several large, randomized controlled clinical trials; however, use of bortezomib for relapsed/refractory MM in real-world medical practice has rarely been studied prospectively.

Aims: eVOBS is a non-interventional, observational study designed to prospectively assess the efficacy and safety of bortezomib-based therapies for patients with MM in everyday practice. Final data are reported here.

Methods: Consenting adults scheduled to receive bortezomib for MM were enrolled between June 2006 and December 2010 at clinics in Belgium, Brazil, Canada, France, Greece, Spain, Sweden, and Turkey. Patients were also enrolled in Russia but are not included; these data were previously presented at EHA 2012 (Abdulkadyrov et al, abs #1507). Therapies received in the year prior to starting bortezomib were recorded retrospectively. Prospective observational data were collected over 3 years after bortezomib initiation. Data were electronically captured at baseline and after every bortezomib cycle. Upon discontinuation or progression, data on subsequent therapies, survival, and disease progression were collected every 12 weeks. Responses were investigator-assessed per EBMT, SWOG, M-protein reduction, or other (not specified) criteria. Adverse events (AEs) were graded per NCI-CTCAE v3.0.

Results: Overall, 873 pts were enrolled, with a median follow-up of 34.6 months; median age 65 years (range 27–88 years), 58% male, 28%/48% had stage II/III disease (Durie-Salmon or ISS), 25% had a creatinine clearance of <50 mL/min. Hypertension (47%) was the most frequent comorbidity. Median number of prior therapies received was 2. 41%/26% of patients initiated bortezomib in 2nd/3rd line therapy. In the year prior to starting bortezomib, 30% of patients had received thalidomide-based treatment, 13% melphalan-prednisone, and 10% had lenalidomide-based treatment. 30% of patients had no treatment in the year prior to starting bortezomib. 52% of patients initiated bortezomib with dexamethasone, and 17% received bortezomib monotherapy. 82% of patients started bortezomib at 1.3 mg/m^2. Median number of bortezomib cycles received was 5 (range 1–29). Discontinuations were mostly due to treatment completion (31%), AEs (25%), or disease progression (16%). 69% of patients had partial response or better (≥PR) as best response within the initiated line of therapy, including 37% complete response (CR)/near-CR. Median time to ≥PR was 56 days (95% CI: 49–63). Best response plateaued after 6 cycles. Median progression-free survival (PFS) and overall survival (OS) were 12.5 months (95% CI: 11.3–13.5) and 36.1 months (95% CI: 33.1–41.6), respectively. PFS and OS were significantly longer in pts with deeper response to bortezomib-based therapy, fewer prior therapies, better renal function, less advanced disease at first MM treatment, and age <65 years (P<0.001 for all parameters and endpoints). All-grade AE, grade ≥3 AE, and serious AE rates were 82%, 55%, and 45%, respectively. Common grade ≥3 AEs were thrombocytopenia (8%), anemia, and pneumonia (each 5%). 21% of patients had baseline peripheral neuropathy (PN) (14% grade1, 5% grade2, 2% grade 3/4). 51% of patients without baseline PN (n=689) had new-onset PN (10%/1% grade 3/4). The cumulative risk of developing PN plateaued after 6 cycles. In patients with vs without baseline PN, a lower starting dose of bortezomib (≤1 mg/m²) was more common (18% vs 11%, P=0.014). Median treatment duration was shorter in patients with grade ≥2 baseline PN vs no or grade 1 PN at baseline (4 cycles vs 5 cycles, P=0.04).

Summary / Conclusion: These data indicate that in everyday practice, bortezomib is active in the treatment of relapsed/refractory MM. AEs were consistent with the known safety profile for bortezomib.

B1505

ISOTYPE MATCHED IMMUNOGLOBULIN RECOVERY RATES IN IGG AND IGA MYELOMA PATIENTS AT MAXIMUM RESPONSE SUGGEST SUBTLE ISOTYPE SPECIFIC DIFFERENCES IN IMMUNE-RECONSTITUTION

P Young[1*], R Hughes[1], S Harding[1], H Avet-Loiseau[2], H Ludwig[3]

[1]Clinical R&D, The Binding Site Group Ltd, Birmingham, United Kingdom, [2]Hospitalier Universitaire, Nantes, France, [3]Center for Oncology and Haematology, Wilhelminenspital, Vienna, Austria

Background: The recent availability of immunoassays measuring Ig'κ and Ig'λ (HLC) isotypes for IgA and IgG immunoglobulins has allowed analysis of the impact of monoclonal plasma cell biology previously hidden from our view. These tests offer quantitative alternatives to immunofixation (IFE), and have been reported as an aid to monitoring IgA and IgG multiple myeloma (MM). Furthermore, the the Ig'κ / Ig'λ ratio (HLCr) has prognostic relevance at presentation and at maximum response. Intriguingly, the isotype matched immunoglobulin (uHLC) suppression (e.g. the level of IgGκ in an IgGλ monoclonal gammopathy patient) has also been shown to predict MGUS transformation to MM.

Aims: To assess the correlation between Ig'κ / Ig'λ ratios and IMWG response criteria in disparate group of MM patients and to analyse isotype matched immunoglobulin recoveries in different response categories.

Methods: Serial samples from 25 IgG (18 IgGκ; 7 IgGλ) and 21 IgA (14 IgAκ; 7 IgAλ) MM patients were analysed using commercially available immunoassays (The Binding Site, UK) to establish HLCr cutoffs for each isotype that classified patients as CR, VGPR, PR, SD and PD. These responses were validated in 131 IgG (90 IgGκ; 41 IgGλ) and 65 IgA (40 IgA κ; 25 IgA λ) MM patients. Responses were dichotomized into good response (VGPR and CR) v 0.81=near perfect agreement 0.81-0.61=substantial agreement,) in addition recovery of serum uHLC concentrations was calculated at maximum response (MR).

Results: Comparison of responses showed good agreement between HLCr and IMWG-assigned responses for both IgG and IgA MM patients at maximum response: IgG: good response v ≤PR (sensitivity: 0.93 (95% CI 0.85-0.98), specificity: 0.89 (95% CI 0.78-0.96); IgA: good response v ≤PR (sensitivity: 0.95 (95% CI 0.75-0.99), specificity: 0.89 (95% CI 0.76-0.96), and good overall agreement between individual assigned response criteria: IgG Weighted Kappa: 0.81 (95% CI 0.72-0.93); IgA Weighted Kappa: 0.86 (95% CI 0.79-0.95). HLCr ratios were abnormal in all MM presentation samples. Suppressed uHLC was noted in 98% IgGκ (88/90 (median 0.6g/L (range: 0.1-2.3g/L)) and

73% IgGλ (30/41 (median 0.8g/L, (0.1-4.0g/L)) MM patients. By contrast 75% IgAκ (30/40 (0.1g/L, (0.01-2.0g/L)) and 44% IgAλ (11/25 (0.3g/L, (0.01-1.22g/L)) MM patients had supressed uHLC. 20/20 (100%). IgG MM patients achieving a CR had normal uHLC serum concentrations (IgG kappa normal range: 2.19-10.70g/L; IgG lambda normal range: 0.90-6.74g/L) at maximum response, compared to 31/36 (86%) of patients achieving a VGPR and 21/74 (28%) of patients achieving ≤PR. However, there was a substantially lower incidence of uHLC recovery in IgA patients achieving CR (18/26; 69%), VGPR (10/15; 67%) or ≤PR (15/24; 63%).
Summary / Conclusion: There is good agreement between IMWG and HLCr assigned responses at maximum response in both IgA and IgG MM patients. IgG MM patients had a greater degree of uHLC suppression than IgA MM, which may be influenced by the concentration dependent, catalytic half-life of IgG and/or by differences in the biology of between IgG and IgA myelomas. Recovery of uHLC was high and correlated with response in IgG patients, but was lower and not associated with response in IgA MM. Further work is required to understand this phenomenon, particularly in the setting of immune-modulatory therapy.

B1506
DESCRIPTIVE STUDY CASES OF AMYLOIDOSIS: SUBANALYSIS OF CARDIAC INVOLVEMENT
E Gonzalez[1], I Arias[1], E Fonseca[1], R Fernandez[1*], A Gonzalez[1], L Gutierrez[1], A Gonzalez[1], V Robles[1], F Dominguez[1], C Fernandez[1]
[1]Hematologia, H. de Cabueñes- Gijon, Gijón, Spain

Background: Amyloidosis is a protein misfolding disorder in which soluble proteins aggregate as insoluble amyloid fibrils, that cause functional and structural organ damage. The most common form of systemic amyloidosis are light-chain amyloidosis, but it's the reactive AA amyloidosis the mostly detected in our area. Cardiac involvement may occur with or without clinical manifestations, and is considered as a major prognostic factor.
Aims: To review the cases of amiloidosis in our area, and obtain data on cardiac involvement
Methods: Retrospective case series, between January 1994 to March 2012, obtained from medical history of biopsy confirmed cases
Results: We identified 99 patients with mean age at diagnosis 70 years (range 25-84 years), 43 women and 56 men. All patients had biopsy-proven amyloidosis. There were 50 secondary amyloidosis, 41 light-chain amyloidosis, and 8 localized amyloidosis. Inflammatory diseases were presented in 9, blood diseases in 17, solid neoplasia in 5 and infectious diseases in 10. The main clinical manifestations were dysregulation of intestinal habit, heart failure, edemas and syncope. The affected systems were: kydney 61 (27 nephrotic syndrome), heart 43, digestive 31, autonomic nervous system 29, skin 8 and lung 1. Troponin I was elevated in 15. ECG was abnormal in 43 (atrial fibrillation or flutter 16, auricular-ventricular block and bundle-branch block auricular6, pseudoinfarct pattern8, low voltages8, repolarization changes5, and ventricular hypertrophy signs 1). Echocardiographic characteristics: 35 had left ventricular diastolic dysfunction, and 4 systolic dysfunction, ventricular hypertrophy 28, pericardial effusion 14, byrrefingency 16, auricular enlargement 16, valvulopathies8, and pulmonary hypertension 8. In AL amyloidosis 26 had monoclonal component, 18 IgG subtype, and 22 Lambda light chain. 13 had Bence-Jones proteinuria and 18 renal insufficiency. The preferred sites for biopsy were abdominal fat 45, rectum 14, kidney 17, skin8, endomiocardial biopsy2, bladder2, liver3, lung1, bone marrow7, tongue 1 and necropsy 4**.** The treatment was in 18 Prednisone and Melphalan, 4 Bortezomib-Dexametsone, 2 Lenalinomide, 1 polychemotherapy and 8 required hemodyalisis. 42 patients had more than 2-years overall survival
Summary / Conclusion: 1. On our environment amyloidosis is not exceptional, with an approximate incidence of 6 cases / year. 2. The most common type is A. secondary, unlike similar series, probably because of the absence of complete hematologic studies, essential in these patients. 3. Clinical involvement was the most common cardiac and renal failure. 4. The most common treatment for the AL, was prednisone plus melphalan-dexamethasone. 5. The 50% of total cardiac amyloidosis had involvement being a decisive factor in evolution, so it should perform echocardiography in all patients with suspected amyloidosis 6. The main features in the ECG were arrhythmias and right bundle branch block. Ultrasonography diastolic dysfunction was the most common finding with wall hypertrophy

B1507
THE IDEAL DOSE SETTING AND THE POSSIBILITY OF THERAPEUTIC DRUG MANAGEMENT OF LENALIDOMIDE ACCORDING TO PLASMA CONCENTRATION IN MULTIPLE MYELOMA
N Takahashi[1*], S Shida[1], M Miura[2], T Niioka[2], M Matsumoto[3], M Hagihara[4], M Motegi[5], M Kume[6], J Kuroki[7], A Kitabayashi[8], Y Hatano [9], N Fujishima[1], Y Kameoka[1], H Tagawa[1], M Hirokawa[1], K Sawada[1]
[1]Hematology, AKITA UNIV., [2]Pharmacology, Akita univ. hospital, Akita, [3]Hematology, Nishi-Gunma Hospital, Shibukawa, [4]Hematology, Eiju General Hospital, Tokyo, [5]Hematology, Senboku General Hospital, Daisen, [6]Hematology, Hiraka General Hospital, Yokote, [7]Hematology, Yuri General Hospital, Yurihonjo, [8]Hematology, Akita Kumiai General Hospital, Akita, [9]Hematology, Yamamoto Kumiai General Hospital, Noshiro, Japan

Background: Lenalidomide, a novel therapeutic agent, has been found to be effective for myeloma. The initial lenalidomide dose can determined on the basis of renal function and peripheral blood cell counts, dose adjustments, particularly after drug administration, were necessary in some cases because of interindividual differences in pharmacokinetics.
Aims: We aimed to develop an equation for the predicted total area under the observed plasma concentration–time curve (AUC) of lenalidomide and to set the ideal lenalidomide dose in patients with multiple myelomas by using only 1 or 2 sampling points.
Methods: Twenty-one myeloma patients treated with lenalidomide were enrolled in this study after obtaining written informed consent. Plasma concentrations of lenalidomide from samples obtained just prior to and1,2,4,8, and 12 h after oral administration of lenalidomide were analyzed using high-performance liquid chromatography (HPLC). Pharmacokinetic analysis of lenalidomide was carried out with a standard non-compartmental method. The $AUC_{0\text{-}24}$ was calculated using the linear trapezoidal rule.
Results: The plasma concentrations of lenalidomide at 2 and 4 h (C_{2h} and C_{4h}, respectively) after its administration were highly correlated with the $AUC_{0–24}$ value for lenalidomide. The correlation were observed between the measured and predicted $AUC_{0\text{-}24}$ values for lenalidomide by using only the C_{2h} and C_{4h} sampling points in the equation (P<0.0001). Moreover, the results of receiver-operating characteristic curve (ROC) analysis of best sensitivity and specificity showed that the ideal $AUC_{0–24}$ of lenalidomide could be set below 940 ng· h/ml to avoid hematological toxicity.
Summary / Conclusion: The predicted $AUC_{0–24}$ value might be a new indicator for the management of lenalidomide therapy. In this study, the threshold predicted $AUC_{0–24}$ values suggested that 4 of 21 patients (19%) should have received a lower initial dose than that recommended by Dimopoulos, et al. It is possible to adjust the ideal dose by using the equation for $AUC_{0–24}$ with the C_{2h} and C_{4h} values in a test before lenalidomide therapy is actually initiated. Therapeutic drug management (TDM) of lenalidomide can be performed by establishing the minimum effective concentration and the minimum toxic concentration in a large prospective study in the future. These findings should provide economic benefits and facilitate personalized medicine in myeloma therapy with lenalidomide.

B1508
RENAL FAILURE IS REVERSIBLE AFTER THERAPY WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA
V Goranova-Marinova[1*], A Nedeva[2], I Nikolov[2], P Georgiev[1], I Hristova[1], I Gigov[2], J Raynov[2], S Goranov[1]
[1]Clinic of Hematology, University Hospital "Sv.Georgi", Plovdiv, [2]Department of hematology and oncology, Military Medical Academy, Sofia, Bulgaria

Background: The involvement of kidneys in patients with multiple myeloma (MM) is an adverse prognostic factor which influences the clinical course, therapeutic response and the survival of the patients. Conventional chemotherapy could not improve the outcome in this high risk group. After the introduction of Bortezomib in the therapeutical regimens, literature data report high rates of therapeutic response along with an improvement of the renal function. Nowadays Bortezomib containing regimens become a standard therapeutic approach in patients with MM and renal failure (RF).
Aims: To study the therapeutic response and the outcome of the RF after therapy with Bortezomib (Velcade) based regimens in patients with multiple myeloma MM.
Methods: For the period 2006-2011, 111 patients with MM, treated with Bortezomib – containing regimens were studied in two university clinics of hematology: University Hospital "Sv. Georgi", Plovdiv and Military Medical Academy, Sofia. In 33 (29.7%) RF was found. Mean age 57.8±9.1y M:F/ 1.1: 1. In the whole group patients in ISS-III – 42 (37.8%) are predominant, with IgGk variant 62 (55.9%). 7/33 were on chroniodyalisis. The therapeutic response, its duration and the median of survival (MS) were compared between the groups with and without RF. Statistical analyses were performed with SPSSv18.0.
Results: No significant differences between the two groups were found in sex and age distribution, levels of Hв and LDH. Patients with RF are predominantly in ISS - III (P<0.001, R=+0.659). In the group with RF, light-chain variants are significantly more frequent (P<0.001, r=0.292), the proportion of patients with level of β2M >3.5мсg/l is significantly higher (P<0.001, R=+0.614), so as patients with hypoalbuminemia <35g/l (P=0.014, r=-0.312) and advanced bone lesions (P=0.033, r=+0.413). Therapeutic response is achieved(CR+VGPR+PR) in 84 (76.4%) in the whole cohort and in 18 (75.0%) for the patients with RF (NS).Reversal to normal level of serum creatinin after therapy was registered in 15 (45.5%), reduction with > 50% was found in 12 (36.4%). Independence from hemodyalisis achieved 3/7 болни. ASCT was performed in 14 (17.9%) in the group without RF and in 6 (18.2%) in the group with RF (NS). Time to progression for the whole group was 14 mo; in the RF group - 11 mo, and 28 mo for the patients without RF (NS). MS in the RF group was 28 mo vs MS 58 mo for the patients without RF (P<0.005) and MS for the whole group - 51 mo.

Summary / Conclusion: The application of Bortezomib- based regimens in patients with MM results in similar outcomes in patents with standard risk and patients with RF. The high rate of therapeutic response (CR + VGPR) is combined with improved renal function in about 80%. Thus the first proteasome inhibitor is the only medicine by now which is applied without dose reduction and is therapy of choice in patients with MM and mild to moderate RF.

B1509

PROGNOSTIC VALUE OF IGM HEAVY IMMUNOGLOBULINS CHAIN ANALYSIS IN IGM MGUS AND WALDENSTRÖM MACROGLOBULINEMIA

I Murillo-Flórez[1*], A Montes-Limon[1], J Quintero-Gutierrez[1], M Andrade-Campos[1], J Grasa[1], P Giraldo[1,2,3], D Rubio[1]

[1]Department of Hematology, Miguel Servet University Hospital, [2]Biomedical Network Research Center on Rare Diseases (CIBERER), ISCIII, [3]Aragon Health Sciences Institute (IACS). , Zaragoza, Spain

Background: Monoclonal IgM is the biomarker that characterize to Waldenstrom's macroglobulinemia (WM), a rare low grade B-cell lymphoma derived of the lymphoplasmacytic cell, but a serum IgM component also is present in MGUS. New determinations of heavy immunoglobulins chains have been developed as biomarkers to apply at clinical practice.

Aims: The aim of this study is present our experience in the use of free light chain assay (sFLC) and IgMk/IgMl ratios (HLCR) as biomarker at diagnostic in order to discriminate between MGUS and WM, and to evaluate their potential prognostic value during disease course.

Methods: 50 patients were examined following clinical protocol; serum samples were collected and kept frozen at -70ºC in the Biobank. Analysis of IgM was performed with the sFLC, (Freelite® test, the Binding Site, Birmingham, UK) and the HLCR, (Hevylite® immunoassay the Binding Site). Freelite® test is a nephelometric measurement of kappa and lambda light chains that circulate as light chain monomers or dimers and that are not bound to immunoglobulin heavy chain. Hevylite® immunoassay is based on specific polyclonal antibodies that recognize epitopes spanning the junction of the heavy and light chains of the individual immunoglobulin isotypes, it measures specifically IgMkappa and IgMlambda, separately. For ease of comparison IgM hevylite ratios were expressed as the involved monoclonal immunoglobulin/uninvolved polyclonal immunoglobulin (iHLC/uHLC).

Results: The study included a series of 29 WM, 21 IgM-MGUS. The median age was 67 years; M/F ratio 1.38. Median IgM HLCR was 381.8 in WM symptomatic, 75.84 in WM asymptomatic and 15.65 in IgM MGUS (P=0.001). Median IgM HLCR was higher in WM patients requiring treatment at diagnosis (370.7 v 43.897 P=0.026) and also it was higher at relapse/refractory (478.5 v 44.24 P=0.012). Median uHLC was higher in IgM-MGUS than WM patients to IgMk andIgMl: 0.39 g/L v 0.21 g/L, P=0.036; and 1.2 g/L v 0.32 g/L, P=0.019. Relapse/refractory patients had a mean uHLC lower than the patients who did not relapse (0.29 g/L v 0.52 g/L, P=0.04). Median sFLC level was 64 mg/L (10.88–993) in WM and 31.7 mg/L (6.08–141) in IgM MGUS (P=0.05). Median sFLC level was higher in WM patients requiring treatment at diagnosis than patients not requiring treatment (73.7 v 36.85 P=0.039). Median sFLC level was not significative in relapse/refractory patients (P=0.168) and it was not separate between WM asymptomatic and WM symptomatic (P=0.092).

There was a good correlation between IgM HLCR and sFLC ratio (r=0.3, P=0.044) but not with sFLC level; also IgM HLCR, sFLC level and sFLC ratio did not predict for overall survival (OS) and progression free survival (PFS) in our study. Mean estimated OS was 78.3 months (95% CI: 53.67-102.94) and PFS 69.7 months (95% CI: 47.28-92.13).

Summary / Conclusion: At diagnostic IgM HLCR and sFLC seems identifies patients WM / IgM MGUS and high levels of HLCR and sFLC were also seen in patients requiring treatment. IgM HLCR discriminates between WM symptomatic, WM smoldering and progressing patients. Uninvolved polyclonal immunoglobulin was significantly lower in Relapse/refractory patients, showing that these patients have a less robustimmune system. Further studies are needed to evaluate their value prognostic.

B1510

LENALIDOMIDE 25 MG + LOW-DOSE DEXAMETHASONE: EFFICACY & SAFETY IN CHINESE PATIENTS WITH RELAPSED/REFRACTORY MYELOMA

X Du[1*], J Jin[2], Z Cai[2], F Chen [3], D Zhou[4], L[5], X Ke[6], X Li[7], D Wu[8], F Meng [9], H Ai [10], J Wang [11], J Zhang [12], J Mei [12], J Hou [13]

[1]Department of Hematology, Guangdong General Hospital, Guangzhou, [2]The First Affiliated Hospital, Zhejiang University, Hangzhou, [3]Xiangya Hospital of Central South University, Changsha, [4]Peking Union Medical College Hospital, [5]The 301 Military Hospital, [6]Peking University Third Hospital, Beijing, [7]Shanghai Sixth People's Hospital, Shanghai, [8]The First Affiliated Hospital of Suzhou University, Suzhou, [9]Nanfang Hospital, Southern Medicine University, Guangzhou, [10]The 307 PLA Hospital, Beijing, [11]Changhai Hospital, Shanghai, China, [12]Celgene Corporation, Summit, NJ, United States, [13]Shanghai Changzheng Hospital, Shanghai, China

Background: In China, patients (pts)with relapsed/refractory multiple myeloma (RRMM) have a clinical need for more effective treatments. In addition, multiple myeloma pts who cannot tolerate bortezomib and/or thalidomide (THAL) are left without effective treatment options. Previous studies performed in western countries have demonstrated that lenalidomide (LEN) is a more effective immunomodulatory drug than THAL, and is associated with less dose-limiting toxicity. In addition, LEN + low-dose dexamethasone (LoDEX) was associated with a response rate of 53% in heavily pretreated RRMM pts.[1] The MM-021 China Registration Trial assessed the safety, efficacy, and pharmacokinetic profile of LEN + LoDEX in Chinese pts with RRMM.

Aims: In this post-hoc analysis the starting dose, dose modifications, and duration of LEN treatment were assessed.

Methods: In this phase2, multicenter, open-label study,199 pts received LEN (25 mg/day on days 1–21) and LoDEX (40 mg on days1,8, 15, and 22; or 20 mg in pts aged > 75 yrs) in 28-day cycles until progression.LEN starting dose was adjusted per protocol according to creatinine clearance (CrCl): 25 mg/day for pts with none-to-mild renal insufficiency (RI) (CrCl ≥ 60 mL/min); 10 mg/day for moderate RI (CrCl ≥ 30 to < 60 mL/min); and 15 mg/every other day (eod) for pts with severe RI (CrCl < 30 mL/min). All pts provided informed consent.

Results: Pts had a median age of 59 yrs and 57% had received ≥ 4 prior therapies. Overall, 66% (n = 131) of pts had none-to-mild RI, 27% (n = 54) had moderate RI, and 7% (n = 14) had severe RI. Per protocol the majority of pts (n = 144; 72%) initiated LEN treatment according to the recommended starting dose of 25 mg/day; 45 (23%) pts started at 10 mg/day, and 10 (5%) pts at 15 mg/eod. The median number of LEN cycles administered was 9 (range 1–25). Dose reductions were required in 38 (19%) pts across all starting doses, with a median time to first dose reduction of 3.1 mos. The median average dose was 25 mg (range 6.3–25.0), indicating compliance with the planned treatment schedule. Overall clinical outcomes are shown in the Table.

Summary / Conclusion: Consistent with observations from other studies, LEN 25 mg was generally well tolerated in Chinese RRMM pts and provided clinical efficacy despite renal condition.

B1511

EFFICACY AND SAFETY OF PERCUTANEOUS VERTEBROPLASTY IN PATIENTS WITH SPINAL MYELOMA LESIONS.

E Abella[1*], J Soler[2], A Angona[1], J Ares[3], M Zauner[4], A Solano[5], J Serra[6], C Besses[1]

[1]Hematology, Parc de Salut Mar, Barcelona, [2]Hematology, Parc Tauli, Sabadell, [3]Radiology, IMI Parc de Salut Mar, Barcelona, [4]Radiology, Parc Tauli, Sabadell, [5]Radiology, Parc de Salut Mar, [6]Radiology, CRC Mar, Barcelona, Spain

Background: About 80-90% of patients with multiple myeloma (MM) will develop skeletal related complications, including diffuse osteopenia, focal lytic lesions, pathological fractures, and bone pain, mainly located in vertebrae and skull. The therapeutic intervention for bone disease is based on analgesic medications, byphosphonates, radiation therapy and in some cases percutaneous vertebroplasty (PV) or balloon kyphoplasty. PV was described by Galibert and colleagues in 1987 as a minimally invasive procedure involving the injection of polymethylmetacrilate (PMM) associated to a radiopaque substance within a collapsed vertebral body via a percutaneous approach, under fluoroscopic computed tomography (CT) image guidance. PV seems to have a satisfactory efficacy in almost all patients (90-100%) with an improvement of pain. All studies reported small volume, local intradiscal or paravertebral cement leaks, usually being asymptomatic. Severe life-threatening complications are very uncommon (<1%) and in some reports have been related to a cement volume of greater than 4 mL.

Aims: To evaluate the efficacy and safety of percutaneous vertebroplasty (PV) in the treatment of spinal myeloma lesions (SML) refractory to analgesia, byphosphonates or radiation therapy.

Methods: Forty-two patients with SML, from 2 centers were eligible. Vertebral fracture or collapse was confirmed by computed tomography or magnetic resonance imaging. PV of more than one vertebra was performed if feasible. Pain response was evaluated by a qualitative scale at 24 h, one and six months after PV. Complications appearing during the follow of 30 days were considered secondary to PV .

Results: One hundred and ten PV were performed in 49 procedures. The number of vertebrae treated in each procedure was: 1 in 14 cases, 2 in 15 cases, 3 in 15 cases, 4 in 4 cases and 5 in 1 case, being the T12 the most frequent localization (16 cases). Cement leakage was observed in 46% of all patients. Six out of 42 patients (14%) experimented complications related to PV: two cases of psoas hematoma, one patient with pulmonary insufficiency, two patients suffered a pulmonary embolism (one died because of cement embolism) and one patient presented a subdural hematoma without neurological repercussion. Twenty-four hours after PV, 83% of patients referred a decrease in pain. The evaluation at 1 and 6 months later, showed an improvement of pain in 83% and 70%, respectively.

Summary / Conclusion: PV is effective for pain control in 70-80% of myeloma patients with SML at short and long-term. However, some patients may experience life-threatening effects. Further studies with more patients and more follow-up are needed to confirm the efficacy and the incidence of adverse effects.

B1512

"REAL WORLD" DATA FROM PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA WHO HAVE BEEN TREATED WITH LENALIDOMIDE AND DEXAMETHASONE, ACCORDING TO THE STANDARD CLINICAL PRACTICE

Background: Lenalidomide is highly effective in the treatment of relapsed/refractory multiple myeloma (RRMM). However, there is limited published data about the efficacy and safety of lenalidomide treatment in a "Real World "(RW) patients setting outside clinical trials.

Aims: To assess the outcome and safety of lenalidomide treatment in a RW setting within the context of its approved indication through the analysis of retrospectively collected data from a registry in Greece.

Methods: This was an open label, retrospective, multicenter, non-interventional study on collecting and analyzing RW patient data in the treatment of RRMM in Greece, in accordance with the definitions of the International Society for Pharmacoeconomics and Outcomes Research (ISPOR). Patients signed an informed consent at the time of the data collection. The primary endpoints were: a) clinical improvement and complete response (CR) according to the EBMT criteria, b) dose modifications or treatment discontinuation. The secondary endpoints included a) time to first observed clinical improvement and CR, b) duration of treatment, c) duration of response (DOR), d) adverse events percentage requiring hospitalization, e) incidence of deep vein thrombosis (DVT), extramedullary relapse and improvement of humoral immunity.

Results: We collected data from followed 212 patient records (M/F: 120/91, mean age 68±9.8 years). Seventy-four patients (35.1%) received lenalidomide as 2nd line therapy and 137 (64.9%) as >2nd line. Sixty percent of patients received lenalidomide >24 months from diagnosis. The median number of cycles administered was 12 (range 1-57). Initial dose of lenalidomide was higher in patients <65 years compared to older patients (recommended dose of lenalidomide i.e. 25mg was administered in 84.5% of patients <65 vs 64.5% of elderly patients, *P*=0.02). Elderly patients received lenalidomide earlier in the course of the disease (*P*=0.04). Overall, objective response (≥partial response) was observed in 161 patients (77.4%); 42 patients (20.2%) achieved a CR. Median time to first observed clinical improvement and to best response was 2 and 5 months, respectively. Median time to CR for 2nd line or >2nd line was 4 and 11 months, respectively. Quality of response was independent of lines of therapies or previous treatment with thalidomide or bortezomib. Median DOR was 34.4 months. In patients who received lenalidomide until progression median DOR was not reached, whereas in patients who discontinued, it was 19 months (*P*<0.001). In the multivariate analysis, performance status and initial dose were predictive of DOR (*P*<0.05 for both parameters). Dose reductions were observed in 31% of patients (87% due to adverse events). Permanent treatment discontinuation occurred in 38.9% (adverse events: 26%, disease progression: 18.9%). Neutropenia was the most common adverse event leading to treatment discontinuation (6.6%). Median time to treatment discontinuation was 16.8 months. Performance status and initial dose of lenalidomide predicted for treatment discontinuation in the multivariate analysis (*P*<0.05 for both parameters). Adverse events occurred in 68.9% of patients (12.7% needed hospitalization). Myelosuppression was the most common adverse event (49.4%). Lenalidomide-related peripheral neuropathy was observed in 2.5% of patients. Extramedullary relapse occurred in 3.8% and DVT in 5.7% of patients. Improvement of humoral immunity between baseline and time to best response occurred in 50% of patients (P<0.001).

