Background: Idiopathic hypereosinophilic syndrome (HES) is a rare diagnosis with a poor prognosis. Management of HES is challenging due to heterogeneous clinical presentation. Complications include haemorrhage, thrombosis, multi-organ failure, rapid clinical deterioration and death. Thromboses can vary from ischemic colitis, sinus thrombosis to DIC and TTP (Ohguchi ,2009).There is an urgent need to control the eosinophil count and prevent thrombosis and haemorrhage. Conventional treatment includes steroids, hydroxycarbamide and interferon-alpha. Several case reports document the utility of cytotoxic agents such as AraC either alone or in combination.
Aims: We describe two cases of HES with eosinophil counts > 100x10^9/L highlighting diagnostic and management challenges.
Methods: CASE 1: 60 year old female on rivaroxaban thromboprophylaxis post knee replacement presented with swelling and discolouration of her right leg. Ultrasound Doppler was negative for a deep vein thrombosis. DVT was excluded and intramuscular bleed was diagnosed, rivaroxaban was stopped. FBC was Hb 7.6g/dl, WCC 7.5x10^9/L, eosinophils 0.3x10^9/L and platelets 265x10^9/L. She was readmitted the following week with exertional dyspnoea.FBC now Hb 10.5g/dl, WCC 100x109/L (Eo 83x10^9/L). Prednisolone 100mg and heparin anticoagulation commenced for suspected drug- related hypereosinophilic syndrome. BM: mature eosinophilic hyperplasia with normal maturation. Cytogenetics and FIPILI-PDGFRA status negative. Within 24 hours she developed acute onset right hand weakness and CT/MRI imaging suggested transverse sinus thrombosis. Hydroxycarbamide was started, eosinophils remained high. 4 days later, acute confusion occurred. WCC was 134 x10^9/L (Eo 118x10^9/L). AraC 20mg bid normalised eosinophil counts within a week. However falling GCS and hypoxia developed. Repeat CT confirmed multiple cerebral infarcts with small haemorrhages, and anticoagulation discontinued. 7 days later a myocardial infarction occurred and neutropenic sepsis with acute eosinophilic lung disease. Multi-organ failure progressed with further acute cerebral events leading to signs of brainstem infarction/bleed and the patient died a few days later. CASE 2: 55 year old male admitted with headache, flu-like symptoms and bilateral purpuric rash. WCC 16.4x109/L,mild neutrophilia and anaemia. CT revealed hepatosplenomegaly, mediastinal lymphadenopathy and adrenal mass. Investigations for vasculitis and infective causes were excluded. The rash progressed WCC 69x10^9/L, Eo 39x10^9/L, BM: reactive eosinophilia, no evidence of CML/MPN. Commenced prednisolone for suspected vasculitis. Extension of his rash, ulcers and pneumonia occurred with WCC 184x10^9/L, Eo69.9x10^9/L. Methylprednisolone and broad spectrum antibiotics were initiated. He developed ascites and coagulopathy. Repeat BM consistent with HES, commenced Hydroxycarbamide, but continued to deteriorate with confusion, progressive MRSA pneumonia needing ventilation. Interferon alpha was not effective. Neurological progression with unilateral weakness; CT: multiple cerebral infarctions, ground glass shadowing in lungs and bronchial lavage revealed eosinophilic infiltrate. AraC 10mg bid controlled the eosinophil count. Ventilation was required for 7 weeks and on-going Hydroxycarbamide and interferon alpha. He was discharged for intensive rehabilitation and continues to improve.
Results: As above
Summary / Conclusion: Our cases illustrate diagnostic and management challenges; rapid disease course reinforces the need to urgently control the counts to minimise the thrombo-haemorrhagic complications. Early use of AraC seems an effective cytoreductive agent in HES with extreme eosinophilia.

B1585

SINGLE-AGENT LENALIDOMIDE IS EFFECTIVE FOR TRANSFUSION INDIPENDENCE IN A PATIENT WITH REFRACTORY ANEMIA WITH RING SIDEROBLASTS, THROMBOCYTOSIS AND JAK2 (V617F)

I Nichele[1*], M Ruggeri[1], F Rodeghiero[1]
[1]S. Bortolo Hospital, Vicenza, Italy, Vicenza, Italy

Background: Refractory anemia with ring sideroblasts associated with marked thrombocytosis (RARS-T) is a rare myelodysplastic/myeloproliferative disorder, that has been proposed as a provisonal entity in the 2001 and 2008 WHO classification. JAK2-V617F has been shown in the majority of these patients. The clinical course of RARS-T could be better than that of RARS and worse than that of essential thrombocythemia; however, the clinical and therapeutic experience with such cases is limited, due to the rarity of this disease. Lenalidomide is effective in patients with myelodysplastic syndromes with or without the del(5q) cytogenetic abnormality to reach transfusion independence, while no efficacy data of Lenalidomide are available in essential thrombocythemia to reduce platelet count. The efficacy of single-agent lenalidomide in RARS-T has been recently reported in one report (two patients described).
Aims: We report here the clinical outcome of Lenalidomide in the treatment of one patient with RARS-T and JAK2 V617F.
Methods: A 58-year-old caucasian man was admitted at our hospital in September 2006 for anemia (Hb 9.8 g/dL) and thrombocytosis (platelet count: 1163 x10^9/L). The bone marrow showed approximately 80% cellularity, increased atypical megacaryocytes with often lobulated nuclei and erythroid dysplasia with 30% ring sideroblasts. Cytogenetic analysis showed a normal karyotype, FISH examination was negative, while PCR revealed the presence of JAK2 V617F; a diagnosis of RARS-T associated to JAK2 mutation was made. Due to increase platelets count (1340x10^9/L), hydroxyurea was started after 11 months from diagnosis, with worsening of anemia (Hb 9.6 g/dL pre-therapy to 8.3 g/dL after three months of cytoreduction). Mild steroid therapy (prednisone 10 mg/day for 16 months) showed a transient efficacy while treatment with recombinant erytropoietin (30.000 units/weekly) was no successful. Thus, blood red cells transfusion treatment was started, after 40 months from diagnosis. Because of a high transfusion needs (2 units every months), Lenalidomide 10 mg daily for 21 days consecutive was started after 48 months from diagnosis and Hydroxyurea was concurrently interrupted.
Results: After 3 cycles of lenalidomide, anemia improved (Hb 9 g/dL) and the platelet count decreased to 700 x 10^9/L.
After 6 cycles, the hemoglobin level reached a stable value at > 9 g/dL without need of blood red cell transfusion and the platelet count reached the stable value of 500-600 x 10^9 /L.
Currently, the patient successfully continues 21 days-cycles of 10 mg lenalidomide and he maintains the transfusion independence, after a total of 28 cycle in 2 years of follow-up. No adverse event have been recorded until now.
Summary / Conclusion: Therapeutic experiences with RARS-T cases are limited. We confirm that Lenalidomide as single agent is efficacy in the treatment of our patient with RARS-T and JAK2 V617F, to reach transfusion independence and to maintain the platelet count within the target threshold after a long follow-up. Biological and histological analysis to demonstrate the morphological and molecular response are being carried out.

Non-Hodgkin lymphoma - Biology

B1586

CANINE DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) AS A SPONTANEOUS ANIMAL MODEL OF NON-GERMINAL CENTER DLBCL FOR PRECLINICAL STUDIES

F Nguyen[1*], J Fourel[1], A Moreau[2], J Abadie[1], F Davodeau[3], S Le Gouill[4]
[1]AMaROC, LUNAM university, Oniris, [2]Laboratoire d'Anatomie Pathologique A, Hôtel Dieu, [3]INSERM U892, CRCNA Team 13, [4]Université de Nantes, Hotel Dieu, Service d'Hematologie Clinique, Nantes, France

Background: Relevant preclinical animal models of human cancers are highly warranted to accelerate transfer of innovative therapies into human clinical practice. Spontaneous tumors in dog share important clinical, pathological, and diagnostic similarities with human tumors. Non-Hodgkin lymphoma is highly frequent in dog (33/100,000) and diffuse large B-cell lymphoma (DLBCL) is the most common subtype of lymphoma in dog. However, similarities between human and canine DLBCLs have been poorly investigated so far.
Aims: In order to evaluate the interest of spontaneous DLBCL in dog as a valid animal model for preclinical studies in human, we applied Hans' algorithm to canine DLBCL samples and evaluated the prognostic value of a canine-adapted immunohistochemical double-hit score.
Methods: Between 2005 and 2011, 100 dogs have been diagnosed with DLBCL in the College of Veterinary Medicine of Nantes (France). All DLBCL samples were evaluated for CD10, BCL-6, MUM-1, BCL-2 and c-MYC (clone Y69) by immunohistochemistry using an automated stainer. Thresholds for positivity were 30% for CD10, BCL-6, MUM-1; 10% for BCL-2 and 80% for c-MYC. Dogs' outcomes were obtained from referring veterinarians and owners.
Results: To date, 49 samples have been evaluated. Thirty-three dogs (67%) presented with stage III disease according to the World Health Organization (WHO) staging system of canine lymphomas. Six (12%) samples were classified as immunoblastic, while 43 (88%) were centroblastic. Seven cases (25%) were classified as germinal center-DLBCLs according to Hans' algorithm and 42 cases (75%) were non-germinal center-DLBCLs. 26 cases (53%) carried overexpression of c-MYC. A high immunohistochemical double-hit score (DHS) (c-MYC and BCL-2 positive) was observed in 6 cases (12%). Twelve dogs (24%) received no treatment, 26 (53%) received prednisolone alone, and 11 (22%) received CHOP-like chemotherapy regimen. Median overall survival according to treatment options was 19 days, 45 days and 220 days, respectively. In multivariate analysis, 4 parameters (absence of treatment, high WHO clinical stage, non-germinal center phenotype and a high DHS) were associated with shorter OS (P=0.01).
Summary / Conclusion: The present analysis shows that Hans' algorithm could be applied in dog and that non-GC DLBCL is more frequent than GC DLBCL. As observed in human DLBCL, a high DHS is associated with worse outcome. Our preliminary results suggest that spontaneous DLBCL in canine may be used as a model for non-germinal-center DLBCL (and not GC) for preclinical investigations.

B1588

SHRNA AGAINST CD44 EFFECT DIFFUSE LARGE B CELL LYMPHOMA CELLS

R Feng[1*], X Wei[1], F Huang[1], Y Wei[1], W Duan[1], Z Yi[1], Z Zheng[1], Q Zhang[2], B Ye[3]

[1]Hematology, Nanfang Hospital, Southern Medical University, [2]Cancer Research Institute, Southern Medical University, Guangzhou, China, [3]Cell Biology, Albert Einstein College of Medicine, New York, United States

Background: CD44, expressed predominantly in activated B-cell-like diffuse large B-cell lymphoma(DLBCL), has been reported to predict inferior survival in DLBCL patients.We have previously substantiated that CD44 expression still remain its prognostic significance even in the R-CHOP era.
Aims: To study the effect of CD44 down-regulation with lentivirus-mediated small hairpin RNA (shRNA) interference on the biological features of activated B-cell-like diffuse large B-cell lymphoma cell line SUDHL-2.
Methods: A lentiviral vector for RNAi of CD44 which contained green fluorescent protein(GFP) was constructed Package cells phoenix293 was used to produce virus stocks Then SUDHL-2 cells were infected with the recombinant lentivirus and the cells with CD44 knock-down were selected by FACS for GFP expression CD44 expression in the cells was determined by RT-PCR and FACS The proliferation,apoptosis and invasion were evaluated by MTT methods, FACS and transwell migration assay, respectively.
Results: DNA sequencing demonstrated that the lentivirus RNAi vector was constructed successfully Clones of SUDHL-2 cells infected with the recombinant lentivirus were selected and exhibited substantial knock-down of CD44 mRNA and protein expression compared with the control cells The proliferation ability of cloned SUDHL-2 cells were inhibited The apoptosis rates at early and late phase were 6.26%, 36.40% respectively in cloned SUDHL-2 cells and in control cells were 2.9%, 2.56% at early phase and 6.1%, 6.58% at late phase. The migrating number of cloned SUDHL-2 cells(34.53±8.05)% was also significantly decreased compared with the control cells(78.67±2.64 %, (78.00±6.13% (*P*=0.290).
Summary / Conclusion: The lentivirus-mediated shRNA of CD44 is efficient in down-regulating CD44 expression and inducing apoptosis, inhibiting proliferation and invasiveness of SUDHL-2 cells, suggesting that CD44 might have an oncogene role in the tumorigenesis and progression of ABC-DLBCL.

B1589

SEVEN MICRORNAS DIFFERENTIATE PATIENTS WITH EBV-POSITIVE DIFFUSE LARGE B-CELL LYMPHOMA OF THE ELDERLY FROM DIFFUSE LARGE B-CELL LYMPHOMA NOT OTHERWISE SPECIFIED: A MICRORNA SIGNATURE PROFILE PROPOSAL

T Andrade[1*], A Evangelista [2], N Borges[1], J Jampietro[3], M Macedo[3], M Begnami[3], A Alves[1], G Colleoni[1]

[1]UNIFESP, [2]Barretos Cancer Hospital, [3]AC Camargo Cancer Hospital, Sao Paulo, Brazil

Background: EBV-positive diffuse large B-cell lymphoma of the elderly (EBV+DLBCLe) is considered a provisional entity in the latest World Health Organization classification. It affects individuals older than 50 years without prior documented immunodeficiency. This disorder has unfavorable clinical course even after the advent of immunotherapy associated to anthracycline-based chemotherapy. It is linked to Epstein-Barr virus and the physiopathology is related to the presence of the virus itself, senescence and immunological deterioration. Currently there is not a characteristic pattern of expression of microRNAs in EBV+DLBCLe.
Aims: To characterize a signature profile for this new entity and to explore its peculiar characteristics as biomarkers and potential alternative therapeutic targets for EBV+DLBCLe.
Methods: One hundred and twenty four cases of patients of DLBCL treated at Hospital São Paulo UNIFESP/ EPM between 2000 to 2010, had paraffin blocks available for immunohistochemical and molecular analyses. Seventy of 124 patients have more than 50 years and are potential candidates to be considered EBV+DLBCLe. *In situ* hybridization was used for EBV detection (EBER-1, Invitrogen) in a tissue microarray (TMA) slide. Total RNA was obtained from tumor slides using the kit Recover All Total Nucleic Acid Isolation (Applied Biosystems). From the total RNA we obtained cDNAs using Megaplex Pools for microRNA Expression (Applied Biosystems). The cDNA was inserted into two platforms containing 384 human microRNA each (Taqman Low Density Arrays) on 7900 Real Time PCR Systems (Applied Biosystems). Data analyses were made in mathematical-statistical environment "R". The normalization method dct-2 was performed using the endogenous RNU48, and it was identified as the most stable among samples by software Normfinder. It was also used RNU6 recommended by the manufacturer, in a comparative way. MicroRNAs differentially expressed in EBV-positive group compared to EBV-negative were identified by means of nonparametric tests rank products (package RankProd) and Wilcoxon rank-sum (R-Stats). We considered differentially expressed microRNAs which average fold change above or below 1.5.
Results: 8.5% of cases of DLBCL were considered EBV+DLBCLe after *in situ* hybridization for EBV. We selected four samples of EBV-positive cases and four of EBV-negative matched by age, gender, stage and IPI to be analyzed in the PCR platforms. We found 10 deregulated microRNAs among the two groups. However, only seven microRNAs achieved statistically significant differences and will be the start point of a microRNA signature profile proposal to be validated in a larger multicentric cohort (total of 20 EBV+DLBCLe versus 40 DLBCL, paired by age, gender, stage, IPI and cellular origin according to Hans et al. algorithm). Among them 6 were overexpressed in EBV+DLBCLe comparing to EBV-negative DLBCL whereas 1 was underexpressed.
Summary / Conclusion: All microRNAs found are already described and involved in cancer. Five are reported in previous studies in non-Hodgkin lymphomas and one of them is correlated with clinical outcome and poor prognosis. The main routes involved are reduction of NF-KappaB DNA-binding activity and deregulation of the PI3K-AKT pathway. The merit of the present study is to put all the microRNAs together to create a specific expression profile signature for EBV+DLBCLe with the aim to define potential therapeutic targets as alternatives for R-CHOP. (Supported by FAPESP 2010/17668-6).

B1590

SYNERGISTIC CYTOTOXICITY OF EDELFOSINE, GEMCITABINE AND CLOFARABINE IN T-CELL LYMPHOMA

B Valdez[1], A Zander[2], Y Li[1], G Song[1], B Andersson[1*]

[1]Stem Cell Transplantation and Cellular Therapy, University of Texas MD Anderson Cancer Center, Houston, United States, [2]Stem Cell Transplantation and Cellular Therapy, University Hospital Hamburg-Eppendorf, Hamburg, Germany

Background: Edelfosine (1-O-octadecyl-2-O-methyl-rac-glycero-3-phosphocholine, ET-18-O-CH3) is an antitumor alkylphospholipid, a new type of anticancer drug, with immunomodulatory activity. It has shown clinical activity in lung and brain cancers, and pre-clinical activity in non-Hodgkin lymphoma, leukemia, breast cancer and pancreatic carcinoma. Edelfosine (Ed) induces apoptosis by recruitment of Fas/CD95 and subsequent DISC formation in lipid rafts. On the other hand, gemcitabine (Gem) and clofarabine (Clo) are nucleoside analogues which are used for treatment of various solid tumors and hematological malignancies. These are antimetabolites which inhibit DNA synthesis and repair, and induce apoptosis.
Aims: To investigate Ed for a potential synergistic cytotoxicity with Gem and Clo in lymphoma cells.
Methods: Cells were exposed to drugs individually, or in combinations, for 48 hours and analyzed by MTT assay, flow cytometry and Western blot.
Results: Exposure of J45.01 cells to IC_{10} – IC_{20} of these drugs for 48 hrs resulted in strong synergistic cytotoxicity. While the individual drugs inhibited cell proliferation by 5-20%, their combination inhibited survival by ~85%. Apoptosis with triple-drug combination increased to ~70%. The observed [Ed+Gem+Clo]-mediated cell death correlated with activation of DNA damage response as shown by increased phosphorylation of histone 2AX, SMC1 and KAP1. Furthermore, changes in the mitochondrial integrity are indicated by a dramatic decrease in the mitochondrial transmembrane potential, increase in the production of reactive oxygen species and release of pro-apoptotic factors from the mitochondria to the cytoplasm. The activation of apoptosis is also shown by cleavage of PARP-1, caspase8, caspase3, MCL1 and ANP32B. Exposure of the Jurkat-derived cell line I9.2, which is null for caspase8, to [Ed+Gem+Clo] resulted in only 40% inhibition of cell proliferation (as compared with 85% inhibition in caspase 8-positive J45.01 cells), suggesting the relevance of caspases in the antitumor activity of the three-drug combination. These observations are consistent with decreased phosphorylation of the prosurvival proteins p38, MAPK and AKT in cells exposed to [Ed+Gem+Clo]. The three-drug combination also caused translocation of nucleolar proteins to nucleoplasm, suggesting induction of nucleolar stress, which has been shown to activate p53-dependent cell growth inhibition.
Summary / Conclusion: Combination of the alkylphospholidid Ed with the nucleoside analogues Gem and Clo provides synergistic cytotoxicity in lymphoma cells by activating DNA damage response, induction of apoptosis via increase in reactive oxygen species and leakage of mitochondrial membrane, inhibition of the p38, MAPK and AKT signal transduction pathways, and induction of nucleolar stress. The observed synergism can be used as a mechanistic impetus for evaluating this drug combination as a part of cytoreductive treatment programs in patients with lymphomas.

MOLECULAR AND IMMUNOHISTOCHEMICAL ANALYSIS OF CELL CYCLE REGULATORY GENES IN DIFFUSE LARGE B-CELL LYMPHOMAS

F Kontsioti[1*], P Foukas[2], S Papageorgiou[1], V Mpakou[1], M Kefala[2], C Kontos[3], E Ioannidou[1], M Atta[1], Ai Bouchla[1], K Girkas[1], C Roubakis[1], I Panayiotides[2], G Dimitriadis[1], V Pappa[1]
[1]Second Department of Internal Medicine and Research Institute, [2]Pathology Department, Attikon University General Hospital, [3]Biochemistry and Molecular Biology, University of Athens, Athens, Greece

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignancy of mature B cells with heterogeneous prognosis. Biological markers have been used in an attempt to improve the discriminative capacity of the International Prognostic Index (IPI). Abnormalities of cell cycle constitute a marker of clonal expansion and may contribute to disease progression; thus the investigation of cell cycle regulatory genes´ expression may be of prognostic relevance.
Aims: This study focuses on verifying the findings of our previous analysis regarding the expression levels of cell cycle regulatory genes in DLBCL. The first cohort of patients was treated with CHOP chemotherapy and the analysis was performed at the mRNA level. The second group included patients treated with R-CHOP and the analysis was performed by immunohistochemistry.
Methods: Our first analysis included 45 newly diagnosed cases of DLBCL and 15 cases of non-neoplastic lymphadenopathies used as controls. RNA was extracted from fresh frozen tissues and analyzed by RNase Protection Assay. Two sets of probes were used that included cyclins, cyclin dependent kinases and their inhibitors. This study included 99 newly diagnosed cases of DLBCL. Immunohistochemistry was performed on paraffin-embedded tissue sections. A semiquantitative analysis was performed and the intensity of immunostaining was assessed as follows: 0 (<1% positive cells), 1-weak staining (1-10%); 2-moderate staining (>10-50%) and 3-intense staining (>50%). 20,2% of the examined cases scored 0, 22,2% scored1, 30,3% scored 2 and 27,3% scored 3. Clinical characteristics were recorded. There were 50 males and 49 females. The median age was 66 years. The median freedom from progression (FFP) was 3 months, the median relapse-free survival (RFS) 18 months, the median progression-free survival (PFS) 16 months and the median overall survival (OS) 23 months. The revised IPI score was estimated as “very good” for the6,8% of patients, “good” for the 33,9% and “poor” for the rest of the patients (59,3%).
Results: Regarding our first cohort of patients the expression at the mRNA level of the cell cycle regulatory genes did not correlate with any of the clinical parameters nor the prognostic markers. 92% of the CHOP-treated patients with low IPI (0,1) expressed cyclin-dependent kinase (cdk10), while only 56% of the patients with high IPI (2,3,4,5) expressed this gene. The expression of cdk10 was also associated with significantly better overall survival (P=0,0329). Regarding the second cohort of patients treated with R-CHOP immunohistochemichal analysis was performed focusing on cdk10 expression with the following results. 40,3% of the examined lymphomas belonged to the GBC phenotype and 59,7% of the cases to the non-GBC phenotype, according to Hans *et al* algorithm. The association between cdk10 expression and clinicopathological variables revealed that a significantly higher number of cases within the non-GBC group was cdk10 positive, compared to the GBC group (P=0.03). Cdk10 expression was not associated with survival or disease free survival. However, cases with cdk10 positive expression were associated with significantly shorter freedom from progression time (P=0,006).
Summary / Conclusion: Our study has shown that putative markers of prognostic significance already published at the era of CHOP chemotherapy in DLBCL, lose their discriminative capacity in the era of R-CHOP. Although the expression of cdk10 at the mRNA level was associated with low risk disease and higher overall survival, these results were not confirmed at the protein level in the era of R-CHOP chemoimmunotherapy.

B1592

CYTOGENETIC CHANGES AND HISTOLOGIC ASSESSMENT OF BONE MARROW INVOLVEMENT OF NK/T CELL LYMPHOMA IN KOREAN

Q Choi[1*], D Lee[1], S Kim[1]
[1]Laboratory Medicine, Seoul National University College of Medicine, Seoul, Korea, Seoul, Korea, Republic Of

Background: NK/T cell lymphoma is derived from a proliferations of NK cell and is characterised by an immunophenotype of CD2+, surface CD3-, cytoplasmic CD3e+, CD56+ and T cell receptor (TCR)-, lack of TCR gene rearrangement, and strong association with EBV. No specific chromosomal translocation has been identified by conventional cytogenetics, so far, though del(6q), i(1q), +8, i(17q), and 11q23 rearrangement are reported.
Aims: To investigate the patterns of bone marrow involvement and recurrent cytogenetic changes in NK/T lymphoma,we retrospectively studied bon marrow biopsy specimens, and fluorescent in situ hibridization (FISH) for del(6q), i(1q), +8, i(17q), and 11q23 rearrangement.
Methods: We retrospectively studied trephine biopsy specimens by CD56 immunohistochemistry and Epstein-Barr virus-–encoded RNA in situ hybridization (EBER ISH) from 68 consecutive patients. FISH for del(6q), 1q, +8, i(17q), and MLL 11q23 rearrangement were performed on available bone marrow mononuclear cells in 11 patients with microscopic BM involvement, using 19 probes (MYB(6q23), CEP XY, Tri-1q, cep8(+8), Rb(del13q), 7q31, p53(del17q), N-myc, BCL6, PDGFR-a, EGR, MLL, TEL-AML, inv16, 19q, del20q, BCR-ABL, PML-RARA, IGH-MYC). Results of conventional cytogenetics are reviewed.
Results: The incidence of BM involvement was 30.9% (21 of 68 patients) and in patients with BMI, CD56 were positive in infiltrated cells in 80.0% (12/15), and granzyme in 80.0% (4/5) and EBER in 66.7% (6/9). 1 of 12 patient showed EBER positive cells without evidence of infiltration of malignant cells. By G-banding, 8 of 43 patients (18.6%) showed cytogenetic aberrations. Cytgenetic aberrations were present in 27.8% (5 of 18 patients) among patients with BMI, while among in patiens without BMI, 12.5% (3/24) showed aberrations. FISH analysis revealed sex chromosome loss (45.5%), MLL rearrangement (9.1%), monosomy 11 (9.1%) and p53 deletion (9.1%). trisomy8, 6q deletion, iso17q and 1q gain were not detected.
Summary / Conclusion: Frequency of BM involvement in NK/T lymphoma in Korean is higher, compared to reported low frequencies of BMI. For determination of BM involvement which is pivotal in directing treatment strategy, IHC and EBER are essential. G-banding in conjunction with FISH analysis could give addtional complementary information for BMI.

B1593

FREQUENT LOSS OF THE TUMOR SUPPRESSOR TNFAIP3 IN SÉZARY SYNDROME

F Braun[1*], P Grabarczyk[1], M Möbs[2], J Eberle[2], M Beyer[2], W Sterry[2], M Vermeer[3], C Tensen[4], G Przybylski[5], C Schmidt[1]
[1]Molecular Hematology, University Greifswald, Greifswald, [2]Dermatology, Allergology, Charité University Berlin, Berlin, Germany, [3]Dermatology, Leiden University Medical Center, [4]Dermatology, Leiden University Medical Center, Leiden, Netherlands, [5]Human Genetics, Polish Academy of Sciences, Poznan, Poland

Background: TNFAIP3 (A20) is known as one of the negative regulators of the NF-κB pathway. It`s inhibitory effect on NF-kB is based on the co-operative activity of two ubiquitin-editing domains. This function of A20 has been recognized for a number of substrates involved in transmission of signals from cell surface receptors to NF-κB, for example the receptor-interacting protein 1 (RIP1), the TNF receptor associated factor 6 (TRAF6) and the I-kB kinase (IKK). Particularly interesting is the NF-κB signaling pathway, since its constitutive activation has been identified as a key feature in CTCL (Cutaneous T Cell Lymphoma), including Sézary syndrome. Despite recent therapeutic improvements, the prognosis for patients suffering from Sézary syndrome is still poor.
Aims: To establish more specific and targeted therapies, a better understanding of the underlying molecular mechanisms driving the aberrant proliferation is required.
Methods: Using high resolution comparative genomic array hybridization (array CGH) we found bi- and monoallelic deletions of the TNFAIP3 gene in a high proportion of SS patients as well as a biallelic deletion in the SS-derived cell line SeAx.
Results: We demonstrated that inhibition of A20 activates the NF-κB pathway thereby increasing the proliferation of normal T lymphocytes. On the other hand, the reconstitution of A20 expression slowed down the cell cycle in SeAx cells. In a current study we extended the number of Sézary syndrome patient samples and determined gene copy number of A20 using an optimized competitive PCR assay. In this independent group of SS patients deletions were found in nine out of 17 (53%) Sézary syndrome samples.
Summary / Conclusion: In this study we showed that A20 is also a putative tumor suppressor in the T-cell malignancy - Sézary syndrome and underscore the relevance of A20 deletion in this tumor entity.

B1594

GENETIC POLYMORPHISM OF GLUTATION-S-TRANSFERASES M1 AND T1 (GSTM1 AND GSTT1) AND ENZYMES OF FOLATE METABOLISM IN THE PATIENTS WITH NON-HODGKIN MALIGNANT LYMPHOMAS

O Berezina[1*], A Weiner[2], E Voropaeva[3], T Pospelova[1], M Filipenko[2]
[1]Novosibirsk State Medical University, [2]Research Institute for Chemical Biology and Fundamental Medicine SB RAS, [3]Research Institute for Therapy SB RAMS , Novosibirsk, Russian Federation

Background: Non-Hodgkin's lymphomas (NHL) is a heterogeneous group of malignant lymphoproliferative disorders that have different rates of tumor progression, which may be the result of not only mutations in a phase of initiation, promotion and progression of lymphoma, but the initial genetic characteristics of thecells, such as polymorphisms of genes. NHL are most commonly diagnosed at advanced stages (III и IV). It is important to research new factors of the etiology of this disease. Genetically determined differences in the activity of enzymes of the second phase of xenobiotic biotransformation and folate metabolism can cause unequal predisposition to cancer, including NHL.
Aims: of this study was to investigate the role of deletions in glutathione-S-transferases M1 and T1 and some SNPs in folate genes (the C677T and A1298C SNPs in the *MTHFR* gene, A2756G in *MTR*, A66G in *SHMT1*, G1958A in *MTHFD1* and 844ins68 in *CBS)* in genetic susceptibility to non-Hodgkin's malignant lymphoma in the west-Siberian region.
Methods: 146 unrelated patients from the Novosibirsk City Haematological Center with various types of NHL were investigated. Genomic DNA was isolated from leukocytes in venous blood and also from buccal epithelium, using the standard methods of DNA separation. A PCR-restriction fragment length polymorphism (RFLP) assay was used to detect the *MTHFD* G1958A and *CBS* 844ins68 SNPs. Genotyping of the *MTHFR*, *MTR*, *MTRR* and *SHMT1* gene SNPs was carried out by real-time PCR allelic discrimination with TaqMan probes, *GSTM1* and *GSTT1* genes were analyzed by using real-time PCR with SYBRE Green and the following registration of melting curves. The alleles and genotypes distribution of SNPs in patients were compared with their distribution in healthy white Russian subjects from Novosibirsk.
Results: We determined the allele and genotype frequencies for *GSTM1* and *GSTT1* genes and seven SNPs in folate metabolism in NHL and control groups. For all these SNPs, the genotype frequencies were in Hardy-Weinberg equilibrium in the control group. For *GSTM1* gene it was noticed a higher rate of deletion genotype in patients with indolent lymphoma compared with the control group and aggressive NHL. This fact allowed us to estimate the contribution of *GSTM1* gene deletion in a predisposition to development of indolent NHL. It was revealed, the carriers of mutant *GSTM1* genotypes had 2-fold increased risk of indolent NHL in comparison with the normal genotype carriers (OR =1,96, CI [1.072-3.581], p <0,02). But the polymorphisms G1958A *MTHFD1* and C1420T SHMT1 showed significant association with aggressive NHL. Allele *1958A MTHFD1* was associated with decreased risk of diffuse large B-cell lymphoma (OR=0,429; C.I. [0.279-0.659], P<0,00008). Allele 1420T *SHMT1* was associated with increased risk in the group of another types of large B-cell non-Hodgkin's lymphoma (OR =1,862; C. I. [1,073 –3,231], p < 0,026). Any association of folate genes with indolent non-Hodgkin's lymphoma was not revealed.
Summary / Conclusion: Thus, the diverse impact of single nucleotide substitutions in the genes of the second phase of xenobiotic biotransformation (*GSTM1*) and folate metabolism (*MTHFD1, SHMT1*) on development of indolent and aggressive NHL can show the different molecular mechanisms of neoplastic transformation and it requires the investigation of the gene complex in order to determine predisposition to the development of non-Hodgkin's lymphoma.

B1595

GERMINAL CENTER LYMPHOMA CELL LINES: TOOLS FOR THE STUDY OF CLONAL EVOLUTION?

H Quentmeier[1*], R Amini[2], M Berglund[3], W Dirks[1], S Ehrentraut[1], R Geffers[4], R MacLeod[1], S Nagel[1], M Scherr[5], H Drexler[1]
[1]Leibniz-Institute DSMZ, Braunschweig, Germany, [2]Department of Immunology, Genetics and Pathology, Uppsala University and Uppsala University Hospital, [3]Department of Radiology, Oncology and Radiation Science, Uppsala University, Uppsala, Sweden, [4]Genome Analysis Research Group, Helmholtz Centre for Infection Research, Braunschweig, [5]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Medical School Hannover, Hannover, Germany

Background: The evolution of tumor clones and the clonal architecture of tumors can be followed by the analysis of clone-specific mutations. These studies are done best at the single cell level. However, the necessary techniques are very challenging. Immortalized cell lines providing unlimited supplies of clonal cells would facilitate this work substantially. Yet, according to a widely accepted concept cell lines originate from one cell of a tumor carrying a set of mutations that allow continuous growth *in vitro.* If more than one cell happens to divide in the culture vessel, one clone should eventually outgrow the other. The data presented here contradict this common view.
Aims: We set out to find out whether molecularly-defined subclones can be detected in immortalized cell lines.
Methods: Immunoglobulin hypermutation and cytogenetic analyses were performed to detect subclones in B-cell lines. Gene expression of subclones was performed by microarray analysis and qRT-PCR analysis. Methylation specific PCR and bisulfite sequencing were conducted to determine the methylation status of individual genes.
Results: In several germinal center lymphoma-derived cell lines, we detected subclones with unique immunoglobulin hypermutation patterns. Clone-specific expression of various B-cell markers in the diffuse large B-cell line U-2932 allowed separation of the individual clones. According to the combined results of immunoglobulin hypermutation and cytogenetic analysis, both U-2932 clones derived from one mother clone with genomic *BCL2* amplification. The subclones acquired secondary lesions leading to the overexpression of *BCL6* in one, and *MYC* in the other subclone. Some 200 genes were differentially expressed in the two clones including transcriptional targets of *BCL6* and *MYC*. Other genes were epigenetically regulated as evidenced by DNA methylation analysis. Ectopic regulation of *BCL6* variously modulated new candidate target genes, confirming dual activating and silencing functions.
Summary / Conclusion: Genetically distinct subclones of cell lines may prove to model tumor heterogeneity *in vitro* allowing for functional analysis of oncogenes against a syngenic background.

B1596

CHARACTERIZATION OF CD19+CD5+ NON-CLL LYMPHOPROLIFERATIVE DISORDERS WITH AND WITHOUT T(11;14)

L Lopez-Anglada[1*], C Fernandez[2], E Lopez[3], R Martos[4], J Galvez[5], Fernandez Ferrero[6], S Blasco[7], J Alonso[8], G Martin [9], R Cantalejo [10], C Aguilar [11], B Vidriales[1], J Miguel[1]
[1]Hospital Clinico de Salamanca, Salamanca, [2]Hospital Virgen de la Concha, Zamora, [3]Hospital del Bierzo , Ponferrada, [4]Hospital de Segovia, Segovia, [5]Hospital Clinico Valladolid , Valladolid, [6]Hospital de Leon, Leon, [7]Hospital Nuestra Señora de Sonsoles, Avila, [8]Hospital Rio Carrion, Palencia, [9]Hospital Virgen del Puerto, Plasencia, [10]Hospital Santos Reyes, Aranda de Duero, [11]Hospital de Santa Barbara, Soria, Spain

Background: Mantle cell lymphoma (MCL) is characterized by the presence of t(11;14)(q13;q32), and shows a typical immunophenotype CD19+CD5+ that can be identified by flow cytometry (FCM). However, cases with typical MCL immunophenotype without t(11;14) are frequently detected in the clinical routine flow cytometry laboratory.
Aims: To characterize cases CD19+CD5+ (no CLL) lymphoproliferative disorders, analyzed in the clinical routine laboratory of flow cytometry, trying to identify profiles that could predict the presence of t(11;14).
Methods: We retrospectively analysed a total of 119 patients with CD19+CD5+ (non-CLL) lymphoproliferative disorders detected in the clinical laboratory of the University Hospital of Salamanca (Spain), in which information of immunophenotype, cytogenetics, and molecular biology (bcl-1) was available. The clonal B cell population was detected in peripheral blood (n=63), bone marrow (n=35) and lymph node (n=21). Erythrocyte-lysed samples were stained using selected panels of monoclonal antibodies, using four-color direct immunofluorescence technique and according to previously well described methods, aimed to identify and characterize B neoplastic cells; the complete diagnosis was performed with ancillary technics as molecular biology (bcl-1), karyotype and fluorescent in situ hybridization (FISH) for t(11;14).
Results: From the 119 samples with CD19+CD5+ immunophenotype (no CLL), 49% (59/119) of cases were t(11/14) positive. (8% by the three techniques; 8% by karyotype and FISH; 19% by FISH and MB; 46% only by FISH; and 19% only by MB). The 83% of t(11;14) positive cases showed a typical CD22+/CD23- immunophenotype, in addition to bright expression of CD20 and FCM7+ positivity. CD38 expression was negative in 53% of cases. Negative cases for t(11;14) showed CD22+/CD23- and CD38 in a slight lower frequency (60% and 32%, respectively), with similar expression of CD20. In t(11;14) positive cases the CD22+/CD23- was more homogeneous. The percentage (mean) of clonal B cells infiltrating PB, BM and lymph nodes was of 46%; 28% and 68% in cases t(11;14) positive vs 34%, 32%, and 57% in t(11;14) negative cases. Therefore, in general the percentage of infiltration was slightly lower in t(11;14)cases. Concerning clinical behaviour, as expected, the percentage of infiltration was higher in cases with a clinical behaviour of CLPD than in cases with a clinical behaviour of NHL, in cases both with and without t(11;14) (mean 39% and 44% vs 29% and 21%). Of the 23 cases with lymph node study, 2 cases were classified as splenic marginal zone NHL, 1 as DLBCL and 20 cases were classified as MCL. From the total, 73% of cases received therapy until now, and 83% of them had a NHL clinical behaviour. The rest 17% treated patients had a CLPD clinical behaviour, and the time to treatment was longer (mean 395 days) than in cases with NHL clinical behaviour (mean 95 days) (P=0.02).
Summary / Conclusion: Although cases with typical MCL immunophenotype are frequently detected in the routine clinical laboratory, the t(11;14) is detected only in half of the cases, and both t(11;14) positive and necative cases can have a indolent or agresive behaviour.

B1597

GLUTATHIONE S-TRANSFERASE GENOTYPES INFLUENCE PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA

O Novosad[1*], N Svergun[2], A Martynchyk[1], E Aleksik[1], I Kryachok[1], N Khranovska[2]

[1]oncohaematology, [2]Experimental Oncology Department, National Cancer Institute, Kiev, Ukraine

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma, accounting for approximately 30% of all newly diagnosed cases and more than 80% of aggressive lymphomas. The aim of this study was to investigate whether the genetic polymorphism of glutathione S-transferase P1 (GSTP1), which is a phase II detoxifying enzyme known to be a resistance factor for anticancer drugs, could be a prognostic factor of DLBCL.

Aims: patients with DLBCL

Methods: The case group comprised 82 patients with DLBCL (median age: 48 years, range: 18–76; males: 37, females: 45) treated in the National Cancer Institute, Ukraine. The patients were treated with R-CHOP-like regimens. Genomic DNA from peripheral blood of all individuals was analyzed for identification of *GSTP*1 polymorphism (c. 313 *A* > *G*, p. Ile105Val) using Allelic Discrimination Real-Time PCR.

Results: Of the 82 patients with DLBCL, 44 (53.7 %) were homozygous for the A313A GSTP1 genotype, 27 (32.9 %) were heterozygous (A313G), and 11 (13.4 %) were homozygous for the G313G genotype. The GSTP1 genotype distribution was conformed to Hardy-Weinberg equilibrium ($\chi 2$=1.88; P=0.17). Observed distribution was in agreement with previously reported findings in a healthy Ukrainian. We did not fined associations between demographic characteristics of the patients and GSTP1 genotype. The frequency of the homozygous wild genotype of the GSTP1 was higher in patients with advanced disease (stages III-IV) than in patients with stages I-II (59.5 versus 49.5 %, P=0.12). The overall response rate was 78.1 % (64/82) with a complete response of 72 % (59/82) and a partial response – 6 % (5/82). A complete response rate after the first-line therapy was better for the patients with the *A*313*G* or *G*313*G* genotype in comparison with the patients with homozygous wild genotype (79 % (30/38) versus 66 % (29/44), P=0.05). The highest incidence of primary drug resistance was observed for patients with A313A genotype of GSTP1 (62 %, 13/21) compared to patients with *A313G* (28.5 %, 6/21) and *G313G* genotypes (9.5 %, 2/21). Among the patients with complete response 17 (28.8 %) had relapse or progression and 7 patients dead (11.9 %) during the follow-up (median – 18 months; range 6–36 months). There was a trend for a lower risk for early relapse for patients with increasing number of mutant G allele (P=0.09) in our cases, but it should be confirmed by further studies with a larger cohorts of patients.

Summary / Conclusion: The obtained results suggest that the homozygous wild genotype of GSTP1 gene (*A*313*A*) is associated with a worse clinical response to the therapy and a higher risk of the early relapse for the DLBCL patients. Hence the further investigations of GSTP1 polymorphism is very promising, since it might provide a possible application of this genetic marker as an independent prognostic factor of DLBCL.

B1598

PRIMARY CENTRAL NERVOUS SYSTEM DIFFUSE LARGE B-CELL LYMPHOMA (PCNSDLBCL) HARBOR FREQUENT BCL6 BUT NOT MYC OR BCL2 TRANSLOCATIONS, AND BELONG TO THE NON-GERMINAL CENTER SUBTYPE (NON-GC)

G Tapia[1,2*], A Muñoz-Mármol[1], M Baptista[3,4], A Gaafar[5], M Puente-Pomposo[6], J Navarro[3,4], C Sanz[1], R Marginet-Flinch[1], M López-Peña[1], J Ribera[3,4], AAriza[1,2], J Mate[1,2]

[1]Pathology, Hospital Germans Trias i Pujol, [2]Universitat Autònoma de Barcelona, [3]Hematology, ICO-Hospital Germans Trias i Pujol, [4]Institut Josep Carreras, Badalona, [5]Pathology, [6]Hematology, Hospital Universitario Cruces, Bilbao, Spain

Background: Translocations involving *MYC* gene can occur in up to 10-15 % of diffuse large B-cell lymphoma (DLBCL), and have been associated with a bad prognosis, especially if present concomitantly with *BCL2* or *BCL6* translocations ("double-hit" and "triple-hit" lymphomas). Translocations involving those genes have not been widely evaluated in PCNSDLBCL.

Aims: The objective of the study was to evaluate the immunophenotypic and molecular profile of PCNSDLBCL, focusing on the presence or absence of *MYC*, BCL6 and BCL2 translocations.

Methods: Cases of PCNSDLBCL were collected from the Department of Pathology of two institutions (Hospital Germans Trias i Pujol, Badalona and Hospital de Cruces, Bilbao, Spain). Immunohistochemical stains regarding CD20 (clone L26, Dako), CD3 (clone PS1, Novocastra), CD10 (clone 56C6, Novocastra), BCL6 (clone PG-B6p, Dako), and multiple myeloma oncogene 1 (MUM1) (clone MUM1p, Dako) were re-evaluated and cases were classified as GC-like or non-GC according to Hans algorithm. The proliferating index was evaluated using the Ki67 antibody (clone MIB1, Dako). The status of *MYC*, *BCL2* and *BCL6* genes was evaluated by fluorescent in situ hybridization (FISH) using dual-colour break-apart commercial probes (LSI MYC DC BA, LSI BCL6 DC BA and LSI BCL2 DC BA; Abbot Molecular, Abbot Park, IL, USA) in two tissue microarray constructed with representative cores.

Results: A total of 49 cases were included in the study. The median age was 59 years (range 13-80) and 23 were female (27%). In 9 cases there was a subjacent immunodeficiency (8 cases with HIV infection, 1 case was a renal transplant recipient). Immunohistochemical staining was positive for CD10 in 3/49 evaluable cases (6%), BLC6 in 34/48 (71%), and MUM1 in 48/49 cases (98%). According to this phenotype, 4 cases were classified as GC-like. The mean proliferative index (Ki67) was 72 % (range 40-95%). *MYC* translocation was demonstrated in 1 of 48 evaluable cases (2%) and *BCL6* translocation in 19 of 47 (40%). *BCL2* translocation was not demonstrated in any case. Moreover, copy gain or losses without translocations involving *MYC*, *BCL2* and *BCL6* genes were observed in 17%, 36% and 11% of the cases respectively.

Summary / Conclusion: PCNSDLBCL belong to the non-GC subtype and undergo frequent translocations of *BCL6*, but not *BCL2* or *MYC* genes, indicating a different molecular profile from its nodal counterpart.

B1599

GENETIC POLYMORPHISMS ARG399GLN IN DNA REPAIR GENE XRCC1 AND RISK OF HIGH-GRADE NHL ENTITIES

E Voropaeva[1*], T Pospelova[2], M Voevoda[3], O Berezina [2]

[1]Laboratory of molecular-genetic studies of therapeutic diseases, Scientific Research Institute of Therapy, The Russian Academy of Medical Science, [2]Department of Therapy, Hematology and Transfusiology, State Medical University, [3]Scientific Research Institute of Therapy, The Russian Academy of Medical Science, Novosibirsk, Russian Federation

Background: The pathogenesis of non-Hodgkins lymphomas (NHLs) as and other tumors remains unknown. The results of epidemiologic studies suggest that single nucleotide polymorphisms in DNA repair genes may contribute to individual susceptibility for development of cancers different localization. Gene *XRCC1* (X-ray repair cross-complementing group I) participate in control of cell cycle and genome stability. Protein XRCC1 enrolled in organization of enzymes complex, which are repairing DNA. Polymorphism Arg399Gln gene *XRCC1* results in restitution of arginine to glycine in protein XRCC1 structure and depression of its activity. A number of molecular epidemiologic studies investigated association polymorphisms Arg399Gln in the DNA repair gene XRCC1 with different neoplasm's including Hodgkin's disease and acute lymphoblastic and myeloblastic leukemias, but insufficient evidence is available for NHL.

Aims: The purpose of the present study was study genotype distribution of single nucleotide polymorphism Arg399Gln gene *XRCC1* in patients with different histological NHL entities and estimate the association of this polymorphism with NHL risk.

Methods: We studied the single nucleotide polymorphism Arg399Gln gene *XRCC1* in 98 unrelated patients with NHL. To estimate the association of polymorphism with NHL risk the genotype distribution of Arg399Gln single nucleotide polymorphism in patients were compared with the distribution 180 in healthy, white Caucasians Russian subjects. Genotyping was carried out with use of PCR-RFLP.

Results: We evaluated a significant elevation of mutant Gln/Gln genotype *XRCC1* frequency in patients with NHL compared with normal controls. Analysis indicated that mutant gomozygosity is a significant risk factor of NHL (OR=2.2, 95% CI, 1.19-4.12). A positive association between genotype Gln/Gln gene *XRCC1* and risk of high-grade lymphomas (OR=2.6, 95% CI, 1.20-5.73), in particularly Diffuse large B-cells lymphoma (DBLCL) (OR=4.88, 95% CI, 1.62- 14.77), was observed. In contrast, Arg/Arg genotype was significantly lower in the cases, especially in patients with high-grade lymphomas and DLBCL than the controls and persons with Arg/Arggenotype *XRCC1* showed a more significant decrease in risk of high-grade lymphomas (OR=0.42; 95% CI, 0.18-0.98). Non-statistically changes genotypes distributions were observed for patients with low-grade NHLs and the controls. There was no statistical low-grade NHLrisk change in persons with the genotype Arg/Arg (OR=0.74; 95% CI, 0.34-1.44) or the genotype Gln/Gln (OR=1.79; 95% CI, 0.84-3.83) of the *XRCC1* Arg399Gln polymorphism.

Summary / Conclusion: These data suggest that genetic polymorphisms Arg399Gln in DNA repair gene *XRCC1* may modify the risk of high-grade NHL entities.

B1600

CASTLEMAN'S DISEASE: IMMUNOHISTOCHEMICAL ASSESSMENT OF NEOANGIOGENESIS IN POEMS-SYNDROME

N Semenova[1*], S Bessmeltsev[1], V Baykov[2], A Michailov[3], Y Krivolapov[3], K Pozarisskiy[4], V Rugal[1]
[1]Russian research institute hematology and transfusiology, [2]St-Petersburg state of medical university I.P. Pavlov, [3]North western state university of medicine I. Mechnikov, [4]Russian national center for radiology and surgical technologies, Saint-Petersburg, Russian Federation

Background: Castleman`s Disease (CD) is an IL-6-dependent angiofollicular hyperplasia of the lymph nodes. The lesion occurs in two histological patterns (hyaline vascular and plasma cell) and may be local or multicentric. POEMS-syndrome is a rare complication of multicentric CD. The features of POEMS are polyneuropathy (P), organ enlargement-organomegaly (O), endocrinopathies (E), M-protein in the serum (M), and skin (S) changes. Most often the syndrome manifests with edema of the skin, subcutaneous fat and effusions in the serous cavities of the body. Overproduction of VEGF is currently discussed among probable pathogenetic mechanisms of POEMS.
Aims: The aim of the study was to check whether neoangiogenesis in the affected lymph node correlates with the development of POEMS in multicentric CD patients.
Methods: 15 patients with multicentric CD were included in the study. The diagnosis of CD was based on histopathological and laboratory findings. The spread of the CD as well as presence of the fluid in the serous cavities were estimated with CT scans. Polyneuropathy was proven by neuro-muscular conductometry. Presence of M-protein in the serum was detected by electrophoresis. Immunohistochemistry for CD31 was used to detect vascular endothelium in the lymph nodes. Perimeters of the vessels and vessel fraction area were calculated using image analysis VideoTest® software. Vessel fraction area index was calculated as mean value in 10 standard fields of view per case. The statistical significance was considered with p≤0,05 (Student criterion).
Results: Among 15 patients with multicentric CD included in the study 11 patients had hyaline vascular histological pattern and 4 patients had plasma cell or mixed pattern. All of 4 patients with plasma cell or mixed pattern had manifestations of POEMS. Vessel fraction area index in patients without POEMS was 11,5±0,83 % (M±m), and in patients with POEMS raised up to 29,4±8,4 % (p≤0,05). For comparison, single patient with tuberculosis infection and reactive lymphadenopathy had vessel fraction area index of only6,5%.
Summary / Conclusion: In multicentric CD substantial increase in vessel fraction area index is observed in patients with POEMS-syndrome as compared to those without POEMS. This finding may be related to the expected role of VEGF in the pathogenesis of POEMS.

Non-Hodgkin lymphoma - Clinical

DIAGNOSTIC SIGNIFICANCE OF PRETREATMENT SERUM LEVEL OF OSTEOPONTIN AND MACROPHAGE CHEMOTACTIC PROTEIN-1 IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

A Duletic - Nacinovic[1*], T Juranovic[1], T Valkovic[1], I Seili - Bekafigo[1], I Host[1], D Petranovic[1], E Fisic[1], K Lucin[2], S Stifter[2], N Jonjic[2]
[1]Hematology, Clinical Hospital Centre Rijeka, [2]Pathology, Faculty of Medicine, University of Rijeka, Rijeka, Croatia

Background: Diffuse large B cell lymphomas (DLBCL) are heterogeneous diseases which vary in biological expression and clinical course. While standard clinical prognostic factors predict outcome in DLBCL, predicting the outcome of patients might be further refined using biological factors. Some biological factors play a role in stimulation of malignant growth, metastasis and angiogenesis; however, their clinical relevance has not yet been well established for most of them.
Aims: The focus of this study was to determine pretreatment serum level of osteopontin (OPN) and macrophage chemotactic protein-1 (MCP-1) in patients with diffuse large B cell lymphoma and to investigate whether these factors provide prognostic information.
Methods: We measured pretreatment serum levels of OPN and MCP-1 by Enzyme-Linked Immunosorbent Assay (ELISA) in 67 patients newly diagnosed as diffuse large B-cell lymphoma and in 30 healthy controls. All patients were treated with rituximab-CHOP chemotherapy.
Results: The serum OPN levels were found elevated in untreated DLBCL patients compared to controls: in patients ranged from 25 to 238 pg/ml; median 94.2 pg/ml while OPN levels of the healthy controls ranged from 13 to 46.5 pg/ml; median 30.0 pg/ml (P=0.00008). There were significant differences in the serum MCP-1 levels between DLBCL patients and controls (median 1395.14 pg/ml vs. 779.3 pg/ml, P=0.035). Serum OPN levels higher than the median level was related to advanced Ann Arbor stage (P=0.026), International Prognostic Index of 2 or higher (P=0.005), ECOG ≥2 (P=0.004). The complete remission rate after treatment was higher in patients with low OPN serum levels than in those with high OPN serum levels (67.5% versus 32.4%, P=0.002). Elevated serum levels of OPN were strongly associated with shorter overall survival (P=0.007) and event-free survival (P=0.04). In multivariate analysis with International Prognostic Index criteria, OPN remained a significant predictor for overall survival (P=0.043). MCP-1 level was significantly correlated with age (P=0.005) and serum lactate dehydrogenase level (P=0.046), bat were not strongly correlated with other potential prognostic factors and it failed to show prognostic significance. A more advanced disease and/or poor prognostic factors were seen in patients who had both serum OPN and MCP-1 levels higher than the median level of the patients.
Summary / Conclusion: Our results showed that pretreatment serum level of OPN is significantly related to outcome in DLBCL patients.

B1602

THE USE OF PET-CT IN THE DIAGNOSIS OF ADULT T CELL LEUKAEMIA – LYMPHOMA SUBTYPES

A Macklin-Doherty[1*], A Danaee[2], M Moonim[3], D Wrench[1], G Mikhaeel[4], S Whittaker[5], A Pagliuca[6], R Marcus[7], V Warbey[8], P Fields[1]
[1]Haematology, Guys & St Thomas' NHS Foundation Trust, [2]Haematology, Guys & St Thomas' Hospital, [3]Histopathology, St Thomas' Hospital, [4]Clinical Oncology, [5]Dermatology, Guys & St Thomas' NHS Foundation Trust, [6]Haematology, Kings College Hospital, [7]Haematology, Kings' College Hospital, [8]Radiology, St Thomas' Hospital, London, United Kingdom

Background: The treatment of adult T-cell leukemia lymphoma (ATLL) is poor with median survival rarely exceeding 10 months in the aggressive subtypes. The diagnostic sub categorisation of the disease is important prognostically according to the original classification proposed by Shimoyama, which comprises acute (leukaemic), lymphomatous, smouldering and chronic subtypes. Acute and lymphomatous ATLL constitute the aggressive types and convey a worse prognosis. The role of PET-CT has been extensively investigated in the context of both Hodgkin's and Non-Hodgkin's lymphoma. However, to date no publications have characterised the appearances of the discrete ATLL subtypes on PET-CT.
Aims: Our aim was to characterise the appearances of ATLL subtypes on PET-CT, with particular emphasis on distinguishing aggressive disease from the indolent forms. In addition, we wished to investigate whether a correlation existed between the degree of marrow involvement and 18F-fluoro-deoxyglucose (FDG) uptake on PET-CT.
Methods: We retrospectively analysed 21 cases of ATLL treated at our institutions diagnosed between 2001–2012. 17 of these patients had PET-CT scanning performed as part of their initial diagnostic investigations and 4 after treatment or at progression. Bone marrow samples were described according to degree of disease involvement and correlated to intensity of FDG uptake on PET-CT. Clinical outcomes were correlated to PET-CT and bone marrow findings.

Results: The median age of patients was 49 years (male =9, female =12). 3/21 (14.3%) were categorized as aggressive acute subtype, 12/21 (57.1%) lymphomatous, 3/21 (14.3%) smouldering and 3/21 (14.3%) chronic. The median overall survival for all subtypes was 20.9 months (range 1.3-73.4 months). 16/21 (76.2%) of the patients have died. Patients with intense uptake on PET-CT at baseline (11/17, mean SUVmax 29.6, range SUVmax 9.6-85.2) displayed a tendency to markedly shortened median survival of 10.5 months compared to those with minimal/no uptake (5/17, mean SUV max 2.2, range SUV max 0-3.06) of 24.6 months regardless of subtype, although this was not statistically significant with our number of patients (P=0.28). All lymphomatous cases (n=10) demonstrated evidence of intense FDG avidity at baseline (mean SUVmax 24.5, range SUVmax 9.6-41.0) except 1 patient with no FDG avid disease who had a solitary lesion excised. All 3 cases of smouldering disease had either low or no FDG uptake (mean SUV max 2.0, range SUV max 0-2.88), no evidence of bone marrow involvement and remain alive and well. In 2 cases with excision of a solitary lesion, no uptake was demonstrated elsewhere. Of 19 assessable patients, 7 had documented marrow involvement: 3 had <5% disease bulk of which 1 had FDG uptake in bone. The 2 patients with high bone marrow involvement of 40% and 85-90% respectively both demonstrated intense skeletal FDG avid uptake (mean SUV 15.9).
Summary / Conclusion: In this series, patients with lymphomatous aggressive ATLL all demonstrated intense FDG avid uptake. All cases of smouldering subtype demonstrated minimal FDG uptake. In patients with resected localised skin disease and no evidence of FDG uptake, observation with serial HTLV-1 viral loads may identify those patients at high risk of progression to a more aggressive phenotype. The number of patients with marrow involvement was small, and intense FDG uptake appears to have been associated with greater disease bulk and more aggressive subtypes. Overall this retrospective analysis suggests PET-CT is useful in the diagnostic subclassification, and potentially prognosis of ATLL.

B1603

THE IMPACT OF FCΓ RECEPTOR POLYMORPHISMS AND GLUTATHIONE-S- TRANSFERASES POLYMORPHISMS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP

A Anastasopoulou[1*], G Georgiou[2], M Angelopoulou[2], K Lilakos[2], P Diamantopoulos[1], N Viniou[1], M Kyrtsonis[3], D Palaiologouu[3], J Meletis[2], G Pangalis[4], P Panayiotidis[3], T Vassilakopoulos[2]
[1]1st Department of Internal Medicine, [2]Haematology Department, [3]1st Propedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, [4]Haematology Department, Athens Medical Center, Athens, Greece

Background: FcγRIIIa polymorphisms have been associated with response to single-agent rituximab in patients with follicular lymphoma and Wandelstrom macroglobulinemia but data regarding DLBCL and follicular lymphoma patients treated with R-CHOP are conflicting. Glutathione transferases (GSTs) polymorphisms have been associated both with favorable and unfavorable outcomes in a variety of cancer types. In Korean DLBCL patients they have been associated with chemotherapy related toxicities.
Aims: In the present study, we evaluated the prognostic impact of polymorphisms of the FcγRIIIa, GSTT1, GSTM1 and GSTP1 genes on the outcome of patients with DLBCL treated with R-CHOP.
Methods: DNA was isolated from peripheral blood or bone marrow samples of 109 patients. The 158V/F polymorphism of the FcγRIIIa gene and the deletions of GSTT1 and GSTM1 were analyzed using multiplex PCR techniques. The Ile^{105}Val polymorphism of the GSTP1 gene was analyzed using a PCR-RFLP technique. PCR products were evaluated on ethidium bromide-stained agarose gels.
Results: Of the 109 patients tested for the FcγRIIIa-158V/F polymorphism, 28 (26%) were carriers of FcγRIIIa-158V/V, 23 (21%) of F/F and 58 (53%) of V/F. With respect to GST polymorphisms, 45 patients (52%) were GSTM1-null, 22 (25%) were GSTT1-null, 10 patients (11%) were GSTP1-105V/V, 42 (47%) were Ile/Ile and 38 (42%) were heterozygous. Eleven patients (13%) were GSTM1/GSTT1-double null, while 45 (52%) had only one deleted gene and 31 (36%) had no deletions. There were no significant associations between FcγRIIIa or GST genotypes and patients' characteristics. Presence of GSTM1-null genotype was not associated with concomitant presence of GSTT1-null genotype (P=0.85), neither was presence of GSTP1-105V/V associated with concomitant presence of GSTM1/GSTT1-double null genotype (P=0.77). The 5-year EFS was 76% for FcγRIIIa-158V/V, 70% for V/F and 64% for F/F (P=0.68). For the GSTP1-105I/V polymorphism, 5-year EFS was 86% for V/V, 67% for V/I and 74% for I/I (P=0.58). The 5-year EFS was 72% for GSTM1-null patients versus 69% for GSTM1+ (P=0.66) and 77% for GSTT1-null versus 69% for GSTT1+ (P=0.47). Finally, 5-year EFS was 90% for GSTM1/GSTT1-double null patients versus 68% for patients with one deleted gene and 71% for patients with no deletions (P=0.59). Given that patients with GSTP1-105V/V genotype and patients with GSTM1/GSTT1-double null genotype had the highest EFS rates (86±13% and 90±9% respectively), further evaluation showed that presence of either GSTM1/GSTT1-double null genotype or GSTP1-105V/V genotype (19 patients in total), was associated with a marginal improvement in EFS compared to any other genotype (P=0.13).
Summary / Conclusion: Our data indicate that there is no individual effect of GSTs polymorphisms on EFS of DLBCL patients treated with R-CHOP. However, carriage of either GSTP1-105V/V polymorphism or GSTM1/GSTT1-double null genotype is present in 20% of patients and is slightly associated with improved EFS. This finding needs confirmation in a larger group of patients.