Summary / Conclusion: Our study on RW patient data confirms that lenalidomide is highly effective and safe in the treatment of RRMM, producing high objective responses and CR rates. Median duration of response was significantly longer in patients who did not discontinue therapy. Permanent treatment discontinuation was mainly due to adverse events. The latter finding addresses the need for suitable management of side-effects, according to guidelines, in order to avoid treatment discontinuation. Incidence of DVT and extramedullary relapse was low. Importantly, lenalidomide improved humoral immunity in 50% of patients.

B1513

BORTEZOMIB, NON-PEGYLATED LIPOSOMAL DOXORUBICIN, DEXAMETHASONE (PAD) REGIMEN AND AUTOLOGOUS STEM CELL TRANSPLANT IN NEWLY DIAGNOSED MULTIPLE MYELOMA: PRELIMINARY RESULTS OF A PILOT STUDY

A Falcone[1*], G Rossi[1], C Bodenizza[1], A Carella[1], M Dell'Olio[1], M Greco[1], A LA Sala[1], S Mantuano[1], L Melillo[1], E Merla[1], M Nobile[1], G Sanpaolo[1], P Scalzulli[1], N Cascavilla[1]

[1]Hematology and Stem Cell Transplantation Unit, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, Italy

Background: Induction therapy followed by Autologous Stem Cell Transplant (ASCT) is considered the standard approach in newly diagnosed young patients with Multiple Myeloma (MM). It has been previously reported substantial activity in the front-line setting with Bortezomib, Doxorubicin and Dexamethasone (PAD) induction therapy, which was based on the scientific rationale of dual apoptotic signaling leading to in vitro synergy between bortezomib and doxorubicin (Ma et al, 2003) and additive activity with dexamethasone (Hideshima et al, 2001). In a phase II study, the combination of Bortezomib, Pegylated liposomal Doxorubicin and Dexamethasone was evaluated as induction before ASCT a high response rate was obtained: 58% of very good partial response (VGPR) including 13% of Complete Remission (CR). The treatment-related mortality was 3% and grade 3 to 4 adverse events (AEs) included thrombocytopenia (17%), neutropenia (10%), peripheral neuropathy (16%), and pneumonia (10%) (Palumbo A et al. 2010).

Aims: A phase IIb pilot open label trial in newly diagnosed MM patients (pts) was planned as Bortezomib, Non-pegylated Liposomal Doxorubicin and Dexamethasone induction therapy followed by consolidation with ASCT and maintenance with Bortezomib. Aims of our study were efficacy and safety in terms of ORR, toxicities and both overall and progression free survivals.

Methods: From January 2009 to February 2013, 29 pts (M/F: 15/14) with a median age of 63 years (range: 48–73) were enrolled in the study; twelve pts (41,4%) were more than 65 yrs. At diagnosis 55% of pts had Durie and Salmon staging II and 45% of them had the staging III. Patients showing ISS 1 were 7%, ISS 2 were 35% and ISS 3 were 58% of. Five pts had a renal impairment, extensive bone disease was documented in 19 cases and 3 patients showing extramedullary disease. Fourty-eight percent of pts had IgG, 21% IgA, 24% light chain and 7% non secretory MM. Unfavorable cytogenetic was recorded in 38% of cases. Planned treatment: Bortezomib$_{1,3}$ mg/mq iv d$_{1,4,8,11}$; Dexamethasone orally at the dose of 40 mg/d on days$_{1,4,8,11}$, in pts 65-70 yrs old and at the dose of 20 mg on d$_{1,4,8,11}$; Non-Pegylated Liposomal Doxorubicin 30 mg/mq on d 1 of a 28-day cycle up to 4 cycles. After PAD regimen pts underwent to high-dose cyclophosphamide (4 g/m2) with G-CSF support, peripheral stem cell harvest and ASCT (MEL 200 and 100 in pts over or above 65 years, respectively). After ASCT, all pts received maintenance with Bortezomib alone twice a month.

Results: Twenty-six pts were treated with PAD regimen and 22 of them underwent to ASCT. Majority of pts (93%) achieved more than a PR including 58% (15/26) of CR and 35% of VGPR (9/26 after 4 courses of PAD. Two pts (7%) achieved a PR. After ASCT all pts achieved at least VGPR including 86% (19/22) of CR. After a median follow-up of 22 months (range 3-50), PFS and OS are 91% and 100%, respectively. PAD regimen resulted well tolerated and WHO grade 1-3 AEs included neuropathy (19%), hematologic toxicities (42%), infections (9%), gastrointestinal toxicities (18%). No case of cardiac toxicity was observed

Summary / Conclusion: Sequential PAD, ASCT and Bortezomib as maintenance is an attractive regimen to maximize the efficacy of ASCT. PAD in frontline setting is a highly effective and well tolerated regimen. Our results from this promising pilot study need further testing in randomized phase III trials.

B1514

LIMITED SURVIVAL FOLLOWING SEQUENTIAL EXPOSURE TO CURRENTLY AVAILABLE NOVEL AGENTS IN MULTIPLE MYELOMA (MM): THE CASE FOR NEW THERAPEUTIC STRATEGIES

J Tarrant[1*], C Parrish[1], S Feyler[2], J Ashcroft[3], R Owen[1], G Cook[1]

[1]Haematology, Leeds Teaching Hospitals, Leeds, [2]Haematology, Calderdale NHS Trust, Huddersfield, [3]Haematology, Mid Yorkshire NHS Trust, Wakefield, United Kingdom

Background: The treatment landscape of MM has significantly changed in the last decade, with a significant improvement in overall survival (OS) being demonstrated. Current treatment strategies involve sequential exposure to proteasome inhibitors (PI) and immunomodulatory drugs (IMiDs), athough the most effective sequencing of exposure has yet to be determined. Furthermore, the outcome for patients relapsing after exposure to the available novel agents remains unclear.

Aims: We have therefore examined the outcomes of patients who demonstrated progressive disease following exposure to IMiDs and Bortezomib in a "real-life" single centre setting, with the aim of describing progression-free and overall survival and identifying factors that may predict outcome.

Methods: Patients were considered eligible for this retrospective study if they have received sequentially Thalidomide-, Bortezomib- then Lenalidomide-

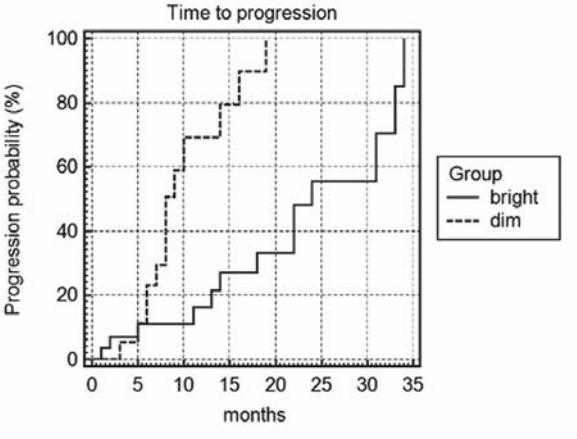
based combination therapy (LenCom) for MM. Case records were examined for key diagnostic details as well as depth and duration of response to PIs. Details of LenCom were recorded and T_0 was defined as the time point at which LenCom was discontinued, whether for disease progression or intolerance. Responses to therapy subsequent to T_0 and PFS/OS were defined for each patient.
Results: Between Jan'07-Sept'12, 56 patients were identified that met the inclusion criteria (28 Male and 28 Female). Median age at diagnosis was 59 yrs (range 33 to 87) with the distribution of ISS: 20% stage I, 28% stage II & 28% stage III (23% Unclassified). The median number of prior lines of therapy before LenCom was 3 (range 2-6). First line therapy was thalidomide-based in 64% with 36% having undergone HD melphalan/ASCT and 9% undergoing tandem ASCT/RIC AlloSCT. Second line therapy was bortezomib-based in 42% patients and all patients received novel agent-containing regimens in the following sequence: thalidomide/bortezomib/lenalidomide (with 53% patients receiving lenalidomide as 4th line or later). The median time from diagnosis to commencing LenCom was 52.5 months (mns) (4-146). At the last follow up, a median of 6.5 cycles of LenCom were administered to all patients and 7 cycles in those who had discontinued LenCom. 39 patients (70%) had reached T_0 (PD n=27, intolerance n=12). The median time from diagnosis and lenalidomide commencement were 64 mns (20-159) & 9 mns (0-32) respectively. Post-T_0, 23 patients received further therapy (thalidomide-based n=11, bortezomib-based n=3, clinical trial therapy n=4, HD Dex n=3, donor lymphocyte infusion n=2) and 7 patients received supportive care (unspecified n=9). 13 patients (57%) demonstrated PD as maximum response to first post-T_0 therapy. With a median follow-up of 4.3 mns (1-33), 28 patients have died (PD n=17, infection n=6, other n=5). The median OS from diagnosis and commencement of LenCom were 100 mns & 18.4 mns, respectively. The median PFS from commencement of LenCom was 16.2 mns. The median OS from T_0 was 6.8 mns, influenced by the beta2microglobulin at T_0 (< vs. ³ 3.0: 9 vs. 4.8 mns, P=0.027). The depth of response to LenCom affected the PFS (P<0.001) but not the post-T_0 OS (P=0.68).
Summary / Conclusion: This study demonstrates the poor outcomes for patients progressing from lenalidomide-based therapy after sequential exposure to all current available novel agents. This is an area of need for clinical development for both effective combination regimens and new biologically active agents if we are to truly extend the survivorship in MM.

B1516
ADDING CYCLOPHOSPHAMIDE TO LENALIDOMIDE-DEXAMETHASONE – A SAFE STATEGY TO IMPROVE RESPONSE IN RELAPSE/REFRACTORY MULTIPLE MYELOMA
I Coelho[1*], M Neves[2], C Costa[1], S Esteves[3], G Esteves[2], C João[1]
[1]Hematology, Instituto Português de Oncologia, Lisboa, [2]Hematology, Centro Hospitalar Lisboa Norte, [3]Clinical Research Unit, Instituto Português de Oncologia, Lisboa, Portugal

Background: Lenalidomide is an immunomodulator approved for relapsed/refractory Multiple Myeloma (rrMM). Cyclophosphamide is a safe alkylating agent with effect in MM. Combination strategies exploring synergistic effects aiming to achieve better responses are important in rrMM, with eventual impact on prolongation of these patients' survival.
Aims: We studied the efficacy and safety of adding cyclophosphamide to lenalidomide-dexamethasone (LenDex) in rrMM patients (pts) treated in two reference centers between May 2007 – Sep 2012, for at least 2 cycles.
Methods: We developed a multicentric, retrospective cohort study. Progression free survival (PFS) was evaluated from the start of treatment with LenDex.
Results: We reviewed 149 pts with rrMM treated with LenDex. Of these, 16 pts received intensification with cyclophosphamide per os in addition to LenDex (CRD) when they were clinically and/or biologically losing response. The analysis only included pts treated with more than 2 cycles of CRD: 50% males; median age at diagnosis 60 yo; median age at start of CRD 65 yo. The median number of previous lines was 2 (range: 1-6), and the main subtypes were IgG K 25%, IgA K 19% and light chain K 19%. 43% had high-risk cytogenetics; 31% extra-medular disease; 13% amyloidosis. Ten pts (63%) recieved lenalidomide 25 mg/d, four pts (25%) recieved 10 mg/d and two pts (12%) recieved 10 mg/d x 21 days (cycles of 28 days), 31% dexamethasone 20mg/week (range: 16-160mg/week) and cyclophosphamide was administrated at doses varying between 200 mg and 500 mg/week (median 300 mg/week). Overall, 7 pts (44%) improved their response again (2 pts (13%) to VGPR, 5 (31%) to PR) with impact in PFS when compared to patients who had SD/PD with LenDex and that were not intensified with CRD (median: 29 months vs 9 months); 4 pts (25%) achieved stable disease and 5 (31%) had progressive disease. The median overall survival, evaluated from start of CRD, was 15 months (median follow up 7 months; range: 2-38). Toxicity was mainly haematological (in 10 pts (63%), of grade III/IV in 8 pts). Three pts (19%) had infections. Thrombotic events were not found, prophylaxis was performed in all patients.
Summary / Conclusion: Adding cyclophosphamide to the regimen LenDex, in patients who are losing response, as a strategy to achieve a better biological and clinical response, seems to be a feasible, efficient and tolerable therapeutic option in patients with rrMM.

B1517
EVALUATION OF CD 45 EXPRESSION ON PATIENTS WITH MULTIPLE MYELOMA AND ITS EFFECT ON THE TIME TO PROGRESSION
A Jungova[1*], M Holubova[1], S Vokurka[1], D Lysak[1], P Jindra[1]
[1]Hemato-oncology department, Charles University hospital Pilsen, Pilsen, Czech Republic

Background: Multiple myeloma is a disease characterized by the clonal proliferation of plasma cells with paraprotein production.Plasma cells usually have the specific immunophenotype CD38 +, 138 +, normal plasmocytes show a phenotype CD19+CD56-, while mature myeloma cells are CD19-CD56+. The surface antigen CD45 (protein tyrosin phosphatasis, receptor type C, PTPRC) normally expresses itself in young plasma cells. However, during the differenciation into mature plasma cells it goes down. The antigen-mediated signalization and activation of lymphocytes and plasma cells describe this character. CD45 negative cells are more resistant to apoptosis.According to the literature, there should be a low expression of the CD45 negative factor affecting the early progression of independent cytogenetic findings.
Aims: To compare the time to progression / relapse on patients with multiple myeloma with regard to CD 45 expression.
Methods: A retrospectiveanalysis. Evaluated were samples from 71 patients with myeloma from 5/2011 to 12/2012. Cytogenetic risk by Avet-Loiseau, 2005: negative = normal karyotype, changes on chromosome 13 and 17, t (4; 14) at (14, 16), positive = everything else and t(11;14).
Flowcytometric analysis: using 8-color flow cytometry which detected the presence of plasma cells to using cytometer FACS Canto II.
Identification of plasma cells with sequential gating using a combination of the antigens CD38, CD138, CD45 and the scatter properties of plasma cells, the expression of antigens on atypical, atypical and normal plasma cells, positive control by CD138 +, negative control by CD8- with adjustment of the sequential gates, for the detection of MRD limit sensitivity 0, 01% (10 e-4).
Results: According to theintensity of the flow cytometric expression of CD45 two groups were defined; low expression "dim" and higher expression "bright". Group parameters were compared to"dim"(n = 25) vs. "bright" (n = 46): median age 58 years (38-69) vs. 62 years (40-72) (P=0.30), male / female ratio 13/12 vs. 24/22 (P=1.0), unfavorable cytogenetics 16/21 (76%), r. 25/42 (60%) (P=0.26), not surveyed cytogenetics in 16% pts. vs 9% pts., the frequency of CR after the 1st line treatment 3/25 vs. 8/46 (P=0.73), the frequency of autologous SCT in 1st line 23/25 (92%) vs. 38/46 (83%) (P=0,48). Living patients 21/25 (84%) vs 43/46 (93%), median follow up by living patients was 11 months (1-40), vs. 20 months (1-98), median of progression 8 vs. 22 months (P=0,0003). The probability of progression at 24 months was 100% vs. 52% (P=0.0003).



Summary / Conclusion: The effect of CD45 expression in comparison to the risk of progression on patients with myeloma was evaluated. We compared a group with low and higher CD 45 expression. There was no difference in the demographic parameters, cytogenetics risk or 1st line treatment. The group with a low expression of CD45 had a significant lower TTP and therefore a higher probability of early progression. A research over a longer period and a larger group of patients is necessary.

B1518
FREQUENCY DYNAMICS AND PROGNOSTIC IMPACT OF WEIGHT LOSS AND BODY MASS INDEX IN MULTIPLE MYELOMA AT DIAGNOSIS
R Ríos[1*], F Jaén[2], J Ramos[2], F López[1], E Molina[3], P López[1], J Sáinz[4], M Sánchez[3], J Jiménez-Moleón[5], J de Pablos[1], L Moratalla[1], M Jurado[1]
[1]Hematology, [2]Internal Medicine, University Hospital Virgen de las Nieves, [3]Granada Cancer Registry, Andalusian School of Public Health, [4]Genomics, Genomic Oncology Area, GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Regional Government,

[5]Preventive Medicine and Public Health, University of Granada, Granada, Spain

Background: Several meta-analysis have shown that obesity [body mass index (BMI) ³ 30 Kg/m^2] is a risk factor for multiple myeloma (MM). MM behaves like many other cancers, and a general syndrome is frequently seen, including asthenia, anorexia and weight loss (WL). We hypothesized that the quantity and speed of WL, along with BMI, could have a prognostic impact in MM.
Aims: To assess the prognostic impact of WL and BMI at diagnosis in MM patients
Methods: We retrospectively analyzed clinical records of all symptomatic MM patients diagnosed from 2000 to 2013 in a population-based study, according to The Granada Cancer Registry. BMI was recorded at diagnosis. WL was measured in Kg during a given period of time in months (mo), as reported by patients. Patients with WL were divided in two groups: those with a well characterized phenomenon in time (mean WL in Kg/mo was calculated) and those that could no specify an amount of Kg or a period of time. We constructed overall survival (OS) curves according to Kaplan-Meier method. Log-rank test was used to compare OS curves. The statistical package used was SPSS v.20.
Results: 279 patients were diagnosed with MM during the thirteen years of the study, 128 males and 151 females (54,1%), median age 67 years (12-91). BMI was available in 173 patients: 54 (31,2 %) had obesity, 79 (45,7 %) overweight (BMI 25-29,9), 35 (20,2 %) normal range (BMI 18,5-24,9) and 5 (2,9 %) underweight (BMI < 18,5). WL data were available in 214 cases: 55 cases (25,7 %) had WL, 66 (30, 8 %) did no refer WL and was unknown in 93 (43,5 %). Median WL was2,5 Kg/mo (range: 0,83-7). Median OS was 18 mo (IC 95 %: 10,8-25,1), 40 mo (IC 95 %: 23-57) and 29 mo (IC 95 %: 18,6-39,4) for patients with, without or unknown WL, respectively (P=0,046). Median OS in patients with more o less intense WL (> o <2,5 Kg/mo) was similar. Likewise, OS between patients with measurable or unsettled WL was also similar. According to BMI categories, OS was 1 mo (IC 95 %: 0,1-1,8), 34 mo (IC 95 %: 11-57), 49 mo (IC 95 %: 0-102) and 61 mo (IC 95 %: 37,1-84,9) for underweight, obesity, overweight and normal weight, respectively (P<0,001).
Summary / Conclusion: At the moment of MM diagnosis, underweight is associated with a dreadful OS and obesity shows a tendency to shorter OS. At least one of every four patients shows WL. Even considering a potential bias in patient personal referral to WL, losing weight seems to be a negative prognostic factor that warrants a deeper study in bigger series; however, potential confounders of WL should be excluded.

B1519

PREDICTIVE VALUE OF LIGHT AND HEAVY CHAIN ANALYSIS IN MULTIPLE MYELOMA PATIENTS TREATED WITH BORTEZOMIB

I Murillo-Flórez[1*], M Andrade-Campos[1], A Montes-Limon[1], J Quintero-Gutierrez[1], J Grasa[1], P Giraldo[1,2,3], D Rubio[1]
[1]Department of Hematology, Miguel Servet University Hospital, [2]Biomedical Network Research Center on Rare Diseases (CIBERER), ISCIII, [3]Aragon Health Sciences Institute (IACS). , Zaragoza, Spain

Background: The incorporation of new biomarkers useful to evaluate the immune production as free light chains (FLC) and Immunoglobulin heavy / light chain (HLC) ratios and the quantification of uninvolved isotype, could identify potentially risk factors to predict the response to therapies that included Bortezomib.
Aims: Present our experience in the use of new biomarkers to assess the response to treatment in patients diagnosed with Multiple myeloma.
Methods: We have analyzed these biomarkers in serum of 70 patients diagnosed with multiple myeloma (50 IgG, 20 IgA) treated with Bortezomib between 2004-2010. The analysis of FCL and HCL has been performed at diagnosis, after four cycles and at end of treatment with Bortezomib using FreeLyte and HeavyLite assay of The Binding Site Ltd. The evaluation of response has been defined according IMMWG criteria. The serum samples were collected and stored frozen at -70ºC in the Biobank at Miguel Servet University Hospital. The concentration of involved immunoglobulin has been compared with the M-component; the ratio of FCL and HCL and the degree of immunoparesis have been correlated with the intensity of response, the progression-free survival (PFS) and the overall survival (OS).
Results: A total of 28 females and 42 males with a mean age of 68 years has been included. In 11 patients an hematopoietic stem transplant were performed and were analyzed separately. Considering the original immunoglobulin isotype concentration, our results show that the follow-up of HCL ratio is more sensitive than monoclonal component to evaluate a strict response after Bortezomib therapy and the increase of HLC ratio of uninvolved isotype is associated with a longer PFS and OS.
Summary / Conclusion: Our results suggest that HLC ratio is a satisfactory marker of follow-up response and probably the uninvolved isotype concentration as marker of immunoparesis is correlated with the PFS and OS

B1520

LENALIDOMIDE/DEXAMETHASONE (RD) IN REFRACTORY/RELAPSED MULTIPLE MYELOMA: A RETROSPECTIVE MULTI-CENTER STUDY FROM "RETE EMATOLOGICA PUGLIESE" (REP).

G Mele[1*], G Guaragna[1], S Capalbo[2], G Palumbo[2], G Polimeno[3], P Di Tonno[4], A Guarini[5], C Minoia[5], P Curci[6], R Rizzi[6], R Ria[7], A Vacca[7], N Di Renzo[8], G Rediconto[8], N Cascavilla[9], M Falcone[9], G Tarantini[10], C Buquicchio[10], V Pavone[11], B Rossini[11], G Palazzo[12], E Iannitto[12]
[1]Haematology, Antonio Perrino Hospital, Brindisi, [2]Haematology, Ospedali Riuniti Hospital, Foggia, [3]Haematology, F. Miulli Hospital, Acquaviva delle Fonti (Bari), [4]Haematology, Di Venere Hospital, [5]Haematology, IRCCS Giovanni Paolo II° , [6]Haematology, [7]Internal Medicine, University of Bari Medical School, Bari, [8]Haematology, V. Fazzi Hospital, Lecce, [9]Haematology, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (Foggia), [10]Haematology, San Nicola Pellegrino Hospital, Trani (Bari), [11]Haematology, Cardinale Panico Hospital, Tricase (Lecce), [12]Haematology, SS Annunziata Hospital, Taranto, Italy

Background: Several data are available on the efficacy of the combination lenalidomide/dexamethasone in patients with relapsed Multiple Myeloma (MM).
Aims: We reported here a multi-center series of 290 patients with refractory/relapsed MM treated with lenalidomide/dexamethasone as salvage therapy.
Methods: Two hundred ninety patients (141 females and 155 males - median age 70 years [42-88]), were treated in 12 haematogical centers (REP). Median Hb value was 11 gr/dl (range 7-17,2), absolute neutrophil count 3.200/µl (range 700-14.360), PLT count 182.500/µl (range 3000-542.000).Median clearance creatinina value was 80 ml/min (range 1-225). In 18/45 analyzed patients karyotype had cytogenetic abnormalities; del 13q was observed in 12 patients, t(4;14) in 2 patients, t(11;14) in 2 patients, del 17p in 1 patient; complex karyotype was observed in 1 patient. Fifty-three % of patients presented with at least one severe comorbidity (diabetes mellitus, chronic obstructive bronchopneumonia, hypertension, atrial fibrillation or other cardiac arrhythmias, coronary heart disease, peptic ulcer, renal and hepatic dysfunction).The median number of previous lines of therapy was 3 (1-4). Ninety-nine patients had undergone autologous stem cell transplantation.The initial dose of lenalidomide was 25 mg/day in 170 patients, 15 mg/day in 56 patients, 10 mg/day in 54 patients and finally 5 mg/day in10 patients. In 14 cases lenalidomide/dexamethasone was associated to other drugs.
Results: Two hundred forty-six of 296 patients were evaluable for response. Patients received a median number of 7 cycles of lenalidomide/dexamethasone therapy (1-37). ORR was 68%: namely, according to IMWG uniform response criteria, 27 patients (16%) achieved a CR, 60 patients (36%) a VGPR, 81 patients (48%) a PR. Median time to best response was 4 months (1-11).Median duration of response to treatment received was 12,5 months (1-40). Median time to progression was 7 months (1-40).Grade 3/4 haematological toxicities occurred in 29 patients (17%), non-haematological toxicities in 59 patients (35%), causing interruptions of the treatment or reduction of daily dose. Quality of response correlates with number of previous treatments.
Summary / Conclusion: Our retrospective analysis confirms that lenalidomide/dexamethasone is effective in inducing significant responses in refractory/relapsed MM.

B1521

IMMUNOPHENOTYPIC ASSESSMENT AND CLINICAL OUTCOME IN PATIENTS AFFECTED BY MULTIPLE MYELOMA (MM)

S Improta[1], A Gagliardi[1*], M Villa[1], M Esposito[1], C Tommasino[2], G Fossati[2], L Mastrullo[1]
[1]U.O.C. Ematologia, [2]U.O.C. Patologia Clinica, P.O. San Gennaro ASL Napoli 1 Centro, Napoli, Italy

Background: The survival of patients affected by MM is variable depending upon the tumour mass at the diagnosis and by the intrinsic biological characteristics of tumour cells. Flow cytometry and immunological methods have allowed the characterization of a series of surface antigenic molecules expressed on either MM or normal cells. With this technique several molecules differentially expressed on normal and MM cells and correlated with the prognosis of MM patients have been identified. In details B-associated antigens, growth factor receptors, myeloid antigens and adhesion molecules can be found on pathological plasma cells.
Aims: Some studies have demonstrated that in about 50% of MGUS patients and 33% of MM patients the plasma cells express CD117 (c-kit), while normal plasma cells are CD117 negative. Moreover, both the normal plasma cells and those of patients with MGUS are usually positive for the CD43.
Methods: In the last 5 years we have analyzed, at diagnosis, the bone marrow blood of 71 patients affected by MM. 49 out of 71 presented a IgG component and the remaining 22 patients were IgA. On the basis of the staging criteria (ISS), 38/71 pts. were in stage II and 33/71 in stage III; the clinical stage (remission, progression or stable disease) was defined with clinical re-evaluation after chemotherapy and/or re-staging at 6 months from diagnosis.
Results: The immunophenotype of bone marrow plasma cells demonstrated the expression of CD38 (very bright) and of CD138 while CD19 was absent; 49/71 were CD43+(dim) and 20/71 CD117+(dim). 15 out of 20 CD117-positive

patients showed a specific immunophenotypic pattern (CD117+/CD43-). These patients were in stage II and showed a favorable clinical outcome, as demonstrated by a higher DFS and OS than the remaining patients, regardless of the treatment administered.
Summary / Conclusion: The possible prognostic role of CD117 and CD43 in MM warrants further clinical investigation on a larger series of patients even on the basis of new therapeutic strategies.

B1522
LONG-TERM USE OF LENALIDOMIDE IN PATIENTS WITH RELAPSED MYELOMA IN A SINGLE CENTRE: RESPONSE, TOXICITY AND FACTORS AFFECTING SURVIVAL.
K Lewis[1*], A Khakwani[2], J Byrne[1], N Russell[1], C Williams[1]
[1]Centre for Clinical Haematology, Nottingham University Hospitals Trust, [2]Department of Epidemiology and Public Health, University of Nottingham, Nottingham, United Kingdom

Background: *Background.* Lenalidomide is licensed for the treatment of relapsed multiple myeloma after ≥ 1 therapy, although reimbursement is available for patients in the UK after ≥ 2 therapies. Treatment (combined with Dexamethasone) is recommended until disease progression but data on its efficacy and toxicity is limited outside of clinical trials. This study looks at Lenalidomide usage at a single centre: Nottingham University Hospital (NUH), which has the most patients on the drug in the UK.
Aims: *Aim:* The aim of this study is to evaluate the response, toxicity and survival of patients with relapsed myeloma on Lenalidomide, and factors impacting on these.
Methods: *Methods:* All patients initiated on Lenalidomide between 1st June 2009 and 31st December 2010 at NUH were included in this study. Using retrospectively collected data we performed univariate and multivariate Cox regression analysis to calculate the likelihood of death (hazard ratios) based on several patient features (sex, age, complications) as well as starting dose and dose modification of Lenalidomide. The cut-off date for our cohort was 31st January 2013 to allow for at least 2 years of follow-up. Response was evaluated using modified IMWG/EBMT criteria.

	Univariate analysis				Cox regression	
	Pts	Events	EFS (SE)	p	HR (95% CI)	p
Age				0,0002		
< 6 months	40	26	32% (7)		2,70 (1,21 – 6,04)	0,01
> 6 months	43	11	72% (7)		Reference	
Group				0,007		
Group 2	24	16	28% (9)		2,64 (1,30 – 5,35)	0,007
Group 1	59	21	62% (6)		Reference	
MLL Status				0,001		
MLL (+)	58	32	42% (6)		2,92 (0,90 – 8,42)	0,07
MLL (-)	24	4	81% (8)		Reference	
Day 8 response				0,01		
≥ 1000 blasts	12	9	20% (12)		1,25 (0,74 – 3,63)	0,58
< 1000 blasts	69	27	59% (6)		Reference	

Results: *Results:* A total of 83 patients were included in the analysis of whom 44 (53%) were male. The median age was 71 yrs (range 30 –87); 25 (30%), 32 (39%) and 26 (31%) were aged <65 yrs, 65-75yrs and >75yrs, respectively. The median number of lines of previous therapy was 3 (range 1-10). Median number of cycles of Lenalidomide received was 15 (range 1-45) with 24 patients (29%) reaching ≥ 24 cycles. 55 patients (66%) started at 25mg and dose modifications occurred in 52 patients (63%) in the whole cohort. Of the 83 patients, maximal response on Lenalidomide therapy was assessable in 81 patients, with an ORR (CR+VGPR+PR) of 69 % with 14 (17%), 8 (10%) and 34 (42%) achieving a CR, VGPR or PR, respectively. In those who achieved ≥ PR, mean time to maximum response was 7.3 cycles (range 1-37). Of the 83 patients, 56 (67%) had at least 1 in-patient hospital stay during their time on Lenalidomide, the most frequent cause being infection. Overall, 56 patients (67%) have stopped Lenalidomide; of these 68% were due to progressive disease and 32% due to toxicity. The median OS of the whole cohort from time of commencing Lenalidomide is 730 days (IQR 255-989 days). Factors affecting survival were examined and the adjusted hazard ratios revealed that women have better survival (HR 0.36, 95%CI 0.18 – 0.73) compared with men when adjusted for confounders (P=0.003). Factors significantly associated with poor survival on multivariate analysis were no dose modifications of Lenalidomide, grade IV thrombocytopenia, grade IV neutropenia and eGFR <30, with p-values of 0.002, 0.0018, 0.026 and 0.0013, respectively. Starting dose, grade III anaemia or presence of VTE were not significantly associated with survival.
Summary / Conclusion: *Conclusions:* This study shows that nearly 70% of patients with relapsed myeloma, despite being heavily pre-treated, can achieve a partial response or better to Lenalidomide and many may remain on the drug long-term. Response can continue to deepen up to 3 years into receiving treatment. A median OS of 2 years after starting Lenalidomide is reported in this study, with dose modifications of the drug significantly improving survival. The development of certain drug related toxicities can significantly shorten survival.