B1604

MANTLE CELL LYMPHOMA WITH AN INDOLENT BEHAVIORS

A Rodriguez[1*], M Vargas[2], I Trigo[2], J Reyes[1], M Portero[1], A Figueredo[1]
[1]Hematology, [2]Genetics, HUVairgen macarena, Sevilla, Spain

Background: Mantle cell lymphoma makes up from 3 to 10% of non Hodgkins lymphomas. Median age of presentation is 60 years with male predominance. Morfologically limphocytes are small with a slightly indented nucleus and have a characteristic chromosomal translocation (11;14) (q13;q32). The survival of patients varies from 3 to five years, prognostic factors associated with a poor outcome comprise an increased mitotic index, blastic variant, 12 trisomy, aberrant karyotype, p53 gen mutations and peripheral blood involvement.
Aims: Evaluate Mantle cell lymphoma with indolent behavior in our institution
Methods: We have reviewed all mantle cell lymphomas diagnosed during the last 6 years in our Hospital. We studied 20 patients, 16 of them showed an indolent behaviour similar to B cell chronic lymphoid leukemia in A stage of Binet. We showed the results of these patients
Results: The male/female ratio of the patients was 2 to 4. The median age of our subjects was 72 years (range: 62-84 years) At diagnosis most of the patients had associated comorbidities, the most frecuent was HTA. Two patients suffered autoimmune hemolytic anemia before diagnosis of MCL was made and both of them showed good response to corticotherapy. Perypheral blood involvement was present in all cases , no anemia, and no thrombocytopenia appeared, morfologically limphocytes were small with a slightly indented nucleus coarse chromatine, without nucleoli, in one patient blastic cells were present in blood. Cells expressed strong inmunoglobulin , more often lambda light chain, CD5 and FMC7 while they were negative for CD10 and CD23 antigens. Only 3 patients had supra and infradiafragmatic lymphadenopathies inferior to 2 cms. 5 cases showed moderate splenomegaly . A FISH study in peripherical blood was performed in all patients which confirmed positivity for the translocation (11;14), without any others added abnormalities. None of the patients received treatment because of they were asymtomatic, the median follow up was 3 years, range (2-7 years)
Summary / Conclusion: There is a variant of indolent MCL similar to B cell chronic lymphoid leukemia in that affects peripheral blood without adenopathies. This asymptomatic patients without adenopathies should be treated by therapeutical abstention.
All of them were diagnosed following a inmunophenotype in peripheral blood on finding a lymphocytosis. It is important study prognosis factor of an index type of proliferation and added genetic anomalies to t (11;14) so as take therapeutical decisions

B1605

SIMPLE PROGNOSTIC PARAMETERS IN DLBCL: PRETREATMENT SERUM ALBUMIN LEVEL AS AN INDEPENDENT PREDICTOR FOR EFS AND OS

R Gurion[1,2*], A Abulafia[1,2], O Spilberg[1,2], O Bairey[1,2]
[1]Davidoff Center, Hematology Institute, Rabin Medical Center, Petach Tikva, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: The International Prognostic Index (IPI) is a widely used and accepted prognostic model for diffuse large B cell lymphoma (DLBCL). In the rituximab era, R-IPI is used as well. In the last years, several groups looked for additional simple prognostic parameters, not included in the original IPI, i.e. absolute lymphocyte count (ALC), absolute monocyte count (AMC) and absolute neutrophil count (ANC), with diverse results.
Aims: The aim of the present study is to evaluate the prognostic value of these parameters such as, ALC, AMC, ALC/AMC, ANC/ALC, hemoglobin and albumin level at diagnosis in patients with DLBCL and compare with known prognostic models as IPI and R-IPI.
Methods: We retrospectively reviewed data of 166 adult patients with DLBCL who were diagnosed at Rabin Medical Center, Israel, between the years 2004-2008. The mean age was 63.4 years, 43% were male, 62% with stage III/IV, 28% with ECOG performance status 0-2, 59% with elevated LDH level and 85% were initially treated with R-CHOP. The median follow up was 6.6 years (range 3.6-9 year).
Results: The 5 years overall survival (OS) for the entire group was 67.5%; for patients with lower IPI (0-2) – 76% (n=83); and for patients with higher IPI (3-5) – 48.8% (n=80). In univariate analysis, pretreatment hemoglobin and albumin levels had statistically significant effect on EFS and OS. Five years OS was 77.3% in patients with pretreatment albumin >3.5 g/dl, compared with 47.9% in patients with albumin level ≤3.5g/dl (P<0.001). Five years EFS was 68.9% *vs.* 45.8%, respectively (P<0.001). Five years OS was 81.7% in patients with pretreatment hemoglobin >12g/dl, compared with 56.5% in patients with hemoglobin level ≤12g/dl (P=0.003). Five years EFS was 74.6% *vs.* 51.1%, respec-

tively (P=0.002). However, univariate analysis did not identify pretreatment ALC, AMC, ALC/AMC and ANC/ALC as predictors for EFS and OS. Multivariate analysis using Cox regression, included the above parameters as well as IPI/R-IPI, showed that pretreatment albumin level was independent prognostic factor (P=0.001) for EFS and OS and its effect was significant as IPI or R-IPI effect.
Summary / Conclusion: Our data showed that albumin level is a strong prognostic factor for EFS and OS, and its effect is as good as IPI or R-IPI effect.

B1606
MANAGEMENT OF THE HBV REACTIVATION IN ISOLATED HBCAB POSITIVE PATIENTS AFFECTED WITH NON HODGKIN LYMPHOMA
M Masarone[2], A De Renzo[1*], R Della Pepa[1], V La Mura[3], G Signoriello[4], G Beneduce[1], V Rosato[5], I Migliaccio[1], C Cimmino[1], S Luponio[1], F Perna[1], F Pane[1], M Persico[2]
[1]Division of Hematology Federico II University, [2]Hepatology, II University, Naples, [3]Center for Liver Disease, First Division of Gastroenterology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, [4]Department of Statistical Sciences, [5]Gastroenterology and Endoscopy Department, II University, Naples, Italy

Background: Occult HBV infection (OBI) is defined by the persistence of HBV in the liver without serum HBsAg and HBVDNA. It represents a life threatening risk if the carrier experiences immunosuppression. An OBI can be present in about 18% of HBcAb+ patients. International guidelines suggest a strict surveillance for ALT and HBV markers in patients undergoing immunosuppressive therapies, in particular monoclonal antibodies. In Non-Hodgkin Lymphoma (NHL), OBI reactivation can occur in 3 to 25%. The real prevalence remains to be established.
Aims: To determine the prevalence of occult HBV reactivation in a large cohort of patients undergone immunosuppressive treatments for NHL and to confirm the association with monoclonal antibodies.
Methods: We analysed 498 NHL patients in a single centre of Southern Italy from 2005 to 2011. We evaluated HBV markers, type and NHL localization, treatment type and HBV reactivation.
Results: Fourty percent was treated with monoclonal antibodies and 60.3% without. Ninety six patients were HBcAb+ and HBsAg-. HBV reactivation occurred exclusively in ten subjects of this subgroup, 5 treated with Rituximab and 5 without. Every patient was treated with Lamivudine. No one experienced liver-related death.
Summary / Conclusion: Our data report a prevalence of OBI reactivation of 10.42% in HBcAb positive patients. This event occurred in 50% of cases in patients treated with no monoclonal antibodies. Each reactivation was treated with Lamivudine. This report enlightens the importance and the cost-effectiveness of a strict surveillance in HBcAb+ HBsAg- patients, in order to detect an occult HBV reactivation, also in NHL patients treated with monoclonal antibodies-free protocols.

B1607
EPIGENETIC MARKERS AS PREDICTORS OF RESPONSE IN YOUNG POOR RISK DIFFUSE LARGE B CELL NON HODGKIN'S LYMPHOMA (DLBCL)
T Hamid[1*], F Abu- Taleb[2], A Bahnassy[3], O Khorshid[1], S El- Shorbagy[2], A Zikri[4]
[1]Medical Oncology Department, NCI - Egypt, Cairo, [2]Medical Oncology Department, Zagazig University, Zagazig, [3]Pathology Department, [4]Biology Department, NCI - Egypt, Cairo, Egypt

Background: Young patients with poor risk DLBCL are characterized by truly refractory disease. Dose intensification of the standard combination chemotherapy is one of the methods to improve treatment results. DNA methylation is an important regulator of gene transcription; alteration in DNA methylation is common in development and progression of malignancy
Aims: To evaluate the promoter methylation (PM) of 4 genes: p16, p53, MGMT and GST as effective tools in predicting the outcome and prognosis of young poor risk DLBCL patients treated with CHOEP – 14 regimen
Methods: The study included 51 patients with high and high intermediate risk aaIPI DLBCL patients who were treated with CHOEP – 14 regimen. Promotor methylation of the tested genes was done by specific methylation PCR.
Results: Complete remission (CR) was achieved in 38 patients (74.5%). The CR rate was significantly affected by B-symptoms (P=0.03), extra nodal sites (P=0.03) and dose intensity of myelosuppressive drugs (P=0.001). PM of the studied genes was associated with significantly poor response (P=0.001) for the four tested genes. There was also significant relation between the methylation index and the response rate. The relapse rate was 23.7%. The 3 years DFS was 68.8% and 4 years OS was 96% with only one treatment related mortality. There was significant relation between the DFS and p53 PM as well as with p16 PM (P=0.02 and 0.05 respectively) while this relation was not significant with the other two tested genes. The main reported toxicity was myelosuppression, while non hematologic toxicities were infrequent and regressive
Summary / Conclusion: Hypermethylation of the studied genes correlated with poor response; however more studies are required to validate these findings.

B1608
NEITHER CONSOLIDATION RADIOTHERAPY NOR MAINTENANCE WITH RITUXIMAB OFFER ADVANTAGE TO PATIENTS WITH LARGE B CELL LYMPHOMA TREATED WITH STANDARD THERAPY
A Vega[1*], c espinel[1], d sandoval[1], l aguilar[1], b rubio[1], c borjas[1], o garces[1]
[1]IMSS, Guadalajara, Mexico

Background: Most patients (pts) with diffuse large B cell Lymphoma (DLBCL) treated with R CHOP achieve complete remission (CR). However, a significant percentage relapses. Different strategies try to decrease relapse. Consolidation with radiotherapy (RT) has played a role in the management of DLBCL, but its utility in the Rituximab era is less known. Although a modest benefit of Maintenance with Rituximab (MR) has been suggested, guidelines do not support its use in DLBCL. We present the results of 105 pts with DLBCL who achieved CR after treatment with R CHOP(Epirubicin 75 mg/m^2 substituted Doxorubicin= R CEOP).
Aims: Assess the potential benefit of consolidation RT or MR to decrease relapse. Four groups of pts were defined: first, pts with no further treatment after R CEOP courses, consolidation with RT comprised the second group, MR formed the third group and a fourth group included pts who received RT and MR.
Methods: Between January 2006 and December 2011 all pts ≥ 18 years in CR were included. Risk factors reviewed: age <60 versus ≥60 years, Eastern Cooperative Oncology Group performance status (ECOG 0-2vs >2), Ann Arbor Stage (I-II vs III-IV), Extranodal Disease (ED), Bulky disease(BD) (≥10 cm), International Prognostic Index (IPI low vs high risk),6 versus 8 courses R CEOP, RT and MR. After CR and R CEOP courses, physicians decided if adjuvant treatment was necessary based on their clinical judgment. Involved field RT was delivered at a total dose of 36 Gy. MR was started 3 to 6 months after the last course of R CEOP and consisted of 2 different schedules: Rituximab 375 mg/m^2 one dose weekly for 2 consecutive weeks every 6 months or Rituximab one single dose every 3 months; both schedules until completing 2 years. Time to relapse was measured from the application of the sixth course of R CEOP to relapse.
Results: Median age was 61 years (18-86). Median follow up of all pts was 24 months (1-72). Fifty seven (54%) pts were ≥60 years (69% of them did not receive adjuvant therapy). Seven (7%) subjects had ECOG >2. Advanced Disease was present in 38 (36%)pts. Fifty one (48.5%) pts showed ED. BD was observed in 50 (48%) pts (54% of them received RT). High risk IPI in 22 (14.6%)pts. Seventy six (72%) pts received 6 courses of R CEOP. Sixty six pts (62.8%) received adjuvant therapy: RT 21 (20%) pts, MR 31 (29.5%)pts and 14 (13.3%)pts received RT plus MT. The differences between groups were an older age for the no adjuvant therapy group (p< 0.05) and BD for the RT group (p< 0.04). In all, 17pts (16.1%) have relapsed at a median time of 9 months (3-54).The group with no therapy had 8 relapses, RT 3 relapses, MR 5 relapses and one relapse occurred in the group with both therapies.The 3-year relapse free survival rates were 79.4%, 85.7%, 83.8% and 92.8% for the no adjuvant therapy, RT, MT, and both therapies groups (p <0.4), respectively. For those relapsing, the risk factors were advanced stage (p < 0.009) and high risk disease (p < 0.008).
Summary / Conclusion: The majority of pts are in CR. Nevertheless, most cases had low risk disease. We did not observe difference between groups. BD is usually an indication for RT. However, near half of the pts with BD did not receive RT, and did not have an increase incidence of relapse. MR did not offer benefit. Advanced and High risk diseases were the only risk factors associated to relapse. Therefore, it seems reasonable not to use any further treatment in low risk disease after standard therapy. Prospective trials with larger number of pts are needed to evaluate RT in the rituximab era.

B1609
PROGNOSTIC RELEVANCE OF BASELINE NEUTROPHILE-TO-LYMPHOCYTE RATIO IN DIFFUSE LARGE B-CELL LYMPHOMA : RESULTS FROM A PROSPECTIVE COHORT STUDY
J Hong[1*], J Lee[1], S Lim[1], H Jung[1], S Kim[1], M Kim[1], M Choi[1], W Chang[1], S Park[1], Su Lee[1], W Kim[1], C Jung[1], Y Ko[2], S Kim[1]
[1]Division of Hematology-Oncology, [2]Department of Pathology, Samsung Medical Center, Seoul, Korea, Republic Of

Background: The systemic inflammatory response and host immunity has been associated with prognosis of various human cancers. The neutrophile-to-lymphocyte ratio (NLR), representing both inflammatory response and imuune status, has been proposed as a reliable marker to predict clinical outcomes in cancer patients.
Aims: The aim of this study is to determine prognostic significance of baseline NLR in patients with diffuse large B-cell lymphoma (DLBCL).
Methods: Subjects were selected from the Samsung Medical Center Lymphoma Cohort Study (a prospective cohort study registered at www.clinicaltrials.gov as NCT00822731). Survival analysis were performed by Kaplan-Meier methods and the log-rank test. To evaluate the independent prognostic significance of NLR, multivariate Cox regression models were applied. The optimal

cutoff value of NLR was decided by using ROC curve analysis.
Results: A total of 334 DLBCL patients receiving R-CHOP chemotherapy were included in this study. A NLR value of 3.1 corresponded to the maximum combined sensitivity and specificity on the ROC curve and the AUC (area under the curve) was 0.635 (95% CI 0.581-0.687, P=0.0009). With a median follow-up of 31.1 months (range, 0.3-55.5), patients with baseline NLR>3.1 (n=125) showed poorer overall survival (OS) (P<0.001) and progression-free survival (PFS) (P<0.001) compared to patients with baseline NLR≤3.1 (n=209). The expected 3-year OS and PFS rates were 63.0% vs 86.1% (P<0.001) and 58.0% vs 77.7% (P<0.001), respectively. In univariate analysis, the following variables were predictive of OS: NLR>3.1 (P<0.001), age older than 60 (P<0.001), ECOG≥2 (P<0.001), stage≥3 (P<0.001), high-intermediate or high IPI risk group (P<0.001), extranodal involvement≥2 (P<0.001), and bone marrow involvement (P=0.001). In multivariate analysis, NLR>3.1 (HR 2.0; 95%CI 1.2-3.4, P=0.009), age older than 60 (HR 3.0; 95%CI 1.8-4.9, P<0.001), ECOG≥2 (HR 1.9; 95%CI 1.1-3.3, P=0.021) retained its statistical significance as independent poor prognostic factors for OS.
Summary / Conclusion: This study suggests that baseline NLR is a simple and significant independent prognostic factor for OS in DLBCL patients treated with R-CHOP chemotherapy. Further studies are anticipated exploring the mechanisms of associations between NLR and clinical outcomes in DLBCL, such as inflammatory transcription factors and cytokines.

B1610

18-FLUORODEOXYGLUCOSE (FDG) OUTPERFORMS 18F-FLUOROTHYMIDINE (FLT) IN IDENTIFYING TRANSFORMATION OF FOLLICULAR LYMPHOMA, IN PARTICULAR THROUGH HETEROGENEITY IN UPTAKE

M Wondergem[1*], N Rizvi[2], O Hoekstra[2], R Boellaard[2], S Cillessen[3], J Regelink[1], M Chamuleau[1], N Hoetjes[2], P van de Ven[4], S Zweegman[1], J Zijlstra[1]
[1]Hematology, [2]Nuclear Medicine, [3]Pathology, [4]Epidemiology and Biostatistics, VU university medical center, Amsterdam, Netherlands

Background: Diagnosing transformation of follicular lymphoma (FL) to diffuse large B-cell lymphoma is important, since therapy regimens for FL are not effective in transformed lymphoma. Currently, transformation is probably underdiagnosed as transformation is known to occur focally whereas in general a biopsy is performed randomly. FDG-Positron Emission Tomography (PET), imaging glucose utilization, is known to correlate with proliferation rate. However, FLT might more specifically image proliferation through visualization of thymidine uptake.
Aims: Therefore we performed a prospective study to identify which PET-tracer, FDG or FLT, can be used to distinguish between FL and transformed lymphoma.
Methods: FDG- and FLT-PET scans were performed in 17 patients with FL and 9 patients with biopsy-proven transformed lymphoma. We measured SUVmax (standardized uptake value) of the lymph node with the highest uptake per patient and measured the range of uptake in involved nodes per patient. To reduce partial volume effects only lymph nodes larger than 3cc (measured as the A50 isocontour on the PET scan) were incorporated in the analysis. Scans were made on the Philips Gemini TF PET-CT camera, 1 hour after injection of 185 MBq of FDG or FLT.
Results: The SUVmax was significantly higher in transformed lymphoma as compared to FL for both FDG (median 22.0, range 14.6-42.4 in transformed and 10.9 (5.2-20.4) in FL, P<0.0001) and FLT (median 11.5, range 5.5-16.3 in transformed and 8.0 (3.6-16.6) in FL, P=0.03), however, with considerable overlap. Additionally we determined the range of FDG and FLT uptake in each individual patient. The FDG range was significantly higher in patients with transformed lymphoma versus patients with FL (6.0-37.5 versus 0.03-7.9, P<0.001) allowing discrimination between transformed lymphoma and FL. In contrast, FLT did not discriminate (P=0.07, ROC curve: AUC for FDG 0.967 vs FLT 0.716).
Using ROC curve analysis cut off values could be determined. Using a cut off of 14.5 for FDG SUVmax in the lymph node with the highest uptake, transformation was diagnosed with a sensitivity of 100% and a specificity of 82%. With a cut off of 6 for FDGrange, sensitivity was 100% and specificity 71%. For FLT no cut off values could be determined due to overlap of values. For validation, we analyzed FDG PET scans in 4 additional patients with transformed lymphomas and 5 patients with FL using these cut off values. Moreover, we used the same cut off values for 9 transformed lymphomas and 11 FL from literature (Bodet Millin Haematologica 2008). In these validation sets the 100% sensitivity could only be retained using the cut off of 6 for FDG range. The lower specificity found in the validation set (55-80%) is acceptable since it only leads to excess biopsies (when a FL is misclassified as a transformed lymphoma) and not to mistreatment of a patient (when a transformation is missed).
Summary / Conclusion: FDG-PET distinguishes better than FLT-PET between FL and transformed lymphoma. An intraindividual FDGrange of 6 or higher is highly suspicious of transformation and should guide diagnostic procedures.

B1611

FIRST-LINE THERAPY COMBINATION WITH RITUXIMAB AND FLUDARABINE IN PATIENTS WITH EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA OF THE MUCOSA-ASSOCIATED LYMPHOID TISSUE TYPE.

E Domingo[1*], A Salar[2], A Muntañola[3], M Canales[4], H Pomares[1], O Servitje[5], F Gallarrdo[6], C montalban [7]
[1]Hematology, Institut Catala d'Oncologia, [2]Hematology, Hospital de Mar-IMAS, Barcelona, [3]Hematology, Mutua de Terrassa, Terrassa, [4]Hematology, Hospital la Paz, Madrid, [5]Dermatology, Hospital Universitari de Bellvitge, [6]Dermatology, Hospital del Mar-IMAS, Barcelona, [7]Internal Medicine, Hospital Ramon y Cajal, Madrid, Spain

Background: There are no consensus guidelines regarding the best therapeutic option for patients for patients with extranodal marginal zone lymphomas of the mucosa-associated lymphoid tissue (MALT) type.
Aims: To evaluate the efficacy and safety of combination first-line therapy with Rituximab plus Fludarabine in extranodal MALT lymphoma patients.
Methods: Patients with untreated or de novo extranodal MALT lymphoma received a combination of rituximab (375 mg/m2 iv) on Day 1 and fludarabine (25 mg/m2 iv) on days 1 to 5 (patients aged > 70 years days 1-3), every 4 weeks. After 3 cycles a work-up was done: those patients who achieved complete remission (CR) received an additional cycle and those in partial remission (PR) received three more cycles.
Results: Twenty-seven patients were included. The median age was 60 years (32-83 y) and 15 (56%) were women. Twelve had gastric MALT lymphoma and 15 extragastric MALT lymphoma. Nine patients (33%) had stage IV disease. After 3 cycles, 16 (59%) of the patients were in RC and 10 (37%) were in PR (1 patient was not evaluated). Thirteen (48%) patients received a total of 4 cycles, 11 (41%) 6 cycles and 3 (11%) 3 cycles. At the end of treatment, 23 (89%) of the patients were in CR and 3 (11%) in PR. With a median follow-up of 66 months, 20 patients (74%) are in CR and 4 (15%) in PR. One patient died due to another malignancy and in two patients we lost follow-up. Toxicities were mild and mostly hematological.
Summary / Conclusion: First-line therapy with Rituximab and Fludarabine is a very active treatment, with a favorable safety profile and long lasting responses for patients with extranodal MALT lymphomas.

B1612

RITUXIMAB, CYTARABINE AND PLATINUM-BASED SALVAGE REGIMEN FOR RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMAS (DLBCL): A SINGLE RETROSPECTIVE SURVEY OF 66 PATIENTS

G Laboure[1*], K Bouabdallah[1], P Dumas[1], M Dilhuydy[1], N Milpied[1]
[1]Hematology department, Chu Bordeaux, Pessac, France

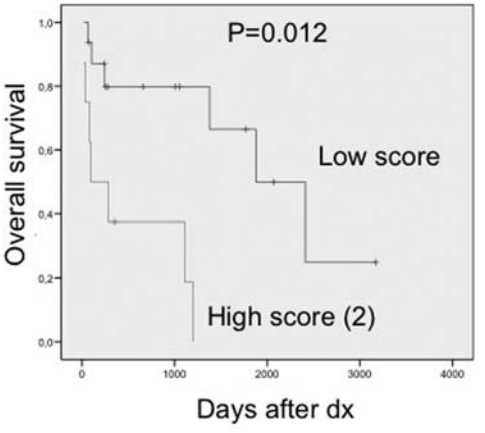
Background: Addition of Rituximab to CHOP-like first-line chemotherapy regimen has dramatically improved the outcome of DLBCL. Approximately 33% of patients (pts) experience relapse or refractory disease and underneed salvage therapy including high-dose therapy and autologous stem-cell transplantation (ASCT). However the best pre-transplant salvage regimen still remains to be determined (*Gisselbrecht C., CORAL study, J.C.O, 2010*).
Aims: The aim of this retrospective study is to evaluate the response rate after Rituximab, Cytarabine and Platinum-based salvage therapy in relapsed or refractory DLBCL before ASCT.
Methods: Sixty-six pts with refractory or relapsed de-novo DLBCL (n=52) or transformed indolent lymphoma (n=14) are reviewed between 12/2006 and 11/2012. All patients except 1 receive Rituximab in first or subsequent line treatments and all receive salvage regimen based on Rituximab 375 mg/m² d1 i.v., Dexamethasone 40mg/d d1-4 p.o., Cytarabine 2g/m² d2-3 i.v., with either Cisplatinum 100mg/m² d1 i.v.(n=22; 33%) or Carboplatinum AUC 5 d1 i.v. (n=44; 67%). Tumor response is assessed after 3 or 4 cycles by CT-scan (n=4; 6%), PETscan (n=60; 91%) or clinical assessment (n=2; 3%). When it is feasible, pts with CR or PR undergo BEAM conditioning regimen followed by ASCT.
Results: Relapse after first-line therapy occures in 16 pts with a median time of 18 months (7-76). In 50 pts, disease is considered as refractory based on positive PETscan (Deauville criteria) at intermediate assessment after 4 cycles of RCHOP-like regimen (n=43; 86%) or after the end of the front-line therapy (n=7; 14%). Median age is 57 years (23-73). Salvage therapy is administered for 2 (n=11; 17%), 3 (n=48; 73%) or 4 cycles (n=7; 11%) before assessment. The ORR is 74% with 41% CR, 33% PR,6,1% SD and 19,7% PD. Among the responding pts (n=49; 74%), 43 pts (88%) receive BEAM conditioning followed by ASCT. Six pts (12%) are not transplanted because of age (n=4), comorbidity (n=1), active infection (n=1). After a median FU of 13mo (3-65), over the 66 pts, 49 pts (74%) are alive, in CR (n=40; 61%) or in PR (n=3; 5%), 13 pts (20%) died from progressive disease. Among the whole cohort, 5y-OS is 67% without median reached. Among pts in ORR, 1y- and 3y-DFS are 86% and 78% respectively.
Summary / Conclusion: Rituximab-Cytarabine and Platinum-based salvage therapy shows an impressive response rate in relapsed or refractory DLBCL. Although retrospective date, our results compare favourably with published results.

B1613

CELL PROLIFERATION (KI-67) AND BCL2 AS PROGNOSTIC MARKERS IN PERIPHERAL T-CELL LYMPHOMA

R Fernández[1*], A González[2], L Gutiérrez[1], D Cuervo[3], E González[1], F Domínguez[4], C Fernández[1]
[1]Hematology, Hospital de Cabueñes, Gijón, [2]Stem Cell Transplant Unit, HUCA, Oviedo, [3]Internal Medicine, [4]Pathology, Hospital de Cabueñes, Gijón, Spain

Background: Peripheral T cell lymphomas (PTCL) comprise a heterogeneous group of rare malignancies, characterized by an aggresive clinical course and a poor survival. Although the International Prognostic Index (IPI) and the PTCL prognostic index (PIT) are used for prognostic stratification, their predictive utility is in need of improvement. Proliferation index and chemokine expression may have prognostic significance.
Aims: To investigate the prognostic value of proliferation index (as determined by Ki-67) and BCL2 protein expression (assessed by immunohistochemical methods) in a retrospective cohort of pts with PTCL.



Methods: 37 PTCL cases (28 male, 9 female; median age, 58 year [range, 28-81]) diagnosed between the years 2002 and 2012 were identified. Histology subtypes were as follows: PTCL-not otherwise specified (18, 49%), anaplastic large cell lymphoma-primary systemic type (9, 24%), angioimmunoblastic T-cell lymphoma (7, 19%), T/NK nasal type (2, 5%), intestinal T-cell lymphoma (1, 3%). Proliferation index and bcl-2 expression were reviewed by local hematopathologist. Clinical data was obtained thorough chart review.
Results: Most patients had advanced stage disease, 92% were stage III-IV (Ann-Arbor). 69% had elevated IPI score (3-4-5), and 84% elevated PIT score (2-3-4). The majority of patients (35) received initial treatment with CHOP-like regimens. For the whole group with a median follow-up of 43 months (range 2-139), the median OS was 12.7 months (95% CI, 0-42.1). The median profliferation rate (Ki-67) for the entire group was 80% (range, 10 - 91%; interquantile range, 66 - 80%). Pts with high Ki-67 (>= 80%) at diagnosis (n=21) had a worse OS (median 9.5 months) compared to those with Ki-67 <80% (80.3 months). This difference showed statistical significance (P=0.04) and the Hazard ratio (HR) for Ki-67 >= 80% was 2.7. We found no significant correlation between IPI or PIT scores and Ki-67. By histologic type, angioimmunoblastic T-cell lymphoma showed lower Ki-67 than all other types (55% vs 80%; P=0.013) and this subgroup had better outcome. BCL-2 expression was detected in 76% of the cohort, and showed negative impact on survival (P=0.015; HR=2.347).
We incorporated these variables into a scoring system: 1) a Ki67 index >= 80%, 2) BCL-2 expression. Patients were stratified into two risk groups: low (0 or 1 risk factor) and high risk (2 risk factors). Patients with a high score (2) had: less OS, when compared to the low-risk population (P=0.012) (fig. 1).
Summary / Conclusion: Ki-67>=80% and BCL-2 expression have a negative impact in survival in pts with PTCL, and should be applied in clinical practice.

B1614

AGE DISTRIBUTION OF LYMPHOMA PATHOLOGY SUBTYPES AS PART OF HAEMATOLOGICAL MALIGNANCIES IN JORDAN: A RETROSPECTIVE ANALYSIS OF 2653 CASES IN A TERTIARY CANCER CENTRE.