B1523
THE CHOICE OF REGIMENS BASED OF BORTEZOMIB FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: EXPERIENCES FROM CHINA
Z Cai[1*], J He[1], L Yang[1], X Han[1], G Zheng[1], W Zheng[1], G Wei[1], W Wu[1], X Ye[1], J Shi[1], W Xie[1], L Li[1], J Zhang[1], W Huang[1], H Huang[1], X Zhang[2], J Fu[3]
[1]Hematology, The First Affiliated Hospital of Medical College, Zhejiang University, [2]Hematology, Red Cross Hospital of Hangzhou, Hangzhou, [3]Hematology, Shaoxing People's Hospital, Shaoxing, China

Background: Novel drugs, such as Bortezomib, have significantly improved the response rates in multiple myeloma (MM). But how to chose the bortezomib based regimens as the initial therapy of MM while there few prospective randomized trials even the retrospective reports that compared modern combinations with bortezomib. Here, we report on four bortezomib-based therapies in newly diagnosed MM patients in the Chinese population from three blood treatment centers.
Aims: To evaluate the effect and adverse events of four bortezomib-based therapies in newly diagnosed MM patients in the Chinese population from three blood treatment centers.
Methods: In the initial eight 28-day cycles, newly diagnosed symptomatic patients were treated with combination therapy including bortezomib plus dexamethasone (PD) and the triplet combinations of PD with adriamycin (PAD), cyclophosphamide (PCD), thalidomide (PDT) between February1, 2006 and May 31, 2012. Among the above regimens, bortezomib (1. 3 mg/m^2) was given intravenously on days1,4,8, 11, while dexamethasone (20 mg/m^2/day) was given intravenously on days 1–2, 4–5, 8–9, 11–12, adriamycin (10 mg/m^2) was given intravenously on days 1–4, cyclophosphamide (200 mg/m^2) was given intravenously on days 1–4 and thalidomide (100 mg) was administered orally each day.
Results: The overall response rate (ORR) (≥ partial response, PR) of all the 164 eligible patients was 89.6% (including 29. 3% very good partial response (VGPR) and 26. 8% complete response/near complete response (CR/nCR). The ORR of patients in PTD, PCD, PAD and PD groups are 86.7%, 95.4%, 91.4 and 78.8%, respectively. The rate of VGPR and better in these groups are 53.3%, 65.2%, 62.9% and 33.3%, respectively. The ORR and the rate of VGPR and better in PCD groups were superior to PD□*P*=0.025, 0.003□.
The median PFS was 16.0months (95% CI: 11.9 –20.1 months) in the patients who received PDT, and 23.0 months (95% CI: 7.5-32.5 months), 23.9 months (95% CI: 10.3-37.5 months) and 21.8 months (95% CI: 7.7-36.0 months) in PCD, PAD and PD respectively with no significant differences between. The 2-year respective PFS was 31.9±9.0%, 46.0±9.0%, 44.0±12.0%, 40.0±11.0% in PTD, PCD, PAD and PD regimens, respectively. At the time of analysis, 33 (20.1%) patients had died, including 10 patients who had received PTD, 14 patients in PD groups, 7 in PCD groups and 2 in PAD groups with the causes of death consisted of treatment-related, myeloma, and others, respectively.
The median OS of the 164 patients was not reached, while 5-year respective OS was 53.8±8.0%, and there was significant differences between the groups (*P* =0.007).The median OS for PD arm was 41,8 months (95% CI: 20.2-63.4 months) while other arms were not reached, but the median OS for PTD, PCD and PAD was significant longer than PD (*P*=0.043, 0.028, 0.009).The 3-year respective OS was 64.0±9.0%, 69.0±12.0%, 76.0±17.0%, 58.0±10.0% in PTD, PCD, PAD and PD regimens. The frequently observed toxicities were neutropenia, thrombocytopenia, fatigue, infection, herpes zoster, and peripheral neuropathy. Peripheral neuropathy was more frequently reported in PTD group without routine anti-viral therapy, but much more lower in other groups with anti-viral therapy. The incidence of neuropathy was extremely higher in PTD regimen than other groups, especially grade 2 and 3.
Summary / Conclusion: Our experience indicated that bortezomib-based regimens were active and well-tolerated in the Chinese population, triplet combinations PCD, PAD regimens are superior to PTD or doublets, especially the PCD regimen.

B1524
THERAPEUTIC RESPONSE IN PATIENTS WITH MACROFOCAL FORM OF MULTUPLE MYELOMA , TREATED WITH BORTEZOMIB - CONTAINING REGIMENS
V Goranova-Marinova[1*], A Nedeva[2], P Georgiev[1], I Nikolov[2], I Hristova[1], I Gigov[2], J Raynov[2], S Goranov[1]
[1]Clinic of Hematology, University Hospital "Sv.Georgi", Plovdiv, [2]Department of hematology and oncology, Military Medical Academy, Sofia, Bulgaria

Background: There is a small but well recognized in the clinical practice group of patients with multiple myeloma (MM), characterized by multiple bone lesions and small tumour burden – the so called "macro-focal form" of MM.
Aims: To analyze the incidence, clinical manifestation, therapeutic response and prognosis of the patients with macro-focal form of MM, treated with Bortezomib – containing regimens

Methods: For the period 2006-2011, 111 patients with MM, treated with Bortezomib – containing regimens were studied in two university clinics of hematology: University Hospital "Sv. Georgi", Plovdiv and Military Medical Academy, Sofia. Mean age was 58.2±8.8y, M: F / 1.05: 1. Clinical stage was defined according to ISS. In 12 (10.8%) macro-focal form of MM was found. Response rates in the groups with macro-focal and classic form were compared and a comparison of major parameters of the disease activity and bone metabolism in the two groups was performed. For statistical analysis SPSSv18.0 was used, the assessment of median survival was done by Kaplan-Maier method with log rank test.
Results: The patients with macro-focal form of MM were predominantly in an early clinical stage acc to ISS (P=0.002, r=-0.323), more frequent were the non-secretory and light - chain variants (P<0.001, r=+0.441). There were no patients > 65y, no severe anaemia, no renal impairment, no hypoalbuminemia were registered in the patients with macro-focal form. Hypercalciemia was found in 2 (16.7%). The share of patients with macro-focal form with elevated LDH was significantly higher 6 (50%) vs 11(11.1%), P=0.036 r=+0.409. All the patients had generalized bone lesions, grade II+III (P<0.001; R=+ 0.658). Patients with macro-focal form received therapy with VelDex as 2 and 3 line. In all of the them paraprotein disaapeared or was found only by IF, plasma cells in bone marrow were 1-2%. In 10 (83,3%) bone lesions did not progress in size and alleviation of bone pain was found. In 2 (16.7%) there were X-ray data of significant reduction of the size of the bone lesions; 3 (25%) underwent ASCT. After therapy a significant increase of AP level and decrease of Ca, LDH and β2M was found. By the time of analysis all the patients are in remission, no median of survival is formed.
Summary / Conclusion: MRI and PET are very helpful in the diagnostics and monitoring of the macrofocal form of MM. They distinguish between the plasma cell infiltration of the bone marrow and osteolytic foci in the structure of the bone. Although this is a small group of patients, data confirm the findings from similar studies: the application of Bortezomib results in suppressing not only the activity of the disease, but also bone resorbtion.

B1525
LENALIDOMIDE CONSOLIDATION THERAPY FOLLOWED BY LENALIDOMIDE MAINTENANCE AFTER FIRST LINE THERAPY FOR MULTIPLE MYELOMA
N Takezako[1*], N Sekiguchi[1], A Miwa[2]
[1]Hematology, Disaster medical center of Japan, Tachikawa, [2]IMCJ, Shinjyuku, Japan

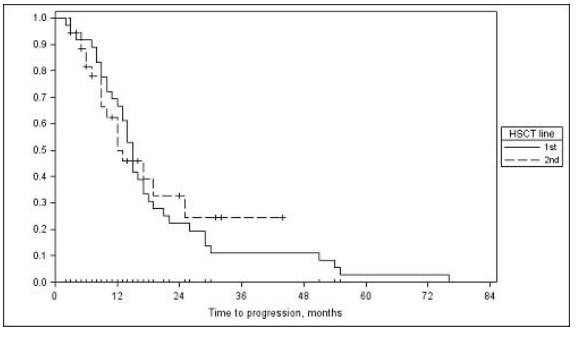
Background: Multiple myeloma is still incurable disease. However, the prognosis of this disease has been improving according to the administration of novel agents. Among of these novel agents, lenalidomide is confirmed the validity of maintenance setting by a randomized controlled study. In addition, the immunoregulatory function of lenalidomide is not clear.
Aims: This phase 2 study investigated the efficacy of lenalidomide maintenance therapy after induction therapy and clarified the immunoregulatory function of lenalidomide.

	Pre-Consolidation (n=35)	Consolidation (n=35)	Maintenance (Best response) (n=35)
sCR	0	9	15
CR	0	2	0
VGPR	15	16	13
PR	19	8	7
SD	1	0	0

Methods: We assigned 35 patients younger than 75 years of age, who were not achieved complete response (CR) after first line therapy, to receive consolidation treatment with reduced lenalidomide (at a dose of 15 mg per day, on days 1 to 21 of each 28-day cycle, for four cycles) and dexamethasone (at a dose of 20 mg per day, on days 1 to4, days 8 to 11, and days 15 to 18, every four weeks, for four cycles) followed by maintenance therapy with lenalidomide (5 mg per day for two years). The primary end point was best response during maintenance therapy. The secondly end points was to clarify the changing of the cell in peripheral blood during therapy using flow cytometry.
Results: Not only consolidation therapy, but also maintenance therapy improved response rate (CR 0, Very Good Partial Response (VGPR) 15, Partial Response 19 before consolidation therapy; stringent Complete Response (sCR) 9, CR 2 VGPR 16, PR 8 after consolidation therapy; sCR 15, CR 0, VGPR 13, PR 7 best response during maintenance therapy). After all, 80% of patients achieved VGPR and more. Thirty-there patients (94%) are still on the study, while two patients discontinued because of progressive diseases. Median progression free survival is not reached. The rates of grade 3 or 4 peripheral neuropathy were not high (3 cases). However, grade 4 skin rush was observed in three patients whose CCL17 level were higher than 1000 pg/ml. Cytotoxic T lymphocytes which were positive $CD3^+$, $CD8^+$, and $CD57^+$ increased in almost patients' peripheral blood during maintenance therapy (31 patients). In addition, Natural killer cells, which were CD3-, $CD16^+$, and CD56+, increased in many patients during maintenance therapy (28 patients). γδ-T cells did not increase during maintenance period.
Summary / Conclusion: Lenalidomide plus dexamethasone consolidation therapy followed by low dose lenalidomide maintenance therapy after first line therapy significantly improved response rates among patients with multiple myeloma. However, some patients were suffered from severe skin rush, so we must invest which type of patient is suffered from critical skin adverse event in the future.

B1526
SECOND AUTOLOGOUS TRANSPLANTATION FOR PATIENTS WITH RELAPSED MULTIPLE MYELOMA
V Peceliunas[1*], A Bertasiute[1], T Zvirblis[1], L Griskevicius[1]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Background: currently the best treatment option for multiple myeloma (MM) patients relapsing after autologous stem cell transplantation (ASCT) remains to be defined. A second ASCT is one of the available options. There are few published data about the safety and effectivenes of this treatment.
Aims: to compare time to progression (TTP) between the first-line ASCT (1ASCT) and the second ASCT (2ASCT) performed at disease relapse. To compare the safety of 1ASCT and 2ASCT.
Methods: we retrospectively reviewed MM patients' recordswho received multiple ASCT at Vilnius University Hospital in 2001-2102. Patients who received 2ASCT for progressive disease were selected for the analysis. Patients who received their second ASCT due to suboptimal response or as planed multigraft procedure were excluded from this analysis.



Results: we indentified 36 patients who received 2ASCT at disease relapse. The median age of patients at 1ASCT was 57 years (32-69) and at 2ASCT was 59 (39-70) years. The median overall survival for the whole group was 123 months . The median time between 1ASCT and 2ASCT was 23 months (4-87). All patients received induction chemotherapy before 1ASCT. Only one third of the patients (N12, 33.3%) received induction containing novel agents (thalidomide – 8 and bortezomib – 4)before the first transplant. 66.6% (24/36) of patients received induction chemotherapy before 2ASCT. All of these regimens contained novel agents (bortezomib – 19 and thalidomide – 5). 12 patients were retransplanted without induction chemotherapy. Conditioning regimen was mainly Mel200 and dose intensity was not different between 1ASCT and 2ASCT. All patients engrafted. There were no transplant related deaths. There were significantly lower mucositis scores and fewer febrile neutropenia episodes after 2ASCT as compared to 1ASCT (p values 0.007 and 0.019, respectively). Median TTP (calculated since the date of the respective ASCT) was not different after 1 ASCT and 2ASCT (15 and 12 months respectively, P=0.783) (Figure 1).
Summary / Conclusion: The second ASCT is safe and effective treatment option for MM patients relapsing after their first ASCT.

B1527

EARLY ACHIEVEMENT OF A GOOD QUALITY RESPONSE PREDICTS BETTER OUTCOME IN MULTIPLE MYELOMA

L Canepa[1*], S Aquino[1], F Guolo[1], C Ghiggi[1], L Giannoni[1], M Miglino[1], G Pastori[1], E De Astis[1], M Bergamaschi[1], M Clavio[1], F Ballerini[1], I Pierri[1], M Spriano[1], A Carella[1], M Gobbi[1]
[1]Haematology, IRCCS S.Martino-IST Genova, Genova, Italy

Background: Prolongation of progression free survival (PFS) and overall survival (OS) remains the ultimate goal of cancer therapy. Response criteria for MM elaborated by the International Myeloma Working Group have been widely used to facilitate precise comparison between new treatment strategies and to better define the exact magnitude of response. The importance to achieve CR after completion of a therapeutic program remains a goal in MM treatment; nevertheless association between CR and survival outcome has been noted in several analyses, whereas in a number of clinical trials CR is often, but not consistently, associated with better OS. Furthermore analysis of OS in MM is becoming increasingly complicated due to the impact of novel agents as rescue therapies. Little is known about the relationship between the speed of achievement of a substantial response and survival end points in MM
Aims: We report a retrospective analysis of 48 MM patients treated at diagnosis by our institution with bortezomib based regimens in order to evaluate whether early acquisition of a good quality response impacts on outcome. To this aim, responses obtained after 2 courses of therapy were analyzed for the impact on PFS and OS.
Methods: From January 2009 to December 2012, 48 MM patients were treated by our institution with bortezomib based regimen, as induction therapy at diagnosis. Median age was 59 years (range 39-78); males were 28; bone lesions were present in 40 patients (83%); 31 patients were in III stage (65%); median number of administered courses was 4 (range 2-10). Median follow up was 23 months (range 2-75). PFS was defined according to IMWG criteria. A CM reduction ≥75% after 2 courses of therapy was defined as Early Good Response (EGR). Survival curves were calculated for PFS and OS by the Kaplan Meier method and were compared using a 2-sided log-rank test. Patients undergoing autologous stem cell transplantation were censored at the time of transplant. Cox regression analysis was performed using various parameters as covariates.
Results: All patients were evaluable for response. After 2 courses of therapy 38 overall responses were observed (CR +nCR =4, VGPR =9, PR=25). At the end of therapy 41 patients reached at least a PR (CR +nCR =10, VGPR =11, PR=20). At the time of analysis 41 out of 48 patients are alive. At univariate analysis EGR (P=0.006) and a response ≥PR at the end of therapy (P=0.005) significantly impact on PFS. At multivariate analysis the only independent factor influencing PFS was EGR (P=0.041). The projected PFS at 60 months for EGR and non-EGR patients is 53% and 19% respectively (P=0.006). OS was affected only by age and poor response to therapy (PD).

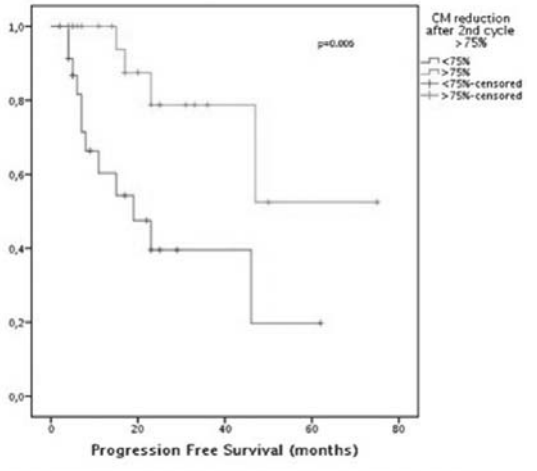


Fig.1 : PFS after 2 courses of therapy according to achievement of CM reduction ≥75%.

Summary / Conclusion: Achievement of CR has been considered as the first primary end point of new therapeutic strategies in MM. Recently several large clinical studies have demonstrated that not only the acquisition of CR, but also the maintenance of durable CR appears to influence outcome. Our data suggest that, in addition to the achievement and maintenance of CR, the early acquisition of a good quality response, even if not complete, is a significant predictor of PFS. As reported in other hematological malignancies (CML,HD), also in MM early evaluation of response could become the driver to address subsequent therapeutic approaches. Consequently, as Rajkumar suggests, CR could be considered a reflection of underlying disease biology, rather than a primary end point of therapy, functioning as a prognostic marker for those patients with inherently favorable disease.

B1528

EFFICACY OF LONG-TERM LENALIDOMIDE TREATMENT OF MM PATIENTS WITH AT LEAST ONE PRIOR THERAPY BASED ON CZECH LOCAL DATA

V Maisnar[1*], I Spicka[2], V Scudla[3], E Gregora[4], Z Adam[5], J Jarkovsky[6], R Hajek[7]
[1]4th Department of Medicine - Clinical Haematology, Faculty Hospital Hradec Kralove, Hradec Kralove, [2]1st Department of Medicine, General Faculty Hospital, Prague, [3]3rd Department of Medicine, Faculty Hospital Olomouc, Olomouc, [4]Deaprtment of Clinical Haematology, Faculty Hospital - Kralovske Vinohrady, Prague, [5]Department of hemato-oncology, Faculty Hospital Brno - Bohunice, [6]Biostatistical Institute, Brno, [7]Department of Clinical Haematology, Faculty Hospital, Ostrava, Czech Republic

Background: Multiple myeloma is a hematological malignancy that usually relapses in spite of the clinical response to initial therapy. In two randomized phase III trials (MM-009 and MM-010), lenalidomide and dexamethasone significantly prolonged time to progression and overall survival (OS) in patients with relapsed/refractory multiple myeloma (rrMM) compared with dexamethasone alone. Lenalidomide with dexamethasone is now accepted as valid and effective treatment option for most patients with rrMM. We conducted analysis on Czech local data from the Registry of monoclonal gammopathies conpared the results of continuous lenalidomide plus dexamethasone therapy in clinical trial patients and patients treated according the health insurance coverage.
Aims: Our aim was to demonstrate the clinical value of continuous lenalidomide treatment until disease progression in the absence of reimbursement restrictions on Czech local data.
Methods: Totally, we collected and analyzed data from 250 MM patients with at least one prior therapy, all patients signed informed consent form of their data collection to Czech Registry of monoclonal gammopathies. 46 patients were treated by continuous lenalidomide plus dexamethasone within standard arm of some clinical trial and 204 patients obtained the same therapy, but maximally 8-10 cycles according the health insurance companies rules based on Czech Myeloma Group guidelines. We analyzed therapy response in both group of patients and also Kaplan-Meier survival estimates were compared between patients on continued treatment versus the patients treated with local reimbursement restrictions.
Results: Overall, patient basic characteristics were comparable in both groups, with no significant p-values for any of the variables documented. Median of previous lines of therapy was 2 in both patient groups. Overall response rate was statistically significantly better in group of patients with continuous lenalidomide therapy (58.8 versus 38.9 %, P=0.014). Overall survival (OS), time to progression (TTP), disease free survival (DFS) and duration of response (DOR) were all found to be statistically significantly longer (with p values between 0.001 and 0.005) in population treated in clinical trials. As with other therapies using combination of lenalidomide plus dexamethasone at first relapse is more effective regarding response rate and durability than using it after multiple salvage therapies. The results of continuous lenalidomide treatment within clinical trials was similar to those obtained in registration studies including observed side effects of therapy.
Summary / Conclusion: Czech myeloma group confirmed on local data obtained from Registry of monoclonal gammopathies benefits of continuous lenalidomide plus dexamethasone treatment until disease progression. Continued lenalidomide treatment is associated with better therapy response results and also with a statistically clearly significant survival advantage. Our findings so confirmed results of some other studies dealing with similar themes.

B1529

MATHEMATICAL MODEL OF SERUM FREE LIGHT CHAIN DECLINE IDENTIFIES A KINETIC PREDICTIVE MARKER OF SURVIVAL IN PATIENTS WITH MYELOMA TREATED WITH BORTEZOMIB, DEXAMETHASONE AND STEM CELL TRANSPLANTATION

M Heiblig[1*], F Lachenal[2], L Karlin[1], B You[3]
[1]Hematology, Centre Hospitalier de Lyon Sud, Lyon, [2]Hematology, Centre Hospitalier de Bourgoin Jallieu, Bourgoin Jallieu, [3]Oncology, Centre Hospitalier de Lyon Sud, Lyon, France

Background: According to 2011 International Myeloma Working Group recommandations, serum-free light chain (sFLC) assessment is indicated in non secretory Multiple Myeloma (MM). sFLC monitoring is now routinely used for diagnosis and early response treatment assesment but its actual prognosis values regarding survival is not clear.
Aims: Based on mathematical modeling, this study aimed at evaluate the predictive value on progression free survival (PFS) of modeled sFLC kinetics during frontline tratment.
Methods: Model-based analysis of sFLC kinetics from 28 newly diagnosed MM patients treated at a single institution with 4 cycles of bortezomib and dexamethasone plus autologous stem cell transplantation (ASCT). MONOLIX program was used to fit Box-Cox transformed [sFLC] concentration-time profiles during the4 induction cycles to the equation : [sFLC(t) =[sFLC1*exp(-KDEC1*t)]+[sFLC2*exp(-KDEC2*t)]+[sFLC3*exp(KPROD*t)]] where $KDEC_1$ and $KDEC_2$

represent the decline rates of sFLC while KPROD is the involved light chain production rate observed after the end of the decrease.The predictive values of the modeled kinetic parameters , regarding PFS were tested using logistic regression, and survival analysis.
Results: Median PFS was 17.9 months . Three modeled kinetic parameters categorized by their medians had strong predictive values regarding PFS using univariate tests: sFLC decline rate $KDEC_1$ (median PFS = 38.6 months if $KDEC_1 \geq$ median vs 14 months if $KDEC_1 <$ median, P=0.01); light chain production rate KPROD (median PFS = 24.9 months if KPROD < median vs 7.8 months if KPROD ≥ median, P=0.01); and initial SFLC production slope sFLC3 (median PFS = 24.9 months if sFLC3 < median vs 14 months if sFLC3 ≥ median, P=0.03). The same model based analysis for M-protein decline was not significant (P=0.53). Using multivariate analysis, the onlyremaining significant predictive factor of PFS was: $KDEC_1$ (HR, 0.11; 95% CI 0.01-0.88; P=0.04).
Summary / Conclusion: The modeled kinetic parameter of SFLC decline, $KDEC_1$, may be easily used as an early predictor of survival after frontline ASCT in MM. Validation in larger studies is warranted.

B1530
STUDY OF THE PROGNOSTIC VALUE OF SERUM FREE LIGHT CHAINS RATIO AT DIAGNOSIS IN SPANISH POPULATION WITH MULTIPLE MYELOMA
J de Veas Silva[1], C Guitarte[1*], M Rodriguez[1]
[1]Clinical Biochemistry, Hospital Universitario Virgen Macarena, Sevilla, Spain

Background: Monoclonal gammopathies are a group of disorders characterized by clonal expansion of B cells that usually secrete intact monoclonal immunoglobulin, monoclonal free light chains or both.The quantification of serum free light chains (FLCs) is used in the diagnosis, monitoring and prognosis of monoclonal gammopathies.
Aims: The aim of this study is to evaluate the prognostic value of serum FLCs ratio at baseline in newly diagnosed multiple myeloma (MM) in a Spanish population.
Methods: We studied 73 patients with newly diagnosed multiple myeloma (56 intact immunoglobulin MM (IIMM) and 17 light chains MM (LCMM)) during a period of five years (2008-2012). Serum free light chains were measured by turbidimetry (Freelite™, The Binding Site, Birmingham, UK). Survival was defined as the time from initial diagnosis to death or the last follow-up and was calculated by the method of Kaplan and Meier. The survival curves were compared using the log-rank test. A p value <0.05 was considered to be significant. Statistical analysis was performed using IBM SPSS Statistics 20.
Results: FLCs ratio was calculated as k/lratio and we used the median FLCs ratio like cut-off with a FLCs ratio of >26 and <0.24 for kappa and lambda MM respectively for assessing survival. The FLCs ratio was categorized in two groups: "low" (sFLC ratio <26 and >0.24) or "high" (sFLC ratio ³ 26 and £ 0.04). There were 37 patients in group "low" and 36 patients in group "high". Of the 73 patients studied, 17 died and 56 survived during five year follow-up. In group "low" died 4 patients (10.81%) whereas in group "high" died 13 patients (36.11%). The percentage of deceases in each isotype of MM was the following: 50% (IgD IIMM), 33% (IgA IIMM), 29% (Lambda LCMM), 22% (Kappa LCMM), 14% (IgG IIMM), 0% (IgM IIMM). The five years survival was 59% and 88% in patients in groups "high" (with an abnormal FLCs ratio ³ 26 and £ 0.04) and "low" (with a FLCs ratio between <26 and >0.24) respectively (P=0.007). The estimated relative risk of the event (death of the patient) occurring in group "high" was 4.11 (1.57 – 10.71 95% IC) higher than in group "low".
Summary / Conclusion: An altered baseline serum FLCs ratio at diagnosis is an important predictor of poor prognosis in patients with multiple myeloma in our population. So, serum FLCs ratio can be used as survival predictor. The patients with IgA and IgD isotypes have a poor prognostic.

B1531
DIFFERENCES AMONG MGUS AND MGUS WITH ASSOCIATED DISEASES AT DIAGNOSIS AND FOLLOW UP
J Wong [1*], E Perez-Persona[1], M Quintana[1], I. Gonzalez[1], I. Oiartzabal[1], B. Moreno[1], A Campeny[1], C Menchaca[1], A Mendizabal[1], M Ardanaz[1], J Guinea[1], A Pereda[1]
[1]Hematología, Txagorritxu Hospital, Vitoria Gasteiz, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic premalignant clonal plasma cell or lymphoplasmacytic proliferative disorder. MGUS has been reported in association with several non-malignant disorders (including autoimmuine disorders). Nevertheless, it is not clear whether these conditions are pathogenetically related or merely represent coincidental associations.
Aims: Compare the characteristics at diagnosis and follow-up of patients with MGUS with those MGUS associated with other disorders (MGUSad).
Methods: A total of 327 MGUS with at least 3 years of follow-up were identified in our hospital. Medical history was revised in order to identify disorders associated with MGUS according to Bida et al. (*). Recorded data from each MGUS were: presence of immunoparesis (defined as a decreased below 25% the lower normal limit in the level of 1 o 2 immunoglobulin (Ig), of the uninvolved Ig), evolving type (defined as an increase in the level of serum M –MC- protein of at last 10% with respect previous year determination) and cuantification of free light chains (FLC). Additionally, sustained immunoparesis we consider in those patients with immunoparesis at diagnosis and at last in a second determination in the follow-up.
Results: From 2007 to 2011, 327 patients with MGUS were identified in Hospital Txagorritxu. 201 (61.5%) were consider associated to other entities while on 126 (38,5%) no other disease could be identified.
Associated conditions with MGUS were: hypertension 50.6%, osteoporosis 10.6%, polyarthrosis 18,2%, chronic liver diseases 15.4%, autoimmune diseases 21.7%, malignant diseases 13.1% and tuberculosis 3.1%).
No different in median age at diagnosis was observed (64 vs. 65 p: 0,782). Regarding the presence of paresis and FLC ratio at diagnosis, no differences were observed between MGUS and MGUSad (18,9 vs 12,4; p:0.05 and 17,8% vs 18,2; p: 0.615, respectively). Considering MC, 25% of MGUS were considered as evolving type vs 24% of the MGUSad (p:0.570). Significatively, sustained immunoparesis were observed in 18,5% of MGUS vs. only 9,7% of MGUSad (p:0.013). We also could identified 6 multiple myeloma patients progressed from a MGUS. According to their medical history, 3 of them would be considered as MGUSad. Sustained immunoparesis and evolving type was documented in 2 of them.
Summary / Conclusion: It has been suggested that the reduction of uninvolved immunoglobulins can be considered a predictive marker of progression. In our study, MGUS with associated disease show lower rates of sustained immunoparesis. It could be hypothesized that pathogenesis of MGUSad has different origin than a primary neoplastic entity.

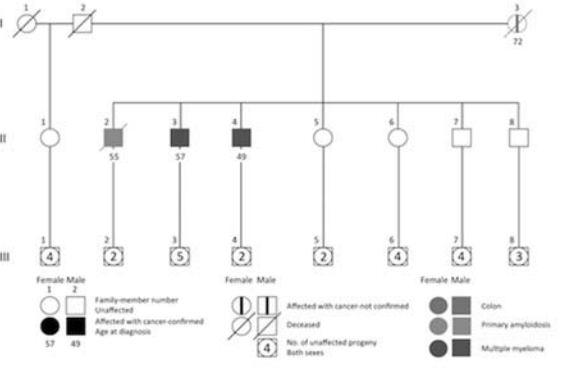
FAMILIAL MULTIPLE MYELOMA
T Firatli-Tuglular[1*], T Toptas[2], I Kaygusuz-Atagunduz[1], C Adiguzel[1]
[1]Department of Hematology, Marmara University Hospital, Istanbul, [2]Department of Hematology, Van Training and Research Hospital, Van, Turkey

Background: A recent data derived from 239 cases with multiple myeloma (MM) and 220 controls disclosed an increased cancer risk among individuals with first-degree relatives with MM (RR = 5.64; CI, 1.16-27.51). An increased risk for MM was also seen if the first-degree relatives had experienced another tumor disease (RR = 1.21; CI, 0.86-1.17). The medical literature contains reports of around 130 families with two or more cases of MM, MGUS, or WM, about 80 of these contain ≥ 2 cases of MM.
Aims: We describe here a family with familial multiple myeloma and associated cancer. We aimed to screen three generation for plasma cell disorders, to get information about the associated cancers, and impact of environmental factors.
Methods: Two brothers with multiple myeloma and all their siblings and progeny were invited. Subjects were informed about the screening program. Serum protein end immunofixation electrophoresis analyses were performed in all. In addition, all persons were asked to complete a questionnaire containing items questioning the environmental exposure to several factors.



Results: Three siblings in one generation were affected with plasma cell disorders, two with multiple myeloma and one with primary amyloidosis. The patient with primary amyloidosis was 55-year-old at diagnosis. He had kappa light chain disease involving liver, kidney, bone marrow, spleen, and heart. Stage IV kidney disease with low level proteinuria progressed to end-stage renal disease while he was receiving bortezomib-cyclophosphamide-dexamethasone treatment. He had Mayo Clinic stage III cardiac involvement at the time of diagnosis. He died almost two years after the diagnosis because of dialysis-related problems. He had complete response except organ response. Two

other siblings were diagnosed with MM, seven and six years ago, respectively. They were 57 and 49-year-old at diagnosis. Former underwent two autologous hematopoietic stem cell transplantation (ASCT) for IgG kappa MM. He has complete remission. The latter underwent ASCT for IgG lambda disease. He has a stable disease for the last three years. All affected siblings lived in a village located in a damp and rainy geographic area during the first two decades. All were in close contact with plants and livestock. They were exposed to pesticides/insecticides. Only the patient with amyloidosis was a smoker. Their mother has died due to mass on her liver and colon. However her diagnosis was not confirmed.
Summary / Conclusion: Summary/conclusions: We note that familial MM patients were more likely to report exposure to farming, damp, and pesticides, compared with unaffected family members. Genetic and environmental factors that may influence development of MM should be elucidated.

B1533
HIGH-DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA. A SINGLE CENTER EXPERIENCE FROM EHU1ST NOVEMBER OF ORAN.
A Bekadja[1*], S Osmani[1], S Talhi[1], N Yafour[1], M Brahimi[1], A Arabi[1], R Bouhass[1]
[1]Hematology and cell therapy, Etablissement Hospitalier Universitaire 1st November, Oran, Algeria

Background: Autologous stem cell transplantation (ASCT) after a high dose conditioning is an established treatment modality with definitive indications for multiple myeloma (MM). However, this line of treatment requires many expensive resources, such as freezing of the harvest product in order to maintain cell viability until stem-cell reinfusion. The storage of harvested stem cells, in standard refrigerators at +4°C, is an alternative to cryopreservation.
Aims: We evaluated the efficacy and safety of autologous hematopoietic stem cells in adult patients undergoing autologous stem cell transplantation (ASCT) for multiple myeloma (MM), with non-cryopreserved hematopoietic stem cell.
Methods: Autologous stem cell were mobilized using G-CSF (15µg/kg/day) alone. Leukapheresis to harvest stem cells was performed on day -2 and -1. The grafts were kept in a conventional blood bank refrigerator at 4°C until reinfusion on day 0. The conditioning regimen consisted of melphalan 200 mg/m^2 in all patients. The post chemotherapy myeloablative phase was managed without growth factors.
Results: Between May 2009 to 31nd December 2012, 109 adults with MM were treated in our center in Oran. The median age at ASCT was 55 years (range, 27-67). There were 65 males and 44 females. The median harvested CD34$^+$ cell count was 3.37×10^6/kg (range, 1.22 to 13.22). All patients had neutrophil engraftment on the median of day 10 (range, 7-17) and platelet transfusion independence on the median of day 13 (range, 9-24). In the 107 evaluable patients, the median post-transplant overall survival had not been reached; the estimated overall survival at 5 years was 71% and the median disease-free survival was 35 months .One hundred days transplant-related mortality was 1.8%.
Summary / Conclusion: High-dose chemotherapy and autologous transplantation without cryopreservation is an effective and safe method which simplifies the procedure and is feasible and cost saving in the treatment of MM in developing countries.

B1534
PREVALENCE OF OLIGOSECRETARY MYELOMA AND ITS CLINICAL IMPLICATION: AN ASIAN SINGLE-CENTER EXPERIENCE
J Hong[1*], J Lee[1], S Lim[1], H Jung[1], S Kim[1], M Kim[1], M Choi[1], W Chang[1], S Park[1], S Lee[1], J Jang[1], S Kim[1], C Jung[1], K Kim[1]
[1]Division of Hematology-Oncology, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Oligosecretary myeloma is a subgroup of multiple myeloma (MM) characterized by low levels of serum and urine monoclonal(M) protein below thresholds of measurable disease (a serum M protein ≥ 1g/dL, a urine M protein ≥ 200 mg/day). Clinical data about oligosecretary myeloma is still scarce.
Aims: In this study, we aimed to investigate prevalence of oligosecretary myeloma, incidence of oligosecretary myeloma during disease progression, and its prognostic implication.
Methods: We retrospectively identified MM patients in Samsung Medical Center. We reviewed the serum/urine electrophoresis studies and serum free light chain (FLC) assays of the patients at the time of initial diagnosis and at the time of disease progression.
Results: A total of 390 patients with MM were included in the analysis. At initial diagnosis, 38 among 390 patients (9.7%) had oligosecretary myeloma. Among 352 patients with MM at initial diagnosis, 32 patients (9.1%) changed to oligosecretary myeloma during disease progression. Oligosecretary myeloma at initial diagnosis and during disease progression had measurable disease on serum FLC assay in 62.5% (no./total no, 15/24) and 55.6% (no./total no, 15/27) of the patients, respectively. Median time from the the diagnosis of MM to the onset of oligosecretary myeloma was 22.3 months (range, 8.1-74.8). Median OS from the onset of oligosecretary myeloma to death is 28 months (95% CI; 10.6-45.4). Common clinical presentations of oligosecretary myeloma at disease progression were progression of bone lesions (n=14, 43.8%), hypercalcemia and/or azotemia (n=11, 34.4%), and plasmacytoma (n=4, 12.5%). Median overall survival of MM (n=320), oligosecretary myeloma at initial diagnosis (n=38), oligosecretary myeloma during disease progression (n=32) were 49.4 months (95% CI, 37.3-61.5), 55.2 months (95% CI, 35.8-74.6), and 62.1 months (95% CI, 34.8-89.4), respectively (P=0.41).
Summary / Conclusion: In the current study, we found that 9.7% of newly diagnosed MM had oligosecretary myeloma and additional 9.1% of MM changed to oligosecretary myeloma during disease progression. It seemed that there was no significant differences in overall survival between MM and oligosecretary myeloma. Further studies are anticipated regarding feasibility of FLC assay for the prediction of response and progression on oligosecretary myeloma.

B1535
THE CONTRIBUTION OF SERUM FREE LIGHT CHAINS ASSAY TO THE DIAGNOSIS AND FOLLOW - UP OF PATIENTS WITH MULTIPLE MTELOMA- CLINICAL AND LABORATORY CORRELATION (A SINGLE MEDICAL CENTER EXPERIENCE
M Haj[1*], R Kassem[1], M Quitt[1]
[1]Hematology, Carmel Medical Center, Haifa, Israel

Background: Measurement of serum free light chains (sFLC) has recently become available for the diagnosis and monitoring of patients with plasma cell dyscrasias. The International Myeloma Working Group has considered the use of the sFLC for screening in combination with serum protein electrophoresis and serum immunofixation essay. The baseline measurement would serve as a prognostic value, as well as for monitoring patients with oligosecretory myeloma and establishing a stringent complete response.
Aims: The aim of our study was to evaluate the contribution of the sFLC assay to the diagnosis and follow up of patients with multiple myeloma in a single center. We studied the correlation between (sFLCs) levels and clinical and laboratory indices that are widely used in the diagnosis and follow-up of patients with multiple myeloma.
Methods: We performed a retrospective study of 50 patients with multiple myeloma who were treated in Carmel Medical Center Hematology Department in Haifa between 2006 and 2012. The study was approved by the hospital's Helsinki committee. Four patients were excluded from the study due to lack of full medical information. The clinical and laboratory data of remaining 46 patients were collected from the electronic medical files. The laboratory data included levels of sFLC, hemoglobin, creatinine, calcium, serum protein electrophoresis (SPEP), albumin, beta2-microglobulin (B2M), bone marrow aspirate and biopsy, as well as bone disease status at the time of diagnosis, before and after each treatment cycle, when possible. Statistical analysis was performed on 70 out of 144 treatment cycles in which full information on the sFLC levels before and after each treatment cycle was available. The proportion of sFLC change before and after each treatment cycle was compared to the proportion of change in hemoglobin, creatinine, calcium, M-protein, albumin, and B2M.
Results: The statistical analysis of the clinical and laboratory findings showed that a decrease in sFLC levels was associated with a decrease in creatinine levels (P=0.048), and an increase in hemoglobin levels (P<0.0001) following the treatment. The decrease of sFLC was associated with a decrease in M-protein levels following each treatment cycle. A statistically significant correlation was found between the percentage of decrease in SFLC levels and B2M (P<0.0001) and the percentage of increase in levels of albumin (P=0.001)). These findings are important as they are correlated with the response to treatment as defined by the International Staging System (ISS). Furthermore, a return of sFLC to levels of <=30 was associated with a good treatment response as defined by the International Myeloma Working Group uniform response criteria. However we found that three of our patients had an active extramedullary disease despite of normal levels of sFLC. We did not find correlation between the improvement of sFLC levels (P=0.922) in patients responding to the treatment and various types of multiple myeloma.
Summary / Conclusion: Our findings are in concert with previous findings in literature which stress the importance of serum FLC analysis at diagnosis, follow up and evaluation of response to treatment in patients with multiple myeloma. However, the results of our study raise the question of the value of sFLC analysis in evaluating the response to treatment in patients with extensive bone and extramedullary disease, as three of our patients with such a presentation had near normal levels of sFLC. We assume that further prospective studies on contribution of sFLC in larger groups of myeloma patients are warranted.

B1536
MULTIPLE MYELOMA: A TEN YEAR EXPERIENCE OF A CENTRAL HOSPITAL
C Gonçalves[1,1*], C Moreira[1], M Coutinho[1], R Lopes[1], R Cabral[1], L Regadas[1], AJorge[1], L Mendonça[1], F Campos[1], L Pinho[1], L Xavier[1], C Casais[1], A Mota[1], J Coutinho[1]
[1]Hematology, Hospital Santo António, Porto, Portugal

Background: In spite of the introduction of novel drugs (Bortezomib or Lenalidomide) for the treatment of Multiple Myeloma (MM), this is still an incurable malignant disease. The introduction of new drugs, has been advocated as

improving patients´ outcomes but it also implies a consequent increasing cost for Health Services, sometimes with scarce evidence for a real benefit. Nevertheless, benefits from high cost treatments are expected if the overall survival of patients can be improved.
Aims: The primary objective of our study was to compare the overall survival(OS) of Multiple Myeloma treated with and without the new drugs in our institution for a ten years period. The survival outcome among groups of patients according to treatment options and age were also compared.
Methods: All MM patients diagnosed and treated at our Hospital between January 2000 and December 2011 were retrospectively analysed. Details of age, stage of the disease, and treatment regimens were performed. The Kaplan-Meir method was used for survival outcome estimates.
Results: The population included a total of 189 patients (94 males and 97 females) with a median age of 66 years (range 31-95 years) and staged: Stage IA 10% (19), Stage IB 1%(2),Stage IIA 31,4% (60), Stage IIB7,3% (14) Stage IIIA 27,2% (52) and Stage IIIB 18,8% (36). Six patients were not staged. Twenty nine patients (15%) died before any treatment or only received dexamethasone. Thirty nine patients (21%), aged under 65 years, were treated with Idarubicine+dexamethasone (dexa), or thalidomide+dexa or bortezomib+dexa before being submitted to high dose melphalan(HDM). Thirty nine patients (21%), aged under 65 years failed the aim of HDM. Patients aged equal or above 65 years (n=111; 58%) were treated with different chemotherapeutics regimens, without introducing the new drugs (bortezomib or lenalidomide) on first line. The Kaplan-Meir method was used for survival outcome estimates. The overall survival (OS) at five years for the total population studied was 40%. Patients under 65 submitted to HDM had a OS at five years of 65%. In contrast, the OS of patients not submitted to HDM was 40%. When we analysed the population treated with the new drugs (submitted or not to HDM) the OS was 55%, in comparison of 45% of OS in the population not treated with bortezomib or lenalidomide.The overall survival (OS) at five years for the total population studied was 40%. Patients under 65 submitted to HDM had a OS at five years of 65%. In contrast, the OS of patients not submitted to HDM was 40%. When we analysed the population treated with the new drugs (submitted or not to HDM) the OS was 55%, in comparison of 45% of OS in the population not treated with bortezomib or lenalidomide.
Summary / Conclusion: The proportion of newly diagnosed patients that didn´t start treatment or only had dexamethasone was very high, contributing to 15% of all of our population. The overall survival at five years was better than it was years ago. The population treated with the new drugs seems to have a better outcome. As expected, patients submitted to HDM have the best performance. We may expect that the introduction of the new drugs in first line also in the patients older than 65 years will have a positive impact on the final general outcome of MM patients.

B1537

HEMOSTASIS IN PATIENTS WITH MULTIPLE MYELOMA BEFORE AND DURING HIGH-DOSE CHEMOTHERAPY.

E Urnova[1,2*], O Pokrovskaya[1], L Mendeleeva[1], M Gracheva[3], A Balandina[3], S Vasiliev[4], F Ataullakhanov[3], V Savchenko[2]
[1]Department of high-dose chemotherapy of paraproteinemic hemoblastosis , [2]Bone Marrow Transplant Department, [3]Laboratory of physical biochemistry, [4]Laboratory of clinical coagulology, National Research Center for Hematology, Moscow, Russian Federation

Background: The incidence of thrombosis in patients(pts) with multiple myeloma(MM) is about 10% and it increase in the presence of additional risk factors, such as central venous catheter and chemotherapy. This fact underline the importance of preventive anticoagulant therapy.
Aims: The aim of the study was to investigate the blood coagulation status in patients with MM before and after heparin administration
Methods: 17 pts: 11 males, 6 females at the age of 40-60 years (median 52years) were included in the study. Immunochemistry variant was IgG in 7 pts, Ig A in3, Bense-Jones in6, and 1 case of non-secretory MM. Induction therapy included bortezomib + dexametazone±cyclophosphomide±adriamycin and after it all pts achieved at least VGPR. All pts received heparin-sulphate in continuous infusion 500 IE/hour as thromboprophylaxis before and during high-dose chemotherapy. Hemostasis analisis was performed before and 24 hours after heparin administration. Routine tests were used: Activated Partial Thromboplastin Time (APTT). D-dimer level and also integral methods: thromboelastography (TEG) and thrombodinamics. TEG characterized by parameters of reaction time (R), clot formation time (K), angle and maximal amplitude (MA). Thrombodinamics is a new method based on a spatial fibrin clot growth registration. Hemostasis status was estimated by the clot growth rate (Vst, norm at range 20-30 mkm/min).
Results: Before heparin administration APTT study showed there was normal coagulation in 15 pts (88%) and 2 patients had hypocoagulation. The TEG data confirmed mild hypocoagulation (K – 11.2min, angel – 18.4 degrees, MA – 43.6mm) in 1 pt with APTT elongation (45 sec). Other pt with APTT elongation had normal TEG. Mild hypercoagulation was detected with TEG in 3 (18%) pts. One of them had decreased R (5.4 min) and K (1.5 min), and two had increased MA (64.3mm and 68 mm). In 2 pts D-dimer levels were elevated (754 and 1907ng/ml). TEG data of other pts showed normocoagulation. Vst was elevated (31-49 mkm /min) in 8 pts (47%) and was normal in other 9 (53%). Maximal Vst (49 mkm /min) was registered in the case with minimal APTT (26 sec) and increased R and K (5,4 and1,5 min). Mild hypocoagulation was detected in 7 pts (41%) a day after heparin administration with APTT (38-53 seconds) and TEG (according 1 or 3 parameters: R – 28,4 – 33,8 min, K – 9,2 – 16,8 min, angel – 13,1 – 20,6 degrees, MA – 42,3mm). In other 11 pts (59%) these parameters were normal. In 1 pts with elevated D-dimer level it became normal, in other – remained elevated (881 ng/ml). Thrombodinamics showed hypocoagulation in 10 pts (59%, 11-19 mkm /min). Vst was normal in 3 pts (18%), increased in 4 pts (23%, 33-36 mkm/min). Among all 17 pts during high-dose chemotherapy only in 1 case catheter-associated thrombosis was diagnosed. In that case hypercoagulation was confirmed by thrombodinamics and D-dimers, but not with APTT and TEG before and after heparin administration.
Summary / Conclusion: The results of our study confirm the possibility of thrombotic complications during high-dose chemotherapy. thrombodinamics seems to be more sensitive vs. routine tests to reveal hypercoagulation condition.

B1538

BENDAMUSTINE : A NEW OPTION FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

C Cerchione[1,1*], E Madonna[1], L Marano[1], N Pugliese[1], S Avilia[1], G Cerciello[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU “Federico II”, Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, that produces both single- and double-strand breaks in DNA, and shows incomplete cross resistance with other alkylating drugs. proved to be effective either in relapsed/refractory and in new diagnosed MM as single agent or combined with steroid and has also additive/synergistic activity with bortezomib. Here we evaluate the efficacy and tolerance of bendamustine in combination with bortezomib-dexamethasone in patients with relapsed/refractory multiple myeloma and focus on individual factors associated with outcome. Prognosis of relapse is severe in relapsed and refractory multiple myeloma, and we need new options for managing these patients.
Aims: Our aim is to investigate the role of Bendamustine in patients affected by relapsed and refractory multiple myeloma, considering safety and efficacy of this treatment option. We performed a retrospective analysis of patients of our division with relapsed/refractory MM, who had received bendamustine as salvage therapy.
Methods: 16 patients, 9 males, 7 females, with advanced relapsed/refractory multiple myeloma, received a chemotherapy schedule containing Bendamustine. Median age at diagnosis was 62.6 years (range 39-82) while age at start of treatment was 67 years (range 48-83), and median number of prior lines of treatment was 5.7 (range 4-8). ISS was equally distributed, and cytogenetic characteristics were evaluated only in 6 patients, and only 2 of them had cytogenetic abnormalities, and in particular one of them had del13q and in the other one was observed t(11;14). All the patients had previously been treated with schedule containing bortezomib and lenalidomide, while 90% of them had been treated with melphalan, 75% with cyclophosphamide and 38% with anthracyclines, and 30% had also received radiotherapy. 69% of patients had undergone single autologous stem cell transplantation. The last treatment before bendamustine was a bortezomib-based regimen in 30%, an IMIDs-based regimen in 53%, a combined bortezomib/IMIDs-based regimen in 23%, while 15% of patients had received other chemotherapies. All the patients were relapsed/refractory to last therapy received.
Results: We considered in our study patients who had completed at least two courses of Bendamustine schedule. A total of 47 cycles was administered (median3, range 2-6). In 91% of patients bendamustine was variously associated to bortezomib (66%), or IMIDs (25%) and only in 8% it was combined only with dexametasone. In our schedule, Bendamustine was given, at a median dose of 142 mg/sqm (range 100-200) on day +1 and +8 every 28 days = After a median follow-up of 3 months, median OS from diagnosis was 60.2 months, while OS from start of Bendamustine was 3.6 months (range 2-6 months). 2/16 patients died for other causes (one for cardiovascular disease and the other one had a gastric cancer). Grade 3 transfusion-dependent anemia occurred in 42% while in 57% grade 3 neutropenia occurred. However, only 1 patients interrupted the schedule due to hematologic toxicity (it was the one affected by gastric cancer). We observed no serious extrahematologic toxicity, only grade 1 gastrointestinal side effect, treated by common antiemetic drugs. According to IMWG uniform response criteria, 11 out of 16 evaluable patients achieved a partial response after a median time of 3 months with an overall response rate of 68%. In particular, for 3 patients of this study, Bendamustine schedule was a bridge to second autologous autologous stem cell transplantation, after having achieved a PR.
Summary / Conclusion: In our study we have considered a group of patient with refractory/relapsed multiple myeloma, and it confirms that Bendamustine can be considered an effective option in advanced patients and moreover it could be considered as a bridge to pre-autologous stem cell transplantation. However, these results have to be validated by controlled studies involving larger number of patients.

B1539

TWENTY-FIVE MG LENALIDOMIDE EVERY OTHER DAY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND RENAL FAILURE

C Cerchione[1,1*], E Madonna[1], R Fabbricini[1], L Marano[1], N Pugliese[1], S Avilia[1], G Cerciello[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Lenalidomide is a derivative of Thalidomide, with tumoricidal and immunomodulatory activity. It is available as oral agent, which is effective in the management of newly diagnosed, relapsed or refractory multiple myeloma and as maintenance therapy after autologous stem-cell transplantation.
Aims: With normal renal function, Lenalidomide administered orally reaches its maximal plasma concentration after a median time of 0.6-1.5 h, and it is eliminated through glomerular filtration and active tubular secretion in 3 to 4 hours. Serum half life increases up to 9 hours if moderate/severe renal impairment is present (creatinine clearance <50 or <30 mL/min, respectively). In the latter cases a reduction of the daily dose is recommended. However, there is no theoretical assumption that protracting the full standard doses could be equally effective and tolerated in patients requiring reduced doses.
Methods: Twelve patients, 7 female and 5 male, with a median age of 61.2 years (range: 49-81) affected by advanced resistant and progressive multiple myeloma (median number of previous treatment lines:3, range : 0-5, all including bortezomib) with concomitant renal failure (median calculated creatinine clearance 48.3 ml/min, range : 18-119) were treated with monthly 21-day courses of 25 mg lenalidomide every other day and dexamethasone.
Results: Disappearance of urinary light chain and reduction of serum creatinine were detected in four patients (33%); four patients (33%) had a partial response, and two of them (16%) were in stable disease, whereas two patients (16%) had signs of progressive disease. No patient experienced significant myelotoxicity; four patients required red cell transfusions. No SAE occurred during treatment.
Summary / Conclusion: These preliminary observations point to a significant therapeutic effect in more than half of a small population of patients (66%) with advanced disease. However, these results have to be validated by controlled studies involving larger number of patients.

B1540

SERUM FREE LIGHT CHAIN QUANTIFICATION IN MONOCLONAL GAMMOPATHIES AND MULTIPLE MYELOMA PATIENTS

A Gagliardi[1*], S Improta[1], M Villa[1], A Lucania[1], A Russo[2], B Dente[3], L Mastrullo[1]
[1]U.O.C. Ematologia, [2]U.O.C. Patologia Clinica, P.O. San Gennaro ASL Napoli 1 Centro, [3]U.O.C. Patologia Clinica, P.O. San Paolo ASL Napoli 1 Centro Napoli, Napoli, Italy

Background: Identifying patients with optimal response and long term survival is important for clinical guidance because patients with these features are likely not need further therapy. Serum Free Light Chains (sFLC) are used for better assessment of treatment response, thus patients are considered to achieve stringent Complete Response (sCR) by having CR criteria plus normal serum Free Light Chains Ratio (sFLCR) and absent clonal cells in bone marrow.
Aims: sFLC are commonly assessed in patients with monoclonal gammopathy of undetermined significance (MGUS) and smoldering MM (SMM) as indicators of disease progression.
Methods: In the last two years, we have examinated 40 patients with Monoclonal Gammopathy (MGUS) and 30 patients with Multiple Myeloma (MM) in course of therapy. We have assessed serum Free Light Chains (sFLC) and serum Free Light Chains Ratio (sFLCR) for evaluation of progression disease and treatment response. Serum FLC concentrations were measured by nephelometry, using particle-enhanced, high-specificity, homogeneous immunoassays.
Results: We observed an increase of sFLC in patients with monoclonal gammopathy in evolution, with simultaneous progression of monoclonal component (M-spike). In MM patients sFLC and sFLCR were evaluated for assessing the response to treatment, and we observed a strict correlation with disease status. Moreover, in MM patients sFLC monitoring proved to be the earliest indicator of disease relapse.
Summary / Conclusion: Our results confirm the role of sFLC in the monitoring of MGUS and MM patients. Specifically in MM patients sFLC and sFLCR evaluation seems to be very useful in identifying patients response and early relapse.

B1541

THE PREVALENCE OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) AND ASYMPTOMATIC MULTIPLE MYELOMA (AMM) FOR HIGH RISK GROUPS

I Oner[1], A Unal[2*], C Pala[2], S Sivgin[2], M Keklik[2], T Patıroglu[2], G Akyol[2], M Cetin[2], B Eser[2]
[1]Erciyes University, Kayseri, Turkey, [2]Hematology, Erciyes University, Kayseri, Turkey

Background: To determine the frequency of monoclonal gammopathy of undetermined significance (MGUS) among elderly patients presented to outpatient clinics with bone and diffuse bodily pain with elevated erythrocyte sedimentation rate (ESR). In addition, it is also aimedto compare the results of the Immunofixation Electrophoresis (IFE) and Serum Free Light Chain (FLC kappa/lambda) assays used in the diagnosis of monoclonal gammopathies and to determine which method is more sensitive in terms of the diagnosing MGUS.
Aims: To compare the results of the Immunofixation Electrophoresis and Serum Free Light Chain assays used in the diagnosis of monoclonal gammopathies and to determine which method is more sensitive in terms of the diagnosing monoclonal gammopathy of undetermined significance.
Methods: One hundred and sixty patients older than 50 years of age with ESR≥50 mm/h were included to the study. In these patients, IFE, FLC kappa/lambda, immunoglobulin levels (IgG, IgM, IgA, and IgE), bone marrow aspiration and biopsy, complete blood count, biochemical tests (serum calcium, phosphorus, total protein, albumin, alkaline phosphatase, and creatinine, etc.) and ß-2 microglobulin levels were studied. Patients were compared in terms of IFE and FLC values by stratifying according to diagnosis made including MGUS, AMM or MM.
Results: Of the 160 patients evaluated, monoclonal gammopathy was detected in 44 patients (27.5%). Monoclonal gammopathy was detected by IFE in 36 patients (22.5%), whereas it was detected by FLC in 30 patients (18.7%). There were 22 patients (13.75%) in whom monoclonal gammopathy was detected by both methods (IFE and FLC). In our study, MGUS incidence was found as 20% in the high-risk patient group.
Summary / Conclusion: MGUS was detected in the 20% of the patients older than 50 years of age presented with ESR elevation and diffuse bone pain. In the present study, it was found that both methods had similar sensitivity; however, IFE was found to have slightly higher sensitivity, when FLC and IFE methods were compared regarding detection of monoclonal gammopathy. It was concluded that, among the elder population, patients presented with diffuse bone pain, especially those with elevated ESR, should have to be evaluated in terms of MGUS.

B1542

EPIDEMIOLOGICAL DATA OF MULTIPLE MYELOMA IN ALBANIA

T Caja[1,2,3*], E Petrela[2], P Xhumari[1], P Pulluqi[1], A Ivanaj[1], E Zajmi[3]
[1]Hematology, [2]Statistic, [3]Emergency, University Hospital Center Mother Teresa Tirana, Tirana, Albania

Background: Multiple Myeloma includes a maximum of 10% of hematological diseases. Frequency constantly increases with the age of the general population. Currently about 35% of patients with Multiple Myeloma are younger than 65 years old, 28% are 65-74 years old, and 37% are older than 75 years. The data of recent demographic curve, probably in the nearest future, will increase the incidence of elderly patients.
Aims: To present some epidemiological data for patients with Multiple Myeloma in Albania.
Methods: A retrospective study includes patients with Multiple Myeloma in the Hematology Service for 17 years. We studied the annual dynamics incidence, the dynamics of the distribution of the cases based on age, sex, geographic distribution in 36 districts of our country.
Results: We evaluated 428 patients with Multiple Myeloma, hospitalized during the period 1995-2011, 57.5% male and 42.5% female. Mean age 60.6±10 years, 29.6-83.5 years age variation. Emergency hospitalizations in a year for MM are 15.49%. Annual incidence dynamics analysis gives 19 cases in 1995, 10 cases in 1996, 6 cases in 1997, 14 cases in 1998, 13 cases in 1999, 19 cases in 2000, 13 cases in 2001, 26 cases in 2002, 21 cases in 2003, 25 cases in 2004, 45 cases in 2005, 37 cases in 2006, 34 cases in 2007, 31 cases in 2008, 42 cases in 2009, 41 cases in 2010, 32 cases in 2011. Annual incidence per 100 000 inhabitants: 1995: 1.06, 1996: 0.56, 1997: 0.34, 1998: 0.77, 1999: 0.73, 2000: 1.05, 2001: 0.79, 2002: 1.56, 2003: 1.25, 2004: 1.46, 2005: 2.74 , 2006: 2.25, 2007: 2.07, 2008: 1.88, 2009: 2.55, 2010: 2.49, 2011: 1.95. Higher incidence per 100 000 inhabitants was observed in the age group 55-64 years old (62.32), and in some cities (27.9) compared to some others (2.8). Died in hospital an average 2.7 cases per year, from all the patients with MM.
Summary / Conclusion: Multiple myeloma is a disease with increase of new cases per year. The sheer number of new cases with MM per year is 25 compared with another previous study that was 17 new cases per year, as well as the increase in the annual incidence / 100 000. MM incidence increases with age, but the youngest average age of patients with Multiple myeloma in our study relates to the youngest average age of the Albanian population. Males are more affected than females in the ratio 1.3 /1, in comparison with previous

studies we see that there is an increase of the number of women with Multiple Myeloma in Albania.

B1543

A NEW OPPORTUNITY IN RELAPLSED AND REFRACTORY MULTIPLE MYELOMA : PEGYLATED LIPOSOMAL DOXORUBICIN, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (CED)

C Cerchione[1,1*], E Madonna[1], R Fabbricini[1], L Marano[1], N Pugliese[1], F Pane[1], L Catalano[1]
[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Patients affected by multiple myeloma almost invariably become chemo-resistant: hence, one of the main topics in clinical research is the quest for therapeutic alternatives to overcome refractory disease.
Aims: Since 2009, we have treated patients affected by Multiple Myeloma, relapsed and refractory to most of the therapeutic options available, with a chemotherapy based on a combination of pegylated liposomal doxorubicin, cyclophosphamide and dexamethasone (CED), at monthly doses respectively of 35 mg/m^2 on day1, 800 mg/m^2 on day 1 and 20 mg/d on days 1-4, with very interesting results.
Methods: Eighteen patients (11 women, 7 men), with a median age of 60 years, (range: 43-75) affected by advanced, relaplsed and progressive multiple myeloma, whose median number of previous treatments was 3 lines (range 2-6) were treated with monthly CED courses (median number of courses: 3; range: 1-17).
Results: One patient (5%) had a complete remission (CR), in nine patients (50%) there was a partial response (PR); the disease remained stable in two patients (11%) and six patients (33%) did not benefit from CED treatment. Median response duration was 6 months (range: 2-20). The toxicity profile of CED was satisfactory: hematological toxicity (WHO grade 2) was observed in 7 patients (38.8%) and there were extra-hematologic side effects only in two cases (11%) : an episode of acute renal failure in one patient and bradycardia in another.
Summary / Conclusion: In conclusion, we believe strongly that these results can encourage further studies as they have been obtained in patients with severely advanced disease stage, previously not exposed to anthracyclines. These preliminary data point to a significant result in 55% of patients with particularly advanced disease. However, these results have to be validated by controlled studies envolving larger number of patients.