A Addasi[1*]
[1]Lymphoma Service/Program, Khcc, Amman, Jordan

Background: Lymphoma is the fourth most common newly diagnosed cancer in Jordan, a small country with a population of 5.85 million.
The age distribution of lymphoma pathology subtypes as a part of the overall haematological malignancies burden in Jordan has not been hitherto well characterized.
Aims: To characterize the clinico-pathological features of lymphoma, and their age distribution, in patients referred to King Hussein Cancer Center (KHCC)(aka Al Amal Cancer centre in the period 1997 to 2003), the major cancer tertiary referral centre in Jordan.
Methods: A retrospective analysis was conducted of all lymphoma patients referred to KHCC/Al Amal Centre, between 1/6/1997 and 31/1/2012. Clinical features and histological subtypes were retrospectively collected for all patients with a diagnosis of lymphoma, and incorporated in the Lymphoma Service Database
Results: Over the 15 year period of 1997-2012, 5153 patients with haematological malignancies were referred to KHCC/Al Amal Centre . Of those, 2653(51%) had a diagnosis of lymphoma, and thus were registered in the Lymphoma Service Database, of whom 160 (3%) were diagnosed with SLL/CLL and were included in the lymphoma cohort for the purpose of this analysis. 3219 of the cases above(62%) were aged 18 or older. 1692 patients (38%)younger than 18 years of age were classified as pediatric cases. 1150 of the latter group had a diagnosis of leukemia(53% of leukemia cases). On the other hand, 542 pediatric patients were diagnosed with lymphoma, constituting 20% of the lymphoma cases. There were 1074 cases (21% if all cases) of Hodgkin Lymphoma. B-cell lymphomas formed 1310 (87.3%) of the NHLs, whereas T-cell lymphomas formed (104)12.7% of the NHL total. Diffuse large B-cell lymphoma was the most common subtype, with 510 cases (50.7% of all NHLs). Follicular centre-cell lymphomas, B-cell small lymphocytic lymphoma, mantle-cell lymphoma, marginal zone B-cell lymphomas (including MALT lymphomas), and Burkitt lymphoma amounted to 90 (6.4%), 160(11.3%), 14(1.0%), and 43 (3.0%) and12(0.9%) respectively. Among the T-cell lymphomas, mycosis fungoides and anaplastic large-cell lymphomas of T/null-cell type accounted for 31(2.1%) and 27(1.9%) of all NHL cases, respectively.
Summary / Conclusion: To our knowledge, this is the biggest lymphoma series to be reported in Jordan to date. Non-Hodgkin lymphoma appears to constitute a smaller share of the lymphoma burden in Jordan in contrast to Hodgkin Lymphoma, as opposed to Europe and the US, with nearly one third of the cases being classified as Hodgkin Lymphoma. T cell lymphomas constitute a smaller proportion of NHL as opposed to other reports from Eastern Asia, Lymphoma constituted the vast majority of haemtological malignancies in adults, with HD (21%of all cases) and DLBCL (9.9%of all cases) accounting for roughly two thirds of all adult cases. ALL/LL, as expected, accounted for the majority of the haematological malignancies in the pediatric age group The lymphoma clinicopathological features, however, show important differences from those described in the rest of the world. Follicular lymphoma and mantle-cell lymphoma are less common in Jordan compared to Europe and the USA. Peripheral T-cell lymphomas and T/NK-cell lymphomas of nodal and extranodal nasal types, which are common in other Asian countries, are also less prevalent. DLBCL, as a result, formed a bigger proportion of NHL in Jordan. As described above, HD formed a bigger proportion of haematological malignancies in general, and lymphomas in particular, in Jordan.

B1615

MUM1/IRF4 /BCL6 EXPRESSION FAILS TO PREDICT SURVIVAL IN PATIENTS WITH GERMINAL CENTER B LYMPHOMA TREATED WITH IMUNOCHEMOTHEARPY-SINGLE CENTAR EXPERIENCE

S Trajkova[1,2*], I Panovska-Stavridis[1,2], A Stojanovic[1,2], D Dukovski[1], M Ivanovski[3], S Stankovic[1,2], A Pivkova-Veljanovska[1,2], M Popovska-Simjanovska[1], L Cadievski[1], G Petrusevska[4], L Cevreska[1,2]
[1]Hematology, University Clinik for Hematology, [2]Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of, [3]Hematology, [4]Institute of Pathology, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Diffuse large B-cell lymphoma is subclassifed into molecular subgroups that correspond to different stages of lymphocyte developmentnamely germinal center B-cell like and activated B-cell like. Myeloma associated oncogene MUM1/ IRF4 is a hallmark of activated B cell lymphoma (ACB). But MUM1 is also expressed in the nucleus or cytoplasm of small percentage of germinal center (GC) B cells located in the “light zone . Unlike normal GC B cells, lymphoma cells in approximately 50% of MUM1 (+) DLCL-B co expressed MUM1 and BCL6.
Aims: In line that MUM1 is predictor of inferior survival the aim of this study was to evaluate MUM1/IRF4/BCL6 immunohistochemical approaches for predicting the survival of patients with GCB lymphoma treated with imunochemotherapy
Methods: Our study enrolled 84 patients diagnosed and treated at the University Clinic of Hematology in the period between January 2002 and January 2012. They were all treated with R-CHOP regimen and the median follow-up of the patient was 36 months. We analyzed biopsy simples immunochemically for markers of germinal center(BCL6), postgerminal center(MUM1), and apoptosis marker (BCL2).
Results: The patients were divided in two groups BCL6+/MUM1+ (39pts;46,4%)and BCL6+/MUM1-(45pts;53,5%). The median overall survival time(OS) were 122,4 months in BCL6+/MUM1-group, and 90 months in BCL6+/MUM1+group respectively. The groups were statistically comparable regarding the prognostic parameters as IPI, performance status.
Summary / Conclusion: Our results did not show any statistical survival advantage and better outcome for the patient classified as GCB DLBL(BCL6/MUM1-) when treated with R-CHOP and indicate that immunohistohemical markers do not really reflect the molecular diversity of the tumor. They also support the studies that suggests that Rituximab eliminates or modulates the significance of some already established prognostic markers for DLBL and indicate that previously recognized markers should be re-evaluated in the context of the

modern therapy and that new prognostic indicators for DLBL has to be identified.

B1616
THE USE OF FLIPI AND FLIPI 2 IN FOLLICULAR LYMPHOMA
R Damas[1*], M Brochado[1], F Trigo[1], J Guimarães[1]
[1]Hematology, Hospital São Joao, Oporto, Portugal

Background: Is has been proposed the use of two different prognostic scores when staging Follicular Lymphoma. FLIPI (Follicular Lymphoma International Prognostic Index) is a prognosis index developed in the pre-rituximab era and divides patients into different overall survival (OS) risk groups. FLIPI 2 was developed in the post-rituximab era and is prognostic for progression free survival (PFS).
Aims: To evaluate FLIPI and FLIPI 2 prognostic value.
Methods: We analysed retrospectively 106 patients with follicular lymphoma diagnosed (1997-2012) in our hospital.
Results: The median age at diagnosis was 56 years-old [33;85], 54.7% were male and 43.4% were over 60 years. The median follow-up was 43 months [1;175]. 65.1% patients were in advanced stage (III-IV-Ann Arbor staging system) and 19.1% had B symptoms at diagnosis with 60.4% of extranodal sites. Lymphoma grade was classified (WHO) 1)31.6%, 2)50.7% and 3A) 17.7%, 3B grade lymphomas were not included in the analysis. 36.6% had liver/spleen enlargement and 7.6% had serous effusions. Bulky mass (>6cm) was present in 10.7% and 9.7% had >= 5 nodal sites involvement. 80% had hemoglobin <=12g/dl, no patients had leucopenia (<1.0x10^9/L) and 3% had thrombocytopenia (<100x10^9/L), 31.4% and 24.4% had LDH (lactate dehydrogenase)/B-2 microglubulin elevated. FLIPI: low risk: 45.9%, intermediate risk: 38.8% and high risk: 15.3% (98 patients) and FLIPI 2: low risk: 53.4%, intermediate risk: 29.3% and high risk: 17.3% (75 patients). The treatment strategy was grouped: "Watch&Wait" (WW) (33%) and chemotherapy/radiotherapy (67%). The majority of WW were patients with early stage disease (I-II:58,8%; P<0.0001) and 68.8% had low FLIPI risk (P<0.02). Patients treated with chemotherapy/radiotherapy were mainly at advanced stages (III-IV:79.7%; P<0.0001) and 50% had intermediate FLIPI (P<0.02). No significance found in FLIPI 2 between these two. Comparing different variables in FLIPI/FLIPI 2 we found 13.5% with both high B-2 microglubulin and LDH and 29.8% with only one (P<0.01). In advanced stages 72.1% had bone marrow involvement (P<0.0001). No significance found between nodal regions >=5 vs bulky mass. The 5-year OS was 93.8% and PFS was 63.5%. Six patients have died. FLIPI showed significance in OS with 100% (low risk), 89.1% (intermediate risk) and 83.6% (high risk) patients alive after 5 years (P<0.046) and in PFS with 72.9% (low risk), 59.6% (intermediate risk) and 25.9% (high risk) without progression/relapse after 5 years (P<0.035). FLIPI 2 showed no significant differences either in OS or PFS. In FLIPI, only age and hemoglobin had significance in OS 98,1% (< 60years;P<0.05) and 97.1% (hemoglobin <=12 g/dl; P<0.02) and this was also true for PFS using FLIPI 2: 74% (P<0.001) and 75.1% (P<0.0001) respectively.
Summary / Conclusion: Only variables common to FLIPI and FLIPI 2 had significant prognostic value. Surprisingly patients with hemoglobin lower than 12 showed better OS and PFS at 5 years. As expected FLIPI had value in OS but FLIPI 2 did not show significance in PFS. Whether FLIPI or FLIPI 2 should be used to decide treatment in not clear. This study showed that 68.8% WW group had low FLIPI, hence this maybe helpful to determine therapeutic strategy. The group chemotherapy/radiotherapy was mainly at advanced stages with 50% intermediate FLIPI.

B1617
BENDAMUSTINE PLUS RITUXIMAB IN PATIENTS WITH RELAPSED OR REFRACTORY WALDENSTRÖM'S MACROGLOBULINEMIA (WM)
S Improta[1], M Villa[1*], A Gagliardi[1], A Lucania[1], P Della Cioppa[1], M Esposito[1], L Mastrullo[1]
[1]U.O.C. Ematologia, P.O. San Gennaro ASL Napoli 1 Centro, Napoli, Italy

Background: WM is an incurable disease, with an overall medial survival of only 5-6 years. Age, hemoglobin level, platelet count, β(2) microglobulin, and monoclonal IgM concentrations are characteristics required for prognosis. First-line therapy of WM has been based on single-agent or combination therapy with alkylator agents (e.g. chlorambucil or cyclophasphamide), nucleoside analogues (cladribine or fludarabine), and the monoclonal antibody rituximab.
Aims: Novel therapeutic agents that have demonstrated efficacy in WM include thalidomide, lenalidomide, bortezomib, everolimus and bendamustine.
Methods: We report the treatment outcome for 16 (9 male, 7 female; median age: 70y, range: 67-78) relapsed/refractory Waldenström's macroglobulinemia (WM) patients. Treatment consisted of bendamustine (90 mg/m(2) I.V. on days2, 3) and rituximab (375 mg/m(2) I.V. on day 1) for all patients. One rituximab-intolerant patient received bendamustine alone. Each cycle was 4 weeks, and median number of treatment cycles was 4.
Results: The clinical stage (remission, progression or stable disease) was defined with clinical re-evaluation after chemotherapy and re-staging 6 months after end of therapy. At best response, median serum IgM declined from 3500 to 500 mg/dL, and hematocrit rose from 29.9% to 37.8%. Overall response rate (CR + PR) was 81.2%. Overall therapy was well tolerated. Prolonged myelosuppression was more common in patients who received prior nucleoside analogues.
Summary / Conclusion: Bendamustine in combination with Rituximab demonstrates an excellent effectiveness in previously treated WM patients, with an acceptable toxicity profile. These agents, when compared to traditional chemotherapeutic agents, may lead in the future to higher responses, longer remissions and better quality of life for patients with WM.

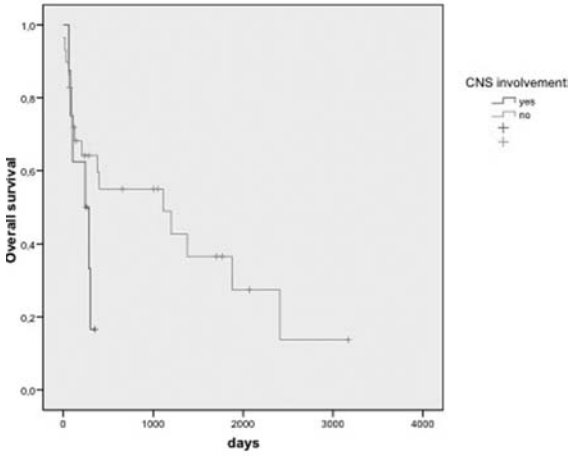
B1618
ORAL MUCOSA NON-HODGKIN'S LYMPHOMAS: A CLINICOPATHOLOGIC STUDY OF 22 CASES
E Georgakopoulou[1], M Moschogiannis[2*], P Tsirkinidis[2], M Achtari[3], X Yiakoumis[2], C Kalpadakis[4], S Sachanas[2], M Angelopoulou[5], T Vassilakopoulos[5], M Siakantaris[6], M Kyrtsonis[5], C Kittas[7], G Laskaris[1], G Pangalis[2]
[1]Dental Clinic, Oral Medicine Center, Ipsiladou 37, Athens , [2]Haematology Department, Athens Medical Center, Psychicon Branch, [3]Dental Clinic, Dental Clinic Paedon Pentelis General Hospital, Athens, [4]Haematology Department, University of Crete, Heraklion, [5]Haematology Department, University of Athens, "Laikon" General Hospital, [6]1st Department of Internal Medicine, University of Athens, [7]Histology , Department of Histology and Embryology, Medical School of Athens, Athens, Greece

Background: Oral non Hodgkin lymphomas (NHL), is a rare subgroup of NHL. Represent less than 5% of the oral cavity malignancies and 2% of all extranodal NHL. The vast majority of them is located in the Waldeyer's ring, mostly in tonsils (70%), but they also may affect the salivary glands, the bone of the jaws and the oral mucosa.
Aims: To report the clinical and laboratory characteristics, as well as the outcome of patients with oral mucosa-NHL (OM-NHL).
Methods: We performed a retrospective analysis of 22 patients records, diagnosed with OM-NHL from 1997 until 2012. Patients with Waldeyer's ring lymphoma (including tonsils), salivary gland lymphoma, and lymphomas that affected the bone of the jaws were excluded from this study. Data, related to histological subtype, clinical stage at diagnosis, international prognostic index (IPI), bulky disease, B-symptoms, treatment administered, response rates, 5-year failure free survival (FFS) and overall survival rate (OS), were recorded.
Results: 12 patients were were male and 10 female, with a median age of 58 years. After staging, (An-Arbor System), oral mucosa was the only site of involvement in 73% (Stage-IE), while 18% were clinical stage II and 9% clinical stage IV. The location of NHL was: tongue 45%, gingival mucosa 23%, palate 14%, lips 14% and the mouth floor 4%. A B-cell phenotype was documented in 64% and a T-cell in 36%. The most common histological subtype was found to be diffuse large B cell lymphoma (DLBCL) in 45%, followed by peripheral T-NHL (PTCL-NOS) in 32%. 9% were diagnosed with mantle cell lymphoma (MCL), 9% with follicular lymphoma (FL) and 5% with anaplastic large cell lymphoma (ALCL). Increased levels of LDH were recorded in one patient, bulky disease in 4/22 patients (2 DLBCL, 1FL, 1 MCL pleiomorphic), B-symptoms also in 4/22 patients (1 DLBCL, 1 FL, 1 MCL, 1 MCL pleiomorphic). Treatment included immunochemotherapy (41%), chemotherapy (31%), immunotherapy (23%) and radiotherapy (RT) followed by chemotherapy (5%). 5/9 patients with NHL of T-cell origin were placed on Interferon-α (INF-α) treatment, while 8/13 patients with NHL of B-cell origin received as first line treatment immunochemotherapy R-CHOP. Among the treatment modalities used in the T-NHL group, INF-α, either as monotherapy or as a rescue therapy in relapsing patients, was highly effective, producing long lasting CRs. After a median follow-up of 64 months, the vast majority of our patients (91%) is alive, while 77% of them are in complete remission (CR). We did not record any significant difference in response and survival rates between the two major histological subtypes (B-NHL versus T-NHL).
Summary / Conclusion: This is one of the largest series focusing on NHL exclusively on the oral mucosa. Our results are contributing in the understanding of the clinical behavior of this NHL subgroup. The percentage of OM-NHL originating from T-cells was significantly higher (36.4%) than that reported for the nodal T-NHL. Response rates are remarkably high, with a long lasting overall survival, independently of the histological subtype.

B1619
RETROSPECTIVE REVIEW OF PERIPHERAL T-CELL LYMPHOMA IN A SINGLE INSTITUTION: OUTCOME AND CENTRAL NERVOUS SYSTEM INVOLVEMENT
R Fernández[1*], L Gutiérrez[1], A González[2], D Cuervo[3], E González[1], F Domínguez[4], C Fernández[1]
[1]Hematology, Hospital de Cabueñes, Gijón, [2]Stem Cell Transplant Unit, HUCA, Oviedo, [3]Internal Medicine, [4]Pathology, Hospital de Cabueñes, Gijón, Spain

Background: Peripheral T cell lymphomas (PTCL) comprise a heterogeneous group of rare malignancies, characterized by an aggresive clinical course and frequent extranodal involvement. Moreover, little data exist on the risk of central nervous system involvement (CNS) by these lymphomas.

Aims: To describe the clinical characteristics and outcome of PTCL patients, and to estimate the frequency of CNS involvement.
Methods: Retrospective analysis of all PTCL cases diagnosed in Gijon (Asturias, Spain), that covers a population of approximately 450,000 people, between 2002 and 2012. Clinical data were obtained thorough chart review. CNS involvement was defined by positive finding in citology or flow cytometry analysis of CSF.
Results: A total of 37 cases were identified, the histology subtypes were: PTCL-not otherwise specified (18, 49%), anaplastic large cell lymphoma-primary systemic type (9, 24%), angioimmunoblastic T-cell lymphoma (7, 19%), T/NK nasal type (2, 5%), intestinal T-cell lymphoma (1, 3%). 3 patients had received another diagnosis (B-cell lymphoma, Hodgkin's disease) prior to the current diagnosis of PTCL. One case was diagnosed post-mortem. Median age at time of presentation was 58 (range 28-81) years, 35% were ≥65 years old. ECOG was 2-4 in 57%, and 68% had B symptoms. Most patients had advanced stage disease: 92% were stage III-IV (Ann-Arbor), 76% had extranodal involvement, and 38% had documented bone marrow involvement. 69% had elevated IPI score (3-5), and 84% elevated PIT score (2-4). Laboratory data showed elevated LDH level in 73% and elevated Beta-2-microglobulin in 76%. A total of 35 pts received initial treatment, the majority received CHOP-like regimens. 8 pts (22%) received consolidation with autologous stem cell transplant (ASCT) in 1st remission. At the end of first line therapy, overall response was 57% (17 pts CR; 4 pts PR), while 7 cases (19%) had disease progression and 22% experienced early death during treatment. Overall, 19 pts (51%) presented relapse/progression: 15 were treated with platinum-containin regimens, and 5 pts underwent salvage SCT (4 allogeneic, 1 autologous). With a median follow-up of 1298 days (range 79-4173), the median OS for the whole group was 382 days (95% CI, 0-1262). Pts who received transplant in 1st remission had better outcomes than as salvage treatment (P=0.029). CNS disease, as detected by flow cytometry, was found in 8 pts (22%), with no case found in angioimmunoblastic subtype and the highest number of cases in ALCL (4 cases, 50%), and NOS (3 cases, 37.5%). Median time to CNS involvement was 67.5 days (range, 33-296), and univariate analysis only identified elevated LDH (P=0.05) as risk factor for CNS disease, without correlation with BM involvement. Median OS for this group of pts was particularly dismal (244 days, CI 29 - 459 days) (fig. 1).
Summary / Conclusion: This 10-year review of patients treated in a single institution confirms the poor clinical outcomes of PTCL: advanced stage, extranodal involvement, high rate of early death, poor response to front-line treatment, and short OS after relapse. We also find a strikingly high frequency of CNS involvement, as detected by flow cytometry. A CNS surveillance and prophylaxis strategy should be considered for this type of lymphomas.



B1620
IMPACT ON SURVIVAL ACCORDING TO HISTOLOGICAL GRADE (1-2 VS 3A) IN A SERIES OF 128 PATIENTS DIAGNOSED OF FOLLICULAR LYMPHOMA IN THE RITUXIMAB ERA. EXPERIENCE IN ICO-HOSPITAL DURAN I REYNALS.
H Marín[1*], S Vilchez[1], F Esteller[2], E Domingo-Domenech[1], A Ramos [1], V Henao[1], A de Sevilla Ribosa[1], E González-Barca[1]
[1]Department of Hematology, ICO-Hospital Duran i Reynals, [2]Department of Pathology, Hospital Bellvitge, Barcelona, Spain

Background: Around 15-25% of all follicular lymphoma (FL) are histological grade 3a and comparing with grade 1-2 have different clinicobiological features.
Aims: To analyze clinicobiological characteristics, response to therapy and outcome of a series of 128 patients according to histological grade 1-2 vs 3a in a single institution.
Methods: Between 2004 to 2012 were identified in our data base among 128 patients diagnosed with follicular lymphoma. Histological grades were: grade 1-2, 91 patients (71%); grade 3a, 30 patients (23%) and grade 3b, 7 patients (6%). Histological grades were reviewed according to WHO criteria. We analyzed the clinical and biological features, response rate and prognosis of 121 patients with histological grades 1-2 and 3a.

	FL grade 1-2 (N=91)	FL grade 3a (N=30)	P
Watch and Wait	6/91	0/30	NS
1st line Chemotherapy (N)	91	30	
R-CHOP/R-COP like (%)	82 (90)	30 (100)	NS
R plus Fludarabine analogues (%)	6 (7)	0 (0)	NS
Monotherapy with rituximab(%)	3 (3)	0 (0)	NS
Complementary Radiotherapy	1 (1)	4 (13)	0.04
CR and CRu (%)	59/89* (66)	26/30 (90)	**0.015**
OS at 5 years (%)	81	73	0.39
EFS at 5 years (%)	59	43	0.4
CD10 (%)	93	82	0.12
Bcl2 (%)	96	93	NS
Bcl6 (%)	100	100	NS
Ki-67 > 50% (%)**	17	41	**0.052**

* Two patients not yet evaluated **Performed in 30 and 22 cases, respectively

Results: The clinical characteristics of patients with histologic grade 1-2 vs 3a were: 41M/50F vs 8M/22F; median age, 57 vs 62.5; stage III-IV, 90% vs 77%; B symptoms, 16% vs 10%; high LDH, 31% vs 41% and high β2microglobulina 57% vs 59%, respectively. The percentage of patients with high risk IPI, FLIPI and FLIPI 2 according to grade 1-2 vs 3a was: 6.5% vs 15%, 42% vs 38% and 43.5% vs 45% respectively. Biological data at diagnosis, therapy, response rates, overall survival and event free survival at 5 years are shown in the table. With a not reached median overall survival, 21 (17%) patients died, 14(15,4%) of them with histological grade 1-2 and 7 with histological grade 3a, mostly due to disease progression. Ki-67 index > 50% at diagnosis predict a worse OS at 5 years (54% vs 91%, P=0.072). The probability of transformation to high-grade lymphoma for grade 1-2 vs 3a was 5.5% vs 10% at 5 years (P=0.13), respectively. In multivariate analysis, IPI, FLIPI and FLIPI 2 at diagnosis of all series were the main prognostic factors for survival.
Summary / Conclusion: In our series, histologic grade follicular lymphoma 3a has peculiar biological characteristics, lower expression of CD10 and especially a higher proliferative index. Although patients with histological grade 3a have a significant higher rate of complete remission, OS and EFS are similar in both groups.

B1621
PROGNOSTIC VALUE OF 18 F-FDG TEP IN DLBCL ELDERLY PATIENTS TREATED WITH IMMUNO-CHEMOTHERAPY
A Tempescul[1*], J Ianotto[1], C Berthou[1], N Lombion[1], P Salaun[2]
[1]Clinical Hematology, [2]Nucleaire Medecine, Teaching Hospital Brest, Brest, France

Background: Diffuse large B-cell lymphomas are heterogeneous family of blood diseases which prognosis depends on specific phenotypic, molecular and pathological features. One of the techniques for the evaluation and response is 18 F-FDG PET scanner. If PET scanner imagings at diagnostic (initial extension) and at the end of the treatment (response evaluation) haveal-ready shown their interest through several studies, the impact of the interim evaluation on survival is not yet consensual.
Aims: We conducted a retrospective, monocentric cohort study, to characterize the predictive value of such interim PET scanner (3 courses of treatment) in DLBCL elderly patients treated with R-PMitCEBO.
Methods: We evaluated39 patients aged over 65 years, diagnosed with DLBCL between 2006 and 2011. Patients received immunochemotherapy (R-PMitCEBO regimen) for 6 cycles. Therapeutic response was evaluated according to Cheason 2005 criteria, after 3 and 6 cycles of chemotherapy. An assessment of overall survival (OS) and disease-free survival (DFS) was performed for all patients. Two evaluations were conducted, the first to compare patients in complete remission versus those who are not (CR / nonRC). The second evaluation compares the patients in complete remission versus those in partial remission. (CR / PR).
Results: Among the 39patients, 24 were in complete remission (CR) after 3 courses, 10 in partial remission (PR) and 5 in stable disease (SD). Two year outcome evaluation (CR / notCR at 3 cycles) find PFS at82% for patients with CR and only 29% for patients in nonCR; OS was 78% in formers against 38% among others. More precisely, evaluation of patients with CR compared to PR, provides a two-year PFS was 82% for formers against 50% for laters and a two-year OS of 78% and 50% respectively.
Summary / Conclusion: In elderly patientstreated with R-PMitCEBO, immunochemotherapy for DLBCL, assessment by 18 F-FDG PET scanner is an essential tool for diagnosic and therapeutic monitoring. The interim evaluation after three cycles of chemotherapy has a strong predictive impact on overall survival and disease-free survival for this profile of patients. The use of interim PET scanner allows to rapidly switch the treatment for a another one to maximise the chances to obtain complete remission instead of partial remission or stable disease.

B1622

LANGERHANS CELL HISTIOCYTOSIS IN ADULT PATIENTS: SINGLE INSTITUTION EXPERIENCE

A Yilmaz[1*], m comert[1], a guneş[1], y anacak[1], n özsan[1], m hekimgil[1], s kamer[1], f şahin[1], f vural[1], g saydam[1]
[1]Ege University of Medicine , izmir, Turkey

Background: Objective: Langerhans cell histiocytosis (LCH) is characterized by abnormal proliferation of histiocytes. It is rare disease with an incidance of 1 -2/ million. Although it is more frequent in children at 1-3 years old, it can be diagnosed in all ages. Disease can be presented by multifocal or localized organ infiltrations. Although all systems and organs mıght be infiltrated, main sites for disease is bone, especially skeletal bones. Treatment options differs according to its presentation as local or multifocal. At local disease, only radiotherapy can be effective modality but patients with multifocal disease should be treated with systemic chemothepies or with combination.
Aims: At this study, we aimed to retrospectively analyse our adult LCH patients diagnosed between 1992-2012
Results: Twenty-one patients, 13 male and 8 female, were retrospectively analyzed. Median age was 29(range, 18-53). All of the patients had bone involvement and bone pain has been most prominent complaint according to the involvement site. We documented poliuria and polidipsia in one patient due to hypophysis involvement in addition to bone. 13 (%15 female, %85 male) patients were presented with local disease and 8(%25 male, 75 female) patients had multifocal disease. The characteristics of the patients were given at table 1. The patients with local disease were treated with only radiotherapy and then followed up. The patients with systemic disease were treated with both radiotherapy and chemotherapy. During the treatment period,any grade 3-4 hematological side effects were not documented. The median period of follow-up was 19 (range, 4-120) months. We determined 7 relapses in 4 patients. All of the relapses were detected with bone lesions and they were treated with radiotherapy successfully. Median overall survival was 19 months. 6 patients were lost to follow up. No deaths were recorded during follow up.
Summary / Conclusion: At this retrospective study with relatively limited number of patients, we reported that adult onset LCH patients were mostly presented as a focal disease with bone pain. The radiotherapy was an effective tretatment modality at these patinets. Although, LCH is a rare disease in adult age groups, it should be considered in patients with bone lesions.

B1623

RITUXIMAB MAINTENANCE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA: SINGLE CENTER EXPERIENCE

M Popova-Simjanovska[1*], L Cevreska[1,2], S Trajkova[1,2], D Dukovski[1], M Ivanovski[1], S Stankovik[1,2], I Panovska-Stavridis[1,2]
[1]Hematology, University Clinic for Hematology, [2]Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of

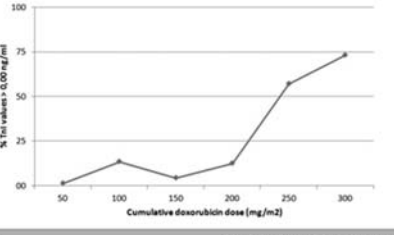
Background: Diffuse large B cell lymphoma (DLBCL) are curable group of lymphoma with improved outcome mainly due to the incorporation of the anti-CD20 monoclonal antibody, Rituximab (R) to the standard chemotherapy regimens. According to clinical and pharmacokinetic data, prolonged exposure to Rituximab is associated with higher response rates and improved quality of response. Although most of the big clinical studies are not finished, so far, initial findings are not very promising in regard to the overall survival (OS) and progression free survival (PFS) for the patients receiving maintenance treatment in comparison with patients without maintenance treatment after completion of standard therapy with R-CHOP.
Aims: Here, we present our experience with the Rituximab maintenance treatment of DLBCL patients (pts) that were treated at the University Clinic of Hematology in the past 4 years.
Methods: Since 2006, at our Clinic, 42 pts with DLBCL that were not included in a clinical study underwent R maintenance treatment. Pts received Rituximab (375 mg/m^2) every 3 months for 2 years. Our control group consisted of 65 DLBL pts that were treated in same period at our Institution and do not underwent maintenance treatment. Our two groups were comparable regarding the age, gender and IPI score distribution. All evaluated pts initially received 8 cycles of standard R-CHOP regimen. Only pts in complete remission underwent R maintenance treatment. CR was required for entrance in the control group two. We evaluated and compared the progression free survival (PFS), overall survival (OS) between the two groups. Moreover, we evaluated the tolerance of R maintenance treatment and the impact of prolonged R use at pts quality of life (QoL).
Results: After a median follow up of 42 months, PFS was excellent with 32,5% in the treatment group and 27.7 % in the control group. There was no significant statistical difference regarding those two parameters in both groups (P>0.05). Maintenance therapy was generally well tolerated, but we noticed marked and prolonged hypogammaglobulinaemia in the maintenance group. Further investigation of the median initial and follow up serum imunnoglobulin G (IgG) levels in both groups showed : 10,7 g/L and5,07 g/L in the treatment group, respectively, and 13,8 g/L and8,9 g/L in the control group. Statistical correlations of those results showed that maintenance group has statistically significant lower IgG levels (t-test, P<0,05).Furthermore, more frequent hospitalizations and requirement of immunoglobulin therapy were registered in the maintenance group due to the occurrence of recurrent infections, which worsened QoL of those pts.
Summary / Conclusion: In our experience R maintenance therapy did not improve PFS or OS in pts with DLBCL. More over, pts from the maintenance group had a significantly higher risk of developing hypogammaglobulinemia. Our results suggest that risk of developing symptomatic hypogammaglobulinemia should be considered before starting R maintenance. It is in our opinion that evaluation of a larger patient population, together with a longer follow-up is needed before establishing R-maintenance treatment as standard therapeutical approach for DLBL pts..