B1544

TREATMENT RESPONSE IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA PATIENTS

I Ioana[1*], C Liviu[1], C Maria[1], I Claudiu[1], I Maria[1], I Mihai[1], O Dacian[1], P Ovidiu[1], S Cristina[1], C Despina[1], I Hortensia[1]
[1]University Of Medicine And Pharmacy „Victor Babeş", Timişoara, Timisoara, Romania

Background: Multiple myeloma is a malignant plasma cell disorder. It is the second most frequent haematological malignancy and characterized by malignant plasma infiltration or the bone marrow and is associated with an increased level of monoclonal protein in the blood and/or urine. The treatment of multiple myeloma (MM) has undergone significant developments in recent years. The development of new agents with potent anti-tumor activity has considerably improved the survival of MM patients.
Aims: Retrospective evaluation of the effect and safety of combination of bortezomib, doxorubicin and dexamethasone (PAD) in the treatment of relapsed/refractory myeloma patients.
Methods: 38 patients were treated for median of four 28-day PAD cycles (1-8). Bortezomib was given at 1.3 mg/m^2 (days1,4,8,11), doxorubicin at 9 mg/m2 (days 1-4) and dexamethasone 20 mg po (days 1-4, 8-11).
Results: 38 patients were evaluable for efficacy and safety, 61% had refractory disease and 39% were relapsed. The median age was 58 years (37-75), 52% were male, 48% female. Median time from diagnosis was 14 months (2-110) and median number of prior therapy lines was 1 (1-4): 72% had undergone conventional chemotherapy, 15% Alkerane and Dexamethasone and 13% were autografted. Overall response rate of 62% was observed, 30% of patients achieved a complete response (CR), 24% a very good partial response(VGPR), 32% a partial response (PR). Stable disease (SD) was observed in 14%. The median progression free survival (PFS) was 17,2 months. The most common grade 3-4 toxic effects were neutropenia 11%, thrombocytopenia 13%, anemia 7%, infections 9%, peripheral neuropathy 4.3% and gastrointestinal disturbances 2.1%. One toxic death (1.1%) due to sepsis was noted.
Summary / Conclusion: The combination of bortezomib, doxorubicin and dexamethasone (PAD) is well tolerated and induced clinically signifiant responses and prolonged remission duration in patients with relapsed and refractory MM

B1545

SIX YEAR RESULTS OF THE THERAPY OF MULTIPLE MYELOMA INTRACELLULAR PROTEASOME INHIBITOR

N Skvortsova[1*], T Pospelova[1], I Nechunaeva[1]
[1]Department of hematology and transfusiology, Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Advances in basic research on the biology of MM have led to the emergence of new effective drugs acting specifically on the mechanisms that regulate the growth of myeloma cells, their apoptotical death, the state of the bone marrow microenvironment, which has opened up new possibilities in the treatment of this incurable disease. Of these, the most promising was the intracellular proteasome inhibitor - bortezomib.
Aims: To evaluate the results of the six-year treatment of multiple myeloma (MM) intracellular proteasome inhibitors.
Methods: From December 2006. to December 2012 - 125 patients with MM were treated (55 men and 70 women) (aged 36 to 81 years (median 65 years)). The majority of patients were diagnosed with stage IIIA process, I stage on the ISS was found in 83 patients, II stage - in 30 and III stage - in 12 patients. Among the immunological types of MM prevailed myeloma G (75%), a myeloma A - was diagnosed in 20% of patients, myeloma Bence-Jones in 5% of patients. Each patient was held from 4 to 10 courses of therapy. As first line Bortezomib therapy was appointed in conjunction with MP in 35 (58,3%) and PAD in 25 (41,7%) patients. As second lines Bortezomib was given to 65 patients with relapsed and refractory MM . Bortezomib monotherapy was used at the dose of1,3 mg/m^2 in 20 patients (30,7%), in combination with dexamethasone in 25 patients (38,6%) and in the protocol CVD in 20 (30,7%) patients. The effect of treatment was assessed using standardized international criteria EBMT. Toxicity assessment was performed using the criteria of the National Cancer Institute of the United States, version 3.0.
Results: In the group of patients treated with Bortezomib as first line therapy - overall response rate was achieved in 82% patients (CR + nCR - in 24% and PR- in 58%). When using bortezomib in second lineas therapy - a complete response (CR and nCR) was achieved in 13 patients (20%), partial response (PR) – in 29 (45%), minimal response (MR) - in 8 patients (11, 9%). Thus, the overall clinical response rate was 76,9% (CR + nCR + PR + MR). The median time to achieve response was 3 months. The main side effects of bortezomib therapy were peripheral neuropathy in 58%, fever in 25%, fatigue in 45% of patients respectively. Infectious complications (herpes zoster, conjunctivitis) were noted in 33% of patients, thrombocytopenia and symptoms of gastrointestinal toxicity were reported in 42% and 35%, respectively. A statistical method of calculating the cumulative fraction of survivals (Kaplan-Meier) was used to evaluate survival, with P<0,05 established as the reliability criterion. In the group of patients who hed received bortezomib therapy, the median survival has not been reached, the 6-year survival rate - 74%.
Summary / Conclusion: Bortezomib is a highly effective therapeutic drug, which plays an important role in the treatment of MM, as I line and the subsequent lines.

B1546

LENALIDOMIDE IN COMBINATION WITH LOW-DOSE DEXAMETHASONE IN RELAPSE/REFRACTORY MULTIPLE MYELOMA: A RETROSPECTIVE STUDY

T Firatli-Tuglular[1*], F Noyan-Atalay[2], A Eser[1], T Toptas[3], F Pepedil[1], I Kaygusuz-Atagunduz[1], C Adiguzel[1]
[1]Department of Hematology, Marmara University Hospital, [2]Department of Hematology, Baskent University Hospital, Istanbul, [3]Department of Hematology, Van Training and Research Hospital, Van, Turkey

Background: Two randomized controlled trials, MM009 and MM010, demonstrated that lenalidomide in combination with dexamethasone was superior to placebo plus dexamethasone in relapse/refractory multiple myeloma (rrMM).
Aims: We aimed to investigate the efficacy and safety profile of this combination in rrMM in a small-sized post-marketing analysis.
Methods: Primary end-point was overall response rate (ORR); secondary endpoints included progression-free survival (PFS) and overall survival (OS). Treatment (Rd) consisted of lenalidomide (25 mg on days 1 to 21) and dexamethasone (40 mg on days1,8, 15, 22) in repeating 4-week cycles. Dose modifications were implemented accordingly, if needed.

Table. Response to lenalidomide according to baseline characteristics

Response, N (%)	Overall	Age, years		Age, years		Previous thalidomide		Plasmocytoma		Previous ASCT	
		≥65	<65	≥75	<75	Yes	No	Yes	No	Yes	No
CR	16 (35.6)	13 (43.3)	3 (18.8)	5 (45.5)	11 (31.4)	8 (38.1)	8 (32.0)	3 (33.3)	13 (35.1)	4 (26.7)	12 (38.7)
VGPR	8 (17.8)	5 (16.7)	3 (18.8)	2 (18.3)	6 (17.1)	5 (23.8)	3 (12.0)	2 (22.2)	6 (16.2)	3 (20.0)	5 (16.1)
PR	11 (24.4)	8 (26.7)	4 (25.0)	3 (27.3)	9 (25.7)	4 (19.1)	8 (32.0)	2 (22.2)	10 (27.0)	5 (33.3)	7 (22.6)
SD	10 (22.2)	4 (13.3)	6 (37.5)	1 (9.1)	9 (25.7)	4 (19.1)	6 (24.0)	2 (22.2)	8 (21.6)	3 (20.0)	7 (22.6)
ORR	35 (77.8)	26 (86.7)	10 (62.5)	10 (90.9)	26 (74.3)	17 (80.9)	19 (76.0)	7 (77.8)	29 (78.4)	12 (80.0)	24 (77.4)
P			0.20		0.67		0.59		0.97		0.80

Results: A total of 46 (31 male) patients were included into the study. Median age was 67.5 (range: 44-86) years. Only 11 patients were older than 75 years of age. Median number of prior therapies was 3 (3-6). Proportions of patients with prior thalidomide use, autologous hematopoietic stem cell transplantation (ASCT), and plasmocytoma were 45.7%, 32.6`%, and 19.6%, respectively. ORR and complete response rates were 77.8% and 35.6%, respectively. Older age, prior thalidomide use, ASCT and plasmocytoma did not have an impact on response rates (Table). Median follow-up, PFS, and OS (95% CI) were 7 (7-12), 17 (8-30), and 18 (14-not reached) months. Grade III-IV adverse events included neutropenia (23.9%), anemia (19.5%), thrombocytopenia (17.4%), deep vein thrombosis (2.2%), infections (10.9%), and fatigue (6.5%).
Summary / Conclusion: Rd is highly active in patients with rrMM.

Background: Bence-Jones myeloma multiplex is a progressive disease characterized by excessive numbers of abnormal plasma cells in the bone marrow and overproduction of incomplete immunoglobulins,containing only the light chain portition of the immunoglobulini.This type of myeloma occurs 15-20%.The median overall survival is approximately 4 years.Pts outcome in Bence-Jones myeloma has been remarkably improved due to the use of combination therapies including chemotherapy and stemm cell transplantation.High dose melphalan with autologus stem cell support has been an integral part of myeloma therapy for more than 25 years.
Aims: A retrospective analysis of outcome of treatment Bence-Jones myeloma.
Methods: Since 1995. until 2011. we were treated 54 pts (37 men and 17 female), average age 56 years (range 36-85). According to the clinical stage, patients were divided as follows: 3 pts ICS, 13 pts IICS, 38 pts IIICS. Regarding ISS score, the group included: ISS1 16 pts, ISS2 9 pts, ISS3 29 pts. Renal insufficiency was present in 30 pts. High risik pts was defined by the presence of following factors: b2M >5,5 mg/l, albumine<3,5gr/dl, CRP>6, high lactat dehydrogenase, renal failure, stage III. Patients treated with induction, consolidation and maintenance therapy.Conventional induction treatments were applied as following regimens: VAD (40), MP (9), CTD (1), PAD(2) and TAD (2).
Results: Conventional chemiotherapy introductory clinical response was achieved in 35pts (65%) (MR-4 pts, PR- 14 pts, VGPR- 17 pts), while in 19 pts (35%) established disease was resistant. Transplantation had been done with 30 pts (56%), while 24 pts (44%) were treated with conventional chemotherapy adjusted to the vital age and comorbiditity. In the group of pts with transplantation done tandem had been carried out with 10 pts and secondary SCT had been done in 4 relapsed pts. With 1 pts with tandem SCT allogenic(singen) SCT had been done. TRM is3,4%. Maintenance therapy with Thalidomid had been done in 25 pts for 4-40 months. Impact of high risk factors on outcome/TTP/OS was of no significance, but the transplanted patients had significantly longer TTP (mediana 8 months vs 6 months, P=o,o11) and longer OS (mediana 44 months vs 21 months ,P=0,0003). 16 pts (30%) of treated pts are living, while 38 pts (70%) died. Univariate log. regres. analysis showed that non-transplant patients are 10,41 times more likely to terminate lethal compared to transplant patients (RR 10,41(95%C.I.43,47-2,52),P<0,001).
Summary / Conclusion: Our study showed ASCT is a more effective method of treatment of patients with BenceJones myeloma compared to the conventional chemotherapy, but the results are still unsatisfactory. One of the major efforts to improve the results of intensive therapy and ASCT involves the integration of novel agents (proteasome inhibitors and immunomodulatory drugs) into the transplantation sequence.

A DATA INTEGRATION STRATEGY FOR HIGH-THROUGHPUT OMICS ANALYSES ALLOWS THE PREDICTION OF NOVEL TRANSCRIPTION FACTOR TARGET GENES

J Wehrle[1*], H. Pahl[1]
[1]Department of Hematology / Oncology, University Hospital Freiburg, Freiburg im Breisgau, Germany

Background: We have demonstrated that expression of the transcription factor “Nuclear Factor Erythroid-2” (NF-E2) is aberrantly increased in patients with Myeloproliferative Neoplasms (MPN). Moreover, NF-E2 overexpression in a transgenic mouse model elicits a MPN-like phenotype, that includes the development of thrombocytosis and, most notably, transformation to acute myeloid leukemia (AML). However, since only a small number of NF-E2 target genes are known, the downstream mechanisms by which transcription factor overexpression promotes a MPN phenotype are not known.
During recent years, the reduced cost and subsequent increase in the use of high throughput methods has increased the public availability of datasets resulting from omics analyses. However, few published studies rely on multiple datasets concomitantly, especially not on data generated by other investigators. Here we provide a strategy for combing several publically available data sets for the prediction of novel transcription factor target genes. This strategy increases the predictive power of the results, thereby providing a more efficient use of resources, time and money. We demonstrate the efficacy of this approach using NF-E2 in the context of MPN as an example.
Aims: To combine available high-throughput datasets to generate highly promising candidates for further analysis as NF-E2 target gene.
Methods: NF-E2-ChIPseq data of K562 cells (ENCODE project) were downloaded both as raw data and as processed files. The peak information representing potential NF-E2 binding sites was used to link these peaks to the closest transcription start site (TTS) using the “ChIP-Seq Tool Set” from UCDavis. In the resulting list of genes, the GeneID was used as a unique identifier. In order to improve the predictive power and decrease the false positive rate of the ChIP-seq experiment, we correlated the results from various expression profiling experiments detailed below with the identified peaks. The following datasets were used: gene expression analysis of peripheral blood granulocytes from PV patients and healthy controls (Görttler et al., 2005), gene expression following NF-E2 modulation in CD34+-HSC (Wehrle et al., 2013) as well as several publically available datasets stored at the ArrayExpress repository, including a set of gene expression analyses from MPN-patients (E-GEOD-26049). In order to combine these datasets, the BioMart database was used to convert each of the different, dataset specific identifiers to GeneIDs. Subsequently, the BioMart database was used to obtain further annotation data such as gene description and chromosomal position. These datasets were merged into a Microsoft Access database, and subjected to further filter steps and analyses.
Results: The strategy detailed above was successfully used to identify novel candidate NF-E2 target genes. A large proportion of these have been subsequently verified by functional analyses including luciferase reporter gene assays of the identified promoter regions, site directed mutagenesis of the identified NF-E2 binding sites as well as induction of target gene expression by reconstitution of NF-E2 in NF-E2-deficient CB3 cells and repression of protein expression by shRNA against NF-E2. (Wehrle et al., 2013 / Peeken et al., unpublished / Reihnemann et al., unpublished / Siegwart et al., unpublished).
Summary / Conclusion: The combination of several high-throughput datasets from different techniques reprocessed to incorporate the same identifier allows the stringent prediction of novel transcription factor target genes. Compared to more conventional approaches, these analyses save a substantial amount of time and resources and result in a higher proportion of verifiable targets.

PROANGIOGENETIC MOLECULES VEGF, HIF-1ALPHA AND ENOS IN MYELOPROLIFERATIVE NEOPLASMS

D Marković [1*], D Leković[2], O Mitrović[3], D Đikić[3], B Beleslin-Čokić[4], T Subotički[3], S Vignjević[3], M Budeč[3], M Gotić[2,5], V Čokić [6]
[1]Laboratory for immunochemistry, Institute for Medical Research, University of Belgrade, [2]Clinic of Hematology, Clinical Center of Serbia, [3]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, [4]Genetic laboratory, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, [5]Medical Faculty, University of Belgrade, [6]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Angiogenesis is important for the progression of hematological malignancies, including myeloproliferative neoplasm (MPN). Hypoxia-inducible factor-1alpha (HIF-1alpha) regulates the transcription of vascular endothelial growth factor (VEGF), a major gene responsible for angiogenesis. Several studies have demonstrated that a nonhypoxic pathway via nitric oxide (NO) is involved in the activation of HIF-1alpha and that NO enhances VEGF produc-

tion through stabilization of HIF-1alpha.
Aims: A target of this study is to correlate the expression of major angiogenic molecules VEGF, HIF-1alpha and endothelial NO synthase (eNOS) in bone marrow and peripheral blood of MPNs. Using this approach, we describe angiogenic factors in polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) according to JAK2V617F mutation status.
Methods: The expression of angiogenicfactors VEGF, HIF-1alpha and eNOS are examined in the bone marrow and granulocytes using immunohistochemistry and Western blot, respectively. Microvessel density is assessed by immunostaining with CD34 and CD105 antibodies. VEGF and HIF-1alpha mRNA levels are measured by real time quantitative PCR. ELISA-based assay with fluorogenic substrates is used to determine total HIF-1alpha in the context of a whole cell as a HIF-1alpha /Cytochrome C ratio.
Results: Using DNA sequencing, JAK2V617F mutation is detected in 90% of PV and per 60% of both ET and PMF patients, out of total 198 MPN patients. By immunohistochemistry, we show that $CD34^+$ cells are generally increased in bone marrow biopsies of PMF patients despite of JAK2 mutation, as well as in JAK2 negative ET patients. The angiogenic marker CD105 demonstrates elevation in the bone marrow of all forms of MPN patients. The highest percentage of both $CD34^+$ and $CD105^+$ cells is observed in PMF patients, not influenced by JAK2 mutant allele burden. VEGF mRNA levels are increased in hematopoietic progenitor $CD34^+$ cells and granulocytes of JAK2 mutation positive PV and PMF patients. VEGF protein expression is double increased in the granulocytes of JAK2 mutation positive ET patients, and also demonstrates an increase in homozygous JAK2 mutation forms of PV patients. Immunohistochemical analyses reveal that the percentage of VEGF-positive cells is increased in the bone marrow of JAK2 mutation positive ET patients. eNOS protein expression is decreased in granulocytes of JAK2 mutation positive ET and PMF patients. Also, eNOS protein expression is generally decreased in the bone marrow of MPNs, except JAK2 mutation negative PMF patients which demonstrates 30% increase. HIF-1alpha gene expression is increased in hematopoietic progenitor $CD34^+$ cells of JAK2 mutation positive PV and PMF patients. HIF-1alpha protein expression is decreased both in granulocytes and the bone marrow of PMF patients, as well as in the bone marrow of JAK2 mutation positive ET patients. HIF-1alpha is reduced in the granulocytes of MPN in comparison to healthy controls, while was diminished in peripheral mononuclear cells. Presence of JAK2 mutation augments HIF-1alpha protein level in PV patients.
Summary / Conclusion: CD105 expression, being highest in PMF, is a better marker of microvessel density compared to CD34. VEGF protein level is generally increased in ET patients, while HIF-1alpha and eNOS protein levels are reduced in MPNs. Presented variations in angiogenic factors expression among certain types of MPNs and its JAK2 mutant allele burden can be of predictive significance.

B1550

EXPRESSION ANALYSIS OF JAK-STAT DEPENDENT S100 CALCIUM BINDING PROTEINS A4 AND A12 IN MYELOPROLIFERATIVE NEOPLASMS

O Mitrović[1*], P Mossuz[2], M Diklić[3], D Šefer[4], B Ilić[5], M Peruničić[4], G Jovčić[3], V Čokić[3]
[1]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia, [2]Hématologie cellulaire, Institut de Biologie et Pathologie, CHU Grenoble, Grenoble, France, [3]Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, [4]Clinic of Hematology, Clinical Center of Serbia, [5]Genetic laboratory, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia

Background: S100 calcium binding proteins are generally up-regulated in tumors and play essential roles in both tumor progression and suppression. S100A4 positively regulates tumor cell proliferation, invasion and metastasis, while proinflammatory S100A12 is mostly expressed in human granulocytes.
Aims: S100A4 and S100A12 are produced via activation of the JAK-STAT kinase pathway, while JAK2 mutation induces constitutive activation of JAK/STAT signaling in myeloproliferative neoplasms (MPN). Therefore, determination of S100A4/12 mRNA and protein levels in peripheral blood and bone marrow can represent the potential markers of development and prognosis in MPN.
Methods: Using immunohistochemistry and proteinarray we analyzed S100A4 and S100A12 protein expression in bone marrow and granulocytes of MPN, respectively, as well as S100A4 and S100A12 mRNA levels in hematopoietic progenitor $CD34^+$ cells and granulocytes of MPN by microarray analysis.
Results: S100A4 gene expression is significantly increased ($P<0.01$) in hematopoietic progenitor cells of ET and PV patients despite to JAK2 mutation, while in PMF do not reach a statistical significance compared to healthy controls. S100A4 gene expression is generally reduced in granulocytes of MPN patients. The level of S100A4 protein was decreased in bone marrow of MPN patients compared to healthy controls, while JAK2 mutant allele burden increased protein expression only in bone marrow of PMF patients. S100A4 protein expression is decreased in granulocytes of PV patients compared to other MPN, regardless of JAK2 mutation. Moreover, S100A4 protein expression is increased in JAK2 positive PMF patients in comparison to MPN patients without JAK2 mutation. In contrary, proinflammatory S100A12 protein expression is increased in JAK2 mutation negative MPN patients compared to mutation positive MPN patients, where PMF patients demonstrated the most increased S100A12 protein expression in granulocytes. S100A12 protein expression was slightly decreased in bone marrow of PV and PMF patients, while was significantly increased in JAK2 heterozygous ET patients, compared to healthy controls. S100A12 gene expression, absent in controls, is increased in hematopoietic progenitor cells of PV patients.
Summary / Conclusion: Overexpression of S100A4 gene in hematopoietic progenitors of MPN is not associated with the presence of JAK2 mutation, while S100A4 protein has decreased expression in bone marrow of MPN. Interestingly, JAK2 mutant allele burden only increased S100A4 protein expression in bone marrow and granulocytes of patients with PMF. S100A12 protein expression was in favor of MPN without JAK2 mutation, but still PMF demonstrates its dominance in granulocytes of JAK2 positive MPN. It is possible that these two members of the S100 family may be a target for therapy or have a role in staging of MPN clinical setting and support in treatment conclusion.

MICRORNA EXPRESSION ANALYSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS, POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTOSIS

A Tombak[1*], Ö Ay[2], M Emin Erdal[2], M Sungur[3], M Uçar[4], A Akdeniz[4], E Tiftik[4]
[1]Internal Medicine Hematology Department, Mersin University Medical Faculty Hematology Department, [2]Medical Biology Department, [3]Biostatistics, [4]Internal Medicine Hematology Department, Mersin University , Mersin, Turkey

Background: MicroRNAs (miRNA) are 19-22 nucleotides in length, non-coding small RNA molecules. These small molecules are thought as non-functioning molecules in the past, but today it was understood that they have critical roles in cell differentiation, proliferation and apoptosis. A miRNA can be specific for a large number of target genes and it is thought that they have critical roles in regulating gene expression.
Aims: In this study, we aimed to open a new door for the development of targeted therapies in Philadelphia chromosome (-) myeloproliferative disorders consisting of primary myelofibrosis (PMF), polycythemia vera (PV) and essential thrombocytosis (ET) by researching the roles of miRNAs in the pathogenesis of these diseases.
Methods: Forty-nine patients with ET, 33 patients with PV, 22 patients with PMF (46 males, 58 females) and 40 healthy volunteers were included in the study. The co-morbidities and drugs used by patients (hydroxyurea, anagrelide, interferon) were noted. *JAK2* positivity was determined. The expression levels of mir155, mir181a, mir221, mir222, mir223, and mir451 were determined by RT-PCR and analyzed by $\Delta\Delta$CT method. The statistical analysis of the data was performed by using Kruskal Wallis and Dunn tests.

Results: Differences were determined in the expression levels of mir155, mir221, mir222, mir223, mir451 among the groups (table 1). It was determined that mir155 was expressed in higher levels in all 3 disorders compared to the control group ($P<0.05$). Mir221 was found in higher levels especially in ET and PMF group ($P<0.05$). Mir222 expression was found lower in PV patients ($P<0.05$) and higher in ET, and PMF patients compared to control group. Mir223 expression was found higher in ET, and PMF group than the control group ($P>0.05$). Mir451 levels were lower in all 3 groups compared to the control group ($P<0.05$). Between the groups, there was no difference in expression levels of mir181a. It was also determined that *JAK2* positivity, co-morbid diseases, drugs used by the patients, and gender did not affect the miRNA expressions.
Summary / Conclusion: In this study, we showed the different expression levels of stated miRNAs. In the future, these molecules can be used for the differential diagnosis and as the targeted molecules in the treatment of myeloproliferative disorders.

APOPTOSIS-RELATED GENES METHYLATION PROFILE IS ALTERED IN MYELOPROLIFERATIVE NEOPLASMS PHILADELPHIA NEGATIVE PATIENTS

R Tognon-Ribeiro[1*], N Nunes[1], L Moura[1], M Souza[2], E Souto[3], L Palma[4], B Simões[4], M Chauffaille[2], F Castro[1]

[1]Department of Clinical, Toxicological and Bromatological Analysis, Ribeirão Preto School of Pharmaceutical Science (FCFRP) - University of São Paulo, Ribeirão Preto, [2]Department of Hematology, Federal University of São Paulo (UNIFESP), [3]Brigadeiro Hospital, São Paulo, [4]Department of Clinical Medicine, Ribeirão Preto School of Medicine (FMRP) - University of São Paulo, Ribeirão Preto, Brazil

Background: Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF) are chronic Myeloproliferative Neoplasms chromosome Philadelphia negative (MPN Ph-) characterized by a myeloaccumulation and apoptosis deregulation. Epigenetic regulation, such as altered DNA methylation profile of apoptosis-related genes promoters CpG islands may be involved in this process.

Aims: (1) To investigate the apoptosis-related genes promoters CpG island methylation status in MPN Ph- patients and SET-2 JAK2 V617F positive cell line; (2) To compare apoptosis-related gene methylation profile among PV, ET and PMF patients and (3) To associate JAK2 V617F mutation status with methylation results.

Methods: This study enrolled six patients: 2 PV, 2 ET and 2 PMF (4 males and 2 females, mean age(ma)=60 years). For each disorder, one patient was JAK2 V617F positive and the other was JAK2 V617F negative. For the control group, 3 health subject were studied (1 male and 2 female, ma=55.3y). This research was approved by the local ethics committees (protocol n. 247) and the consent form was signed by the patients and volunteer controls. The DNA was isolated from leukocytes and SET-2 cells by phenol-chloroform protocol, treated with RNAse and purified using MiniElute Purification kit®. The methylation profile of *APAF1*, *BAD*, *BAG1*, *BAX*, *BCL2*, *BCL2L11*, *BCLAF1*, *BID*, *BIK*, *BIRC2, BNIP3L, CASP3, CASP9, CIDEB, CRADD, DAPK1, DFFA, FADD, GADD45A, HRK, LTBR, TNFRSF21, TNFRSF25, WRAP53* genes was analyzed by *Epi-Tect Methyl qPCR Array System*®. The results were expressed as hypermethylated (HY) or unmethylated (UM) percentage of the gene.

Results: JAK2 V617F positive PV patients showed higher HY percentage of *BCL2* (8.42%), *CASP3* (16.16%), *CASP9* (14.17%), *CRADD* (33.58%), *DFFA* (13.93%), *TNFRSF25* (9.66%) and *WRAP53* (10.16%) than controls (mean percentage of HY: 0.74%, 1.23%, 6.25%, 3.59%, 1.48%, 1.21% and 1.77%, respectively). JAK2 V617F negative PV patient showed increased HY percentage of *CRADD* (23.6%), *DFFA* (8.77%) and *WRAP53* (10.61%) in comparison to controls, as for JAK2 V617F positive PV, but *CIDEB* HY percentage was higher in JAK2 V617F negative PV patient (34.68%) compared to controls (mean: 4.10%) and JAK2 V617F positive PV (1.88). Furthermore, JAK2 V617F positive PMF patients showed *CRADD* (18.7%), *DFFA* (13.20%) and *WRAP53* (7.64%) with higher HY percentage than controls and JAK2 V617F negative PMF patients. In contrast, *LTBR* gene HY percentage was lower in JAK2 V617F positive PMF (6.66%) compared to controls (mean: 27.68%), to JAK2 V617F positive PV (30.76%), JAK2 V617F negative PV (19.10%) and JAK2 V617F negative PMF (30.09%). ET patients, SET-2 cells and controls showed a very similar apoptosis-related gene methylation profile. *LTBR* gene HY percentage was lower in JAK2 V617F positive ET (11.57%), JAK2 V617F negative ET (11.08%) and SET-2 cells (1.03%) than in controls (mean: 27.68%).

Summary / Conclusion: Increased methylation may be involved in apoptosis-related genes deregulated expression in MPN, as highlighted by *BCL2*, *CASP3*, *CASP9* and *CRADD* hypermethylation percentage results in JAK2 V617F positive PV patients. Supported by FAPESP (2011/20135-2, 2011/51616-6).

B1553

HUMAN PLATELET LYSATE AS A POTENTIAL SUBSTRATE FOR STUDYING MECHANISMS OF MYELOFIBROSIS DEVELOPMENT

E Bulycheva[1*], A Zaritskey[1], P Butylin[1]

[1]Institute of hematology, Almazov Federal Heart, Blood and Endocrinology Center, St.Petersburg, Russian Federation

Background: Mechanisms of myelofibrosis development in chronic myeloproliferative disorders are a subject of current research interest, because despite lots of new therapeutic options this phenomenon remains to be hardly treated. Human platelet lysate (HPL) is a good substrate to explore the inner mechanism of influence of megakaryocytic system on bone marrow stromal cells in laboratory experiments.

Aims: Characterization of human platelet lysate (HPL) from patients with primary myelofibrosis (PMF) and post-polycythaemia vera myelofibrosis (post-PV MF). Exploration of how HPL influence proliferation rate of mesenchymal stromal cells (MSC). Evaluation of collagen expression, as a main component of extracellular matrix, in MSC cultured in presence of HPL.

Methods: HPL was produced from pooled platelet concentrate of healthy donors and platelet-rich plasma of patients with PMF and post-PV MF; patients' HPL was normalized according to protein concentration. MSC were isolated from bone marrow of healthy donors and cultured in presence of varying concentrations of HPL (5, 10, 20%) or 10% fetal bovine serum (FBS) as negative control. Proliferation of MSC was quantified using MTT assay. Concentration of vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), transforming growth factor – beta (TGFβ) and hepatocyte growth factor (HGF) was determined in HPL from fourteen patients with PMF and three patients with post-PV MF using specific ELISA kits. Immunofluorescence was used to estimate collagen type 1 and type 3 expression in MSC in different culture conditions.

Results: We observed a significant increase in VEGF and bFGF concentration (2,5 and2,4 fold, respectively, compared to the age-matched healthy controls, P<0.01) in HPL from patients with myelofibrosis. For TGFβ and HGF we found a tendency to increase in concentration (1,2 and1,7 fold, respectively), but the difference was statistically insignificant (P=0,2). In case of culturing MSC with HPL from patients with myelofibrosis, we found that cells maintained their proliferative activity at the same level as with HPL from age-matched healthy controls (optical density – 0,155 and 0,145, accordingly, P=0,17). Using immunofluorescence with specific antibodies, we showed a constant high expression of collagen type 1 in MSC regardless of culture conditions, whereas expression of collagen type 3 increased when cells were cultured in higher concentration of HPL (20%).

Summary / Conclusion: To the best of our knowledge, this is a first attempt to reproduce cellular events in myelofibrosis using HPL from patients with chronic myeloproliferative disorders. Our data demonstrate that patients' HPL can be used as a substrate for culturing of mesenchymal stromal cells in order to study the mechanisms of myelofibrosis, as it contains increased concentration of growth factors and maintains MSC proliferation rate. We also showed that composition of extracellular matrix proteins depends on the HPL concentration. This is an ongoing study and we are working further to evaluate HPL from patients with myelofibrosis.

B1554

JAK2 46/1 HAPLOTYPE, JAK2V617F MUTATION AND CLINICAL CARACERISTICS OF THE MACEDONIAN PATIENTS WITH CLASSICAL MYELOPROLIFERATIVE NEOPLASMS

I Panovska-Stavridis[1*], M Ivanovski[1], S Trajkova[1], D Dukovski[1], M Popova-Veljanovska[1], N Matevska-Geshkovska[2], L Cevreska[1], A Dimovski[2]

[1]University Clinic of Hematology-Skopje, Medical faculty-Skopje, [2]Center of Biomolecular Sciencies, Faculty of Pharmacy-Skopje, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: It is predicted that the inherited genetic background in the individual patients with classical myeloproliferative neoplasm (MPN) influences the disease susceptibility and the phenotype expression of the MPN. Recently, several groups suggested that JAK2V617F positive MPN are acquired preferentially on a specific constitutional germline JAK2 46/1 haplotype which is tagged by the "C" allele of single nucleotide polymorphism (SNP)rs12343867 (C/T), and indicate the genetic basis for predisposition to MPN. But, subsequent data, showed equal distribution of this SNP among JAK2V617F negative MPN, indicating that it is a potential common inherited susceptibility factor for MPN. Moreover, only few studies investigated the potential role of the JAK2 46/1 haplotype at the MPN phenotype in context of the clinical presentation and the complication of the diseases.