B1624

CARDIOTOXICITY MONITORING WITH A NOVEL COMBINED APPROACH OF TELEMEDICINE AND BIOMARKERS IN LYMPHOMA PATIENTS TREATED WITH CONVENTIONAL AND LIPOSOMAL ANTHRACYCLINES

G Guido[1*], J Olivieri[1], B Caterina[1], M Dottori[2], S Trappolini[1], C Montevecchi[1], G Perna[2], P Leoni[1], A Olivieri[1]
[1]Hematology Clinic, Marche Polytechnic University, [2]Dept. of Medical and Surgical Cardiovascular Sciences, "AOUOORR Ospedali Riuniti" Hospital, Ancona, Italy

Background: Anthracyclines (AC) are highly effective cytotoxic drugs both in solid and hematological malignancies, whose use, however, is limited by the occurrence of cardiac toxicity (CT). In recent studies intensive cardiac monitoring (with echocardiography *or* biomarkers) has shown to provide an early identification of subclinical cardiac damage: in this case prompt suspension of the AC treatment and aggressive management of the asymptomatic cardiac dysfunction can lead to reversal of the cardiac injury. Liposomal AC formulation has been invoked as a CT-sparing treatment with similar antitumoral activity, especially in old patients or those with cardiac disease.
Aims: Study endpoints are: to measure with the combined monitoring approach the incidence of CT, measured as reduction in the left ventricular ejection fraction (LVEF), rises in TnI levels, significant ECG changes.A telemedicine (TM) system was integrated in this setting to allow for an optimization of health care resources, an increased compliance to intensive monitoring without impacting on the quality of care provided



19 patients	Cumulative doxorubicin dose(mg/m^2)					
	50	100	150	200	250	300
TnI controls performed	71	59	45	32	14	15
TnI values > 0,00 ng/ml*	1	8	2	4	8	11
% TnI values > 0,00 ng/ml	1.4	13.6	4.4	12.5	57.1	73.3

Fig.1: Trend for increasing TnI values with increasing cumulative doxorubicin dose

*Only 2 values above 0,08 ng/ml

Methods: This is a prospective observational trial in lymphoma patients undergoing treatment with conventional or liposomal AC. Informed consent was obtained from each enrolled patient. We used a comprehensive approach to monitor for AC CT, using echocardiography, ECG and biomarkers (Troponin I - TnI). Clinical, echo, ECG and TnI data were acquired in our Hematology Clinic and transferred via TM to be evaluated by the reporting cardiologist.
Results: The study enrolled 20 patients, 13 males and 7 females. The median age at diagnosis was 40.9 years (range 20.1 to 78.2 years). 14 patients had a diagnosis of non-Hodgkin's lymphoma and 6 of Hodgkin's lymphoma. Two patients underwent chemotherapy with liposomal AC, all the others with conventional AC. Three patients had at least one cardiovascular risk factor. In six months we performed 216 TM assessments. Compliance to the protocol was excellent as 97.4% of the planned TM evaluations and 94% of the programmed TnI controls, were actually performed. In all cases, the data were successfully transferred to the cardiologist's client. The average time to perform a complete TM assessment was 19 m and 47s, while less than 6 minutes were used for the echocardiographic examination. It took less than 5 minutes on average by the cardiologist to evaluate data from 1 TM assessment and to produce a report. The primary endpoint (reduction in LVEF), did not occur in any of the 19 evaluable patients. In two patients the monitoring detected asymptomatic signs of cardiac ischemia (in one case diffuse T-waves inversion in anterior leads, in the other posterior wall hypocinesia and moderate TnI rise): both patients underwent percutaneous coronary intervention with optimal myocar-

dial revascularization. In both cases patients were aged >65 years and had a cardiovascular risk factor. These cases were not thought to be related to AC. The patients completed the planned chemotherapy course and they are well. In six patients, at some point during the monitoring, a pericardial effusion was found, in all cases not symptomatic. Except the above mentioned case, none of the patients developed a TnI rise above our laboratory cut-off (0.08 ng/ml). However, with increasing cumulative AC doses, we observed a progressive increase in TnI values > 0.00 ng/ml (Figure 1).
Summary / Conclusion: AC CT monitoring is recommended by most guidelines but seldom practiced. Our innovative approach of integrating different detection methods through a TM system allows for a feasible and accurate monitoring of AC CT, and makes possible the application of a preventive strategy for AC CT.

B1625
LOW DOSE BENDAMUSTINE IN LYMPHOPROLIFERATIVE DISEASE: A SINGLE CENTER EXPERIENCE
M Pelosini[1*], R Riccioni[1], E Capochiani[1]
[1]Dipartimento di Oncologia, Centro Aziendale di Ematologia, Livorno, Livorno, Italy

Background: Experience with Bendamustine has grown in various hematologic neoplasms both in relapsed/refractory patients and at diagnosis. Results are very encouraging with clinical and long lasting response. Treatment is usually well tolerated also in older and/or unfit patients and in those with renal impairment.
Aims: We report here our observation of low dose bendamustine in a wide group of hematologic patients treated at our Institution.

Table 1	Patient's features		
Diagnosis		Total number	38
Waldestrom disease	3	Male/Female	19/19
DLBCL	3	Median age	67,4 (20-89)
Multiple myeloma	1		
Mantle cell lymphoma	2	Disease status at treatment	12 (3,5%)
Hodgkin disease	3	Diagnosis	5 (13,3%)
Hairy Cell Leukemia	6 (15,8%)	Refractory Patients	21 (55,2%)
Chronic lymphocytic leukemia	7 (18,4%)	Relapsed	
Follicular lymphoma	10 (26,4%)		

Table 2	ORR	PR	CR	NV	NR	PFS	DFS	OS
All patients	73,6 %	39,5 %	34,2 %	7,9 %	18,4 %	54,5 %	46,3 %	77,3 %
Disease status								
Diagnosis	100 %	41, 7 %	58,3 %	-	-	100 %	100 %	100 %
Refractory	60 %	60 %	-	-	40 %	33 %	50 %	53 %
Relapse > 2	44,4 %	44,4 %	-	11,1 %	44,4 %	23 %	66 %	56 %
Relapse < 2	74,9 %	33,3 %	41, 6 %	16,6 %	8,3 %	75 %	37,5 %	100 %
Diagnosis								
HCL	100 %	-	100 %	-	-	100 %	-	100 %
Follicular Lymphoma	80 %	40 %	40 %	10 %	10 %	88 %	-	67 %
CLL	71,4 %	42,8 %	28,6 %	14,6 %	14,3 %	57 %	-	100 %

Methods: We considered a total of 38 patients with different hematologic diagnosis with a median age of 67.4 years (20-89). 36/38 were treated with low dose (50-60 mg/m^2) Bendamustine (days1,2) in association with rituximab 375 mg/m^2 (day 3) with the exclusion of MM and HL cases. Cycles (4 to 8) were repeated every 28 days. Two patients were treated with lower dose due to comorbities. Patients were treated at diagnosis (31.5%), relapse (55.2%) and progression (13.3). Patients and treatment characteristics are summarized in table 1. Response was defined according to Cheson Criteria, toxicities on the basis of CTC criteria. Statistical analysis we utilized Prism software (MacOS).
Results: 36/38 were evaluable. Treatment was well tolerated in the majority of patients. One patient had to stop treatment due to skin lesions, that occurred in 4 patients (10.5%). Infections were noted in 8/36 patients (21.5%) but not clinically relevant. Hematologic toxicities were mild with 4 case of grade IV neutropenia (10.5%). Among the whole group overall response rate (ORR) was 73.6 % with complete (CR) and partial response (PR) respectively of 34.2 % and 39.5 %. Non responders patients were 3/38 (7.9%). We look for response considering diagnosis (CLL, follicular NHL, HCL) and disease status at treatment (diagnosis, progression and relapse). Patients with HCL (n=6) had impressive response with 100 % CR and no relapses, in those with follicular NHL and CLL had ORR of 80% and 71.4 % respectively Patients at diagnosis have an ORR of 100 % (PR 41,7 %, CR 58.3%), refractory patient responded in 60% cases. We split the group of relapsed patients in those who had less or more than two relapses. Patients in 1st o 2nd relapse had a ORR , PR and CR of, 74.9%, 41.6% and 33.3 %, while in those in subsequent relapse ORR were 44,4% with only PRs and 4/9 patient refractory to treatment. OS, DFS and PFS at 15 months for the whole group were respectively 77,3 %, 46,3 %, 54,8%. But when we split PFS in groups we see how patients at diagnosis had a PFS 100 %, in 1st and 2nd relapse of 77 % , while those treated later or in progression of 33 % and 23 %. Response are summarized in table 2.
Summary / Conclusion: Our experience with low dose bendamustine showed a very good safety and tolerance profile also in elderly and unfit patients with mild infective and hematology toxicities. Responses were satisfactory in the whole group that comprised also multi-treated and refractory patients. Patients at diagnosis and in particular those with hairy cell leukemia had better response with ORR of 100 % and no relapse observed so far. Even those who were treated later in disease history or in progression could be rescued, but often with not long lasting response. In conclusion we confirm the satisfactory data with bendamustine in lymphoproliferative disorders, results that can be obtained also con lower dose and in unfit patients. Results are much better in untreated/low treated patients and with low grade lymphomas, especially in HCL. These observation should be confirmed with longer follow up and more patients.

B1626
HIGHLY ACTION ANTIRETROVIRAL THERAPY (HAART) IMPROVED EFFICIENCY OF CHEMOTHERAPY IN PATIENTS WITH HIV-ASSOCIATED NON-HODGKIN'S LYMPHOMAS (HIV-NHL)
I Davydkin[1*], R Khayretdinov[1], A Nizyamova[1], E Vehova[1], O Danilova[1], E Rogova[1], S Semochkin[2]
[1]The department of hospital therapy with course of hematology, The Samara State Medical University, Samara, [2]Division of Oncology and Hematology, Russian National Research Medical University named by N.I. Pirogov, Moscow, Russian Federation

Background: In total 40 315 patients were diagnosed with HIV infection in Samara region of Russia: 89.8% directly in the town and 11.2% in the surrounding region. 4774 (11.8%) pts died at the time of this analysis. Risk of developing of NHL in these patients was more than 100 times greater than in the general population.
Aims: To analysis of the epidemiology of HIV-NHL, their own experience of their treatment.
Methods:
During2002-2010, 47 patients with NHL-HIV were treated in our center. Three groups of patients were analyzed: (1) 25 received HAART plus CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) chemotherapy (CT) and (2) 15 – only CHOP chemotherapy and 17 only best supportive care. HAART consisted of a combination of three antiretroviral drugs. Response on HAART was defined as increasing the number of CD4+ cells >10x10^6/L and a decrease in viral load <500 copies/ml.
Results: Median of time from diagnosis of HIV infection to NHL development was 3.7 years. Median age pts was 32,5±2,4 years (range, 01-99). Abs (67%) cases were classified as diffuse large B-cell lymphoma (DLBCL), abs (6%) – spleen marginal zone B-cell lymphoma (SMZL), and abs (27%) follicular lymphoma (FL). Abs (47%) patients had a number of CD4+ cells <10x10^6/L at the start of the NHL treatment. The median overall survival (OS) was 18.4 months for the group 1 (HAART plus CT) against 7.5 months (P<0.05) for group 2 (CT) and 4.4 months (P<0.05) for the group 3 (best supportive care). For patients, which therapy was initiated (n=42), unfavorable prognostic factors were age >60 years, AIDS–phase of HIV, Hb <10.0 g/dl, elevated levels of LDH and non-availability of HAART (P<0.05).
Summary / Conclusion: Our data retrospective data suggest that combination of chemotherapy with HAART improved outcome in patients with HIV-NHL. Increasing the number of CD4+ cells and reduction of viral load is essential for the success of chemotherapy.

B1627
THE ROLE OF CONSOLIDATIVE RADIOTHERAPY IN DIFFUSE LARGE B CELL LYMPHOMA PATIENTS WITH BULKY DISEASE.
B Ugur[1], e tekgunduz[1*], S Bozdağ[1], a tetik[1], ı demiriz[1], M Cinarsoy[1], O Kayikci[1], S Namdaroglu[1], F Altuntas[1]
[1]Ankara Oncology Hospital, Ankara, Turkey

Background: Bulky disease, remains to be a significant prognostic factor for non Hodgkin lymphoma patients .The role of consolidative radiotherapy in these patients is still contraversial. Diffuse large B cell lymphoma patients is 30%>40% of all non Hodgkin lymphoma patients.Bulky disease, remains to be a significant prognostic factor for non Hodgkin lymphoma patients .The role of consolidative radiotherapy in these patients is still contraversial.
Aims: So, we aimed to asess the role of radiotherapy in diffuse large B cell lymphoma patients with bulky disease.
Methods: We retrospectively included 92 patients with non hodgkin lymphoma, subtype of diffuse large B cell who had bulky disease in Ankara Oncology Hospital.Bulky disease was defined as the size of lymphadenopathy over 5 cm. Patients characteristics were summarized in Table 1. All patients were treated with six –eight cycles of RCHOP chemotherapy.We excluded patients in whom complete remission with first line chemotherapy could not be achieved and grouped 65 patients in first complete remission in to those treated with radiotherapy(n:22) and not(n:43).We aimed to asess the relapse rates and progression free survival difference between the groups
Results: Median follow up of the patients were 30(6-149) months.Patients in both groups were similar according to age,sex and IPI score. There were statistically significantly higher number of patients with advanced disease status

in non radiotherapy group. The number of patients who relapsed during the follow up were not statistically different between the groups. (5/22 vs 10/43 , p:0.962).Although, 4 years progression free survival was slightly higher in radiotherapy arm(79% ±11% vs 64%±11%) ,it was not statistically significant(p:0,282).
Summary / Conclusion: The use of RT was associated with significant improvements in OS and PFS for all patients with DLBCL in previously reported studies.Although PFS was longer in radiotherapy group, it was not found to be statistically significant in our series.This results has to be assesed in prospective clinical trials.

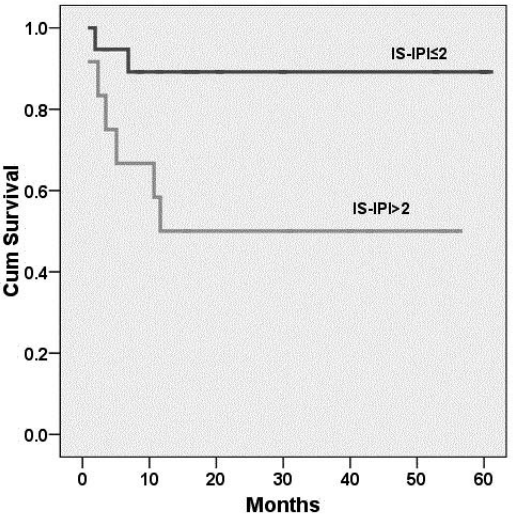
B1628
A 10-YEAR SINGLE-CENTER EXPERIENCE IN PRIMARY GASTRIC DIFFUSE LARGE B CELL LYMPHOMA: FROM PRESENTATION TO TREATMENT AND PROGNOSIS
D Antic[1*], J Jelicic[2], V Djurasinovic[2], V Vukovic[2], N Milic[3], M Todorovic[1], J Bila[1], B Andjelic[2], M Jovanovic[2], L Jakovic[2], B Mihaljevic[1]
[1]Clinic for hematology, Clinical Center Serbia, Medical faculty, University in Belgrade, [2]Clinic for hematology, Clinical Center Serbia, [3]Institute for medical statistic and informatic, Medical faculty, University in Belgrade, Belgrade, Serbia

Background: Diffuse large B cell lymphoma (DLBCL) is a common subtype of non Hodgkin lymphomas (NHL), and its extranodal variant can arise from extranodal lymphatic tissue or non-lymphatic tissue. Primary gastric (PG) non Hodgkin lymphoma is a malignancy localized in the stomach with or without abdominal and/or extraabdominal lymph nodal involvement and constitutes 20-30% of all extranodal NHLs. Management of primary gastric diffuse large B cell lymphoma (PG-DLBCL) remains controversial as well as reliable staging system and prognostic factors. Few decades ago surgery has played a central role in the diagnosis, staging, and treatment of PG-DLBCL but adition of chemotherapy significantly improved survival. Since the availability of Rituximab, there is a lack of comparative studies investigating clinical effectiveness between surgery with immunochemotherapy and immunochemotherapy alone.
Aims: The aim of this study is to compare two treatments (immunochemotherapy alone and surgery plus immunochemotherapy) as well as to define most important prognostic factors.
Methods: Records of all-stages patients with a diagnosis of PG-DLBCL which were treated in the Clinic for Hematology Clinical Center of Serbia, between 2002 and 2012, were reviewed. Patients fulfilling the following criteria were included in this study: patients with histologically proven large-cell B lymphoma of the stomach who received Rituximab plus CHOP (R-CHOP) regimen as first-line immunochemotherapy with or without additional surgical resection.
Results: From 73 patients who were fulfilled inclusion criteria 44 received R-CHOP and 29 underwent surgical resection followed by R-CHOP. All clinical and pathological features were similar between the two groups. 45 patients (61,5%) had complete response to treatment, 11 (15,1%) had partial response to the treatment, 2 (2,7%) had stable disease and 15 (20,5%) had progressive disease. Tumor resection did not improve 5-years OS (75,9% and 65,9%, for surgery plus immunochemotherapy and immunochemotherapy alone, respectively, P=0.293). Ann Arbor clinical stage ≥II (P=0.047), ECOG≥2 (P=0.008), IPI≥2 (P=0.038), stage-modified IPI (for II2 grade of the Lugano staging system) (P=0,036), trombocytosis > 450x10^9/l (P=0.001), level of CRP ≥5mg/l (P=0.028) and albumins level low than 28g/l (P=0.047) were predictors of OS in patients with PG- DLBCL. A new *inflammatory stage* IPI (IS-IPI) risk score (smIPI plus level of CRP) was recognized as the best prognostic tool (P=0,045) in multivariate analysis. There were significant differences among patients with low-risk (score 0,1,2) and intermediate/high-risk groups (score >2) in 5-years OS (89.5% vs 50.0%, P=0.021).
Summary / Conclusion: IPI staging system modified for high level inflammation has shown to be the best prognostic tool for overall survival of PG-DLBCL patients. Adition of tumor resection to immunochemotherapy did not improve survival. In preventing morbidity arising from early or late complications from surgery, immunochemotherapy should be a primary option for DLBCL of the stomach. To confirm clinical effectiveness of Rituximab beyond 5 years studies with longer follow up are needed.



B1629
DIFFUSE LARGE B CELL LYMPHOMA PRESENTING WITH OSSEOUS INVOLVEMENT, CLINICOPATHOLOGICAL CHARACTERIZATION AND SURVIVAL ANALYSIS
H Azim[1*], O Abdelrhman[1], R Abdeltawab[1], R Abdelmalek[1], M Shahin[1]
[1]cairo oncology centre, Giza, Egypt

Background: Primary diffuse large B cell lymphoma of bone is an extremely rare condition that is usually confused with other primary injuries of the bone.
Aims: we have thus conducted this retrospective analysis of our non Hodgkin lymphoma database to determine the clinicopathological and survival characteristics of this unusual presentation.
Methods: DLBCL patients treated at Cairo Oncology Centre (Cairo, Egypt) in the period between 2000-2008 were reviewed. Eligible patients were those who had complete information on date of diagnosis, histopathological and immunohistochemical confirmation of the diagnosis and received CHOP-like chemotherapy. We compared the difference in systemic therapy and pathological parameters between cases presenting with and without osseous involvement. We investigated the impact of osseous involvement on progression free survival (PFS) and overall survival (OS) in a Cox regression model adjusted for age, Ann Arbor stage, performance status, extranodal involvement, presence of B symptoms, IPI score and treatment.
Results: 240 DLBCL patients were included in the analysis fulfilling the inclusion criteria. Of which 21 patients only have definite radiological evidence of bone involvement (8.75%). Bone involvement was isolated in 5 cases, associated with nodal involvement in 4 cases and associated with both nodal and extranodal localization in 12 cases. Median age for the whole group is 53 years while for the bone involvement group it was 54 years. At a median follow up period of 13 months, the median PFS for the whole group was 79 months, for the osseous involvement group it was 34 months. Cases with bone involvement were more likely to have advanced stage (P=0.048), bone marrow involvement (P=0.004), higher IPI (P=0.043). Based on univariate analysis, bony involvement alone was not significantly associated with shorter PFS (P=0.202).while bone involvement was not significantly associated with other adverse clinicopathological factors (elevated LDH, B symptoms or bulky disease).
Summary / Conclusion: According to our data, patients with DLBCL presenting with bony involvement more often present with advanced stage, shorter median PFS and higher risk disease and should be considered for more aggressive treatment.

B1630

EVALUATION OF EFFICACY AND SAFETY OF BENDAMUSTINE TREATMENT IN OSAKA LYMPHOMA STUDY GROUP(OLSG) OF JAPAN

T Kohara[1*], H Shibayama[2], N Uoshima[3], Y Terada[4], E Nakatani[5], H Yoshida[6], J Ishikawa[6], H Masaie[6], A Mugitani[7], T Kumura[7], S Okamoto[7], Y Kamitsuji[3], H Sugahara[8], M Nakagawa [9], M Kawakami [9], J Ishiko [9], H Take [10], S Kosugi [10], S Nakata [10], Y Nagate [10], T Kida [10], Y Moriyama [11], Y Kataoka [11], N Tominaga [12], T Morita [12], S Inoue [12], M Yamada [12], F Urase [13], A Toda [14], K Hayashi [15], N Nakamichi [16], Y Tokumine [17], A Inoue [17], T Tamaki [18], M Tsukaguchi [19], M Shibano [19], H Hattori [20], M Kuwayama [20], N Anzai [21], M Matsuda [22], S Ueda [23], H Matsunaga [23], H Mitsui [24], K Hashimoto [25], N Wada [26], E Morii [26], Y Kanakura [27], M Hino [28], Osaka Lymphoma Study Group [29]

Background: Bendamustine was approved in Japan in December, 2010 and used for the patients with relapsed or refractory indolent lymphoma.
Aims: In this study, we evaluated efficacy and safety of bendamustine in the practical use.
Methods: We analyzed the clinical data of 122 patients who were treated with bendamustine from December, 2010 to March, 2012 in OLSG.

Overall Response Rate (ORR)	BR combination (N=87)	B monotherapy (N=35)
CR/CRu	52 (59.8%)	15(42.9%)
PR	19 (21.8%)	8 (22.9%)
SD	8 (9.2%)	3 (8.6%)
PD	8 (9.2%)	8 (22.9%)
Unknown	-	1 (2.9%)
Prior B regimen numbers: ORR	*P<0.0001*	
1: CR+PR	38 (92.7%)	3 (100%)
1: SD	2 (4.9%)	-
1: PD	1 (2.4%)	-
2: CR+PR	14 (93.3%)	9 (69.2%)
2: PD	1 (6.7%)	4 (30.8%)
≥3:CR+PR	19 (61.2%)	11 (57.9%)
≥3: SD	6 (19.4%)	3 (15.8%)
≥3: PD	6 (19.4%)	4 (21.1%)

Results: The patients' ages were 36 and 90 (median: 68). The ratio of male to female was 52.5:47.5. The histological diagnoses were follicular lymphoma in 70.5% and mantle cell lymphoma in 18.9%. Bendamustine was used in combination with rituximab in 71.3% of cases. The other cases were treated with bendamustine monotherapy. The completion of the planned regimen (six cycles) was done in 29.5%, while the other caseswere discontinued therapy due to the adverse events (36.0%), PD (22.1%) and achievement of CR (24.4%). Regarding response, 59.8% of CR and 21.8% of PR were achieved in combination with rituximab, while 42.9% of CR and 22.9% of PR were achieved with bendamustine monotherapy. CR+PR were achieved in 93.2%, 82.1% and 56.0% of the patients whose prior treatment regimen number were one, two andmore than three respectively. The progression-free survival of the patients treated with bendamustine-rituximab combination was significantly better than bendamustine monotherapy (P=0.0457).The multivariate analysis showed that three factors (sex, serum LDH level and prior treatment regimen number) were prognostic; female, low LDH and one or two prior regimen were favorable factors. Regarding toxicity, the hematological adverse event (HAE)(Grade 4) was observed in 71.3% and non-HAE (Grade3, 4) was observed in 12.6% with bendamustine-rituximab combination, while in 60.0% and 11.4% respectively with bendamustine monotherapy. Furthermore, febrile neutropenia (Grade3, 4) was observed in higher number of cases with bendamustine-rituximab combination than with bendamustine monotherapy.
Summary / Conclusion: Bendamustine was quite effective for the patients with relapsed or refractory indolent B-cell lymphoma. The early use of bendamustine-rituximab combination was supposed to be more effective. However, the combination use caused the more severe toxicity. It is necessary to clarify the best dosage of bendamustine in combination with rituximab expecting the best efficacy and safety in the future study.

B1631

PREDICTING FACTORS FOR GLUCOCORTICOID INDUCED-DIABETES MELLITUS IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS WHO RECEIVED R-CHOP CHEMOTHERAPY

S Lee[1*], N Kurita[1], S Chiba[1]

[1]Department of hematology, University of Tsukuba hospital, Tsukuba, Japan

Background: Glucocorticoids are widely used in treatment of patients with lymphoma in combination with chemotherapy agents, but development of hyperglycemia is one of the major problems. Avoidance of unnecessary tests for screening of glucocorticoid-induced diabetes mellitus (GDM) might improve the quality of life during chemotherapies for patients with lymphoma.
Aims: To evaluate predicting factors for GDM in patients with diffuse large B cell lymphomas (DLBCL) who received R-CHOP chemotherapy.
Methods: A total of 46 patients with DLBCL who received chemotherapy with R-CHOP regimen in University of Tsukuba Hospital from November 2006 to June 2012 were analyzed. Patients with previous diagnosed DM were excluded. Diagnosis of DM was based on the American Diabetes Association's criteria with, fasting plasma glucose (FPG) □ 126 mg/dL or a random plasma glucose □ 200 mg/dL accompanied by classic symptoms of hyperglycemia. Metabolic syndrome was defined by the criteria of the International Diabetes Federation, with body mass index (BMI) > 30 kg/m^2 and any two of the following: 1) raised triglycerides > 150 mg/dL; 2) reduced HDL cholesterol < 40 mg/dL in males, < 50 mg/dL in females, or specific treatment for this lipid abnormality; 3) systolic blood pressure (SBP) > 130 mm Hg or diastolic BP (DBP) > 85 mm Hg. All described values of Hemoglobin A1c (HbA1c) in this study are expressed in HbA1c, NGSP. Univariate analysis was perfromed by chi-square test, and linear logistic regression analysis was used for multivariate analysis.
Results: Total number of patients diagnosed as GDM during R-CHOP chemotherapy was 14 of 46 patients (30.4%). Median total cycle number of chemotherapy was6, and 9 of 14 patients with GDM (64.2%) were diagnosed during the 1st cycle. 3 of 14 patients with GDM were managed with insulin, 1 was with exercise and diet therapy, and rest of patients received no therapy. No acute complications of hyperglycemia were observed. Pre-chemotherapy factors significantly associated with GDM were turned out to be HbA1c level more than 5.8 percent (*P*<.05), metabolic syndrome (*P*<.05), and previous history of hypertension (HTN) or elevated BP (SBP> 130 mmHg, DBP> 85 mmHg) at the start of R-CHOP regimen (*P*<.05) with univariate analysis. By the multivariate analysis, HbA1c level more than 5.8 percent (*P*<.05, RR = 5.4, CI: .1.29- 22.6) and history of HTN or elevated BP (*p* =.054, RR = 4.33, CI: .97- 19.3) were the independently significant factors associated with GDM.
Summary / Conclusion: DLBCL patients with HbA1c level more than 5.8 percent or elevated BP or history of HTN at the start of R-CHOP regimen would be possible indications to check plasma glucose level during the chemotherapy to seek out GDM.

B1632

PROGNOSTIC SIGNIFICANCE OF LOW LYMPHOCYTES COUNT IN THE PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA (DLBCL)

O Markovic[1*], L Popovic[2], D Marisavljevic[1], D Jovanovic[2], B Mihaljevic[3], D Stanisavljevic[4], J Hajder[5], R Zivkovic[5], D Petrovic[2], N Stanisavljevic[5], G Matovina-Brko [2], M Todorovic[3], J Bila[3]

[1]Hematology Department, Clinical Hospital Center "Bezanijska kosa" Medical Faculty, Beograd, [2]Hematology Department, Institute of Oncology, Sremska Kamenica, [3]Institute of Hematology KCS, Medical Faculty, [4]Institute of Statistics, Medical Faculty, [5]Hematology Department, Clinical Hospital Center "Bezanijska kosa" , Beograd, Serbia

Background: Lymphocytes are target for immunochemotherapy and their number is an indicator of immunological status. It was previously reported that low lymphocyte count has a prognostic significance in the patients with diffuse large B cell lymphoma (DLBCL).
Aims: The present study was designed to investigate the clinical and prognostic significance of low lymphocyte count in our group of patients with DLBCL.
Methods: We retrospectively analysed prognostic significance of low lymphocytes count at the time of diagnosis in 277 DLBCL patients. There were 203 nodal and 74 extranodal DLBCL. Only the patients treated with immunochemotherapy (CHOP or CHOP-like chemotherapy plus rituximab) were included in the study. Cut off for low lymphocytes count was determined by ROC analysis.The prognostic values of absolute lymphocyte count with respect to overall survival (OS) and progression-free survival (PFS) were evaluatedby Chi-Square test and two-tailed log-rank test.Correlation of lympho-

cytes count with clinical parameters was also analysed.
Results: Median of lymphocyte count was 1.4x10^9/L (range 0,2-4.9x10^9/L). However, ROC analysis showed that optimal cut off of low lymphocyte count with the best sensitivity and specificity is 1.3x10^9/L. According to ROC analysis low lymphocyte count was found in 121 (43.32%) patients. There was significant statistical correlation between low lymphocyte count and elevated LDH (P=0.01) and "bulky" disease (P=0.001). Low lymphocyte count (1.3x10^9/L) was in significant correlation with event-free survival (EFS, P=0.014) and overall survival (OS) (P=0.04). Namely, median of survival of the patients with normal lymphocyte count was not achieved and in the group of the patients with low lymphocyte count is 23,9 months. On the contrary, low lymphocyte count was not associated with therapy response (P=0,089). A multivariate analysis revealed that only IPI remained associated with OS (P<0.01; HR, 4.286; 95% CI, 1.998 to 9.194). Similar results were found when nodal and extranodal lymphoma were analysed separately.
Summary / Conclusion: Low lymphocyte count is in significant correlation with EFS and OS of patients with CDLBL and can be used as prognostic factor in DLBCL.

Background: Anthracyclines play the major role within polychemotherapy. Liposomal non-pegylated doxorubicin (Myocet) is characterized by a better cardiac tolerance.
Aims: Aim of the study is the characterization of benefit and side effects of COMP in lymphoma, a CHOP-like regimen containing Myocet in real-life-setting.
Methods: 121 patients (m/w 73/48) were analyzed retrospectively by firstly characteristics of patients, and secondly details of COMP-like therapy including outcome and side effects.
Results: Median age, 73 years (26-88); adverse performance status (ECOG ≥2), 46 patients (38%); any cardiac comorbidity, 73 patients (60%). Histology of lymphoma: DLBCL 61%; MCL 12%, follicular lymphoma 9%; CLL 7%; peripheral T-NHL 7%; other NHL 4%. 89 patients (74%) received Myocet-based therapy (±rituximab) in first line, 16 (13%) in second line, and 16 (13%) in third or higher line. Median 6 cycles (1-8) were administered. 7 patients were withdrawn prematurely, 12 patients (11%) died during therapy, among them three with cardiac fatality. The response rate (CR+RR) in evaluable patients was 66% (70/106 pts) and 75% (6/8 patients) in B- and T-NHL, respectively. Response was associated with therapy line (74% in first vs 47% in higher line, P = 0.007). Grad III/IV neutropenia was found in 45%, whereby this was not dependent on therapy line. Survival data will be presented at the conference.
Summary / Conclusion: Myocet-based therapy is highly effective in therapy of lymphoma in difficult situations. Cardiac toxicity (seen during therapy at 11 patients) was not associated with preexisting cardial comorbidity.

Background: Despite the advent of rituximab-based immunochemotherapy, treatment outcomes for patients with high-risk (International Prognostic Index [IPI] score 3-5) diffuse large B-cell lymphoma (DLBCL) continue to be suboptimal with relapse rates at 2 years of 25% or more, even for patients in remission after first-line therapy. Overexpression of protein kinase C (PKC)β, a protein involved in the B-cell receptor signaling pathway, appears to be a poor prognostic marker in patients with DLBCL (Shipp et al. *Nat Med*. 2002;8:68-74). Enzastaurin, a potent, selective inhibitor of PKCβ, has demonstrated clinical activity in a subset of relapsed patients with DLBCL and has a favorable safety profile.
Aims: Based on these results, a Phase 3 trial was initiated to investigate the efficacy of enzastaurin in patients who have achieved complete remission after standard first-line therapy.
Methods: Patients had histologically confirmed DLBCL with IPI score of 3-5 at diagnosis and had achieved a complete response or complete response-unconfirmed to cyclophosphamide, doxorubicin, vincristine, and prednisone, plus rituximab therapy. Patients were randomized in a 2:1 fashion to receive enzastaurin 500 mg daily (after a 375-mg loading dose 3 times daily on Day 1 only) or placebo. Treatment continued until patients developed progression of disease, unacceptable adverse events, or completed 3 years of therapy. All patients were followed for recurrence of disease and survival until death or study closure, whichever occurred first. The primary endpoint was overall disease-free survival (DFS). The trial was designed to have 80% power to detect a hazard ratio of 0.68. The secondary endpoints were event-free survival (EFS), EFS rate at 2 years, DFS rate at 2 years, overall survival, safety, health-related quality of life using the FACT-Lym, health status using the EQ-5D scale, assessments of biomarkers, and pharmacokinetics.
Results: Trial in progress.
Summary / Conclusion: The trial completed patient enrollment (N=757) in April 2010. Two interim analyses were performed by an independent data monitoring committee, with the recommendation to continue the trial. Final results will be analyzed after the last treated patient has been followed for 3 years.

B1635
FOLLICULAR LYMPHOMA IN FIRST RELAPSE: ANEMIA AND HIGH ERYTHROCYTE SEDIMENTATION STRONGLY PREDICT THE OUTCOME
B Andjelic[1*], M Todorovic[1], D Antic[1], J Bila[1], B Mihaljevic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: The prognosis of patients with follicular lymphoma (FL) significantly improved after adding rituximab in treatment plan of these patients, both for newly diagnosed and relapsed patients. FLIPI and FLIPI2, widely accepted prognostic indices in FL were primarily designed for patients with newly diagnosed disease. Nowadays, the precise risk assessment also in relapsed FL patients seems to be necessary, since lot of treatment strategies are available for these patients, less or more agressive.
Aims: The aim of this study was to analyze the prognostic value of routinely determined clinical and laboratory parameters in patients with first relapse of follicular lymphoma.
Methods: The retrospective analysis was performed on 60 patients with diagnosed first relapse of FL grade I, II or IIIa, in the period February 2002-April 2010. In the first line, the patients were treated with R±CHOP or R±CVP. All the patients in the first relapse were treated with fludarabine based regimens (FC, FND), of whom 33 patients in combination with rituximab. The characteristics in first relapse examined as possible risk factors were age, higher hystological grade in relapse, presence of B symptoms, presence of "bulky" tumor (>10 cm in diameter), spleen enlargement, high FLIPI score, anemia (Hgb<12 g/dL), LDH level and erythrocyte sedimentation rate (ESR). Receiver operating curve was used to determine the optimal cutoff value for ESR in prediction of overall survival (OS) for our group of patients. Survival functions were estimated using the Kaplan-Meier method and compared using the log-rank test. A multivariate analysis was performed to evaluate the potential predictive value of the examined characteristics as a risk factor.
Results: The median follow up was 32 months (range 4-115 months). In first relapse, 24 (40%) patients were older than 60 years. Higher histological grade in relapse, B symptoms, bulky disease, spleen enlargement, high FLIPI score, anemia, elevated LDH and ESR>25 mm/h were present in 17 (28.3%), 41 (68.3%), 23 (38.3%), 32 (53.3%), 36 (60%), 20 (33.3%), 26% (43.3%) and 33

(55%) patients, respectively. The patients with B symptoms, high FLIPI score, anemia, and ESR>25 mm/h had significantly worse OS (P=0.000; P=0.001; P=0.003; P=0.000, respectively), while there was a trend toward worse OS in elderly patients (P=0.065) and patients with elevated LDH (P=0.091). Multivariate analysis identified anemia (P=0.034) and ESR>25 mm/h (P=0.005) as independent risk factors for poor outcome. Based on cumulative score of unfavorable prognostic factors identified in multivariate analysis, 2-years OS was significantly better (P=0.024) in patients who didn't have unfavorable factors (2-years OS 81.8% pts), compared to patients with 1 (2-years OS 60.9% pts) or 2 (2-years OS 40% pts) risk factors.
Summary / Conclusion: Modern clinical researches are having the aim to individualize treatment approach based on risk for poor outcome. Our findings suggest that some FL patients in first relapse require more effective treatment. Having in mind that more aggressive treatments such as high dose therapy with stem cell transplantation are associated with higher toxicity, the optimal approach according to risk has to be defined in new prospective studies.

B1636
ORBITAL AND OCULAR ADNEXAL MALT (MUCOSA-ASSOCIATED LYMPHOID TISSUE) LYMPHOMAS, TEN YEAR EXPERIENCE
M Smiljanić[1*], R Milošević[1], D Antić[1,2], B Anđelić[1], V Đurašinović[1], M Todorović[1,2], B Mihaljević[1,2]
[1]Lymphomas, Clinic of Hematology Clinical Centre of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Orbital and ocular adnexal Non Hodgkin Lymphomas (NHL) consist 2% of all NHL. The most frequent hystological sybtipe is extranodal marginal zone B cell lymphoma, MALT (Mucosa-Associated Lymphoid Tissue). Autoimmune inflamatory disorders as well as chronic infections are important ethiological factors. Various local disease signs and simptoms can occur a long period of time prior to diagnosis. Immunohistochemical markers CD5 or CD43 (sialophorin) are important negative predictive factors. Various treatment modalities are available.
Aims: To investigate clinical and laboratory parameters of patients with ocular adnexal MALT lymphoma (OAML), to compare efficiency between different therapy modalities and to investigate disease outcome.
Methods: Seventeen patients with OAML, diagnosed in Clinic of Hematology, Clinical Centre of Serbia between 2003 and 2013, were inrolled. We researched epidemiologic-demographic, clinical and laboratory characteristics on presentation, importance of Helicobacter Pylori (Hp) infection, clinical stage of disease and prognostic value of CD43. Efficiency of various therapy modalities was compared.
Results: Highest disease incidence rate was in eight decade, it is almost 2.5 times more frequent in male population. Overall median age is 66 years (range 36-79), males 67.5 years (36-79), females 57 years (48-77). No significant statistic difference between age at diagnosis and patients gender was confirmed. Local signs and symptoms of the disease were present much earlier prior to diagnosis (median 8.9 months, range 3-36). Seven patients (53%) had orbital lymphomatous involvement, 4 (23%) conjuctival, 2 (12%) lacrimal gland, one (6%) eyelid and one (6%) uveal involvement. The most frequent sign on presentation was swelling of orbital tissue, conjuctiva or eyelid (7 patients, 33%). Observed laboratory parameters on presentation showed low disease activity: median sedimenation rate 12mm/h (range 2-24mm/h), mean lactat dehydrogenase 333.76U/l (range 200-409U/l), median C reactive protein 1.49mg/l (range 0.20-9.50mg/l) and median beta-2 microglobulin 1.96mg/l (range 1.39-5.60mg/l). A significant presence of Hp infection (66.67%) was recognized. Predictive significance of CD43 was not confirmed. CD5 was negative in all cases. All patients have had localised disease and were staged as IE CS (Ann Arbor lymphoma staging system). One patient had B simptomatology on presentation. Ten patients, aged ≥60 had low intermediate risk (International Prognostic Index, IPI), six aged <60 had low risk and one low intermediate risk (age adjusted IPI, aaIPI). In our group, 5 year progression free survival (PFS) is 60%. There was no significance in PFS between initialy used treatment modalities, surgery vs. chemiotherapy (P=0.9942), surgery vs. radiotherapy (P=0.8296) and chemotherapy vs. radiotherapy (P=0.9191). All patients after initial or relapse treatment achieved disease remissions. No significance was observed between cumulative radiotherapy dosage and treatment outcome. Seven patients (41.17%) had relapse. One patient died due to non-hematologic complications.
Summary / Conclusion: Our results confirms that OAML has good overall therapy response, regardless of initial or relapse treatment modality, as well as good progression free survival and overall survival rate.

B1637
HEPATITIS B REACTIVATION IN PATIENTS WITH NON HODGKIN LYMPHOMA CD 20+ IN MAINTENANCE THERAPY WITH RITUXIMAB
A De Renzo[1*], S Luponio[1], I Ferrara[1], R Della Pepa[1], I Migliaccio[1], G Beneduce[1], C Cimmino[1], R Cuccurullo[1], M Picardi[1], M Masarone[2], M Persico[2], F Pane[1]
[1]Division of Hematology Federico II University, Naples, Italy, [2]Hepatology, II University, Naples, Italy

Background: Anti CD20 antibody (Rituximab) based chemotherapy regimens increase the HBV reactivation risk although sporadic HBV reactivation cases are reported in patients on maintenance with Rituximab single therapy too.
We evaluated how many HBV reactivation occurred among patients Hepatitis B core antigen positive (HBcAB +) and Hepatitis B surface antigen negative (HBsAg-) who received Rituximab single therapy during maintenance.
Aims: The aim of this study is to assess the prevalence of HBV reactivation among patients HBcAb +/ HBsAg – during the maintenance therapy with Rituximab.
Methods: In our Unit, 88 patients with non Hodgkin Lymphoma CD20+ received maintenance therapy with Rituximab (schedule: 375 mg/mq every 3 months for 2 years) from January 2007 to February 2013.
Patients were treated with different chemotherapy regimens: 40% (35/88) with R-CHOP; 52% (46/88) with R-FN; 3%(3/88) with R-F; 5% (4/88) with R-Leukeran. None of these patients received prophylactic therapy with lamivudine during induction or maintenance.
All the patients were given blood tests for HBV (HBsAg; HBsAb; HBeAg; HBeAb; HBcAb) before starting maintenance therapy and liver function tests before each administration of Rituximab.
Results: 20% of the patients (18/88) were HBcAb positive.
64% of the patients (56/88) completed the maintenance treatment: one of thesepatientsoccurred the HBV reactivation.
36% of the patients (32/88) arestillintherapy with Rituximab and 9% of them are HBcAb positive (3/32): all thesepatientsare at risk for HBV reactivation too.
Summary / Conclusion: Inpatients HBcAb +/ HBsAg – treatedwithRituximab in single therapy is indicated the prophylaxiswithlamivudine.
In our observational study the HBcAb +/ HBsAg- patients didn't receive prophylactic therapy with lamivudine during the maintenance therapy with Rituximab and the HBV reactivation occurred in one patient HBcAb+/HBsAg- three months after the end of the maintenance therapy (1/18).
More ambitious prospective studies are required to establish theclinical utility-of prophylactic therapy with lamivudine during the maintenance therapy with Rituximab.

B1638
GOOD PROGNOSIS IN PRIMARY HEPATIC LYMPHOMA WITH OR WITHOUT HCV INFECTION
A De Renzo[1*], R Della Pepa[1], F Perna[1], M Masarone[2], S Luponio[1], G Beneduce[1], I Migliaccio[1], C Cimmino[1], I De Sio[2], G Ciancia[3], M Persico[2], M Picardi[1], F Pane[1]
[1]Division of Hematology Federico II University, Naples, Italy, [2]Hepatology, II University, [3]Department of Pathology, Federico II University, Naples, Italy

Background: Primary hepatic lymphoma (PHL) is an uncommon lymphoid tumor frequently associated with a poor prognosis. PHL was first described in 1965 by Ata *el al* and in 1986 Caccamo et al defined PHL as a lymphoma localized and limited to the liver without extrahepatic involvement. To date, less than 150 cases have been published.
Aims: We report 11 patients with PHL diagnosed from 1995 to 2011 in our center, with a study of the viral status and the result of cytotoxic treatment.
Results: Eleven patients with PHL were identified. The disease occurred in middle-aged men (median age: 58 years). The main presenting complaint was right upper quadrant abdominal pain (4/11 patients). Tumor markers (α-fetoprotein and CEA) were normal in 8 patients tested. Liver scans demonstrated either a solitary nodule or multiple lesions. Pathologic examination revealed diffuse large B cell lymphoma in six patients, one case of follicular lymphoma, one of small lymphocytic lymphoma and one case of T cell lymphoma. Eigth patients (72%) were HCV-positive. Eigth patients received chemotherapy with CHOP regimen (6CHOP, 2 R-CHOP), two patients received R-FN, while a patient with a single focal lesion received surgical treatment. The complete remission rate was 100% (11/11); one of these patients, who had HCV-related cirrhosis, died because of hepato-renal syndrome, and another one died because of Acute Myeloid Leukemia.
Summary / Conclusion: The outcome of patients with PHL who are treated with combination chemotherapy seems excellent. The frequent association of PHL with HCV infection suggests a possible role of this virus in lymphomagenesis. HCV- infection does not appear to influence the outcome of therapy.

B1639
MODIFIED VIGEPP PROTOCOLE AS A NEW SALVAGE REGIMEN FOR RELAPSED REFRACTORY LYMPHOMA PATIENTS
O Kayıkcı[1*], E Tekgunduz[1], S Bozdağ[1], i demiriz[1], a tetik[1], m cinarsoy[1], s namdaroglu[1], b ugur[1], f altuntas[1]
[1]Ankara Oncology Hospital, Ankara, Turkey

Background: Salvage chemotherapy followed by high dose therapy and autologus stem cell transplantation(ASCT) is the standart treatment for relapsed/refractory Hodgkin and Non Hodgkin lymphoma patients.Response of these patients to salvage chemotherapy protocols predict outcomes after ASCT.Currently, the optimum salvage therapy is still not known; platinum,mitoxantron,ifosfamide or gemcitabine based regimens can be preferred according

to the patient characteristics.
Aims: We aimed to share our results with a new salvage regimen 'modified ViGePP protocole' in relapsed/refractory Hodgkin/Non Hodgkin lymphoma patients.

Diagnosis(n) NHL HL	6 16
Median age	39(17-63)
Gender(male/female)	12/10
Stage before ViGePP(n:) Stage 1 /2/3/4	1/5/7/9
Disease status before ViGePP (n) Relapse Primary refractory	14 8
Number of salvage treatment before ViGePP(n) 1 line 2 line >2line	4 12 6
Number of ViGePP courses(n) 1/2/3	2/18/2
Response to 2 cycles ofViGePP (n) CR/PR/Refractory	2/10/7
Auto transplant before/after ViGePP(n) **Allo transplant after ViGePP(n)**	3/9 3
Current status (alive /exitus)	15/7

Methods: We retrospectively analyzed 22 relapsed /refractory Hodgkin/Non Hodgkin lymphoma patients who were treated with modified 'ViGePP' salvage regimen' in Ankara Oncology Hospital. Demographic features and clinical variables of patients are summarized in Table 1. All of the patients had been treated with two or three cycles of modified ViGePP chemotherapy either as first line salvage regimen or after multiple lines of different regimens.Three patients were treated with this regimen for relapse after ASCT.Chemotherapy protocol consisted of vinorelbine 25 mg /m^2 gemcitabine 800 mg /m2 in 1. and 8.days, oral (PO) prokarbazin 100 mg/m^2 1-7 days and oral prednisone 60 mg /m^2 1-15.days. Response assesment has been performed after 2 courses of regimen except 3 patients who had only 1 course
Results: Median time period between diagnosis to ViGePP treatment was 32 (6-179) months. Overall response rate after 2 courses of chemotherapy was 60% (12/20, CR(n:2)+PR(n:10)). Treatment related mortality was 13% (3/22).We observed 18% grade 3 neutropenia,31% grade 4 neutropenia,22 % grade 3 thrombocytopenia, 13 % grade 4 thrombocytopenia.There were no nonhematological toxicities over grade 1.Ten patients were mobilized with filgrastim alone (n:5), after ViGePP regimen(n:4) or after plerixafor (n:1).Median time from the beginning of the treatment to ASCT was 4.5 (2-10) months. Nine patients who had ASCT has been followed in remission (1 PR/8 CR).Three patients who had relapsed after ASCT were treated with ViGePP followed with allogeneic SCT.One year overall survival of all patients was 74%±11%.
Summary / Conclusion: ViGePP salvage regimen has similar response rates with other chemotherapy protocoles without high treatment related toxicity rates.Although our number of patients mobilized with this regimen are low ,we think that it has high mobilization success rates.So we conclude that,it can be used easily as a bridge to transplantation for relapsed/refractory Hodgkin /Non Hodgkin lymphoma patients.

B1640
DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) COEXISTENT WITH HEPATITIS C INFECTION; SINGLE INSTITUTIONAL EXPERIENCE FROM EGYPT
H Azim[1*], R Abdelmalek[1], O Abdelrhman[1], R Abdeltawab[1], M Shahin[1]
[1]cairo oncology centre, giza, Egypt

Background: Hepatitis C is a major health problem in Egypt and many European and North African countries; and cases of DLBCL co existing with HCV positive infection are increasingly encountered.
Aims: So, we have conducted this retrospective analysis of our non hodgkin lymphoma database to clarify the clinicopathological and survival characters of cases with coexistent HCV infection and DLBCL.
Methods: DLBCL patients treated at Cairo Oncology Centre (Cairo, Egypt) in the period between 2000-2008 were reviewed. Eligible patients were those who had complete information on date of diagnosis, histopathological and immunohistochemical confirmation of the diagnosis and received CHOP-like chemotherapy. We compared the difference in systemic therapy and pathological parameters between cases that are hepatitis C antibody (HCV Ab) positive and cases that are not. We investigated the impact of HCV positive status on treatment toxicity and progression free survival (PFS) and overall survival (OS) in a Cox regression model adjusted for age, Ann Arbor stage, performance status, extranodal involvement, presence of B symptoms and treatment.
Results: 230 patients were included in the analysis fulfilling the inclusion criteria. 17 patients were confirmed to be HCV Ab positive whilst the rest of the cases were either negative or unknown. At a median follow up period of 13 months, the median PFS for the whole group was 12.03 months, while for the HCV Ab +ve group it was 8.48; the median OS for the whole group is 13.2 months while for the the HCVAb +ve subgroup it was 8.48 months. ther ewas no statistically significant correlation between HCV positive status and any adverse prognostic indicator like extranodal presentation (P=0.34),B symptoms(P=0.33),elevated LDH (P=0.54) or age>60 years (P=0.32). Based on univariate analysis, HCV Ab +ve status was not associated with shorter PFS (P=0.65). Treatment was tolerated in the majority of HCV Ab +ve patients with only 2 patients showing grade 2 liver dysfunction with treatment.
Summary / Conclusion: According to our data, patients with DLBCL coexistent with HCV infection should be managed in the same way as other DLBCL cases .however, more frequent monitoring of liver function and PCR status and multidiciplinary discussion with the hepatologists is required .

B1641
SAFETY OF BENDAMUSTINA INCLUDING DHAP REGIMEN AS SALVAGE THERAPY IN MULTIRESISTANT LYMPHOMA PATIENTS
C De Risi[1*], V Pavone[1], G Polimeno[2], G Tarantini[3], A Mele[1], B Rossini[1], M Fina[1], G Greco[1], S Sibilla[1], R De Francesco[1], D Carlino[1], M Morciano[1], A Ostuni[4]
[1]hematology, Az. osp. card. G. Panico, Tricase, LE, [2]hematology, Az. osp. F. Miulli, Acquaviva delle Fonti, BA, [3]hematology, Az Osp S.N. Pellegrini, Trani, BA, [4]Immunohemtology and Transfusion Medicine, Az. osp. card. G. Panico, Tricase, LE, Italy

Background: The management of patients (pts) with lymphoma recurring after stem cell transplantation or multiply relapsed disease remains challenging. Many studies have demonstrated the efficacy and safety of Bendamustine combinations in heavily pretreated pts.
Aims: Our study was designed to assess the safety of Bendamustine including DHAP regimen as salvage therapy in pts with refractory/relapsed lymphomas.
Methods: Ten patients were treated at 4-weekly intervals with Bendamustine 90 mg/mq on days1,2; Cisplatin 100 mg/mq over 24 hours on day 2; Cytarabine 2000 mg/mq (two doses) on day 3; Dexamethasone 40 mg on days 1–4 with or without Rituximab 375 mg/mq on day +4. Palonosetron was given as antiemetic prophylaxis on days1,3. A daily G-CSF was admistered starting by day +6 in 4 patients while a pegilated G-CSF was used in 6 patients on day +5. A total of 22 courses were administered and each patient received at least 2 cycles of therapy. The patient's characteristics are shown in table 1. At the time of enrollment 8 pts had a progressive disease.
Results: Chemotherapy-induced grade 1 nausea and vomiting were observed in 4 pts, mainly on days 3 and/or 4. Grade 3 and 4 haematological toxicity consisted of anaemia (3 pts), neutropenia (7 pts) and thrombocytopenia (6 pts). Severe neutropenia and thrombocytopenia were recorded mainly between days +10 and +14 with haematological engraftment (Neutrophils>500/mmc and Platelets>20.000/mmc) after a median of 4 days (range 3-6 days) from the nadir. Three patients had a febrile neutropenia requiring hospitalization and two died because of K. Pneumoniae sepsis. No grade 3 and 4 extra-haematological toxicity was observed. Eight patients are still on therapy.

PARAMETERS		N°
Histological subtypes	HL	4
	DLBCL	1
	PTCL	1
	SMZL	2
	RICHTER	1
	FL	1
Primary Refractory Disease		5
Relapse After ASCT		2
Prior Lines of Chemotherapy≥2		3
Disease Status at Enrollment	Progressive Disease	8
	Partial Response	2
Age Median (range)	53 years	(26-77)

Summary / Conclusion: In our experience, despite patients had multidrug-resistant disease heavily pretreated, the addition of Bendamustine to DHAP regimen seems safe with an acceptable toxicity profile if compared with an historical control group of patients treated at our Institute with DHAP alone. The two patients died due to a sepsis had a primary refractory disease relapsed after ASCT. Survival and response rate analysis, as well as the mobilizing potential of this Bendamustine combination can not be evaluated because of the small number of patients and the short follow-up. We are increasing our series and we hope to be able to present these results further on.

B1642

SPINAL CORD COMPRESSION AS THE INITIAL MANIFESTATION OF B- CELL LYMPHOMA: A CLINICO PATHOLOGICAL REVIEW OF 11 CASES

S Zriba[1], H Ghédira[1*], H Mansour[1], I aouni[1], R Bahloul[1], H Belfkih[1], R Rakez[1], F M'Sadek[1]
[1]Clinical hematology department, Military Hospital, Tunis, Tunisia

Background: In patients with non-Hodgkin's lymphoma (NHL), inaugural spinal cord compression is rare and thought to occur in less than 5% of cases. Even in major centers experience of this entity is modest and optimal treatment thus remains unclear. We retrospectively studied 11 patients who had B-cell lymphoma revealed by spinal cord compression symptoms.
Aims: The aim of this study is to study the epidemiological features and clinical outcome of B-cell lymphoma revealed by spinal cord compression.
Results: We reviewed departmental records covering the 6 years period from 2006 to 2012 and we identified 11 patients presenting with spinal cord compression as their first manifestation of NHL.
They were 6 men and 5 women in this series. Patients ranged from 32 to 82 years of age with a median of 62 years old. Tumor lesions involved the thoracic spine in 4 cases, and the lumbar spine in 7 cases. At presentation 6 patients were non-ambulatory. Dual sphincter impairment was found in 4 patients. Bladder dysfunction was noted in 3 cases only. The pathology study showed two cases with low-grade lymphoma: lymphocytic lymphoma and follicular lymphoma and 9 cases with diffuse large B cell lymphoma. On admission; there were 3 cases in PS=0-1, 4 cases in PS=2 and 4 cases in PS=3. Serum lactate dehydrogenase (LDH) was normal in 7 cases and high in 4 cases. Seven had advanced stage at diagnosis, while 4 had limited disease: including three with localized epidural lymphoma and one with primary bone lymphoma. Nine patients underwent laminectomy for decompression and tissue diagnosis, after which 2 underwent radiotherapy, 2 underwent chemotherapy, and 7 underwent combined-modality treatment. The functional outcome was improvement in all cases, no patient worsened after surgery. Tow patients had autologous peripheral stem cell transplantation. All patients had early physiotherapy and achieved functional independence at the community ambulation level, even if paretic at presentation. The overall survival (OS) at 1 year was 81%. No difference in OS was noted between localized and advanced disease.
Summary / Conclusion: B-cell lymphomas are an uncommon cause of spinal cord compression. Functional outcome can be quite favorable, as can tumor outcome. Residual sensory deficits greater than motor deficits are not uncommon. The clinical and functional response of such patients to treatment and their more favorable overall prognosis emphasis the importance of an accurate histological diagnosis, full disease staging and the subsequent initiation of appropriate therapy.

B1643

EPIDEMIOLOGICAL DATA AND CLINICAL FEATURES OF 205 NON-HODGKIN LYMPHOMA PATIENTS AT A SINGLE CENTER IN TURKEY

G Pamuk[1*], M Uyanik[1], M Akker[1], M Tasci[1], F Puyan[1], M Demir[1], O Harmandar[1]
[1]Department of Hematology, Trakya University Medical Faculty, Istanbul, Turkey

Background: There has been major progress in the diagnosis, classification, and treatment of nonHodgkin lymphoma (NHL).The distribution of NHL in various geographic regions might differ and certain subtypes might prevail in one area.
Aims: There is no data about the epidemiology of NHL in Turkey. We retrospectively determined the annual incidence of hospital-based NHL in Turkey based on patient registration data in our center in northwestern Turkey.We also report on clinical features, treatment modalities and outcomes, survival, prognostic factors.
Methods: We evaluated 205 NHL patients diagnosed between 2002-2011. Our hospital has been the only tertiary referral center for hematological diseases for a mixed rural and urban population of 616000 people for longer than 16 years (316000 males, 300000 females). Patients' demographic and clinical features, treatment modalities, and responses were recorded.The current World Health Organization (WHO) classification was adopted for histopathological diagnosis. Response to therapy was based on 2007 International Workshop Criteria. For survival analysis, time from diagnosis until the end of follow-up or time to death were considered. Informed consent was obtained.
Results: Of 205 NHL patients,121 (59%) were males and 84 (41%) were females (M/F=1.44).During the study period,the annual incidence rate for all NHL was 3.33/100000.The annual incidence in women was 2.8/100000, and in men it was 3.83/100000.At the end of 2011,the overall prevalence of NHL was 33.3 per 100000 population aged >16 years.The prevalence in men (38.3/100000) was higher than the prevalence in women (28/100000).The mean age was 58.4 years (range:15-87).Seventy patients (34.9%) had B symptoms, 39 (19%) had bulky disease,and 99 (48.3%) had extranodal involvement.An intermediate-to-high risk International Prognostic Index (IPI) score was present in 39% of the patients.Diffuse large B cell lymphoma (DLBCL) was the most common subtype (106 patients,52%). Other most frequent histologic subtypes were follicular (18 patients,8.8%), peripheral T-cell (15 patients,7.4%), and small lymphocytic (14 patients, 6.9%) lymphomas. For remission induction, CHOP and CHOP-like regimens were used in 66 patients (32.2%), while R-CHOP was used in 61 patients (30%). For DLBCL patients, in intent-to-treat analysis, the overall response and complete remission rates were, respectively, 60.4% and 43.4%. During a 10-year period, 78 NHL patients died. The median survival was 41 months. Five and 10-year survivals were, respectively, 45% and 25%. NHL patients with B symptoms (28 vs. 60 months,P=0.05), splenomegaly (26 vs. 60 months,P=0.048), intermediate-to-high IPI scores (20 vs. 86 months,P=0.002), high β-2 microglobulin (26 vs. 96 months,P=0.024), and those with bone marrow involvement (26 months vs. unreached,P=0.005) at initial diagnosis had significantly worse prognosis than others. NHL patients who obtained complete remission with first line therapy had significantly longer median survival than patients who obtained partial remission or who were refractory (p values<0.001).
Summary / Conclusion: The incidence of NHL according to our hospital-based data was similar to the incidence in western registries. The most frequent histopathologic subgroup was DLBCL. NHL patients who had poor prognosis were those with B symptoms, intermediate-to-high IPI scores, and bone marrow involvement at initial diagnosis.

B1644

PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) HAVING DEVELOPED MALIGNANT LYMPHOMAS. COMPLETE REMISSION OF LYMPHOMA FOLLOWING RITUXIMAB-CONTAINING THERAPY, BUT NOT OF SLE.

G Catania[1*], E Rossi[2], A Marmont[3]
[1]Hematology, Ospedale SS Biagio e Antonio e Cesare Arrigo, Alessandria, [2]Ospedale gallino, [3]Hematology2, Ospedale San Martino, Genoa, Italy

Background: The development of malignant lymphomas, generally of the non-Hodgkin type (NHL), and with a preference to diffuse large cell B lymphomas (DLCBL), in systemic lupus erythematosus (SLE), has been proven and analyzed in an exhaustive recent literature. The combination of germline and somatic mutations, persistent immune overstimulation and the impairment of immune surveillance facilitated by immunosuppressive drugs, is thought to be at the origin of the increased lymphoma genesis. However the treatment and course of such affected patients is less known, and prognosis is generally estimated as poor.
Aims: Out of more than 500 patients with complete/incomplete lupus and secondary antiphospholipid syndrome (APS) seen and treated at the institutional Day Hospital between 1982 and 2009, 9 developed lymphomas (5 DLCBL, 1 Hodgkin's, 1 follicular lymphoma and 1 indolent lymphocitic lymphoma).
Methods: Eight patients were treated with Rituximab-containing regimen
Results: All patients achieved complete remissions (CR) with a follow-up comprised between 18 and 190 months. In a patient with DLCBL was documented relapse,that was fatal.Two patients achieved complete remission (CR) of both diseases. In the other 5 lupus serology (ANA, APA) persisted, with occasional lupus flares and vascular complications.
Summary / Conclusion: While eradication of the last cancer stem cell is tantamount to cure in neoplastic disease, persistent autoantigenic overstimulation may contribute to the refractoriness of autoimmunity. This analysis proposes the institution of clinical trials with the use of rituximab and stem cell transplantation in the treatment of autoimmune diseases.