Aims: In order to extend further those observations we conduct a retrospective study to assess the frequency of JAK2 46/1 haplotype in a group of patients with MPN in comparison with population controls. Furthermore, we evaluate the association of 46/1 with the JAK2V617F mutational status and the clinical characteristics in the series of patients with MPN that were diagnosed and treated at the University Clinic of hematology-Skopje, Republic of Macedonia.

Methods: The study group consisted of 212 adult (>15 years) patients with MPNs that were diagnosed and followed at our Institution. According to the 2008 WHO criteria 79 patients were classified as Polycythemia vera (PV), 95 as Essential thrombocythemia (ET), 10 as Myelofibrosis primaria (MP) and 28 were classified as atypical (a) MPNs.The 46/1 tag SNP rs12343867 (C/T) was genotyped using the TaqMan SNP genotyping assay (Applied Biosystems, Foster City, CA, USA) according to the manufacturer's instructions. The JAK2 V617F mutation was analyzed by fluorescent allele-specific PCR followed by CE on ABI 310 Genetic analyzer .

Results: The incidence of 46/1-linked C allele was significantly higher in all MPN entities [PRV (0.538), ET (0.437), MF (0,464), and in aMPN (0.55} in comparison with healthy controls (0.290) (P<0,01 for all comparisons); The frequency of the JAK2V617F mutation ranged from 89%in PV, 67% in ET, 60% in MP to _46,4% in the aMPN. The frequency of the JAK246/1 C allele was significantly higher in the JAK2V617F positive patients with PV, MP and aMPN(P<0,01 for all comparisons) except for ET patients, in which genotype distributions were similar among JAK2V617F positive and negative patients (genotype: CC 7/14%, CT 22/29% , TT 67/57%; C-allele frequency 41/43%; P=0,76).
Correlations of the clinical features at diagnosis and long-term prognosis between the two JAK2 46/1 different MPNs groups revealed comparability regarding all tested parameters such as blood counts, NAP score, rate of thrombotic and hemorrhagic complications, disease transformation and survival.

Summary / Conclusion: Our results confirmed latest observations that JAK2 46/1 haplotype is a susceptibility factor for developing ET independent of

JAK2V617F mutational status and does not further affect the clinical course and prognosis of the disease .Our findings indicate that JAK2 46/1 haplotype predispose for development of MPN trough "the fertile ground hypothesis" which suggest that cells that are carrying the haplotype gain selective advantages in situations when oncogenic mutations occur.

B1555

GENETIC ABNORMALITIES IN DIAGNOSTICS OF BCR-ABL-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

M Kozlovskaya[1*], I Martynkevich[1], E Petrova[1], L Martynenko[1], M Ivanova[1], N Cybakova[1], S Gritsaev[1], V Shuvaev[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Genetic mutations result in abmormalities of myelopoietic proteins and lie in the basis of myeloproliferative neoplasms (MPNs) development and its subsequent progression.
Aims: The aim of our study was to assess frequencies of JAK2, MPL mutations and cytogenetic aberrations in patients with BCR-ABL-negative MPNs.
Methods: Blood samples from 547 patients with BCR-ABL negative MPNs were selected. The investigated group included 203 cases of Polycythaemia vera (PV), 102 cases of Essential thrombocythemia (ET), 102 cases of Primary myelofibrosis (PMF) and 140 cases of Chronic myeloproliferative disease, unclassified (CMPD-U). The average age of the patients group was 52 years (18-80 years). The peak of the incidence of diseases was at the age between 50 and 60 years. Polymorphism of JAK2 (V617F) was defined by PCR-RFLP assay. Mutations in exon 12 of JAK2 were detected by sequence analysis in 69 PV patients. Polymorphisms of MPL (W515L; W515K) were defined by Realtime PCR in two replications in 44 ET patients and 51 patients with PMF. Conventional cytogenetics of bone marrow (BM) with Chromosome banding analyses were performed for 129 patients.
Results: The frequencies of JAK2 617F allele have been detected as follows: 99,0% (201/203) in PV, 56,4% (58/102) in ET and 49,7% (50/101) in PMF. The frequency of 617F allele JAK2 in CMPD-U was8,6% (12 of 140 cases) and confirmed MPN diagnosis for these 12 patients. The frequency of mutations in exon 12 of JAK2 was2,9% (2/69) in group of patients with CMPD-U. The frequencies of MPL 515L allele were2,3% (1/44) in ET and 2% (1/51) in PMF. Cytogenetic analysis of the BM cells stratified 129 patients into different prognostic groups. Normal karyotypes were defined in 85,3% cases (110 of 129). Aberrant karyotypes were defined in 14,7% cases (19/129) and included3,9% (5 cases) karyotypes with isolated chromosomal aberrations (del(20q), del(13q) (favourable prognosis),6,2% (8 cases) karyotypes (intermediate risk), and4,7% (6 cases) karyotypes with compelx karyotypes (unfavourable prognosis). Isolated chromosomal aberrations which cause favourable prognosis were defined reliably more often in PV cases than in PMF cases (p<0,0000). Moreover, the frequency of the complex karyotypes was statistically higher in PMF cases as compared to PV and ET cases (p<0,0000). 2 of 6 patients with complex karyotypes in karyotypes had transformation from MPN to AML.
Summary / Conclusion: Point mutations in JAK2 and MPL genes are specific markers for patients with BCR-ABL-negative MPNs. The integration of molecular genetics with cytogenetics helps to stratify patients into different risk groups and optimize treatment strategy.

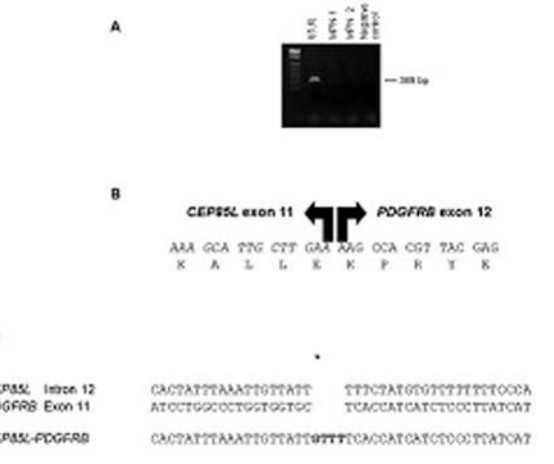
B1556

RECURRENT CEP85L-PDGFRB FUSION IN A PATIENT WITH A TRANSLOCATION T(5;6) AND AN IMATINIB-RESPONSIVE MYELOPROLIFERATIVE NEOPLASM WITH EOSINOPHILIA

N Winkelmann[1,2*], C Hidalgo-Curtis[1,3], K Waghorn[1,3], J Score[1,3], H Dickinson[4], A Jack[5], S Ali[6], N Cross[1,3]
[1]Leukaemia Research Group , Wessex Regional Genetics Laboratory, Salisbury, United Kingdom, [2]Klinik für Innere Medizin II , Universitätsklinikum Jena, Jena, Germany, [3]Faculty of Medicine, University of Southampton, Southampton, [4]Cytogenetics Unit, St. James´s University Hospital, [5]Haematological Malignancy Diagnostic Service, St James's University Hospital, Leeds, [6]Hull Royal Infirmary, Hull Royal Infirmary, Hull, United Kingdom

Background: Fusion genes involving the catalytic domain of tyrosine kinases (TKs) play an important role in the pathogenesis of hematological malignancies and solid tumors. In *BCR-ABL1*-negative myeloproliferative neoplasms (MPNs) several different tyrosine kinase fusion events have been described, most commonly involving the genes encoding the platelet-derived growth factor receptor alpha (*PDGFRA*) or beta (*PDGFRB*). Since the introduction of small molecule kinase inhibitors, TK fusions have emerged as prime therapeutic targets. Here, we present the case of a 45 year old male with persistent unexplained eosinophilia. A bone marrow aspirate and biopsy showed increased cellularity with myeloid expansion and marked eosinophilia without signs of monoclonality. Cytogenetic analysis on a bone marrow aspirate revealed a 46,XY,t(5;6)(q3?3;q2?2).
Aims: In this patient our objective was to investigate the underlying fusion gene of his translocation t(5;6) and if possible use it as a molecular marker during treatment.
Methods: Break apart FISH using previously described in house probes demonstrated that *PDGFRB* at 5q33 was disrupted but *ETV6-PDGFRB,* the most common fusion involving this gene, was not detected by RT-PCR.Standard Gold Taq Polymerase based PCRs were performed on cDNA and gDNA extracted from peripheral blood leukocytes. Sanger Sequencing was performed on cDNA and gDNA in forward and reverse. Peripheral blood samples were received from this patient at 7 different time points before and after treatment.



Results: At the time of initial analysis no similar translocation had been reported and therefore the diagnostic investigations suggested the likely presence of a novel fusion involving *PDGFRB* and an unknown partner gene on chromosome 6. Initial attempts at RACE-PCR were unsuccessful and hampered by limited availability of suitable pre-treatment material. Subsequently, a novel *C6orf204-PDGFRB* (now known as *CEP85L-PDGFRB*) fusion was reported in a patient with T-cell acute lymphoblastic leukemia (T-ALL). Thus, we hypothesized that our patient may harbour the same or similar genetic defect. For the RT-PCR, a product was amplified from the patient with the t(5;6) but not controls which upon sequencing revealed an in frame cDNA fusion between exon 11 of *CEP85L* and exon 12 of *PDGFRB.* For gDNA, Sequencing showed the genomic fusion was between intron 12 of *CEP85L* and exonic sequence of *PDGFRB* exon 11 (Figure 1)**.**Five months after the start of imatinib treatment neither the genomic nor the mRNA fusion was detectable by nested PCR or RT-PCR. *CEP85L-PDGFRB* remained undetectable in all subsequent samples with a follow up of over 3 years. Imatinib was continued without interruption during this time The sensitivity of the PCR assay to detect the *CEP85L-PDGFRB*-fusion gene was 10^{-4} .
Summary / Conclusion: Here, we report a recurrent *CEP85L-PDGFRB* fusion in a patient with eosinophilia and an MPN. The fusion was confirmed by spe-

cific amplification of the genomic breakpoints and reverse transcription polymerase chain reaction (PCR).The patient was treated with imatinib and achieved hematologic and cytogenetic remission. Minimal residual disease screening over 3 years with nested PCR failed to detect *CEP85L-PDGFRB* mRNA or genomic DNA, confirming a long term molecular remission on imatinib. In our view, the detection of the exact gene fusion is clinically relevant for effective long term management of these neoplasms as it enables specific follow up by sensitive molecular analysis.

B1557

CLINICAL SIGNIFICANCE OF IMMATURE PLATELET FRACTION IN BCR-ABL1-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

N Vazzana[1*], R Spadano[1], S Di Zacomo[2], G Rolandi[3], A Dragani[1]
[1]Department of Hematology, Centre for Hemophilia and Rare Blood Disorders, [2]Department of Transfusion Medicine, Molecular Biology Unit, [3]Department of Transfusion Medicine, Coagulation Unit, Pescara, Italy

Background: Platelet activation plays a pivotal role in the pathogenesis of BCR-ABL1-negative myeloproliferative neoplasms (MPN)-associated thrombosis. Evidence is mounting to support a potential usefulness of immature platelet fraction (IPF) measurement for vascular risk stratification in various thrombotic disorders.
Aims: The aim of this study was to characterize the clinical and laboratory determinants of IPF in patients with BCR-ABL1-negative MPN. In addition, we investigated the association between IPF and previous thrombosis.
Methods: One-hundred thirty-five patients have been studied. Sixty-one patients (45.2%) had ET, 25 (18.5%) PV, and 21 (15.6%) MPN-U. Among the 28 (20.7%) patients with myelofibrosis, 25 patients had PMF, while 3 patients had post-TE or post–PV myelofibrosis. Forty-eight patients had a history of previous thrombotic event, including arterial thrombosis (n = 31), venous thrombosis (n = 14), or both (n = 3) events. Complete blood counts, including the measurement of IPF were performed in whole blood by the fully automated hematology analyzer XE-2100 (Sysmex).
Results: In patients on cytoreductive therapy but not in untreated patients, IPF% was significantly higher in those with previous thrombosis than in non-thrombotic patients [2.4 (1.7-3.4) vs. 3.3 (2.4-5.1) %, P=0.011]. Similarly, in patients aged ≥ 60 years but not in younger patients, IPF% was significantly higher in those with previous thrombosis than in nonthrombotic patients [2.6 (1.8 -3.7) vs. 3.6 (2.4 - 5.2)]. In the entire population, a significant inverse correlation has been observed between platelet count and IPF% (Rho = - 0.23, P=0.008). In addition, in non-PV patients, IPF% was not significantly different between JAK2 V617F positive vs. negative patients. Multivariate logistic regression showed that only male gender (odds ratio, 3.3; 95% CI, 1.4 to 8.0; P=0.007) and the upper tertile of IPF% (odds ratio, 3.7; 95% CI, 1.2 to 10.7; P=0.018) are independently associated with a history of previous thrombosis, after adjusting for age, hematocrit, white blood cell count, platelet count, cardiovascular risk factors, underlining diagnosis, JAK2 mutational status and cytoreductive therapy.
Summary / Conclusion: We found that increased platelet turnover, as reflected by high IPF%, is associated with a history of thrombotic events in patients with MPN. In addition, our data support the hypothesis that current antithrombotic therapy might not specifically address this mechanism of thrombogenesis. New prospective studies are warranted to evaluate the usefulness of incorporating IPF% in risk stratification models to better identify patients at increased risk for thrombotic complications and/or treatment failure.

B1558

DISEASE CHARACTERISTICS AND PERIPHERAL BLOOD CD34+ CELLS IN IDIOPATHIC MYELOFIBROSIS

S Improta[1], M Villa[1*], A Gagliardi[1], C Tommasino[2], G Fossati[2], L Mastrullo[1]
[1]U.O.C. Ematologia, [2]U.O.C. Patologia Clinica, P.O. San Gennaro ASL Napoli 1 Centro, Napoli, Italy

Background: Idiopathic Myelofibrosis (IMF) is chronic myeloproliferative neoplasm characterized by constitutive mobilization of hematopoietic stem cells (HSC) and progenitor cells (HPC) into the peripheral blood (PB). The interaction between the chemokine CXCL12 and its receptor CXCR4 plays a pivotal role in determining the trafficking of CD34+ cells between the bone marrow (BM) and the PB.
Aims: IMF is associated with downregulation of CXCR4 by CD34+ cells due to epigenetic events. Altered gene expression was corroborated by the detection of abnormally high CD9 or CD164, and low CXCR4, membrane protein expression in IMF CD34+ cells. Moreover, endothelial precursor cells (CD34+/CD133+) are increased in the blood of a subset of patients with IMF, and peripheral endothelial cells bear the same molecular markers as hematopoietic cells, suggesting a primary role of pathological endothelial cells in this disease.
Methods: We evaluated, by flow cytometry, the number of CD34 positive cells in peripheral blood and the expression of CXCR4, CD9, CD117 and CD133 on these cells. In our institution we are following 31 patients affected by IMF, according to WHO criteria (M: 18, F: 13; median age: 57 years, range: 48-68 years).
Results: In all patients, at diagnosis, we found a high count of CD34+ cells in PB (greater than $15x10^6$/l; median:2,$4x10^6$/l, range:1,8-3,$2x10^6$/l) compared with normal controls and other Philadelphia-negative chronic myeloproliferative neoplasms. In all cases CD34+ cells were negative for CXCR4 while expressing high intensity CD9. About 40% of CD34+ cells expressed CD133, while 20% expressed CD117 at low intensity. In no case was detected coexpression of CD133 and CD117, suggesting a simultaneous presence of two distinct hematopoietic progenitors, endothelial progenitors and myeloid progenitors. We monitored every 6 months the phenotypic pattern of CD34+ cells, and after 36-48 months we observed an increase of myeloid precursors (CD34+/CD117+: 45,7%) compared with a reduction of endothelial precursors (CD34+/CD133+: 15,3%) in patients who showed clinical and laboratory signs of disease progression.
Summary / Conclusion: By comparing these findings with other clinical data, our results seem to confirm that, according to the natural history of disease from an initial stage towards a fibrotic phase (pancytopenia and/or splenomegaly), there was a change in PB CD34+ cells. Immunophenotypic profile of PB CD34+ cells is associated in IMF with patients' clinical characteristics and may have potential prognostic application.

B1559

THROMBOTIC CEREBRAL EVENTS IN ESSENTIAL THROMBOCYTHEMIA

C Cecchetti[1*], A Aroldi[1], M Riva[1], E Pogliani[1], E Elli[1]
[1]Hematology division, San Gerardo Hospital, Monza, Italy, Monza, Italy

Background: Patients with Essential Thrombocythemia (ET) are frequently asymptomatic and many remain so. Symptomatic patients tend to present with thrombotic manifestations in distinct locations. The thromboses are more commonly arterial than venous. The thrombotic cerebral events (TCE) are rare, also if ET patients may present a wide spectrum of neurologic symptoms (NS) at onset or during the course of the disease, secondary to microvascular involvement
Aims: We retrospectively described CTE occurred in 310 patients affected by ET referred in our centre from 1990 to 2012 in order to identify clinical and biological features associated to these complications
Methods: We analysed the incidence of TCE; in particular we evaluated the prevalence of JAK2V617F mutation in this setting and the possible role of JAK2 mutation in the management of CTE
Results: 33/310 patients (10.6%) presented TCE. The average age of TCE patients was 71 years, with prevalence of female sex (21 vs. 12 patients). Only 4 patients were high risk for 2 o more cardiovascular factors (hypertension, diabetes, obesity, dyslipidemia, smoking, thrombophilia). 54,5% of patients developed CTE before diagnosis of myeloproliferative neoplasm (MPN), with a median time of 16 months of latent phase of myeloproliferative disease prior to confirmed diagnosis of ET. Of the 22 TCE preceding diagnosis, 18 were arterial events (8 transient ischemic attack, 9 strokes), only 2 events were venous (2 ocular thrombosis). 7 patients (21,2%) developed CTE as presentation of disease. All these patients received anti-platelets treatment starting from thrombotic event. At time of diagnosis, cytoreductive therapy, mainly with hydroxyurea, was started. Therefore, 11 patients (33,3%) developed TCE after diagnosis of ET, despite of anti-platelet and cytoreduction, with 15% of patients (5/33) with recurrent neurological thrombosis. The blood count at diagnosis and at time of TCE was similar, in particular no leucocytosis or extreme thombocythemia were present. The median value of hematocrit, white blood cell count and platelets at time of CTE were 41%, 7.720/mm3 and 650.000/mm3, respectively. JAK2V617F mutation was evaluated in 30/33 patients, with significant prevalence of JAK2 positive versus negative patients (83,3% vs. 16,7%). All patients with recurrent CTE were JAK2 mutated. Overall, 91% of patients (30/33) are alive, with an average follow-up of 57,6 months
Summary / Conclusion: we observed that 10,6% of ET patients presented CTE, with high prevalence (75,7%) of cerebral events as first presentation at time of diagnosis or as first sign of latent disease, for CTE antecedent to diagnosis. The majority of cerebral events were arterial. Mostly of patientswere females and presented higher prevalence of JAK2V617F mutation. This may lead to the fact that, in selected cases of CTE, where there is evidence of laboratory signs suggestive of MPN, the detection of the *JAK2*V617F mutation provides an early diagnosis of MPN. Moreover, a subgroup of patients (33,3%) developed CTE also after ET diagnosis and during antiplatelet and cytoreductive treatment, with high risk of thrombotic CTE recurrence (15%). This seems to suggest that in this selected setting, an enhancement of thrombotic prophylaxis could be proposed, for example with association of cytoreduction and anti-coagulant oral therapy, in presence of JAK2 mutation or other significant cardiovascular factors or thrombophilia predisposition

B1560

CHARACTERIZATION OF DIFFERENT REGIMENS FOR INTRODUCING SECOND-LINE ANAGRELIDE: RESULTS FROM A MULTICENTER STUDY OF 177 PATIENTS IN FRANCE

J Rey[1*], J Viallard[2], K Keddad[3], J Smith[4], P Wilde[4], J Kiladjian[5]
[1]Onco-Hematology, Paoli-Calmettes, Marseille, [2]Service de Médecine Interne,

Hôpital Haut-Lévêque, Bordeaux, [3]Shire, Boulogne-Billancourt, France, [4]Shire Pharmaceuticals Ltd, Basingstoke, United Kingdom, [5]Centre d'Investigation Clinique, Hôpital Saint Louis et Université Paris7, Paris, France

Background: Anagrelide (ANA) is indicated in the EU for at-risk patients (pts) with essential thrombocythemia (ET) and at least one of: >60 years; platelet count >1000x10^9/L; history of thrombo-hemorrhagic events; in whom prior therapy (PT) is not sufficiently effective or well tolerated. The Summary of Product Characteristics (SPC) recommends starting ANA at 1.0mg/day, in two divided doses and maintaining this dose for ≥1 week. Then the dose may be individually titrated to achieve the lowest effective dose required to reduce and/or maintain platelet count <600x10^9/L, ideally at 150–400x10^9/L. The dose increment must not exceed 0.5mg/day per week and 2.5mg is the maximum single dose. There is no recommendation on how to transition from PT to ANA.
Aims: This observational study (NCT01192347) aimed to identify switch modalities used when introducing ANA and determine their influence on 6-month (mo) outcomes (including efficacy, tolerability and maintenance on ANA at 6 mo) in 44 clinical sites across France.
Methods: Pts were enrolled within 1 mo of switching to ANA; up to 1 mo of retrospective data were collected. As this was a non-interventional study, dosing schedule and follow-up visits were at the investigator's discretion. Pts were followed up for 6 mos. All relevant data were collected and recorded from pt records at the end of the follow-up.
Results: In total, 177 pts were enrolled (safety set n=175), the majority were female (62%) and aged >60 years (76%). Median age was 70 years. Median baseline platelet count was 553x10^9/L. Intolerance to therapy (65%) and inefficacy (41%) were the most frequent reasons for treatment switch (factors not mutually exclusive). ANA starting doses ranged from 0.3–1.5mg/day. The SPC□recommended starting dose was used most frequently (53%). However a notable proportion of pts started on 0.5mg/day (41%). The median ANA dose at study end was 1.5mg/day (range 0.3–4.0mg/day). The method of ANA introduction was consistent with the SPC in 76% of pts. Almost all pts switched to ANA from hydroxycarbamide (93%). Most pts discontinued PT before ANA was introduced (66%; Group A). 22% discontinued PT after introduction of ANA (Group B; 17% within the first mo [Subgroup B1] and 5% in the subsequent 5 mos [Subgroup B2]). A further 9% had not discontinued PT by the end of the follow-up (Group C) and 5 pts (3%) were determined to have no PT. At the end of the follow-up, 85% of pts were still continuing on ANA, Groups: A (82%), B1 (93%), B2 (100%), C (81%). 71% of pts achieved platelet responses, Groups: A (67%), B1 (83%), B2 (100%), C (56%); 42% full response (<400x10^9/L) and 29% partial response (400–600x10^9/L or a reduction of ≥200x10^9/L). The median final platelet count was 412x10^9/L and the absolute median change from baseline was -94.5x10^9/L. 75% of pts who received ANA in line with the SPC achieved platelet response vs 54% of those not consistent with the SPC. 46% pts reported adverse drug reactions (ADRs) all described in the SPC. The most frequent were palpitations (13%), headache (11%), diarrhea 6% and asthenia 6%. 17% pts discontinued ANA due to ADRs (mainly palpitations or headache).
Summary / Conclusion: 85% of pts remained on ANA at the end of the 6-mo follow-up. ANA was introduced using the SPC□recommended dosing schedule in 76% of pts and 71% achieved platelet responses. Overall, ANA was well tolerated and the most frequent adverse events were in line with the SPC. Introducing ANA according to the SPC and subsequently withdrawing PT was associated with the highest platelet response rates.
For the France Observatoire Xagrid (FOX) investigators.

B1561

RISK OF LIMPHOPROLIFERATIVE NEOPLASMS IN PATIENTS WITH CHRONIC MYELOPROLIFERATIVE NEOPLASMS

S Cancio[1*], G Soler[1], J Miguel Torregrosa[1], E Caparrós[1], M Osma[1], F Ortuño[1], G Luengo-Gil[1], V Vicente[1], F Ferrer-Marín[1]
[1]Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain

Background: Over the last years, two large cohorts of patients have reported that chronic myeloproliferative neoplasms (cMPN) patients have a significantly higher risk of developing lymphoproliferative neoplasm (LPN) compared with the general population [1,14% (22/1915) and1,34% (11/820), respectively (Rumi, Haematologica 2011; Vannucchi, Cancer Epidemiol Biomarkers Prev 2009)]. In most cases, diagnosis of LPN was subsequent to the MPN one (91%), and only in 3 cases (9%) the diagnosis of LPN was synchronic or previous to the MPN one. If any genetic susceptibility exists, a random order of onset of the myeloid or lymphoid neoplasm should be expected. Authors of these series attribute the low number of cMPN patients with a previous or concurrent LPN due to a more aggressive behavior of lymphoid neoplasms, so these patients would die before cMPN develops. The molecular mechanisms underline the predisposition of cMPN patients to develop a LPN is not known.
Aims: The **aim** of our study was to evaluate the frequency and time of onset of LPN in patients with cMPN in our health area, and to investigate if specific genetic marker for predisposition to cMPN may also contribute to the risk of developing LPN.
Methods: All consecutive patients with newly diagnosed of cMPN in our unit between 2000 and 2011 were included in this study. Among 155 cMPN cases, 92 (60%) were diagnosed of essential thrombocitemia (ET), 37 (24%) of polycitemia vera (PV), 24 (15.5%) of myelofibrosis and 1 (0,5%) of systemic mastocytosis (SM) by using WHO criteria. In addition to carry out JAK2V617F, c-KIT (D816V) mutation analysis for the SM case, we performed mutational screening of hotspots: CBL (exons 8 and 9), ASXL1 (exon 12), N/K-RAS (exons 1 and 2), IDH1/2 (exon 4), TP53 (exons 4-10) and complete coding regions for RUNX1 and TET2. Mutation analysis was made by conventional Sanger sequencing.
Results: Of the 155 patients included, 4 (2.6%) developed a LPN: in one of them, LPN onset was 2 years before PV whereas in the other 3 patients (2 TE and 1 SM), diagnosis of both neoplasms was simultaneous. All four cases were men over 60 years. Distribution of LPN cases was as following: 2 cases of CLL, both 0-A stage; 1 case of T-LGLL (TCR gamma/delta+), and 1 case of B-cutaneous non-Hodgkin lymphoma. This last patient was the only one who required treatment (CHOP-R and radiotherapy), whereas the rest of the patients remain in therapeutic abstention. In 2 of 3 patients with classic MPN, JAK2V617G mutation was detected, whereas the patient with SM presented the c-KIT mutation (D816V). We were not able to detect any additional mutation genes we had evaluated in patients with both myeloid and lymphoid neoplasms.
Summary / Conclusion: Accordingly to previous studies, the risk of developing a LPN in patients with cMPN is greater in men than women and no correlation with mutational status of JAK2 seems to underlie. By contrast, we did not find a higher incidence of LPN between patients with cMPN over the time, since in our series, both pathologies onset randomly or simultaneously, likely because of the inclusion of LPN patients in early stages of the disease. Despite not described in the two large serious listed above, SM may also be associate rarely to LPN. Although we did not find any additional mutation other than well known JAK2 V617F in classical MPN and c- KIT (D816V) in SM, we cannot exclude that different genes other than *JAK2*V617F might favor the genetic instability predisposing to both LPN and cMPN or that a mutator phenotype exists in these cMPN patients.

B1562

SERIAL ANALYSIS OF GENOMIC ABERRATIONS IN DIFFERENT PHASE OF PATIENTS WITH MYELOPROLIFERATIVE AND MYELODYSPLASTIC/MYELOPROLIFERATIVE NEOPLASMS

C Hahm[1,2], Y Mun[3], C Seong[3], W Chung[1], J Huh[1*]
[1]Department of Laboratory Medicine, Ewha Womans University School of Medicine, [2]Department of Laboratory Medicine, Eone Reference Laboratory, [3]Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic Of

Background: Myeloproliferative neoplasm (MPN) and myelodysplastic/myeloproliferative neoplasm (MDS/MPN) may transform into secondary myelofibrosis (MF), and evolve into acute myeloid leukemia (AML), possibly preceded by a myelodysplastic phase. Genetic mechanisms underlying disease progression remain to be cleared, while chromosomal aberrations are relatively rare in the chronic phase of MPN.
Aims: The purpose of this study was to identify serial genomic aberrations that are associated with disease progression in MPN and MDS/MPN, using whole genome single nucleotide polymorphism based array (SNP-A), which can detect cryptic aberrations or copy neutral loss of heterozygosity (CN-LOH).
Methods: We investigated serial genomic changes of MPN and MDS/MPN patients in different phases of disease. The study group included 10 MPN and 4 MDS/MPN patients (7, polycythemia vera (PV);2, essential thrombocythemia (ET);1, primary myelofibrosis;2, MDS/MPN-unclassifiable;1, chronic myelomonocytic leukemia;1, atypical CML). Median follow up time was 78 months (range 8-154). Whole genome SNP-A (SNP 6.0, Affymetrix, CA) based karyotyping was performed according to manufacturer's instruction.
Results: Four patients (1 PV, 1 ET, 2 MDS/MPN-U) progressed to secondary MF or AML. All PV patients except one developing to MF showed CN-LOH of chromosome 9p at diagnosis and during follow up. One patient with PV developing to MF showed serial genomic changes by SNP-A; CN-LOH of 9p shown at diagnosis changed to gain (copy number 3) of 9p after 18 months and then additional lesions such as 1q gain and 6p deletion were accompanied at 100 months after diagnosis. Moreover, the copy number of 9p increased to four. One ET patient developing to MF showed CN-LOH of 9p, 6q deletion and CN-LOH of 14q at diagnosis and the same genomic changes showed during 106 months follow up. In the other ET patient without disease progression, any genomic aberrations were not found during 84 months. One MDS/MPN, unclassifiable patient demonstrated chromosome 8 gain, 13q deletion and CN-LOH of 20q at diagnosis and throughout follow-up and he progressed to AML at 14 months after diagnosis. During blastic phase, the same previous aberrations were detected and additional lesions such as 5q and 17p deletions were observed. The other MDS/MPN, unclassifiable patient developing to MF showed normal result by SNP-A during 94 months.
Summary / Conclusion: This study suggests that disease progression from chronic phase to secondary MF or AML is associated with genomic changes that can be identified by SNP-A.