B1645

FOLLICULAR LYMPHOMA IN SITU: SERIES OF 8 CASES

R Stulpinas[1*], J Drachneris[1], A Simbelyte[1], L Griskevicius[2,3], U Mickys[1]
[1]National Centre of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, [2]Hematology, Oncology and Transfusion Medicine Center, Vilnius University hospital Santariskiu Klinikos, [3]Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

Background: Follicular lymphoma in situ (FLIS or follicular lymphoma-like cells of uncertain biological significance) is a rare lymphoproliferative disorder defined as colonisation of germinal centers by Bcl2 and CD10 overexpresing B cells. Follicular architecture is usualy preserved, so immunohistochemistry (in particular Bcl2 and CD10) and/or molecular work-up is needed for diagnosis. Clinical significance of FLIS is still obscure. Some cases are found either prior or next to overt lymphoma, or sinchronously with other solid tumors, while some are incidental findings.

Aims: Here we present a series of 8 FLIS cases diagnosed in our institution during the period from July 2010 to January 2013.
Methods: H&E and immunohistochemical staining were performed on routine fomalin-fixed paraffin-embeded lymph node specimens. Immunohistochemical panel included Bcl2 and CD10 markers. t(14;18) FISH analysis was performed using Vysis LSI BCL2 Dual Color Break Apart Rearrangement Probe. Clinical data was available in 5 cases.
Results: One patient had a history of microsatelite instable colonic carcinoma and squamous cell carcinoma of the lung. Both paratracheal lymph node biopsy (performed for staging of lung cancer) and peribronchial lymph nodes in subsequent lobectomy specimen revealed lymph node involvement by FLIS. Two patients had overt lymphoma: one had FL lymphoma and FLIS in the same lymph node, while the other had FL transformed to DLBCL with FLIS in the otherwise uninvolved lymph node. Remaining 5 patients underwent diagnostic biopsies due to lymphadenopathy. The first patient had concomitant pneumonia and elevated LDH of 418 U/l (normal LDH <243 U/l). The second patient with subsequent diagnosis of viral hepatitis C had splenomegaly, pancytopenia, and elevated LDH (470 U/l). The third patient had hepatosplenomegaly, weight loss, fever and malaise, he died of unknown causes 1 month later. The remaining two patients had only lymphadenopathy and one had elevated LDH (254 U/l). On gross evaluation lymph nodes in these 5 cases measured from 0.9 cm to 1.9 cm in greatest dimension. FLIS-involved lymphoid follicles were populated by homogeneous centrocyte-like cells with strong immunohistochemical Bcl2 and CD10 expression while demonstrating fairly preserved tissue architecture. Two out of 5 cases also demonstrated Bcl2 break by FISH analysis.
Summary / Conclusion: Our case series represents different clinical scenarios in which FLIS can be encountered. Though sometimes FLIS was just an incidental finding in cases of synchronous or metachronous lymphoma or solid tumor, 5 out of 8 cases demonstrated that FLIS alone can cause clinicaly suspicious lymphadenopathy leading to lymph node biopsy. To detect FLIS, routine minimal immunohistochemical panel should include Bcl2 and CD10. Close clinical follow up may be indicated for the early diagnosis of overt lymphoma in FLIS cases.

B1646
LYMPHOMA (HODGKIN AND NON-HODGKIN): EPIDEMIOLOGICAL FEATURES IN THE SOUTH EAST OF ALGERIA
M Bitam[1*], h menea[1], s touati[1], m hamzaoui[1], s chichoune[1], r ounissi[1], m saidi[1]
[1]Hematology department, University Hospital of Batna, Algeria., Batna, Algeria

Background: In Western countries: non Hodgkin lymphoma (NHL) represents approximately 85% of lymphomas, their incidence is increasing, and almost 50% are over 70 years old.
The Hodgkin lymphoma (HL) represents approximately 15% of lymphomas: incidence rates have been stable over last 20 years, nearly 70% are less than 50 years at diagnosis, and many people have even less than 30 years.
Aims: Also the goal of this work is a comparative epidemiological study of lymphoma (HL and NHL) recruited in our area (south east of Algeria) over 4 years in the service and to extract their characteristics.
Methods: This is a retrospective comparative epidemiological study, based on the clinical data of patients (pts) diagnosed from January 2009 to December 2012. The diagnosis was confirmed by histological and immunohistochemical study.
Results: During this period, 253 patients with lymphoma were diagnosed, 127 NHL and 126 LH (50% each).The NHL are composed of aggressive NHL: 88 cases (69%), the most common sub type is diffuse large B-cell lymphoma (DLBC: 68%) and T/TNK (19%).The indolent NHL: 39 cases (30.7%); the most common is follicular lymphoma Comparing the epidemiological results found in the NHL with those in the HL we found: Cases/year: 32 versus 31. Median age: 54 versus 29 years. Frequency peak: (50-60) and (65-75), versus (20-30), knowing that 68% of pts with NHL are under the age of 60 years and75% of HL's pts have less than 50 years. Sex ratio (M/F): 0.98 versus 0.89. Notion of cancer in family: 12% versus 3%. Exposure to agriculture products: 9% versus 3%.
Summary / Conclusion: The epidemiological profile of lymphoma over 4 years in the south east of Algeria has some particularities: The LH and NHL; each occupies 50% of all diagnosed lymphoma. A parallel increase in the number of cases for the NHL and HL. The HL affects the young (median age = 29 years, 75% have less than 50 years) while the NHL is more observed in average age (median age=54 years, 68% are under the age of 60 years), this may be related to our young population. The majority of NHL diagnosed are aggressive (69%) with a predominance of DLCB lymphoma (68 %), and predominance of follicular and PCB (43% each) in indolent lymphoma. These data join the literature. These particularities are relevant and they must be the subject of deeper epidemiological and etiological investigations.

B1647
COMPARATIVE STUDY THE EFFICACY OF DIFFERENT ERYTHROPOIESIS-STIMULATING AGENTS IN ANEMIC PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS
N Romanenko[1*], I Kostroma[1], I Karmatskaya[1], K Abdulkadyrov[2]
[1]Hematology, [2]Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background: Anemia in lymphoproliferative disorders (LPD) patients is a frequent symptom and can decrease the efficacy of antitumor chemotherapy, survival rate and overall quality of life (QoL). Pathogenesis of anemia in LPD patients is based on suppression by proinflammatory cytokines, decreasing erythroid precursor's sensitivity to serum erythropoietin and effect of chemotherapy. Therefore erythropoiesis-stimulating agents (ESA) are used as a pathogenetic therapy of anemia in patients with LPD which significantly increase hemoglobin, reduce and prevent RBC transfusions and improve QoL.
Aims: To study the efficacy of different ESA in anemia patients with LPD.
Methods: To our interventional prospective study were included the LPD patients (n=114): low-grade non-Hodgkin's lymphoma (n=17), chronic lymphocytic leukemia (n=26) and multiple myeloma (n=71). The median age of patients was 67 years (range 24-85). All patients had been received two or more cycles of antitumor chemotherapy before they were administrated ESA treatment. Every patient was observed anemia with initial Hb ≤10.0 g/dl. RBC transfusions were administrated to patients whose Hb concentration was <8.0 g/dl until level of Hb was increased up to 8.0-9.5 g/dl. We compared the efficacy of different ESA: Epoetin alfa (n=59), Epoetine beta (n=29), Darbepoetin alfa (n=26). All ESA were administrated to the patients subcutaneously, Epoietine alpha and beta – 150 IU/kg body weight 3 times a week and Darbepoietine alpha – 6.75 μg/kg b/w once per 3 weeks. The target Hb level was 11 g/dl. The planning duration of ESA treatment was within 16 weeks. Positive response was estimated as increasing Hb concentrating ≥2.0 g/dl or achieving target Hb level (11 g/dl).
Results: In the whole group of LPD patients mean baseline Hb concentration was 8.66±1.63 g/dl (3.7-10.0 g/dl). Before ESA-treatment 29 patients had received 2-12 units (median 3) of RBC transfusions during last 2-6 months because of low Hb (3.7-8.0 g/dl). The period of ESA-treatment was from 4 to 24 weeks (mean 9.6±4.6 weeks). During the study period 12 patients (41.4%) followed RBC transfusions after ESA-treatment and 17 patients (58.6%) showed transfusion-independency and 8 new patients began receiving transfusion first time as a result of the anemia progressing. On the whole we observed positive response in 78 patients (68.4%), their Hb concentration increased from baseline to 12.1±1.2 g/dl (11.0-15.7 g/dl; P<0.001) and in group patients with positive response reduced such symptoms as: feeling fatigue, weakness all over, having trouble starting things because of tiredness, depression, drowsiness, giddiness, headaches, pain in thorax and dyspnea. The comparison of efficacy ESA-treatment showed insignificant difference between all ESA. So patients received Epoetin alfa positive response observed 40/59 patients, Epoetin beta positive response – 20/29 and Darbepoetin alfa positive response – 18/26, that is showed similar results (67.8%, 68.9%, 69.2%, respectively) without statistical difference (P>0.1).
Summary / Conclusion: In this study was shown that all ESA is effective reducing symptoms of anemia, increasing Hb in anemic patients with LPD and there wasn't found out significant differentiation between all these ESA.

B1648
MANAGEMENT OF STAGE IA DIFFUSE LARGE B CELL NON-HODGKIN'S LYMPHOMA (DLBL): IS RITUXIMAB REALLY NECESSARY?
K Lang[1*], G Wallace[1], J Ashworth[1], J Lewis[2], V Ratnayake[3], K Saied[1], R Coltart[2], C Pocock[1], J Lindsay[1]
[1]Department of Haematology, [2]Kent Oncology Centre, East Kent Hospital Trust, Canterbury, [3]Department of Haematology, East Kent Hospital Trust, Ashford, United Kingdom

Background: Stage IA DLBL is a distinct entity with a favourable prognosis, where a combination of chemotherapy and local radiotherapy afforded durable remissions in the pre-rituximab era. We set out to review our experience of the treatment of this early stage of DLBL.
Aims: To assess the response and relapse rate of stage IA DLBL treated with chemotherapy and local radiotherapy alone, no patient received rituximab in line with national policy.
Methods: We undertook retrospective case notes review of patients treated with radiotherapy alone and those who received both chemotherapy with 3 cycles of cyclophosphamide, doxorubicin, vincristine and prednisolone (CHOP) and radiotherapy.
Results: Thirty patients were included, treated between 2005 and 2012. The mean age at diagnosis was 78.3yrs (Range 39-95), 23 aged >70yrs. Twenty-seven patients underwent the full course of intended treatment. Of those that did not complete, two discontinued due to intolerance and one declined any therapy prior to commencement. Site of disease frequently involved the head and neck (20 patients), while torso, abdomen and limbs were next most frequent. A greater proportion of deaths occurred in the head and neck group than any other (not all related to lymphoma or treatment). Radiotherapy alone was chosen for 11 patients usually due to frailty, of whom 3 relapsed and 8 died

subsequently (2 from lymphoma). Of the combined modality group (16 patients), there were no relapses and three deaths, none lymphoma related. None of these patients received rituximab. Dosage of radiotherapy was 30Gy in ten fractions in 22 patients (3 relapses), while 6 patients received 35Gy (1 relapse) [patient performance status was often poor thus mandating the use of abbreviated fractionation schedules for many]. Two thirds of patients who relapsed after radiotherapy did so within the first 12 months following treatment.
Summary / Conclusion: Radiotherapy alone or chemo/radiotherapy has shown to be effective therapy for patients with stage IA DLBL. Our series show good tolerability of therapy among an elderly group with an acceptable proportion of relapses with radiation alone and none in the combined modality group. It does not appear that rituximab is mandated in this group of patients.

B1649

REARRANGEMENTS OF BCL-2, BCL-6, CYCLIN-D1, IGH, P53 AND C-MYC AS PROGNOSTIC MARKERS IN REPRESENTATIVE TURKISH DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

O Akay[1*], B Aras[2], S Isıksoy[3], C Toprak[2], F Mutlu[4], S Artan[2], U Oner[3], Z Gulbas[5]
[1]Hematology, [2]Medical Genetics, [3]Pathology, [4]Biostatistics, Eskişehir Osmangazi University Medical School, Eskişehir, [5]Bone Marrow Transplantation, Anadolu Saglık Merkezi, Istanbul, Turkey

Background: Diffuse large B-cell lymphoma (DLBCL) form a highly heterogenous type with different clinical, morphological, immunological and cytogenetic features, treatment responses, and prognosis. During the last decade, most studies dealing with the heterogeneity of DLBCL have focused on genetic and molecular analyses.
Aims: In this study, we aimed to determine the frequency of BCL-2, BCL-6, CYCLIN-D1, IGH, P53 and C-MYC rearrangements in DLBCL and to assess their prognostic impact.
Methods: A total of 44 patients of DLBCL classified according to WHO classification between 1996 and 2011 were chosen for the study. The samples prepared from the paraffin blocks of lymph nodes were analyzed by fluorescence in situ hybridization (FISH).
Results: Twenty-four of the patients were male and 20 were female and age at diagnosis ranged from 27 to 77 years. Advanced stage (III/IV) was observed in 22 cases (50%). 30 patients (68%) presented with high serum lactic acid dehydrogenase (LDH) levels and 15 patients had high serum B2-microglobulin levels. 28 of the patients with available data had a favourable risk group by the IPI. Succesful FISH analysis was performed in all patients. Rearrangement of BCL-6 was found in 27 patients (61.4%), C-MYC in 14 (31.8 %), P53 in 10 (22.7%), BCL-2 in 8 (18.2 %) and CYCLIN-D1 in 4 (9.1%). Furthermore, 18(41%) of cases showed rearrangements of more than 1 gene. Univariate analysis showed that the IPI score (P=0.013), stage (P=0.025), albumin level (P=0.007) and LDH level (P=0.025) were significantly associated with overall survival Patients with rearrangements of BCL-6 (P=0.053), C-MYC (P=0.483) and P53 (P=0.877) tended to have shorter survival times while patients with rearrangements of BCL-2 (P=0.302) were in a trend for better overall survival.
Summary / Conclusion: The presence of different genetic rearrangements in the same lymphoid tissue samples highlight the complex nature of molecular events in DLBCLs, which is a reflection of the morphologic and clinical heterogeneity of this disease. Our initial results are consistent with the previous literature that showed a different prognostic impact for gene rearrangements. The present study will be extended by including more number of patients with longer follow-up duration.

B1650

PRIMARY BONE LYMPHOMA: CLINICOPATHOLOGICAL CHARACTERISTICS AND TREATMENT RESULTS FROM SINGLE CENTER EXPERIENCE

M Puric[1*], D Ristic[1], N Milanovic[1]
[1]Hematology, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia

for less than 2 percent of all lymphomas in adults, 3 percent of primary bone tumors and 3 to 5 percent of all extranodal non-Hodgkin lymphomas. Men are diagnosed slightly more frequently than women. The vast majority of patients present over the age of 30 years.The radiographic appearances of PBL are variable. Despite this variability, the presence of a solitary, permeative, metadiaphyseal lesion with a layered periosteal reaction on plain radiographs and a soft-tissue mass on MR images, especially in a patient older than 30 years, is highly suggestive of lymphoma. The case for a diagnosis of primary bone lymphoma is further strengthened if the soft-tissue mass and marrow changes are associated with surprisingly little cortical destruction. Histopathologically, the majority of PBL cases have been diffuse large B-cell lymphoma (DLBCL). The patients with PBL treated with combined modality therapy were found to have a superior outcome and a significantly better survival, than the patients treated with single modality therapy.
Aims: To analyze the clinicopathological features of primary bone lymphoma, the role of MR in evaluation of response and correlation between the treatment modality and the outcome.
Methods: Totally 11 patients diagnosed with the primary bone lymphoma, were treated in Institution for radiology and oncology of Serbia in period from 2008.y to 2012.y. The treatment modality, the response and its duration (follow up) were registered for all the patients. We used bone scintigraphy for surveying the entire skeleton and magnetic resonance (MR) imaging to determine the exact extent of local involvement. Whole body CT was performed for each patient in initially staging and in response evaluation of initially pathological findings. MR imaging was used to assess the local outcome of treatment. PET/CT was done for some patients.
Results: Median age of patients was 38 years (range, 27-62). There were 9 male and 2 female patients. Three (27%) patients had B symptoms. Almost all patients were diagnosed with diffuse large B cell lymphomas except one with follicular B cell gradus 3A histology. The most frequent primary site of lymphoma was femur (4 patients). Other primary affected sites were: ossis ilei (3), tibia (2), humerus (1) and thoracic vertebra (1). 91% patients presented with Ann Arbor Stage I or II disease. Regional lymphadenopathy was registered in four patients. 82% patients were treated with combined modality therapy. Eight patients were treated with chemotherapy followed by radiotherapy. One patient was treated by surgery after chemotherapy, due to pathologic fracture. In the combined modality therapy group, the patients received IV to VI cycles of R-CHOP and in the only chemotherapy group, VI to VIII cycles of R-CHOP. Only one patient with high Ki 67 received R-EPOCH regimen. The median follow up was 18 months (range, 6-54). The overall response rate (ORR) for all the PBL patients was 100% as none of the patients showed PD during initial treatment. Seven patients (64%) achieved CR and 4 patients (36%) achieved PR. During response evaluation in all patients, NMR showed disappearing of soft tissue component with persistence of some bone lesions and minimal changes during time. FDG-PET revealed CR in four patients and all patients were alive at the time of the last follow-up and all remain in achieved response.
Summary / Conclusion: Our acquired data demonstrate and confirm that the primary lymphoma involving bone has a good prognosis. But, in our patients, we did not confirm earlier results of protocol influence (combined or single modality therapy) on the outcome. As bone changes that are seen on NMR images are pretty stabile during the treatment period and long time after completion of the treatment, it is difficult to achieve adequate response evaluation using NMR imaging. The need for the further multicenter studies (taking into account the rarity of the disease) in order to define the optimum treatment modality and better response evaluation is emphasized.

B1651

HIV-RELATED HEMATOLOGIC MALIGNANCES PRE-HAART (HIGHLY ACTIVE ANTIRETROVIRAL THERAPY) ERA AND HAART ERA: EXPERIENCE IN ONE CENTRE

P Ibarrondo[1*], C De Miguel[1], M Colorado[1], A Bermudez[1], S de Villambrosia[1], E Conde[1]
[1]Hematology, Valdecilla, Santander, Spain

Background: Highly Active Antiretroviral Therapy (HAART) has had a dramatic effect on the natural history of HIV-infected patients. The incidence of AIDS-defining cancers has declined. However, non AIDS-defining cancers have gradually emerged.
Aims: Analyze the clinical and biological features and the outcome of hematologic malignancy among people with HIV infection or AIDS in the era pre-HAART and post-HAART.
Methods: We conducted a retrospective review of HIV-infected patients with hematological malignancies treated in our institution. Pre-HAART era included patients who did not receive HAART.Histological diagnosis was based according to WHO criteria. HAART was defined as a protease inhibitor or a non-nucleoside reverse transcriptase inhibitor along with a backbone of at least two nucleoside reverse transcriptase inhibitors.
Results: Nineteen patients were evaluated, 10 of them belonged to pre-HAART era, and 9 of them belonged to HAAT era. The median age was of 37.3 years, and there was a male predominance. HAART era: the median duration from the diagnosis of HIV infection to development of hematological malignancy was 3 years (range, 0 to 11 years). The histological diagnoses were the following: 3 Hodgkin lymphoma (HL), 5 Non- Hodgkin lymphoma (NHL) and 1 myelodysplastic syndrome. Four of 8 lymphomas had stage II disease and 4 had stage III/IV disease. The 4 patients with stage II disease were concomitantly diagnosed of HIV infection. All patients with advance disease had a previous diagnosis of AIDS, two of them with poor adherence to HAART.
HAART was associated with standard chemotherapy in 8 cases. Five patients died mainly because of chemotherapy-resistant disease. At a median follow-up of 7 months (range, 2 to 48 months), two years progression-free survival (PFS) was 50%. Pre-HAART era: the median time from the diagnosis of HIV infection to development of hematological malignancy was 9 years (range, 2 to 16 years). The histological diagnoses were the following: 3 Hodgkin lymphoma (HL), 7 Non- Hodgkin lymphoma (NHL) and 1 acute myeloid leukemia of intermediate risk. Seven of 10 lymphomas had stage III/IV disease. All of them received standard chemotherapy except one patient with a central nervous system lymphoma. Six patients died: 3 died of lymphoma, 2 patients died after the first cycle of chemotherapy (1 neutropenic sepsis and 1 subdural hemorrhage), and 1 patient died of secondary wasting-HIV syndrome. At a median follow-up of 13 months (range, 1 to 96 months), two years progression-free survival (PFS) was

52%.
Summary / Conclusion: It has decreased the time from HIV-infection diagnosis to hematologic malignancy diagnosis from 9 years to 3 years after HAAR. The reasons for this finding remain unclear. Lymphoproliferative disease was diagnosed at early stage in the HAART era, if the adherence is successfully. Chemotherapy-resistant hematological disease remains the mainly cause of death.

B1652
ONLY RITUXIMAB IN THE EARLY TREATMENT OF INDOLENT LIMPHOMAS RELAPSED AFTER AUTOTRANSPLANTATION
L Pezzullo[1]*, U Sessa[2], S Rocco[3], O Finizio[3], R Fabbricini[3], V Mettivier[3]
[1]Ospedale San Giovanni Di Dio E Ruggi D'aragona, Salerno, [2]Ematologia, Aorn A Cardarelli, Napoli, [3]Aorn A Cardarelli, Napoli, Italy

Background: In the last years the indolent lymphoma has benefited of transplantation procedures.High dose therapy folowed by autotransplantation has been used as salvage or first line tratment for indolent lymphomas.
Aims: The problem is the managment of the relapse of the disease in post-transplant, were as patients higly treated.We reported a single center exsperience in which patients whit indolent lymphomas relapsed after autotransplantatin,were treated only with immunotherapy.
Methods: From january 2005 we have autotransplantated,in our division,23 indolent lymphomas; 15 follicular,7 mantle cells and 1 marginal lymphoma. 13/23 (56%) patients have relapsed by a median PFS of 12 months (range 3-87). All patients received strict follow up with CT and PET and were treated early. 9/13 patients (70%) relapsed (8 follicular,1 mantle cells lymphoma) were treated with 4 weekly doses of rituximab 375 mg/msq for 1 month and then revaluated. If CR have started, maintenance with rituximab 375 mg/msq every 2 months for 2 years. 7/9 patients (80%) revaluated after 4 weekly doses have documented the CR and began rituximab maintenance. All patients who responded had a follicular lymphoma.
Results: With a median follow up of 36 months, 6/7 (85%) patients are in CR and in 4/9 (44%) we have documented grade IV hematologic toxicity (neutrophils<500/mm3) quikly resolved with G-CSF treatment.
Summary / Conclusion: In conclusion, for patients with follicular lymphoma, a strictly follow up may consnent a rapid treatment in relapsed patients after the autologus transplantation and the only immunotherapy may be sufficient to obtain a new CR consolidated by maintenance cycles every 2 months.We need a larger cohort and follow up longer to confirm these data.

B1653
LONGER MEDIAN TIME TO DIAGNOSIS FOR CASES WITH NON HODGKIN LYMPHOMA PRESENTING WITH PLEURAL EFFUSION.
H Azim[1]*, R Abdelmalek[1], R Abdeltawab[1], O Abdelrhman[1], M Shahin[1]
[1]cairo oncology centre, giza, Egypt

Background: Non Hodgkin lymphoma presenting with pleural involvement is a rare presentation that is usually confused with other pleural inflammatory and malignant pathologies with consequent diagnostic dilemmas and delay.
Aims: we have thus conducted this retrospective analysis of our non Hodgkin lymphoma database to determine the clinicopathological characteristics of this presentation.
Methods: Non Hodgkin lymphoma (NHL) patients treated at Cairo Oncology Centre (Cairo, Egypt) in the period from 2000-2008 were reviewed. Eligible patients were those who had complete information on date of diagnosis, histopathological and immunohistochemical confirmation of the diagnosis. We compared the difference in clinicopathological parameters between cases presenting with and without pleural involvement.
Results: In the period from 2000-2008; 380 Non Hodgkin lymphoma patients were included in the analysis fulfilling the inclusion criteria. Of which 26 patients only have definite radiological evidence of pleural involvement (6.8%). Pleura was the only site of disease in 2 cases, associated with nodal involvement in 16 cases and associated with both nodal and extranodal localization in 8 cases (of which 3 cases have pulmonary parenchymal involvement).of the nodal sites involved with the pleura, mediastinal nodes were involved in 13 cases. DLBCL was the diagnosis in 18 cases (69%), small lymphocytic lymphoma in 5 cases and follicular, Mantle cell and anaplastic T cell lymphoma one case each. Cases with pleural involvement were more likely to have higher LDH (P=0.005) and aggressive histology (0.05). Median time from initial presentation to established diagnosis is 2 months; pleural fluid aspirate was used in 10 cases; of which 6 cases needed further confirmation by a tissue biopsy.
Summary / Conclusion: According to our data, patients with NHL presenting with pleural involvement have a longer time to diagnosis with more diagnostic dilemmas, FNA from the pleural fluid should not be routinely considered as the diagnostic procedure of choice for cases with suspected NHL but rather tissue biopsy from accessible sites should be the standard.

B1654
BLASTIC PLASMOCYTOID DENDRITIC CELL NEOPLASM (BPDCN): SINGLE CENTER EXPERIENCE WITH TWO CASES IN ONE YEAR
A Agapidou[1]*, S Vakalopoulou[1], D Markala[2], C Xadjiaggelidou[1], M Tzimou[1], S Chissan[1], T Papadopoulou[1], K Tasios[1], V Garypidou[1]
[1]Second Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, [2]Theagenion Cancer Hospital, Thessaloniki, Greece

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare, highly aggressive hematopoietic malignancy that is characterized by cutaneous infiltration with or without bone marrow involvement and further leukemic spread. Its overall incidence is very low, accounting for 0.44% of all hematologic malignancies. The leukemic form of the disease is an extremely rare situation, representing <1% of all cases of acute leukemia. BPDCN predominantly affects males, with a sex ratio of 3:1, and generally occurs in the elderly.
Aims: The aim of this presentation was to evaluate symptoms, signs and outcome of two cases of BPDCN.
Methods: Between February 2012 and January 2013, we identified 2 patients with BPDCN presenting with skin lesions. Data regarding clinical presentation, diagnosis, staging, treatment and outcome was collected.
Results: First patient was female, 78 years-old, the other one was male, 75 years-old. At diagnosis both had asymptomatic skin lesions. The female patient presented with a cutaneous lesion on her right shoulder since the last month. Laboratory data disclosed anemia (hemoglobin: 11, 3 g/dl) thrombocytopenia (139×10^9/L) and morphologically immature atypical cells in the peripheral blood. Bone marrow aspiration showed 5% infiltration of immature blastic cells with the following immunophenotype: CD45(+), CD123(+), CD85k(+), CD33(-), CD14(-), CD16(-), CD19(-), CD5(-), CD10(-), CD20(-)CD56(+)20%, CD4(+), NG2(+). No chromosomal alterations were detected by cytogenetic analysis of the bone marrow. She had axillary, jugular, submandibular, and supraclavicular lymphadenopathy. Cutaneous, lymph node and bone marrow biopsies, all confirmed the diagnosis of BPDCN. She was treated with Cy-VAD (cyclophosphamide, vincristine, adriamycin and dexamethasone). She achieved CR, continued with induction 2 chemotherapy with Vepesid-Aracytin and died 4 months later of multi-organ failure. The male patient had a generalized purplish dermal rash arising from the head to the lower extremities that presented one week before and progressed very rapidly. Laboratory data revealed anemia (hemoglobin: 10, 9 g/dl), thrombocytopenia (100×10^9/L), WBC: $8.30*10^3$/μL with 42% of morphologically immature atypical cells. Bone marrow aspiration showed 88% infiltration of immature blastic cells with the following immunophenotype: CD45 (+) low, CD43 (+), CD123 (+), CD56 (+), CD4(+), CD34 (-).Cytogenetic analysis showed deletion of the long arm of chromosome 12 - deletion of ETV6 gene and deletion of the long arm of chromosome 17- deletion of P53 gene. Computed tomography scans did not disclosed any pathologic lymphadenopathy. Histopathology of skin lesions showed infiltration of blastic cells. Immunohistochemical analysis confirmed the presence of cells with the same immunophenotypic features. He started chemotherapy with Zavedos and Aracytin (3+7) and he is now in CR after this induction.
Summary / Conclusion: We present two cases of a rare clinical entity with cutaneous and bone marrow infiltration with blastic plasmocytoid dendritic cells. The diagnosis relied on the immunophenotypic features of the malignant cells, particularly with the presence of CD4 (+) and CD 56(+). Several treatment options have been used so far, all with poor results. The ALL-type treatment regimen that seems to result to a better outcome according to a recent publication resulted to a very short survival. Unfortunately neither of them could proceed to bone marrow transplantation, which is a better therapeutic option for younger patients with good performance status.

B1655
IMMUNOCHEMOTHERAPY-INDUCED CARDIOVASCULAR COMPLICATIONS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: RESPONSE TO ZOFENOPRIL
B Samura[1]*
[1]Hematology, Zaporizhzhia Regional Clinical Hospital, Zaporizhzhia, Ukraine

Background: The aim of this study was to determine the protective effect of zofenopril in immunochemotherapy-induced cardiomyopathy. The natural history of immunochemotherapy-induced cardiomyopathy, as well as its response to cardiovascular therapy, remains poorly defined. Hence, evidence-based recommendations for management of this form of cardiomyopathy are still lacking. Zofenopril proved to be effective in patients with coronary artery disease and myocardial infarction, thanks to its unique effective mechanism of action for improving blood pressure control, left ventricular function and myocardial ischemia burden, as well as angiotensin-converting enzyme inhibition. Rituximab is a monoclonal antibody to CD20 that has activity in leukemia and lymphoma.
Aims: This study aims to describe the complications and outcomes of a subset of patients with diffuse large B-cell lymphoma who were treated with immunochemotherapy.
Methods: Patients with diffuse large B-cell lymphoma in whom rituxmab, doxorubicin, cyclophosphamide, vincristine, and prednisolone therapy was planned were enrolled in the study. We included in the study 14 patients in zofenopril and 10 patients in control groups. In the zofenopril group, 7.5 mg twice-daily

oral zofenopril was given during 3 months. The patients were evaluated with echocardiography before and after chemotherapy. Left ventricular ejection fraction (EF) and systolic and diastolic diameters were calculated.
Results: At the end of 3 months of follow-up, 1 patient in the zofenopril group and 2 in the control group had died. Control EF was below 50% in 2 patient in the zofenopril group and in 3 in the control group. The mean EF of the zofenopril group was similar at baseline and control echocardiography (64.6 vs. 64.8, respectively; P=0.2), in the control group the mean EF at control echocardiography was significantly lower (62.7 vs. 49.2; P<0.001). Both systolic and diastolic diameters were significantly increased compared with basal measures in the control group. In Doppler study, whereas E velocities in the zofenopril group decreased, E velocities and E/A ratios were significantly reduced in the control group.
Summary / Conclusion: Prophylactic use of zofenopril in patients with diffuse large B-cell lymphoma receiving immunochemotherapy may protect both systolic and diastolic functions of the left ventricle.