B1563

GENETIC ABNORMALITIES ASSOCIATED WITH THROMBOSIS IN PATIENTS WITH PH-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

O Mishcheniuk[1*], O Kostyukevich[2], I Dmitrenko[1], I Prokopenko[1], V Sholoyko[1], S Klymenko[1]

[1]Hematology and Transplantology, National Research Center for Radiation Medicine NAMS of Ukraine, [2]Hematology, Center of Prophylactic and Clinical Medicine, Kiev, Ukraine

Background: Given the fact that one of the main causes of death in Ph-negative chronic myeloproliferative neoplasms (CMPN) patients is thrombotic complication, a consistent pattern of genetic abnormalities associated with thrombosis might be useful for polycythaemia vera (PV), thrombocythaemia (ET), and primary myelofibrosis (PMF) patients risk assessment.
Aims: The aim of this study was to check whether *JAK2* V617F, factor V gene *G1691A* (factor V Lieden, FVL) and *G20210A* prothrombin gene (PT) mutation has the predictive value for thrombosis in patients with Ph-negative CMPN.
Methods: We examined clinical and molecular genetic parameters of 103 PV, 43 ET, 36 PMF patients, and 156 persons with transient myeloproliferative reactions (TMR).
Results: Seven PMF patients (19%), 6 ET patients (14%), 32 PV patients (32%) and 30 TMR individuals (19%) had at least one confirmed arterial and/or venous thrombosis. In *JAK2* V617F positive PMF patients thrombotic complication occurred more often than in PMF patients without mutation (6 of 18 vs. 1 of 18 patients, P=0.043). Relative risk of thrombosis in *JAK2* V617F positive PMF was 6.0 (95% CI=1.01-44.7; p<0.05). Episodes of atypical thrombotic complications manifested in 13 (28%) unselected Ph-negative CMPN patients with thrombotic complication, 2 of them (4%) had both typical and atypical thrombosis, all of these patients were *JAK2* V617F positive. The FVL allele has been detected in 3.3% of Ph-negative CMPN patients (6 of 182 cases) and in 7.7% (12 of 156) of TMR persons. The difference between groups was on the border of statistical significance (P=0.07). The FVL mutation was detected in 3 of 38 Ph-negative CMPN patients with thrombotic event (7.9%) and in 3 patients without thrombosis (2.9%, P=0.2). The separate analysis shown that the prevalence of FVL mutation was higher in PMF patients with thrombosis compared to those without thrombotic episode (2 of 7 vs. 0 of 29 patients, P=0.03). The prevalence of FVL mutation in PV patients did not differ between groups of patients with and without thrombosis. The PT mutation has been detected in 3 (2.1%) of 142 Ph-negative CMPN patients. The prevalence of PT mutation was higher in ET patients with thrombosis compared to patients without this complication (2 of 6 vs. 0 of 37, P=0.02). Transient myeloproliferative reactions patients with thrombotic episodes demonstrated a higher prevalence of FVL mutation than those without thrombosis (6 of 30 vs. 6 of 126, p<0.05). The FVL mutation in TMR patients was associated with a 4.2-fold (95%, CI=1.46-12.06; p<0.05) increase of probability of having any thrombosis. Relative risk of venous thrombosis was 5.6 (95% CI =1.79-17.28; p<0.05) in carriers of FVL allele. The PT mutation has been identified in 8 (5.1%) individuals with TMR. The prevalence of mutant allele was higher in TMR patients with thrombosis compared to those without the thrombotic event (4 of 30 vs. 4 of 126, P=0.027). It was found that individuals with PT mutation demonstrated a 4.1-fold (95% CI=1.09-15.33, P<0.05) greater probability of having thrombosis. All FVL and PT mutations detected in our study were heterozygous.
Summary / Conclusion: Our data confirm that *JAK2* V617F mutation is the predictor of thrombotic complication in Ph-negative CMPN and support the assumption that FVL and PT heterozygous mutation might further increase the risk of thrombosis in PMF and ET patients respectively.

B1564

HEMOGLOBINOPATHIA YPSILANTI – A RARE, BUT IMPORTANT DIFFERENTIAL DIAGNOSIS TO POLYCYTHEMIA VERA

M Nygaard[1,1*], J Petersen[2], O Bjerrum[1]

[1]Dept Hematology , Rigshospitalet, Copenhagen , [2]Dept Hematology , Herlev Hospital, Herlev, Denmark

Background: Hemoglobin Ypsilanti is a rare high oxygen affinity hemoglobin variant involving an amino acid substitution and is inherited autosomally dominant. Due to the high oxygen affinity of hemoglobin Ypsilanti, hypoxia arises in the tissues, and secondary erythrocytosis develops. Before the inclusion of JAK2/exon 12 mutations in the diagnostic criteria, a patient with erythrocytosis could be difficult to diagnose properly with polycythemia vera (PV). The JAK2 mutation is present in more than 95% of patients with PV, and in the rest, a mutation in exon 12 is almost always found. The number of patients with non-clonal PV is therefore very low, but it is very important to obtain a correct diagnosis due to correct patient information and treatment strategy.
Aims: To highlight the importance of proper differential diagnostics in PV.
Methods: We present a case report of a mother and daughter who were initially diagnosed with PV.
Results: In 2003, the mother (age 51 years) was referred to the hematological department due to a high hemoglobin (B-Hgb) level diagnosed during admission for a suspected transient cerebral ischemic attack. In 2007, her daughter (age 24 years) was also referred due to a high B-Hgb level and a three week history of headache. Neither had leukocytosis, thrombocytosis or hepatospleno-megaly. Chest X-rays and peripheral blood smears were normal. Bone marrow biopsies showed hypercellularity and in the case of the mother, the bone marrow examinations were interpreted in concordance with a myeloproliferative disorder. S-EPO was within normal range for both. EPO-stimulated growth of erythroid colonies were normal in both patients. The JAK2/ and exon 12 analyses showed wild-type in both mother and daughter when these analyses became available. The mother later developed pulmonary embolism after immobilization following surgery. Both were treated with venesection regularly according to guidelines for PV to a hct < 45 %, and being comfortable with this. The mother also received anticoagulant therapy, first as acetylsalicylate and later warfarin after the pulmonary embolism. In 2012, a hemoglobin analysis by β-globin gene sequencing was performed and both were heterozygous for the mutation CD 99 G>T (Asp99Tyr), and therefore a carrier of the Hgb-variant Ypsilanti. The regular venesection was stopped and B-Hgb allowed to increase within normal. The daughter has given birth twice to apparently normal offsprings.
Summary / Conclusion: The pursuit of a correct diagnosis is important - especially today where molecular biology offers the possibility of accurate diagnosis. Erythrocytosis due to high oxygen affinity hemoglobin is usually well tolerated in younger patients, but in elderly patients the risk of thrombosis is increased. Standard venesection treatment with high oxygen affinity hemoglobinopathies may not be rational, since the high oxygen affinity causes tissue hypoxia, if there is no compensatory erythrocytosis. Contrary to PV, the risk of transformation to myelofibrosis or leukemia is not present, which has a great impact psychologically. Furthermore, cytoreductive therapy with e.g. hydroxyurea or interferon-α is not indicated and may cause side effects, affecting quality of life negatively and may imply long-term complications. It is important to suspect high oxygen affinity hemoglobinopathy when there is a family history of erythrocytosis and/or when young persons are affected; especially when no apparent cause or clonal marker is identified. The finding of high oxygen affinity hemoglobin is important, for patient information and optimal treatment strategy.

B1565

THE PREVALENCE OF LEG ULCERS IN PATIENTS WITH MYELOPROLIFERATIVE DISORDERS TREATED WITH HYDROXYUREA

H Poul[1*], P Kessler[1], E Drnkova[2], I Zemanova[2]

[1]Department of hematology and transfusion medicine, [2]Department of angiology, Hospital Pelhřimov, Pelhřimov, Czech Republic

Background: Leg ulcers (LU) represent a common adverse side effect of long-term hydroxyurea (HU) therapy, which is often neglected.
Aims: To describe the prevalence of LU in patients with myeloproliferative disorders (MPD) treated with HU and association of LU with chronic venous insufficiency (CVI) and presence of JAK-2 (V617F) mutation.
Methods: 70 patients aged 39 to 89 years, 33 (47%) women and 37 (53%) men treated with HU for MPD (polycytemia vera 34 (49%), essential thrombocythemia 14 (20%), primary myelofibrosis 20 (29%), MPD unspecified 2 (2%). The average duration of HU therapy was 6.66 years with the average HU dose of 2325.8g per patient. JAK-2 (V617F) mutation was examined in 45 (64%) patients; positive results were found in 31 (69%) cases. All patients were assessed using the CEAP classification of CVI, including ultrasonography of lower limb veins.
Results: CVI symptoms were found in 51 (73%) patients, 35 (50%) of them had both lower limbs affected. LU developed in 16 (23%) patients during the period of HU treatment. In 11(69%) of them LU was associated with CVI, while in 6(38%) cases the ulcer affected the leg without CVI. (1 patient with ulcers of both legs had only one limb with CVI). 19 patients without CVI were followed for 19-870 (median 367) weeks and LU developed in 3 (15.8%) of them. 51 patients with CVI were followed for 20-933 (median 318) weeks and LU developed in 12 (23.6%) of them; the difference was not significant (P=0.4828). The time to LU development was 10 to 547 (mean 233) weeks and 196 to 845 (mean 409) weeks in patients with CVI and without CVI, respectively; the difference was not significant (P=0.1495). The mean cumulative dose of HU administered before LU development was 1848 (55 – 4817) g and 3831 (1635-8648) g in patients with CVI and in patients without CVI, respectively; the difference was not significant (P=0.1931). The mean duration of HU therapy till LU development was 257 (10-846) weeks in 7 patients with JAK-2 mutation and 313 (197-535) weeks in 3 patients without JAK-2 mutation. The mean cumulative dose of HU administered was 2238 (57-8648) g and 3243 (1083-7011) g in patients with JAK-2 mutation and in patients without mutation, respectively. 2 (18%) ulcers healed within 18 and 33 weeks during HU therapy. In 15 cases HU therapy was stopped due to non-healing ulcers and an alternative therapy was administered. 14 (93%) ulcers disappeared after discontinuation of HU therapy, 1 patient died shortly after HU suspension. The average time from HU discontinuation to healing of LU were 30 (8-73) weeks and 44 (5-121) weeks in ulcers associated and non-associated with CVI, respectively; the difference was not significant (P=0.5035). The average time of healing was 47 (8-121) weeks and 9 (5-13) weeks in patients with JAK-2 mutation and in patients without JAK-2 mutation, respectively.
Summary / Conclusion: LU is a common complication associated with HU

therapy; its negative impact on quality of life is significant. The ulcers occur more frequently in patients with CVI and JAK-2 mutation; however their prevalence in patients without CVI is not negligible. The role of HU in development of LU is substantial and the discontinuation of HU therapy is required in most patients.

B1566

THE ROLE OF HISTOLOGICAL FEATURES IN PATIENTS WITH POLICYTHAEMIA VERA

R Latagliata[1*], M Breccia[1], I Carmosino[1], F Vozella[1], A Romano[1], C Montagna[1], A Salaroli[1], A Serrao[1], G Loglisci[1], M Mancini[1], A Tafuri[1], G Alimena[1]
[1]Cellular Biotechnologies and Hematology, UNIVERSITÀ "LA SAPIENZA", Roma, Italy

Background: According to WHO revised classification, bone marrow biopsy is no more needed in the diagnostic process of Policythaemia Vera (PV). However, it was widely used in the past years and is still performed in many PV patients at baseline.
Aims: At present, very few data exist on the correlation between histological features and patient follow-up.
Methods: To address this issue, we revised retrospectively the histological features at baseline of 195 patients with PV [M/F 100/95, median age 58.4 yrs (IQR 48.1 – 67.2), median Hb 18.4 g/dl (IQR 17.1 – 20.1), median Ht 56.6% (IQR 53.0 – 61.8), median WBC 10.4 x 10^9/l (IQR 8.4 – 14.0), median PLTs 505 x 10^9/l (IQR 346 – 717)] observed at our Institution from 1/1982 to 12/2010.
Results: The following histological features were considered: bone marrow fibrosis [grade 0 in 128 patients (65.6%) and grade > 0 in 67 patients (34.4%)], number of megakaryocytes [normal in 34 patients (17.4%) and increased with or without clusters in 161 patients (82.6%)], marrow cellularity [normal or increased with erythroid hyperplasia in 152 patients (77.9%) and increased with granulo-megakaryocytic hyperplasia in 43 patients (22.1%)], lymphoid reactive infiltration [absent in 165 patients (84.6%) and present in 30 patients (15.4%)]. The different histological features at baseline were compared with thrombotic episodes during follow-up [reported in 45/195 patients (23.1%)], evolution in myelofibrotic phase (MP) [21/195 patients (10.8%)], evolution in blastic phase [15/195 patients (7.7%)] and overall survival. Marrow cellularity, number of megakaryocytes and lymphoid infiltration did not show any significant prognostic role: on the contrary, the presence of marrow fibrosis > grade 0 was associated with an increased occurrence of thrombotic episodes during follow-up (P=0.020) and an increased rate of evolution in MP (P=0.040).
Summary / Conclusion: In conclusion, while the histological marrow evaluation is not required for the diagnosis of PV, the recognition of fibrosis seems to have a role in the prognostication of adverse events during follow-up and should be evaluated at baseline.

B1567

COMPARISON OF THE EXPRESSION CANCER-TESTES (CT) ANTIGEN PROFILES IN CML AND POLYCYTHEMIA VERA (PV).

V Misyurin[1*], A Misyurin[1,2,3], M Sokolova[4], A Krutov[1], L Kesaeva[1], I Soldatova[1], E Misyurina[1], A Mastchan[5], S Rumyantsev[5], A Rumyantsev[5], A Baryshnikov[2]
[1]Lab for Molecular Oncology and Genetic Engineering, Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, [2]N.N. Blokhin Russian Cancer Research Center, [3]GeneTechnology LLC, [4]Research Center for Hematology, [5]Federal Research and Clinical Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Since 1951 when W. Dameshek supposed closed interrelation within the group of myeloproliferative syndromes many things had happened and it turned out that CML differs from other similar diseases by presence of Ph-chromosome and BCR-ABL gene and that Jak2 V617F and a few other mutations are the molecular hallmarks of PV, ET and IMF. Nevertheless, all these diseases in some features are still quite similar notwithstanding our ignorance about exact causes of this similarity. Cancer-testis (CT) antigens almost universally express in different malignancies varying in frequency and intensity of expression of particular members of CT antigen family. We have supposed that CT antigen expression profiles may explain or at least further highlight molecular similarity and/or difference between CML and Ph-negative Jak2 V617F-positive chronic myelogenouse disorder (CMD).
Aims: To perform gene expression profiling of a number of CT antigens in CML and Jak2 V617F-positive polycythemia vera (PV).
Methods: In this study we used RQ PCR to analyze and compare mRNA expression of CT antigens SP17, GAGE1, HAGE, NY-ESO1, MAGE1, PASD1, SCP, SEMG, SLLP1, SPANXA, SSX1 and PRAME in blood cells. Quantitative analysis of expression level cancer-testis antigens was carried out relatively using the expression of a housekeeping gene ABL as endogenous control to compensate for irregular cell numbers.
Results: In blood of CML chronic phase (CP) primary pts (N=36) we observed HAGE1, SLLP1, SPANXA and PRAME gene expression with frequencies of 61,1% (22/36), 36,1% (13/36),2,8% (1/36) and8,3% (3/36), respectively. In case of Jak2 V617F-positive PV pts (N=33) we observed only HAGE1 (63,6%, 21/33), SLLP1 (84,8%, 28/33) and PRAME (12,1%, 4/33) gene expression. In contrast to CP of CML, expression frequency of SLLP1 and PRAME in PV samples was higher (84,8% and 12,1% against 36,1% and8,3%). Expression rate of HAGE gene in both diseases was generally similar (61,1% and 63,6%). Expression level of genes found in CP of CML did not differ significantly to compare with PV. We did not find mRNA expression both in CP of CML and PV: SP17, GAGE1, NY-ESO1, MAGE1, PASD1, SCP1, SEMG and SSX1. In AP&BC of CML we have observed additional expression of CT22 (14,4%, 1/7), MAGE1 (14,4%, 1/7) and GAGE1 (14,4%, 1/7) (Fig.1).
Summary / Conclusion: Our data suggest obvious similarity of CT expression profiles of CP of CML and Jak2 V617F-positive PV. This finding reflects clinical relation being observed among these two leukemias. Both CP of CML and PV differ in CT expression profile from CML in AP&BC.

Gene	CML (CP) %	CML (AP+BC) %	PV (JAK2-V617F) %
SSX	0	0	0
SCP1	0	0	0
SEMG1	0	0	0
NY-ESO-1	0	0	0
PASD1	0	0	0
CT22	0	14,4 (1/7)	0
GAGE1	0	14,4 (1/7)	0
MAGE1	0	14,4 (1/7)	0
SPANXA	2,8 (1/36)	14,4 (1/7)	0
PRAME	8,3 (3/36)	28,6 (2/7)	12 (4/33)
SLLP1	36 (13/36)	14,4 (1/7)	84,8 (28/33)
HAGE	61 (22/36)	28,6 (2/7)	63,6 (21/33)

Fig.1. CT antigen expression in CML and PV.

B1568

EFFICACY OF PEGYLATED INTERFERON IN MYELO-PROLIFERATIVE DISORDERS

S Mc Guckin[1*], J Westwood[1], J Lambert[1], M Scully[1]
[1]Haematology, University College London hospital, London, United Kingdom

Background: Pegylated Interferon (Pegasus) is an alternative treatment for patients with myelo-proliferative disorders (MPD), including polycythaemia vera (PV) and essential thrombocytosis (ET).
Aims: Review efficacy of Pegylated Interferon in Myeloproliferative Disorders.
Methods: We reviewed the use of Pegasus in 13 patients with MPDs (ET=10, PV=3) at a single institution over a 13 month period; 7/10 ET and 3/3 PV patients were JAK 2 V617F positive.
Results: 10/13 switched from existing therapies including Hydroxcarbamide, Anagrelide and 3x/week Interferon.We recorded: reasons for switching to Pegasus, starting dose, dose alterations, and any significant side-effects (including derangement in LFTs). Time to response was determined from sequential platelet/haematocrit readings. 5/13 patients (3 ET and 2 PV) commenced weekly Pegasus as a single therapy, of which 3 (all ET) were treatment naïve. The remaining 8 patients all had existing therapies withdrawn following initiation of Pegasus, completing the bridging period over 1 to 7 weeks. 1 ET patient remains on Hydroxycarbamide alongside Pegasus. Reasons for switching to Pegasus included: ease of weekly administration (n=2), planning to or being pregnant (n=4), side-effects of existing therapy (n=3), lower limb ulceration (n=1), non-response to current therapies (n=3). Prior to commencement of Pegasus, baseline median platelet count was 387 x10□/L (range of 173 – 1065x10□/L). Median platelet counts were 413 (124-889x10^9/L) at 1 month and 355 (109-740 x10^9/L) at 3 months after starting therapy. Doses ranged from 45µg every 2 weeks to 135µg/week. Within the PV group, there was no change in median haematocrit between baseline (0.50), 1 month (0.48) and 3 months (0.49). No reported side effects were noted, although 2/13 patients had a mean ALT rise of >90IU/L from baseline, following initiation of therapy.
Summary / Conclusion: Pegylated IFN appears a safe alternative approach in MPD therapy with prompt and sustained control of laboratory parameters.

B1569

HYPEREOSINOPHILIC SYNDROME: DIAGNOSTICS AND THERAPY. SINGLE CENTRE EXPERIENCE

I Nemchenko[1*], A Turkina[1], E Chelysheva[1], G Gusarova[1], A Misiurin[2], L Kesaeva[2], A Kovrigina[3], E Semenova[3], E Domracheva[4]
[1]Scientific Advisory Department of Chemotherapy of Myeloproliferative Disorders, Hematology Research Centre, [2]Molecular Genetics Laboratory "Genotechnology", [3]Department of Pathohystology, [4]Cytogenetical laboratory, Moscow, Russian Federation

Background: Hypereosinophilic syndrome (HES) is a group of rare diseases with persistent eosinophilia >1.5x10/L and organ imparement. It may be of non-neoplastic or neoplastic origin. If the cause of eosinophilia is not found the

HES is considered as idiopathic (IHES).
Aims: to represent our experience in diagnostic and therapy of myeloproliferative diseases (MPD) with eosinophilia and IHES with signs of MPD (myeloproliferative variant of IHES).
Methods: from 1985 to 2012 years there were 96 patients with HES followed up in our centre. The ratio of male and female was 72:24 and the median age was 38 (17 – 70). Diagnostic steps were directed to verify diseases with primary and secondary eosinophilia.
For the proof of the clonal MPD existence standard cytogenetic study and, from the 2003 year, the polymerase chain reaction (PCR) with FIP1L1-PDGFRA and ETV6-PDGFRB primers were applied.
Results: reactive eosinophilia was proved in 16% (14/96) cases: adrenal hemangiopericytoma – 1; multifocal liver damage unknown origin disappeared without cure –1, allergic reaction – 1; autoimmune diseases –8, T-cell lymphomas – 3. It is important to point that the first three cases of eosinophilia could be established postfactum only. The standard cytogenetic study was done in 80 and PCR was done in 61 rest cases of HES. Different chromosomal aberrations were found by G-banding only in 8% of cases (6/80) whereas PCR could prove clonality in 50% (30/61) of cases with HES. In most cases the FIP1L1-PDGFRA – gene expression was found (28/30). All the rest cases of HES with unestablished cause of eosinophilia were considered as idiopathic. In 19/46 cases there were signs of myeloproliferation and the syndrome was interpreted as myeloproliferative variant of HES. The therapy of clonal MPDs and myeloproliferative variant of HES included schemes with different cytostatics, alpha-interferon, hydroxyurea. From the 2003 we began to use imatinib at a dose 100-400 mg o.d. Complete hematologic response (CHR) was received only on imatinib and alpha-interferon. The effectiveness of imatinib was 87% (20/23) in cases PDGFRA- and PDGFRB-positive and 36% (4/11) in cases where PCR was negative or not done. In 14 of 15 cases the complete molecular response was received too. At a therapy with alpha-interferon CHR was received in 3 of 7 cases (43%). Neither chemotherapy no hydroxyurea allowed to get any sustained and prolonged result.
Summary / Conclusion: About 1/3 of HES cases are represented by clonal MPD to verify which a special methods such as PCR or FISH are required. In a small percent of HES the association eosinophilia with some diseases can be confirmed only after resolution of symptoms. If the target therapy is nonsufficient the possibilities of conservative therapy are limited. For the young patients is reasonable to conduct bone marrow transplantation.

B1570
USING MYELOPROLIFERATIVE NEOPLASM SYMPTOM ASSESSMENT FORM (MPN-SAF) TO EVALUATE QUALITY OF LIFE FOR PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA IN QATAR
M Yassin[1*], H Elayoubi[1], r kamzoul[1], N Eldewik[2]
[1]Hematology/BMT, National centre for cancer care and research, [2]qatar medical genetic centre, HMC, Doha, Qatar

Background: Myeloproliferative neoplasms (MPNs), that is, essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF) can lead to significant morbidity and mortality among affected patients. Specifically can be predisposed to thrombohemorrhagic events and vascular complications.progressive cytopenias, constitutional symptoms, cachexia , splenomegaly, and risk of blastic transformation
Aims: Symptomatic burden in (MPNs) is present in most of MPN patients we sought to use broadly applicable instrument (MPN-SAF) to assess symptoms in (ET) among populations of Qatar.
Methods: Using the MF-SAF as a base instrument, we added several key additional symptoms previously identified as present in all subtypes of MPNs including headaches, loss of concentration, dizziness, extremity tingling, insomnia,sexual problems and mood changes on a 0 (absent) to 10 (worst-imaginable) scale. The MPN-SAF was administered jointly with the EORTC-QLQ-C30 as the co-validation instrument using prospective cohorts in Qatar (Patients referred to National Centre for Cancer Care and Research).
Results: 123 MPN-SAF surveys were administered (English (45%), Arabic (55%) , 78 ET patients were JAK 2 V617F positive and 45patients were JAK2 V617F negative) an average of 3.6 years from their MPN diagnosis. Participants were of, age range (22 – 58 years) and gender (52% female) characteristic of disease. Prior hemorrhage (10%) and thrombosis (25%) 78% of patients currently received cytoreductive therapy. 19 items assessed in the MPN-SAF demonstrated consistently that the most common symptoms were decreased quality of life (93%), fatigue (84%), insomnia (65%), sad mood (65%), and sexuality problems (62%). The least common symptoms (<50% prevalence) were fevers (15%), weight loss (10%), abdominal pain (23%), cough (34%), headache (50%), and bone pain (48%) Interestingly, night sweats (present in 58%) The majority found the MPN-SAF easy to understand (90%) and "addressed most of my MPN symptoms" (93%). Comparison to EORTC-QLQ-C30: Strong correlations existed between individual items represented on both the MPN-SAF and the EORTC-QLQC30 including pain, fatigue, appetite and insomnia (all P<0. 001). Additionally key symptomatic elements were highly correlated with the EORTC QLQ-C30 functional subscales. Comparison to Physician Perceptions: Comparison of the results of the MPN-SAF to enrolling physicians' blinded opinion of patients symptoms (7 assessed - night sweats, fevers, fatigue, weight loss,and bone pain) showed excellent correlation with corresponding patients' responses (all P<0. 001). Serial MPN-SAF: Pearson correlations indicate that most MPN-SAF items are well correlated (r >0.5, P<. 001) upon repeat survey administration. Items characteristic of advanced disease, including weight loss, fever, and cough displayed lower Pearson correlations (r=0. 46, –0. 08, and 0. 38 respectively)
Summary / Conclusion: MPN-SAF is comprehensive and reliable instrument which is available in multiple languages (including Arabic and English) to evaluate MPN-associated symptoms. The MPN-SAF is recommended as a uniform symptom assessment tool for MPN patient

NB these data are part of project Sponsored by QNRF NPRP 4-471-31-48.

B1571
PREGNANCY MANAGEMENT AND OUTCOMES IN WOMEN WITH MYELOPROLIFERATIVE DISEASES
E Polushkina[1*], R Shmakov[1], M Sokolova[2], N Khoroshko[2]
[1]Obstetric Physiological Department, Federal State Budget Institution Research Center for Obstetrics, Gynecology and Perinatology Health Ministry of Russia, [2]Scientific Advisory Department of myeloproliferative disorders, Federal State Budgetary Institution Hematology Research Center of Health Ministry of Russia, Moscow, Russian Federation

Background: Myeloproliferative diseases (MPD) rarely occur in women of reproductive age. But in recent years it becomes more often that young women suffer from these diseases. The appearance of new drugs and therapeutic strategies provides good results in survival rate and life prognosis for patients. All this requires special options for management of pregnancy in women with MPD.
Aims: To develop the protocol of preconception planning and pregnancy management and to evaluate pregnancy outcomes and complications in women with MPD.
Methods: Retrospectively we have analyzed 41pregnancies in 21 women (group 1) who did not receive a special treatment of MPD. The prospective group (group 2) included 46 women who were treated according to our algorithm. Our trial included women with main MPD: essential thrombocythemia, polycythemia vera, primary myelofibrosis. Pregnancy management included examination of blood cell count and hemostasis system twice a month, besides this the inherited trombophylia testing, lupus anticoagulant, homocystein level, antiphospholipid syndrome diagnostics and hematologic examination including trepanobiopsy and JAK2V617F mutation. Besides thorough laboratory examination our protocol of pregnancy planning and management included cytoreductive therapy, antiaggregants, low-molecular-weight heparin, plasmapheresis, vitamins of group B. For the cytoreductive therapy we prescribed Interferon alfa which is the safest option in preconception planning and pregnancy management for women with MPD.
Results: Medical abortion was made in 3 (7,3 %) women, spontaneous miscarriages occurred in 65,8% in group 1 without special treatment. First and second trimester spontaneous abortions prevailed among all the miscarriages – 15 (36,6%) cases, stillbirth occurred in 10 (24,4%) cases. Preterm labor were in 14,6 % pregnancies, full-term delivery occurred in 17,1% of cases. Medical abortion was made in 2 (4,3%) women of group 2. Spontaneous miscarriages occurred only in4,5% in the group of women who were treated according to our protocol (2 pregnancies). Five (10,9%) pregnancies ended preterm, while 37 (80,4%) labor were fill-term (*P*=0,000001, OR – 0,07; 95% C.I.: 0,018;0,232). Pregnancy was uncomplicated in 2 (15,4%) and 14 (33,3%) cases in 1 and 2 groups respectively. The most often pregnancy complications were threatening miscarriage - 10 (76,9%) and 22 (52,4%) cases, anemia – 4 (30,8%) and 13 (31%) in 1 and 2 groups respectively. Placental insufficiency complicated 30,8% pregnancies including intrauterine growth retardation (IUGR) in 2 cases in group 1. Although all pregnancies in group 2 were carefully observed and treated 11,2% of them were complicated by placental isufficiency with IUGR in 3 (10,3%) cases.
Summary / Conclusion: Thus pregnancy losses in women suffering from MPD occur in 65,8% without special treatment and complications of pregnancy – in 84,6% cases. The development of protocol for preconception planning and pregnancy management resulted in considerable decrease in miscarriages to4,5% (*P*=0,000005, OR – 24,2; 95% C.I.:4,8;225,9) and a tendency of lowering of pregnancy complications to 66,7% (P=0,5).

B1573
COMMON COMMUNITY INFECTIONS AND THEIR ASSOCIATION WITH MYELOID MALIGNANCIES
G Titmarsh[1*], M McMullin[2], C McShane[1], M Clarke[1], E Engels[3], L Anderson[1]
[1]Centre for Public Health, Queen's University, [2]CCRCB, Belfast, United Kingdom, [3]National Cancer Institute, Bethesda, United States

Background: Antigenic stimulation precedes many haematological malignancies. Limited evidence suggests that community acquired infections may increase risk of acute myeloid leukaemia (AML) and myelodysplastic syndrome (MDS). However, associations between community infections and chronic

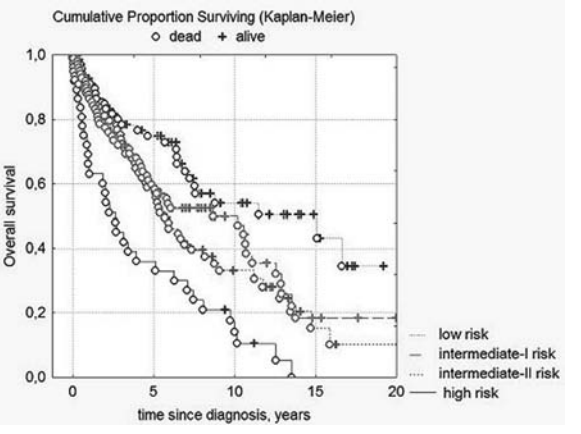
myeloid leukaemia (CML) and myeloproliferative neoplasms (MPNs) have not been investigated.
Aims: Using the SEER-Medicare database, fourteen common community acquired infections were compared between myeloid malignancy patients AML (n=8,489) and CML (n=3,626) diagnosed 1991-2005; MDS (n=3,072) and MPN (n=2,001) diagnosed 2001-2005) and controls (200,000 for AML/CML and 97,681 for MDS/MPN patients).
Methods: Odds ratios (ORs) and 95% confidence intervals were obtained using polytomous logistical regression with adjustment for gender, age and year of diagnosis/selection. Multiple comparisons were considered using Bonferroni correction and significant associations analysed over select time periods.
Results: Respiratory tract infections, including bronchitis (ORs 1.20, 1.25), influenza (ORs 1.16, 1.41), pharyngitis (ORs 1.13, 1.22), pneumonia (ORs 1.28, 1.52), sinusitis (ORs 1.23, 1.25) were associated with AML and MDS, respectively. Cystitis (ORs 1.13, 1.26), cellulitis (ORs 1.31, 1.51) and herpes zoster (ORs 1.18, 1.31) were associated with both AML and MDS respectively while gastroenteritis (OR 1.38) was only associated with MDS. Bronchitis (OR 1.21), pneumonia (ORs 1.49), cellulitis (ORs 1.43) and sinusitis (OR 1.19) were associated with CML while cellulitis (OR 1.34) was the only infection associated with MPNs. Claims for most infections occurred 31-72 months preceding diagnosis although several remained significant >72 months preceding diagnosis.
Summary / Conclusion: Stronger associations between community acquired infections and AML/MDS were observed compared to CML/MPNs indicating that chronic antigenic stimulation may be important in the malignant transformation of immature blood cells of myeloid lineage.

B1574
INTERLEUKIN-8 LEVELS IN ESSENTIAL THROMBOCYTHEMIA: CLONAL OR INFLAMMATORY TRIGGER?
E Cacciola[1*], A Cipolla[1], E Di Francesco[1], E Seria[1], M Torre[1], R Cacciola[1]
[1]Clinical and Molecular Biomedicine, Institute of Haemostasis, Catania, Italy

Background: The patients with essential thrombocythemia (ET) overproduce proinflammatory cytokines known to promote the hematopoiesis, such as interleukin-8 (IL-8). The JAK2V617F mutation expressing cells are featured by an inherited hypersensitivity to cytokine stimulation.
Aims: Therefore, we evaluated platelets, red blood cell (RBC), haemoglobin (Hb) concentration, hematocrit (HCT) and white blood cell (WBC), as myeloproliferative markers, fibrinogen (Fg) and C-reactive protein (CRP), as inflammatory indicators, JAK2V617F mutation and IL-8.
Methods: We recruited 50 patients with ET who fulfilled WHO criteria. Their mean duration of disease was 10 years (range, 5-20 years). Of 50 ET patients, 25 were JAK2V17F mutated (11 males and 14 females, mean age 59 years) and 25 were JAK2V617F WT (9 males and 16 females, mean age 58 years). All patients were on aspirin.
Results: The JAK2 mutated patients had higher platelets, RBC, Hb, HCT and WBC (909±253x109/L, 5.42±7x106/L, 15.2±1.7 g/dl, 46±4%, 11±2.7x109/L) than JAK2 WT patients (753±129x109/L, 5±7x106/L, 12±2 g/dl, 39±3%, 7± 1.5x109/L) (P=0.009, P=0.001, p <.0001, p <.0001, p <.0001), whereas the JAK2 WT patients had higher Fg and CRP (414±3 mg/dl and 6±1 mg/L) than JAK2 mutated patients (286±37 mg/dl and 0.8±1 mg/L) (p <. 0001 and p <.0001, respectively). The JAK2 mutated patients and JAK2 WT patients had elevated IL-8 (274±158 pg/ml and 222±90 pg/ml, respectively).
Summary / Conclusion: On basis of these results it is conceivable that IL-8 may represent the clonal or inflammatory counterpart in mutated and WT patients, respectively. Hence, IL-8 may be an unfavourable prognostic index in mutated ET patients.r

B1575
PRIMARY MYELOFIBROSIS – A SURVEY BASED ON THE 20-YEARS' EXPERIENCE OF A SINGLE CENTER
V Shuvaev[1*], A Abdulkadyrova[1], V Udaleva[1], R Golovchenko[1], I Zotova[1], I Martynkevich[1], L Martynenko[1], M Ivanova[1], N Cybakova[1], E Petrova[1], M Kozlovskaya[1], M Fominykh[1], K Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: As a result of advances in decryption of molecular mechanisms of pathogenesis and invention of target drugs, the chronic myeloproliferative diseases including primary myelofibrosis (PMF) undergo the renaissance of interest nowadays. The information about historical control is needed to assess potential effect and additional costs of new diagnostic and therapeutic technologies.
Aims: The objective of our study was to review the experience of PMF diagnostic and treatment in our center for the past twenty years.
Methods: Our institution has a primary hematological outpatient department which works for about a half of Saint-Petersburg city inhabitants – that is about 2.4 million people.We reviewed patients' charts to obtain information about incidence, symptoms, diagnostic test results, treatment options and relationship to prognostic factors. Statistical methods included descriptive and Kaplan-Meyer method with log-rank test for survival comparisons in Statistica 7.0 package.



Results: Since 1993 to 2012 there were 296 newly diagnosed PMF patients in our center. This yields stable incidence varied from 0.76 to 1.56 with mean of 1.06 new patient per 100 000 inhabitants per year. The age interval was between 16 to 83 years with median of 62 years. The gender ratio was nearly 2:1 as female:male (192 females and 104 males).The most prevalent symptoms of disease were: splenomegaly (71.4%), constitutional symptoms (fever, night sweats, weight loss) (33.3%), thrombosis 25.4%, portal hypertension (5.1%) with esophageal variceal bleeding (1.6%). The most common lab abnormalities were leukocytosis (80%), thrombocytosis (69.5%), anemia (39.3%), and thrombocytopenia (10.2%). Bone marrow fibrosis as histological findings as grade 0 (prefibrotic stage) were noted in 26.7%, grade 1 in 20%, grade 2 in 29.2% and grade 3 in 24.2% of patients. Cytogenetic banding analyses were performed in 76 cases. Normal karyotype was revealed in 72.4% cases, no mytoses had been obtained in 7.9%. Cytogenetic abnormalities were in 19.7% patients with trisomy 8 and complex karyotype as most frequent (13.3% of whole clonal abnormalities for each). JAK2V617F was detected in 50 of 101 (49.7%) examined patients. In addition MPLW515L mutation was revealed in 1 patient. The results of stratification by IPSS/DIPSS+ risk score were the following: low-risk 27.0%/25.7%, intermediate-I - 38.4%/35.9%, intermediate-II – 14.3%/26.0%, high-risk – 20.3%/12.4%. Patients were treated mainly with hydroxycarbamide monotherapy or in combination with other drugs in 81.9% cases, interferon was used in 21.0%, glucocorticoids were used in 11.1% patients. Overall 10-years survival of patients was 44.4% with median of 7.6 years. Blastic transformation occurred in 5.7% patients with median time to blast crisis as of 5.1 years. Overall survival highly significantly influenced by risk stratification as IPSS and DIPSS+. Survival curves according DIPSS+ groups are presented in fig.1.
Summary / Conclusion: PMF is one of the most common hematological malignancies with reduced life duration. Risk stratification systems had high predictive value. Introduction of innovative drugs should be evaluated in comparison with historical control.

B1576
100 MG WEEKLY IMATINIB MAINTENANCE THERAPY IS SUFFICIENT TO SUSTAIN THE MOLECULAR RESPONSE IN PATIENTS WITH CHRONIC EOSINOPHILIC LEUKEMIA
W Prejzner[1*], A Leszczynska[1], A Hellmann[1]
[1]Department of Hematology and Transplantology, Medical University of Gdansk, Gdansk, Poland

Background: CEL is a rare myeloproliferative neoplasm with prominent eosinophilia and presence of a FIP1L1- PDGFRA gene. This fusion gene is much more sensitive to imatinib than BCR-ABL gene, and usually a dose of 100 mg daily is sufficient to achieve response to therapy and molecular remission in most of CEL patient. This imatinib dose is used in induction and maintenance therapy.
Aims: Is the imatinib dose of 100mg weekly sufficient to maintain molecular remission in patinets with CEL?
Methods: 5 patients were diagnosed at the Department of Hematology and Transplantology Medical University of Gdansk. All patients are male and diagnosed was confirm by the presence of FIP1L1-PDGFRA gene detected by the PCR. The median age at diagnosis was 47 (range 39-64) . At the diagnosis median number of WBC was 16 G/L (10,3-29 G/L) and median eosinophils count was 9,2 G/l (5,36-12,0 G/l). Spleen was enlarged (palpable below costal margin) in 3 of 5 patients.

Results: The normalization of eosinophils was achieved at the 25 days (mean value) after starting of induction imatinib therapy. Duration of induction therapy was at least 3 months Confirmation of complete molecular response was performed 3-12 months after starting the imatinib therapy. After normalization of eosinophils count and achieving of molecular response maintance therapy was started (imatinib 100 mg weekly). Confirmatory blood count was performed every 3 months and molecular analysis was performed every 6-12 months. All performed blood count showed normal eosinophils count and nested PCR was negative for the FIP1L1/ PDGFRA gene during maintenance therapy in all patients.
Summary / Conclusion: As the maintenance therapy, imatinib 100mg weekly is effective to sustain the molecular remission in patients with diagnosed CEL.

B1577

A RETROSPECTIVE ANALYSIS ON THE IMPACT OF PROGNSOTIC FACTORS IN 362 PATIENTS WITH PRIMARY MYELOFIBROSIS FOLLOWED IN THE LAZIO REGION DURING A 20 YEARS FOLLOW-UP PERIOD

S Mecarocci[1*], A Rago[1], R Latagliata[2], A Andriani[2], M Cedrone[2], L Annino[2], A Spadea[2], M Breccia[2], M Montanaro[2], N Villivà[2], S Crescenzi[2], R Porrini[2], E Montefusco[2], M De Muro[2], G Avvisati[2], F Spirito[2], A Bagnato[2], G Alimena[2], G Cimino[1]
[1]Sapienza University, Iatina, [2]On Behalf of the Gruppo Laziale SMPC, Ph1 neg, roma, Italy

Background: Primary myelofibrosis (PMF) is a rare chronic myeloproliferative disorders characterized by a heterogeneous clinical presentation, a relatively shortened survival and a propensity to develop acute myeloid leukemia (i.e. blast phase).
Aims: To correlate the clinic-biologic features at presentation with risk of blast phase evolution, we retrospectively collected the clinical records of 362 patients followed in 12 hematologic units of the Latium region and diagnosed between 1981 and 2010.
Methods: Diagnosis was made according to the criteria accepted at the time when the patient was diagnosed. Two hundred-nine (65%) patients were males, 153 females (38%) (M/F= 1.4). Patients mean age was 67 years. Hb < 10 g/dl was present in 85/274 (31%) of patients. Eigtheen/270 (6.6%) patients presented a WBC count >25 x 10^9/L. The presence of Jak2V617F mutation was checked in 143 patients. However, only 83 patients had JAK2 V617 mutation assessed within 1 year from diagnosis. Among these 83 patients 51 (61%) were JA2V617F-positive. 224 (62%) patients received conventional chemotherapies.
Results: At time of analysis, 180 patients were alive, 137 dead and 45 lost to follow-up. With a median follow-up of 48.4 months (range: 1-252) the actuarial survival rates at5, 10 and 20 years were 70%, 35 % and 22%, respectively. Forty-two of 362 patient (11.6%) progressed to a blast phase after a median time from diagnosis of 92 months (range: 2-250 months) for a cumulative incidence rate of 13%, 28% and 28% at5, 10 and 20 years, respectively. At univariate and multivariate analyses only Hb < 10 gr/dl and presence of blasts (>1%) resulted the only independent prognostic factors significantly affecting the blast phase occurrence. JAK2 V617F did not impact on progression to blast phase. A score system combining these two factors (score 0= none; score 1= 1 of the 2 factors; score 2 = both factors) significantly discriminate patients at high, intermediate and low risk of evolution to blast phase (Figure 1).
Summary / Conclusion: In conclusion, our retrospective analysis on a large series of patients demonstrates that progression to blast phase of PMF patients may be predicted by a score system that includes anemia and presence of blasts. These latter are easily and worldwide detectable parameters able to help risk stratification and decision making for PMF patients, an issue that has became extremely relevant in light of the forthcoming availability of the new targeted drugs.

B1578

THE ASSOCIATION BETWEEN JAK2 46/1 HAPLOTYPE AND SUSCEPTIBILITY TO MYELOPROLIFERATIVE NEOPLASMS

J Ouyang[1*], X Feng[1], M Zhou[1]
[1]Hematology, the DrumTower Hospital of Nanjing University Medical School Nanjing China, Nanjing, China

Aims: To investigate wether JAK2 46/1 haplotype was the genetic susceptibility gene for MPN patients and the relationship between JAK2V617F and 46/1 haplotype.
Methods: MALDI-TOF MS was used to analyze two tag SNPs (rs10974944, rs12343867) of JAK2 46/1 haplotype in 77 MPN patients with known JAK2V617F status and 92 healthy persons as control.
Results: The 46/1 haplotype in genotype distribution between the two groups had a statistically significant difference (P <0.05); Individuals carrying at least one variant allele, compared with the wild-type individuals, had an significantly increased risk of MPN by 2.31 times[the OR (95% CI) were 2.31 (1.21-4.39) and 2.31 (1.2-4.47)];While the MPN risk of people carrying the variant homozygotes was increased by 7-9 times[the OR (95% CI) were 7.54 (2.27-24.99) and 8.9 (2.69-29.42)]. Genotype distribution difference between the JAK2 V617F-negative group and positive group was statistically significant (P <0.05). The V617F-negative group and control group did not exist a statistically significant difference (P> 0.05),while the distribution between the JAK2 V617F-positive group and control group had a significant difference (P <0.05). The test of peripheral blood cell levels by single factor analysis of variance showed that the average blood cell levels of patients with 46/1 haplotype mutation compared with that of wild-type patients, white blood cells increased significantly (11.5608/11.5008 vs. 15.3108/16.3779, P <0.05) while neither hemoglobin nor platelet levels between two groups had a significant difference (P> 0.05).
Summary / Conclusion: Our results indicate that the 46/1 haplotype mutation contributes significantly to the occurrence of MPN in populations in Nanjing region of China.

B1579

PRIMARY AUTOIMMUNE MYELOFIBROSIS: REPORT OF TWO CASES

N Bru[1*], R Vallansot[1], C Talarn[1], M Cervera[1], R Aguinaco[1], T Gimenez[1], J Do Nascimento[1], L Sisinni[1], L Calvente[1], L Escoda[1]
[1]Haematology, Hospital Universitari Joan XXIII, Tarragona, Spain

Background: Primary Autoimmune Myelofibrosis (PAIMF) is a rare disease characterized by pancytopenia, mild leukoerythroblastosis, isolated serological immune abnormalities and no splenomegaly. Differential diagnosis include idiopathic myelofibrosis, immune myelofibrosis associated with other disorders, particularly sistemic lupus erythematous (SLE) and secondary myelofibrosis.
Aims: To describe clinical features, diagnosis and outcome of two patients with PAIMF at our institution.
Results: Case 1. A 53 year old female with no relevant medical history was admitted because of several weeks of progressive asthenia and pancytopenia. Isolated bruising in the legs were present and no splenomegaly was found. The haemogram showed leukocytes 3.3 x10^9/L (ANC 1.2x10^9/L), Hb 10.5g/dL, Hct 29%, Platelets 42x10^9/L. The immune panel revealed positive anti-nuclear antibodies 1/40 in a mottled pattern and polyclonal hipergammaglobulinemia. JAK-2(V617F) was negative. Paroxysmal nocturnal hemoglobinuria (PNH) was ruled out by flow cytometry. Bone marrow trephine biopsy showed normal morphology and distribution of haematological lineages with megakaryocytes precursors surrounded by reticulinic fibrosis. Methylprednisolone at 1 mg/kg/d was initiated with a rapid improvement of clinical symptoms, reaching normal haematological values within 4 weeks of treatment. Prednisone was discontinued after 4 months and the patient remained asymptomatic, with normal haemogram until last follow up, 14 months after treatment discontinuation.
Case2. A 76 year old female with a history of hypertension and diabetes mellitus was admitted because of constitutional symptoms and pancytopenia. At physical examination she was pale with no splenomegaly. The haemogram showed leukocytes 2.61x10^9/L (ANC 1x10^9/L with Dhöle bodies and mild leukoerythroblastosis), Hb 6g/dL, Hct 19%, Platelets 94x10^9/L. The immune panel revealed positive anti-nuclear antibodies 1/40 in a mottled pattern. JAK-2(V617F) was negative and PNH was ruled out by flow cytometry. Bone marrow aspiration was dry tap and trephine biopsy showed hypercelularity with isolated groups of small megakaryocytes and areas of reticulinic fibrosis. Methylprednisolone at 1 mg/kg/d was initiated with rapid improvement of clinical symptoms, reaching normal haematological values within 3 weeks. After 2 months treatment was discontinued and the patient remained asymptomatic with normal haemogram until last follow up 5 months after treatment discontinuation.
Summary / Conclusion: PAIMF is an infrequent and benign disease that should be distinguished from other disorders having myelofibrosis. The main difference with idiopathic myelofibrosis is mild leukoeritroblastosis without marked teardrop poikilocytosis in peripheral blood, lack of clustered or atypical megakaryocites in bone marrow and absence of splenomegaly. PAIMF should also be distinguished from myelofibrosis associated with immune disorders, mainly SLE. In cases of co-existing SLE or other immune disorders, combined immunosuppressive agents are usually necessary. Due to the excellent response to corticosteroid therapy, empirical treatment should be considered to patients with *atypical* myelofibrosis.

B1580

CLINICAL-BIOLOGICAL CHARACTERISTICS AND RISK FACTORS ASSOCIATED TO PROGRESSION IN A SERIES OF MYELOFIBROSIS PATIENTS IN A SINGLE CENTER: VALIDATION OF DIPPS-PLUS PROGNOSIS MODEL

S Cancio[1*], J Torregrosa[1], F Ortuño[1], A Jerez[1], G Ortuño[2], Vi Vicente[1], F Ferrer-Marín[1]
[1]Hematology and Clinical Oncology, Hospital Universitario Morales Meseguer, [2]Pathology Department, Hospital Universitario Reina Sofía, Murcia, Spain

Background: Identification of myelofibrosis (MF) patients with expected shorter survival is important for appropriate decision making. For risk stratification, it is recommended to use International Prognostic Scoring System (IPSS) at diagnosis and Dynamic-IPSS (DIPSS) anytime during the disease course. Marked inter-patient variability within IPSS and DIPSS risk groups has been

observed, suggesting a potential role of other risk factors. Incorporation of 3 other factors into the DIPSS-plus scoring system was based on single institution data, which warrant further validation.
Aims: The aim of this study was to analyze the factors associated to disease progression and evaluate whether the new DIPSS-plus prognosis model can be validated in our independent dataset.

Table 1	N
Median age (range)	67 (37-84)
Male/female	14/12 (54/46%)
Symtoms and signs:	16 (61%)
• asymptomatic	10 (38%)
• anemia	10 (38%)
• constitutional syndrome	6 (23%)
• symtomatic splenomegaly	5 (19%)
• palpable splenomegaly	16 (61%)
Hb, g/dL*	11.15 ± 2.47
WBC, x 10^9/L*	13.35 ± 10.49
Platelets, x 10^9/L*	445 ± 284
High LDH levels	23 (88%)
Circulating CD34+,mcL*	102 ± 105
JAK2V617F available	22 (84%)
JAK2V617F/JAK2wt	12/10 (55%/45%)

*Mean ± SD

Methods: All patients consecutively diagnosed in our center of MF according to WHO criteria since 2000 were eligible. Clinical-biological characteristics at presentation and complications during evolution were registered. Based on EUMNET criteria, progression was defined as appearance of constitutional symptoms; or, decrease of Hb ≥ 20 g/L, transfusion requirement for non-transfusion-dependent patients, or increase ≥ 50% of transfusion requirement; or, substantial increase of spleen size; or leukemic transformation. Association between progression and factors at presentation such as grading of bone marrow fibrosis, splenomegaly, LDH, Jak2V617F, circulating CD34+ cells in peripheral blood (PB), unfavorable cytogenetic (CG), anemia, constitutional symptoms, DIPPS and DIPPS-plus risk scale were evaluated by X2 test. Progression free survival (PFS) and overall survival (OS) analysis was carried out with the Kaplan-Meier method. The log-rank test and Cox regression were applied for univariate and multivariate analysis, respectively.
Results: 26 patients were included. Patients´ characteristics at presentation are shown in Table 1. CG analysis were available in 23 cases: standard risk in 87% of the evaluable cases (normal: n=15; del 20q: n=3; del 13q: n=2) and unfavorable risk in the other 13% (+8: n= 2; -5: n=1). Almost 80% of the patients were treated with hydroxyurea and 69% (18/26) did not have any complication. The other 8 patients had different complications including new thrombotic (n=2) or hemorrhagic (n=5) events, infections (n=1), other neoplasms (n=1) or progression (n=5, 2 because of leukemic transformation and the other 3 because of marrow failure). Two factors associated to disease progression: constitutional symptoms (P=0.01) and CD34+ cells in PB (174±100/uL vs 79±90/uL, P=0.08). PFS was 88 months (range 72-103). Due to sample size, we grouped patients in two groups for DIPPS-Plus: Low+Intermediate (Int)-1 vs Int-2+High Risk. Applied at the time of diagnosis, DIPPS-Plus was predictive of PFS (105±4 in low/Int-1 vs 69±13 months in Int-2/high risk, P=0.01). Univariate analysis of the weight of each variable in DIPPS-Plus showed that constitutional symptoms, leukocytosis >25x10^9/L and transfusion requirement are predictive of shorter PFS. In the multivariate analysis, however, only the presence of constitutional symptoms and leukocytosis >25x10^9/L bordered statistical significance. OS was 76 months (range 57-96). An association between risk increases in the DIPPS-Plus model and decrease in OS (91, 86, 74 y 34 months for low, int-1, int-2 and high risk respectively) was observed.
Summary / Conclusion: Our data suggest that DIPSS-plus prognosis model can classify patients into categories with a different PFS, when applied either at diagnosis or throughout disease evolution.

B1581
TWO CASES OF JAK2 V617F-NEGATIVE PV WITH THE N542-Z543DEL MUTATION IN JAK2 12TH EXON.
L Galán[1*], J Nieto[1], F De La Fuente Gonzalo[1], P Gradilla[1], F Fernández[1], A Villegas[1,2], M Zarzuela[1], E Mandly[1], S Redondo[1], H Saccomani[1], J Vázquez Paganini[1], G Gómez[1], J Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]on behalf of Spanish Erithropathology Group, Madrid, Spain

Background: The discovery of V617F mutation in Janus kinase gene (JAK2) revolutionized the classification and diagnosis of BCR/ABL-negative chronic myeloproliferative disorders (BCR/ABL- CMPDs), which includes polycythemia vera (PV), essential thrombocytosis (ET) and primary myelofibrosis (MF). Nevertheless, in a great number of cases, these pathologies exist in absence of this mutation, so it must be other alterations related with their origin and development. It has been demonstrated that mutations in 12th exon of JAK2 are involved in the PV development. Until date, 37 different mutations has been found in the adjacent region to pseudokinase domain of JAK2 (JH2), all of them curses with a PV phenotype similar to that caused by JAK2 V617F mutation.
Aims: Description of two cases of JAK2 V617F-negative PV with a mutation (n542-z543del) in JAK2 12th exon.
Methods: We studied 29 patients diagnosed as PV according to the WHO criteria (2008). Hematological data were obtained with a hematologic counter (Coulter LH750).

PATIENT	SEX	Age at diagnosis	Risk factors	Hb (g/dL)	Ht (%)	RBC (x10^6/L)	Platelets (x109/L)	WBC (x109/L)	EPO (mU/mL)	JAK2 V617F	JAK2 exon12

Table 1: Clinical data of patients. Where Hb= Hemoglobin, Ht= Hematocrit, RBC= Red blood cells, WBC= White blood cells, EPO= Erythropoietin, JAK2= Janus Kinase2, n/d= not determinated *=Out of normal range. [Normal ranges for Female (12.0 - 16.0 g/dL; 36 – 46%; 3.5 - 5.5 x10^6/L, 150-400 x109/L, 4-12 x109/L, 5-30 mU/mL) and Male (13.5 - 17.5 g/dL; 41– 53%; 4.3 - 5.9 x10^6/L; 150-400 x109/L; 4-12 x109/L, 5-30 mU/mL)]. In "Others" the values shown are the average of individual parameters ± their standard deviations.

To determinate the presence of the JAK2 V627F mutation a PCR-ARMS was performed with DNA from whole blood obtained by manual methods (salting out). In some cases in which the mutation was not found, due to clinical evidences (like low erythropoietin levels), we sequenced JAK2 12th exon, using the same biological source, but employing an automatic method for the extraction (Biorobot EZ1). Automatic sequencing was performed following the supplier's instructions in an ABI PRISM® 3100 Genetic Analizer sistem.
Results: From all cases studied, 23 of them (79.3%) showed the JAK2 V627F mutation, 2 (6.9%) carries alterations in the 12th exon of the same gene (in both cases, the n542-z543del deletion in heterocygotic state, previously described by Scott et al. 2007) and in 4 cases (13.8%) any of the mutations studied were found. Clinical features of these patients are summarized in the attached table; they shown middle age at diagnosis (35-50 years), low erythropoietin (EPO) levels, hemoglobin (Hb), hematocrit (Ht) and erythrocyte count (RBC) values over the normal range but no splenomegaly neither thrombotic events.
Summary / Conclusion: The 86,2% of patients diagnosed as PV carried mutations in JAK2 (23 V617F + 2 n542-z543del). Both mutations affect the function of JH2 domain, which loses their regulatory function on the catalytic domain, being constitutively active and over activate their related molecular pathways. This explains, at least in part, the features of the disease.
So, is not strange that the phenotype caused by both mutations was similar but, in cases with exon12 mutations, the age at diagnosis was lower and the hematological parameters a little higher (with predominant erythrocytosis). These data are consistent with those founded in the literature.
Furthermore, there are four cases where mutations studied were not found, but showing a clear PV phenotype (so, it must be caused also by other molecular alterations in JAK2 or other genes). These facts show that other mutations in adition to JAK2 V617F, even if minorities should have a great importance in CMPDs. That might explain phenotypic differences between patients and forms of the disease (PV, ET, MF) and their implications in the clinical, diagnosis and treatment of the CMPDs must be studied more deeply.

PHILADELPHIA CHROMOSOME - NEGATIVE MYELOPROLIFERATIVE DISEASES AND GASTROINTESTINAL BLEEDINGS
E Simonovic[1*], L Macukanovic/Golubovic[2], M Mirjana[1], V Colic[1]
[1]Internal, General Hospital Leskovac, Leskovac, [2]Internal, Clinic of Haematology, Nis, Serbia

Background: Philadelphia chromosome-negative chronic myeloproliferative diseases (CMPD) are a group of malignant clonal diseases of hematopoietic stem cells, which are characterized by an overgrowth of one or more blood lines with normal or nearly normal maturation of those cells in the bone marrow and extramedullary hematopoietic organs. In dependence on the dominating type of cells, morphological and clinical characteristics, we include in this group the following diseases: 1) Polycythemia vera (PV); 2) Agnogenic myeloid metaplasia with myelofibrosis or idiopathic myelofibrosis (IMF); 3) Essential thrombocythaemia (ET); 4) Myeloproliferative diseases that cannot be classified (MPS).
Aims: The aim of the paper is to determine what is the incidence of gastrointestinal bleedings in patients with chronic myeloproliferative disorders.
Methods: The investigation included 155 patients of both sexes aged between 17 and 83 years with a diagnosis of CMPD. Patients with a diagnosis of CMPD are divided into four groups. We used methods of clinical examination, labora-

tory tests, ultrasound examination of the abdominal organs and esophagogastroduodenoscopy and rectosigmoidoscopy.
Results: Gastrointestinal symptoms (nausea, urge to vomit, abdominal pain, feeling of satiety) were found in 36.99% of patients with CMPD. The highest percentage of gastrointestinal symptoms was observed in patients with IMF (46.15%), while in the other group recorded percentage was significantly less, but not statistically significant. The presence of various forms of gastrointestinal bleeding (melena, hematochezia, hematemesis) were observed in less than one fifth of patients with CMPD (19.18%). The highest percentage of bleeding was originating from the proximal gastrointestinal tract (80.2%), as a result of gastric and duodenal ulcers. Only 18.8% of bleedings were from the distal part of the gastrointestinal tract. In groups with PV, ET, between 30 and 40% of patients were with ulcer disease that was significantly higher in comparison to those with IMF and MPS ($p < 0.001$). The highest percentage was in patients with PV, and immediately after them are those with ET. Patients with PV had an increased incidence of peptic ulcer disease, caused by the thrombosis of small arteries in the mucous membrane of the stomach and intestines, the effects of gastric juice, which is almost always hyperacid in those patients, basophilia and hyperhistaminemia.
Summary / Conclusion: Our investigations have shown an increased incidence of gastrointestinal bleedings in patients with true polycythemia, but also a significantly higher incidence of those complications in patients with essential thrombocythemia.

USE OF RADIO-ACTIVE PHOSPHORUS (P 32) IN THE MANAGEMENT OF POLYCYTHAEMIA RUBRA VERA (PRV) AND PRIMARY THROMBOCYTHAEMIA (ET) IN EAST KENT UNIVERSITY HOSPITALS NHS TRUST (EKUFHT) UK (01/01/2008 – 31/12/

S Alhassan[1*], I Dharmasena[1], j lindsay[1], c pocock[1], r senthiraman[1], g shabo[2]
[1]Haematology, [2]Nuclear Mdicine, East Kent University Foundation Hospitals NHS Trust, Canterbury, United Kingdom

Background: : As per the British Committee for Standardisation of Haematology (BCSH) guidelines for ET and PRV published in 2010 and 2005 respectively, P32 therapy is effective in controlling blood counts with few acute side effects. The usual dose is 150-300MBq, and can be repeated after 3 months. The use of P32 is recommended as second line therapy in those who are older than 70 years who fail to respond to or are intolerant of the first line therapy (hydroxycarbamide). P32, the radioactive isotope of Phosphorous, had long been successfully used in treatment of myeloproliferative disease, namely PRV and ET. It is a pure beta emitting radionuclide with a physical half-life of 14.3 days, given intravenously or orally in aqueous solution. It is actively incorporated into the nucleic acids of rapidly proliferating cells, thus suppressing hyperproliferative cell lines rather than eradicating them. Early side-effects of transient leucopoenia and thrombocytopenia are observed. The late potential for leukaemogenicity is a risk but its incidence is comparable to that associated with the chemotherapeutic agents commonly used in management of these conditions. (EANM procedure guideline for ^{32}P phosphate treatment of myeloproliferative diseases; Eur J Nucl Med Mol Imaging (2007)34:1324-27)
Aims: To audit the efficacy of radio-active phosphorus(P32) in the management of PRV and ET and the impact on the haematology out-patient clinic case-load in EKUFHT.
Methods: Data regarding the total number of episodes, Sex and Age group was collected via the Patient Administration System (PAS) of EKUFH NHS Trust. Data regarding the original diagnosis and outcome was collected from the APEX system used in the pathology department of EKHUFHT and from outpatient clinic letters. Response was assessed using the following criteria: Complete Response (CR) = HCT < 0.450 + Platelet count <600X10^9/L at 3-6 months post P32 injection + Not on any cytotoxic drugs OR venesection OR Interferon-alpha OR Anagrelide + being considered for discharge from clinic; Partial Response (PR) = reduced dose of cytotoxic therapy OR reduced frequency of venesections OR on Anagrelide/Interferon alpha (alone/in combination).No Response (NR) = No change in management plan.
Results: Between 01/01/2008 – 31/12/2012 there were 43 episodes (21 male/22 female) of usage of radio-active phosphorus (P32) in EKHUFT (23 (53.5%) episodes for treatment of PRV and 20 (46.5%) episodes for treatment of ET). 25 (58.1%) episodes were CR, 8 (18.6%) were PR and 10 (23.3%) were NR. This led to 18 episodes of discharge from the haematology out-patient clinics (41.9% of the total episodes).
Summary / Conclusion: Radio-active phosphorus (P32) is an effective modality of treatment for those over 70 years of age with a diagnosis of PRV or ET, which reduces/abolishes outpatient clinic attendance; thus contributing to improved quality of life.