B1656
A RARE CAUSE OF GENERALIZED LYMPHADENOPATHY: ROSAI DORFMAN DISEASE
D Cekdemir[1*], A Yilmaz[1], Z Gokgoz[1], N Soyer[1], A Gunes[1], M Comert[1], E Kose[1], G Saydam[1], F Vural[1]
[1]Hematology, Ege University, İzmir, Turkey

Background: Rosai Dorfman Disease is a rare benign disease characterized by generalized lymphadenopathies usually involving cervical lymph nodes. Its association has been reported with other autoimmune conditions and malignancies at the time of diagnosis or during its course. Anemia, polyclonal gammapathy and high sedimentation rate are remarkable findings in the laboratory investigations. Diagnosis is made by biopsy of the involved lymph node. Although the condition is a benign entity presenting with spontaneous remissions, it also may be lethal in the case with multi organ involvement associated with other autoimmune conditions.
Aims: We present here four cases followed in our center with diagnosis of Rosai Dorfman Syndrome.
Results: All of the cases presenting to our center with cervical lymphadenopathy were male and their median age was 49 years (range: 41 – 80 years). Anemia compatible with anemia of chronic diseases was found in all cases at the time of presentation. In regard to laboratory investigations, all cases had high levels of globulin, C-reactive protein and high rate of sedimentation, and polyclonal gammopathy.Diagnoses of all patients were made with biopsy of lymphadenopathy.In regard to follow-up of the patients, anemia worsened and increased level of creatinine was found after follow-up of 4 years without treatment. Biopsy results of the patient for whom renal biopsy was performed because of suspicion of renal involvement is still being waited, and steroid treatment was scheduled to the patient after the result of the biopsy. Hodgkin lymphoma developed in the course of one patient. Complete remission occurred with 4 courses of ABVD chemotherapy.New mass lesion was found in lung parenchyma on imaging studies following 6th course of ABVD chemotherapy.This patient whose result of lung biopsy has come as pulmonary adenocarcinoma is still receiving chemotherapy in the oncology unit for lung cancer. Steroid treatment was given to two patients with complaints of fever, weight loss, fatigue due to anemia (hemoglobin level was 8 g/dL and 6 g/dL, respectively). Fever response occurred with steroid treatment in both patients and their symptoms were controlled. High rate of sedimentation and high level of globulin normalized in the patients with anemia resolved. In one patient receiving steroid treatment, chronic renal failure developed due to accompanying cresenteric glomerulonephritis. The patient is still on chronic hemodialysis program. Steroid treatment is still continuing in both patients.
Summary / Conclusion: Although Rosai Dorfman syndrome is rare, lymphadenopathy should be kept in mind in differential diagnosis. It should be remembered that although it is a benign condition, it may be associated with other autoimmune conditions or malignancies at the time of diagnosis or during its course, and that it should be treated for symptoms due to such associated conditions and the patients should be followed for this.

B1657
POSITRON EMISSION TOMOGRAPHY SCAN FOR FOLLICULAR LYMPHOMA: GOOD CORRELATION WITH CLINICAL AND HISTOLOGIC FEATURES AT DIAGNOSIS
S Novelli[1*], J Briones[1], P Leoz[1], I Espinosa[2], A Flotats[3], J Sierra[1]
[1]Hematology, [2]Pathology, [3]Nuclear Medicine, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: To date, positron emission tomography (PET) scan is not the standard in the staging at diagnosis of follicular lymphoma. Its use is limited to those cases in which residual disease is crucial for therapeutic decisions and only if transformation to a high-grade lymphoma is suspected.
Aims: Our aim is to demonstrate a positive correlation between the standardized uptake value (SUV) at biopsy site detected by PET scan with pathologic (Ki67 and follicular lymphoma histologic grade) and clinical (LDH, beta-2-microgloblin, Ann Arbor stage and Follicular Lymphoma International Prognostic Index -FLIPI) features at diagnosis.
Methods: We retrospectively detected in the last 3 years 10 patients in whom node biopsies were performed taking into account the maximal SUV detected in the PET scan at diagnosis. The statistical analysis was made with SPSS version 20 for MAC-OS; descriptives and one-tailed Pearson's correlation test were calculated.
Results: The mean at diagnosis for SUV at biopsy site was 9.29 (range 4-24), for LDH the mean was198.90 U/L (range 135-290), for beta-2-microglobulin 3 mg/L (range 2-6) and for Ki67% index was 22% (range 5-50%).
Three (30%) patients had a histologic grade1, 6 (60%) cases were grade 2 and 1 patient (10%) was grade 3a. Six cases (60%) were stage IV of Ann Arbor, 3 (30%) were stage III and 1 (10%) case was stage II. The one-tailed Pearson's correlation test showed correlation (r>0) of SUV at biopsy site with beta-2-microglobulin (r=0.667; P<0.05), FLIPI (r=0.744; P<0.05), histologic grade (r=0.797; P<0.05) and Ki67 (r=0.885; P<0,05). We did not find correlation with serum LDH (r=0.120; P=0.37).
Summary / Conclusion: The SUV measured in the PET scan at biopsy site correlates with almost all the daily used pathologic and clinical parameters. The serum lactate dehydrogenase (LDH) is not frequently elevated in low-grade lymphoma, this may be the reason why no correlation was found. The most clinically important correlation detected with SUV is the histologic grade.(figure 1). The follicular lymphoma histologic grade has a prognostic value and also a therapeutic implication. The Pearson's r=0.8 reveals a lineal dependence between both variables. In practice, the computed tomography scan is used for the staging of follicular lymphoma but with this radiologic technique it is impossible to detect which lymph nodes have a higher histologic grade. Many patients are misdiagnosed as follicular lymphoma when in fact they already have a high-grade lymphoma. With this little approach we will consider using prospectively PET scan as guidance for node biopsy at diagnosis and make a new statistical analysis with a higher number of patients.The SUV measured in the PET scan at biopsy site correlates with almost all the daily used pathologic and clinical parameters. The serum lactate dehydrogenase (LDH) is not frequently elevated in low-grade lymphoma, this may be the reason why no correlation was found. The most clinically important correlation

B1658
ERDHEIM-CHESTER DISEASE PRESENTED WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT: A CASE REPORT
D Ozatli[1*], P Buyukkaya[1], E Kelkitli[1]
[1]Hematology, Ondokuz Mayis University, Medical Faculty, SAMSUN, Turkey

Background: Erdheim–Chester disease (ECD) is non-Langerhans form of histiocytosis of unknown origin. It is rare disease. The clinical picture may vary from asymptomatic bone lesions to multisystemic and life-threatening forms with poor prognosis, especially in case of specific central nervous system (CNS) or cardiovascular involvements .It is mainly diagnosed by typical pathologic features with the biopsy specimen displaying the xanthomatous or xanthogranulomatous infiltration of tissues by $CD68^+$ $CD1a^-$ S-100± spumous histiocytes, which distinguished from Langerhans cell histiocytosis. Although steroids has been the most common medical treatment in this disease an optimal therapeutic strategy remains to be defined. Interferon α-2a (IFN-a) has recently demonstrated valuable results in ECD, specisificly with CNS involvement.
Aims: Herein, we present a 35–year-old patient with ECD who had intra cerebral tumor-like lesion, which have occasionally been reported.
Results: A previously healthy 35–year-old woman, except visual impairment in left eye due to cataract for last 2 years, presented to the neurology department with complaints of weakness and headache 5 months ago. Headache was throbbing type on temporofrontal region and last in 5 minutes. Any pathological sign was found on physical examination. Cranial magnetic resonance imaging (MRI) revealed a 3x3.5 cm mass on the level of left basal ganglion, which was heterogenic contrasted on central part. Due to edema and mass, 3. Ventricular and the left frontal horn of lateral ventricular were compressed. Dekzamethazon treatment was initiated. The patient was referred to neurosurgery department for biopsy from that mass. The biopsy revealed infiltration of $CD\ 68^+$ $S\ 100^+$ $CD1a^-$ non-Langerhans histiocytes which were consistent with ECD. The patient was referred to our department. The physical examination of the patient was normal. Although deksamethazon dose was lowered the patient was still receiving it about one month. Laboratory studies revealed an elevated C-reactive protein (>4.4 mg/L) and erythrocyte sedimentation rate (45 mm/hour), and decreased hemoglobin level (10.1 g/dl) which was compatible with iron deficiency anemia. The other laboratory studies including urea and electrolytes, lipids, urinary studies, liver function and antinuclear antibodies were all within normal limits. Radiologic studies including direct x ray and 99Technetium (Tc) scintigraphy of long bones, thoracal and abdominal computed tomographics and heart echocardiography were normal. Dexamethazon was stopped and 3 million units in 3 days for a week interferon α-2a and oral iron treatments were started. Interferon treatment was well tolerated. There was a marked regression on cranial MRI scan after 3 months. The mass was almost completely disappeared and the impression of the mass and edema were not seen.
Summary / Conclusion: As a result, IFN-a was a very effective treatment in our ECD patient with cranial mass, which is rarely seen.

Stem cell transplantation - Experimental

B1659

USAGE AND MIXED CHIMERISM STATUS OF RECIPIENT FREE EDGE FINGERNAILS FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTS

H Liu[1*], Q Niu[1], F Wang[1], W Teng[1], Y Wang[1], C Tong[1]
[1]Ludaopei Hematology & Oncology Center, Beijing, China

Background: based on microsatellite(short tandem repeat, STR) genotyping is the standard method for donor cell engraftment monitoring after allogeneic hematopoietic stem cell transplantation (allo-HSCT). A standard chimerism analysis need pre-transplant blood specimens to identify the STR genotype of the patient's own. But sometimes we can't get the pre-transplant blood specimens, and hair follicles and oral mucosa were not the ideal choice due to hair loss and bleeding in oral mucosa.
Aims: To inspect whether DNA extracted from free edge fingernails specimens from patient after allo-HSCT could be used for STR genotyping and chimerism analyzing, and to observe the chimerism status in fingernails after allo-HSCT.
Methods: Peripheral blood, bone marrow, oral mucosa and free edge fingernail specimens were collected from patients after allo-HSCT and their donor. Genomic DNA was extracted and 15 STR loci genotyping and chimerism analysis was performed.
Results: For the first group which including 12 patients, pairs of fingernail and oral mucosa specimens were collected within one month after allo-HSCT and were comparative analyzed. For the second group which including 13 patients, chimerism status in fingernail samples were analyzed 3 months or longer after allo-HSCT, and 3 patients underwent repeated testing at different times. The results showed that for the first group, 4 oral mucosa specimens showed donor chimerism with varying degrees, but no donor chimerism was detected in all of 12 fingernail specimens. For the second group, 6.7% to 82.6% donor chimerism was detected in fingernail specimens in 5 out of 13 patients. For the 3 patients underwent repeated testing, donor chimerism was continued negative in one cases, but continued positive in the other 2 cases.
Summary / Conclusion: Free edge fingernail samples of patients within one month after allo-HSCT can be used for STR genotyping and chimerism analysis and better than oral mucosa samples. Donor derived skin cells chimerism can be formed and persist in some patients, and this indicated that there are cells in allo-HSCT donor graft can differentiate into skin cells.

B1660

GUT MICROBIOTA TRAJECTORIES AND IMMUNE SYSTEM RECOVERY IN CHILDREN UNDERWENT TO ALLOGENIC HEMATOPOIETICS STEM CELL TRANSPLANTATION (HSCT)

D Zama[1*], R Masetti[2], M Candela[3], C Nastasi[2], E Biagi[3], F Vendemini[2], M Severgnini[4], M Franzoni[2], P Brigidi[3], A Prete[2], A Pession[2]
[1]Paediatric Oncology and Haematology Unit 'Lalla Seràgnoli', University of Bologna, S.Orsola-Malpighi Hospital, [2]Paediatric Oncology and Haematology Unit 'Lalla Seràgnoli', University of Bologna, Sant'Orsola-Malpighi Hospital, [3]Department of Pharmacy and Biotechnology, University of Bologna, Bologna, [4]Institute of Biomedical Technologies– Italian National Research Council, Milano, Italy

Background: Allogeneic HSCT is a potential curative therapy for children with hematologic disorders. The main complications of HSCT are represented by infections and acute graft-versus-host disease (aGVHD), an immunological disorder which could be lethal and limits the use of this procedure. The gut microbiota (GM) evolves as an integral component of the human immune system (IS) and the developmental trajectory of GM represents a crucial factor in the process of immune recovery after HSCT. Human beings share a close mutualistic relationship with the GM, which is crucial for a balanced IS development. Specific intestinal bacterial groups are directly involved in this process, modulating a variety of T cell functions, as Th17, Th1, Th2 and regulatory T cells.
Aims: Characterization of the compositional and functional modifications of GM in children undergone allogeneic HSCT and correlation with the specific patterns of immunological reconstruction after ablative regimen.
Methods: Paediatric patients undergoing allogeneic HSCT at the Pediatric Oncology and Hematology Unit "Lalla Seràgnoli", Sant'Orsola-Malpighi Hospital, Bologna have been enrolled. For each pts blood and faecal samples were collected before HSCT and once every 2 weeks after the day of engraftment for 100 days. Phenotyping and identification of lymphocytes subpopulations was carried out by flow cytometry including CD3+CD4+ and CD3+CD8+ T cells, naïve T cells, memory T cells, B cells, Tregs, NK, Th17, Th1 and Th2.
HTF-MicroBi.Array has been used to rapidly and reliably characterize the GM, it is a validated tool, with a limited detection capacity (30 bacterial groups).
Results: 7 pediatric patients have been considered, 4 of which presented aGVHD (grade II-IV) within 100 days from HSCT. One of them had a intestinal GVHD of grade IV. HSCT deeply revolutionize GM, which progressively recover an "healthy-like" asset within 100 days from HSCT. This process is temporarily compromised by aGVHD. In the 4 patients which developed aGVHD, the appearance of aGvHD seems to temporarily compromise the rebuilding of the ecosystem. The non-aGVHD pts recover a "healthy-like" gut microbiota structure after-HSCT within 100 days, while the pts with GVHD showed a lower level of *Clostridiales* and a significant increase of *Streptococcus* at the onset of aGVHD
Summary / Conclusion: HSCT deeply rearranges the gut microbiota profile, which progressively recover an healthy-like asset within 100 days from HSCT. The results of this preliminary longitudinal study suggest a link between aGVHD and the trajectory of the re-building process of the symbiotic relationship between host and intestinal bacteria.

B1661

NAÏVE AND CENTRAL MEMORY CD4+ T CELLS RATIO AND GVHD

B Choufi[1*], J Trauet[2], M Labalette[2], I Agha[3]
[1]Nord Pas de calais, hôpital Duchenne, Boulogne Sur Mer, [2]Nord Pas de calais, laboratoire immunologie EA 2686, [3]Nord Pas de calais, service des maladies du sang CHRU, Lille, France

Background: Despite the data now available, the exact pathophysiology of graft versus host disease GVHD is still poorly understood. However it is now widely accepted that GVHD is mediated by T lymphocytes and that the process has three stages, from activation of antigen-presenting cells (APCs) to destruction of the target organ. Compared with other transplants, PBSCs contain 10 times as many T lymphocytes; However, following their use for several years, a genuine divergence has been demonstrated in terms of the incidence of acute and chronic GVHD . Phenotype characterisation of T lymphocyte subpopulations is a recent concept, to elucidate their role in the development of GVHD, T cell depletion studies have been performed.In a mouse model, selective depletion of naive CD4(+) T lymphocytes (TNs) in situations of major or minor antigen incompatibility lead to transplant acceptance without GVHD and transfer of antiviral immunity .Naive subpopulations are identified by a positive reaction of CCR7, CD62L and CD45RA , and in adults, 40 to 50% of peripheral T lymphocytes have a memory phenotype. The retrospective study conducted by our team in 2006 concerning the impact of the graft composition on the development of GVHD demonstrated that patients receiving a graft containing a CD4(+)CCR7(+) ratio of > 70% developed early and severe GVHD. However, this ratio has no influence on graft acceptance, the incidence of infectious complications or recurrence.
Aims: To assess the impact of reducing the proportion of the naive and central memory CD4 T cell subpopulation (CD4(+)CCR7(+)) to 50% on anti-infectious immune response
Methods: 8 peripheral blood stem cell (PBSC) donors were analysed cultured in the presence of pp65 antigen recombinant protein of CMV, and ADV before and after partial and selective depletion of the haematopoietic stem cell (HSC) graft CD4(+) CCR7(+) ratio to 50%. The anti-infectious response is assessed using three methods: Elispot, tritiated thymidine (3H) and CFSE. The negative controls are represented by analysis against HTLV-1 antigen
Results: This study demonstrated the feasibility of CD4(+)CCR7(+) double labelling for partial and selective depletion. A CD4(+)CCR7(+) ratio calculated at 50% does not impair the integrity of a PBSC graft's defences against infection. This result also provides proof of concept prior to a future therapeutic trial on pre-graft immunomodulation.
Summary / Conclusion: T lymphocyte subpopulation phenotype characterisation and T cell depletion studies represent a major advance in terms of our understanding of GVHD; the CD4(+)CCR7(+) ratio - the level of which is still to be determined - may represent a new foundation upon which we can build.

B1662

IMMUNOMODULATION OF MESENCHYMAL STEM CELLS IN CHRONIC GRAFT-VERSUS-HOST DISEASE

C De La Mata[1*], C Olmedo[1], A Comino[1], L Moratalla[1], E Lopez[1], A Hernández [1], S Gómez [1], S Garzón [2], R Saldaña [2], P García-Martín [1], C Solano[3], M Jurado[1]
[1]Hematology, Hospital Universitario Virgen de las Nieves, Granada, [2]Hematology, Hospital de Jerez, Jerez, [3]Hematology, Hospital Clínico de Valencia, Valencia, Spain

Background: Chronic graft-versus-host disease (cGVHD) is one of the principal causes of mortality in long-term survivors of allogeneic stem cell transplantation. The immunopathogenesis is unclear, we know that cGVHD is TH-2 mediated, but there are a lot of cytokines that must be studied to clarify the immune response. We know that Mesenchymal Stem Cells (MSCs) possess the ability to impart immunomodulatory effects.
Aims: In this preliminary prospective study, serum and lymphocytes subsets of cGVDH patients after MSC infusion were assessed.
Methods: Patients received intravenous infusion of MSC and were evaluated after7, 20, 42 and 56 weeks. We monitored the immunophenotype profile of lymphocyte subsets and cytokines using Flow Cytometer.
Results: The number of CD19+ cells increased on week 20 after therapy.

CD16+CD56+ subset was increased on the first 7 weeks and remain until week 20 after therapy. Differences were seen on cytokines evaluated, especially on IL-10, IL-2 and TNFa.
Summary / Conclusion: The infusion of MSC appears to have had an impact on cytokines and lymphocytes population. The results are encouraging in that there is possibility for effective therapy using mesenchymal stem cells for patients with cGVDH

B1663
COMPARABLE EFFECTS OF PIOGLITAZONE AND PERINDOPRIL ON CIRCULATING ENDOTHELIAL PROGENITOR CELLS, INFLAMMATORY PROCESS AND OXIDATIVE STRESS IN PATIENTS WITH DIABETES MELLITUS
Z Pallantza[1], A Kampoli[2], A Vlaxopoulou[3], G Paterakis[4], D Tousoulis[2], S Kontos[3], N Papageorgiou[2], C Stefanadis[2], Z Pallantza[3*]
[1]Haematology Department, Hippokration Hospital, Athens, Greece, [2]1st Cardiology Unit, [3]Haematology Department, Hippokration Hospital, [4]Flow-cytometry Unit, General Hospital of Athens "G, Gennimatas", ATHENS, Greece

Background: Comparable effects of pioglitazone and perindopril on circulating endothelial progenitor cells, inflammatory process and oxidative stress in patients with diabetes mellitus
Aims: Endothelial progenitor cells (EPCs) originating from the bone marrow play a significant role in neovascularization of ischemic tissues and in re-endotheliazation of injured blood vessels. The purpose of this study was to investigate if the administration of pioglitazone or perindopril in diabetic patients can modify the number of EPCs in the peripheral blood and alter the endothelial function and inflammatory status of these patients.
Methods: Fifty type 2 diabetic patients were recruited and were randomly assigned to receive either pioglitazone (15mg/day) or perindopril (4mg/day) for a one-month period. In both groups blood sample were drawn on admission (baseline) and after one month of drug's administration. Blood samples were taken in order to count EPCs and inflammation markers such as C-reactive protein (hsCRP), vascular endothelial growth factor (VEGF) and asymmetric dimethilarginine (ADMA). Circulating EPCs were defined by the surface markers CD34+/KDR (CD34 and VEGFR2 expressing cells) and analyzed by flow-cytometry. Moreover the endothelial function of the patients was evaluated both on admission and after treatment with flow mediated dilation (FMD).
Results: We have found that neither pioglitazone (P=0.09), nor perindopril (P=0.5) affected the number of EPCs. Importantly, we have shown that pioglitazone reduced CRP (P=0.04) and ADMA levels (P=0.002). In addition, pioglitazone improved FMD (P=0.04) and increased plasma concentrations of VEGF (P=0.01). On the contrary perindopril had no significant effect on CRP levels (P=0.07), FMD (P=0.23) as well as on ADMA levels (P=0.09). However, perindopril administration increased significantly plasma levels of VEGF (P=0.03). Moreover, both agents did not differ regarding to their effect on ΔEPCs (P=0.34), ΔFMD (P=0.70), ΔVEGF (P=0.27) and ΔCRP (P=0.85). Interestingly, we have found that perindopril had a superior effect than that of pioglitazone considering ΔADMA levels (P=0.01), despite the non significant (post administration) effect on ADMA levels resulting solely.
Summary / Conclusion: Based on the existing data, it seems that both treatments did not affect significantly number of circulating endothelial cells. Importantly, pioglitazone affected beneficially all the study parameters. On the other hand, perindopril increased significantly only VEGF levels, while CRP, FMD and ADMA levels were unaffected. Interestingly, we found that although perindopril had no significant effect on ADMA levels, this effect was greater when compared to that of pioglitazone. Considering our results, we provide also evidence for a possible addition of perindopril to the conventional treatment with pioglitazone which could affect further the neovascularization and reduce oxidative stress in these patients.

Stem cell transplantation - Clinical

B1664
NON CRYO-PRESERVED AUTOLOGOUS PERIPHERAL BLOOD HEMATOPOIETIC STEM CELL TRANSPLANTATION(HSCT) FOR HEMATOLOGIC MALIGNANCIES IN SHIRAZ,SOUTH OF IRAN
M Ramzi[1*], h nourani[1], R Vojdani[1], m dehghani[1], m karimi[1], m zakernia[1], h haghighinejad[1]
[1]hematology,oncology and stem cell transplantation, shiraz university of medical sciences, Shiraz, Iran, Islamic Republic Of

Background: Hematologic malignancy currently represents the main indication for HSCT. clearly, autologous and allogeneic HSCT are established therapies in many of hematologic malignancies. High dose therapy(HDT) supported by autologous HSCT are the preferred choice for lymphoproliferative disorders and multiple myelom.
Aims: In this study we report our experiences in non cry- preserved autologous stem cell transplantation of hematologic malignancies in south of Iran.
Methods: Between Jan 2004 and JAN 2013, 300 patients with diagnosis of hematologic malignancies including Hodgkin's lymphoma(HD) , non-Hodgkin's lymphoma(NHL),Acute myelogenous leukemia (AML)and multiple myeloma(MM)underwent autologous peripheral blood stem cell transplantation in our center in Shiraz university of medical sciences. Patients were treated by intensive chemotherapy followed by reinfusion of non- cryopreserved autologous stem cells. The pretransplant conditioning chemotherapy regimen were CEAM (lomustin 150- 200 mg/m^2, etoposide 1000 mg/m^2, cytarabine 1000-1200 mg/m^2 and melphalan 140 mg/m^2) for Lymphoma,Busulfan 14 mg/kg and etoposide 1000 mg/m^2 for AML and melphalan 140-200 mg/kg for multiple myeloma patients. All apheresis products were kept in a conventional blood bank refrigerator at 4°C for 2-4 days before infusion.
Results: During this time, 86 HD patients with median age 27 years (range;7-51),72 NHL patients with median age 29 years(range;18-64), 92 MM patients with median age 55 years(range;31-70)and 50 AML patients with median age 26(range ;17-51) underwent autologous peripheral blood stem cell transplantation. The median time to platelet count > 20×10^9/L was 15 days (range ;9-39).The median time to ANC > 0.5×10^9/L was 12 days (range ;8-32).All patients have engrafted and there were not graft failure in this study group. 100 days transplant related mortality rate was 2.2% in MM, 3.5% in HD, 4.2% in NHL and6% in AML group respectively.
Summary / Conclusion: Our data reflects the important role of HDT followed by HSCT in improvement of outcome for a variety of hematologic malignancies in our center. We concluded high dose therapy rescued with non- cryopreserved auto SCT is safe and effective method that is feasible in our patients.

B1665
ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHRONIC MYELOGENOUS LEUKEMIA IN THE ERA OF IMATINIB - A SINGLE CENTER EXPERIENCE
M Constanço[1*], C Vaz[1], R Ferreira[1], F Campilho[1], M Rosales[2], S Roncon[2], A Campos Jr[1]
[1]Bone Marrow Transplantation service, [2]Cell Therapy Service, Portuguese Oncology Institute, Porto, Portugal

Background: Tyrosine kinase inhibitors (TKI) have revolutionized treatment of chronic myeloid leukemia (CML). Allogeneic hematopoietic stem cell transplantation (alloHCT) was standard first-line therapy for CML, but it is now reserved for patients (pts) whose disease does not respond optimally to TKI. Whether this strategy of delayed transplantation will increase the risks of late relapse and mortality is not known.
Aims: To evaluate the experience of a single center in the treatment of CML with alloHCT in the Imatinib era and how relapse was managed.
Methods: Retrospective analysis of clinical registries databases of a cohort of CML allografted between 2000-2012pts. Outcomes of interest were transplant-related mortality (TRM), incidence of aGvHD, cGvHD, relapse and relapse-related mortality (RRM) and overall survival (OS)-estimated from the transplant date. Statistical analysis was performed with SPSS®v21
Results: 45 patients (pts) with CML received alloHCT between 2000-2012; median age at transplant 40 years (range 20-58).Median time from diagnosis to transplant was 20 months (range 3-167).Treatment prior to alloHCT: TKI (17 pts), acute leukemia induction (10 pts), acute leukemia induction+TKI (1 pts), others without TKI (17 pts). Disease state at alloHCT: 1st chronic phase (CP; 27 pts), 2nd CP (12 pts), 3rd CP (1 pt), accelerated phase (AP; 2 pts) and blastic phase (BP; 3 pts). Donors were matched in 39 (35 related/4 unrelated), mismatched in4, haploidentical in1 and syngeneic in 1. 29 received a myeloablative regimen (BuCy2+/-ATG) and 16 a reduced conditioning regimen (FluBu+/-ATG). Pts were transplanted with unmanipulated peripheral blood stem cells in 41, cord blood cells in 1 and bone marrow progenitor cells in 3. GvHD prophylaxis was: CsA (14pts), CsA+MTX (14pts), CsA+MMF (10pts), Tac+MMF (3pts), Tac+MTX (4pts). Chimerism at day 100: complete chimerism (30 pts), mixed chimerism (11 pts), graft failure (1 pts); 3 pts were not evaluable (1 syngeneic

and 2 deaths before day 100). Disease status at day 100: persistent disease in 12 and complete molecular response in 31. 40% developed grade II/IV aGvHD and 42% cGvHD. Cumulative incidence of relapse was 44.5% at 5 years; median time from alloHCT to relapse was 9 months (range 6-59 months). Post alloHCT disease progression in 25 pts (12 with post alloHCT persistent disease and 13 relapses): hematological (6 pts), cytogenetic (7 pts), molecular (10 pts), extramedullary (1 pt), hematological and extramedullary (1 pt). They received: donor lymphocyte infusion (DLI; 2 pts), TKI (4 pts), TKI+DLI (9 pts), acute leukemia induction (6 pts: alone-3; plus DLI-1; plus DLI and TKI-2), 2nd alloHCT (2 pts: alone-1, plus DLI and TKI-1), TKI and radiotherapy (1pt), tapered immunosuppression (1 pt). Complete molecular response attained in 13, major molecular response in 3 and 9 failed. Median follow up for 32 alive pts was 86 months (8-155). Cumulative incidence of 90-days, 1 year, and 3 years TRM was 4%, 11% and 11%, respectively. Cumulative incidence of 5-years RRM was3,7% and 37,5% for pts allografted in CP and advanced phase, respectively. 5-year OS of 72,4%, with rates of 86,2% and 50% for pts allografted in CP and advanced phase. At the last molecular follow-up complete molecular remission was achieved in 29 of 32 pts (90,6%).

Summary / Conclusion: AlloHCT value keeps supported by the quality of molecular remissions and continues an option for those who cannot tolerate TKI or when CML progresses on TKI therapy highlighting the fact that transplantation outcome in advanced phase is poor. Post alloHCT therapy with TKI needs to be further investigated.

B1666

DO EOSINOPHILS HAVE A ROLE IN GRAFT-VERSUS-HOST DISEASE?

C Wennerås[1*], J Cromvik[1], M Johnsson[2], K Vaht[1], J Johansson[1]
[1]Hematology and Coagulation, [2]Clinical Chemistry, Sahlgrenska University Hospital, Göteborg, Sweden

Background: Eosinophilia and eosinophilic tissue infiltration have been observed in patients with acute and chronic graft-versus-host disease (GVHD). It is unknown if eosinophils are involved in GVHD or are mere bystander cells.

Aims: The purpose of this study was to determine if eosinophils were activated in the blood of patients with GVHD, if the pattern of activation was the same in acute and chronic GVHD, and how systemic corticosteroid therapy might impact of the activation state of eosinophils.

Methods: Adult hematopoietic stem cell transplant recipients (n=37) with and without GVHD were investigated with respect to absolute and relative eosinophil counts and expression levels of 14 surface markers by 4-color flow cytometry. Multivariate analysis of pattern recognition (Partial Least Squares Projections to Latent Structures-Discriminant Analysis) was used to segregate the various patient subgroups.

Results: Multivariate analysis revealed that eosinophilic data could separate patients with acute GVHD (aGVHD) from those with chronic GVHD (cGVHD): aGVHD patients had lower levels of the integrins CD11c and CD18 compared to those with cGVHD. Eosinophils from patients whose GVHD was diagnosed within 100 days post-transplant also differed phenotypically from GVHD diagnosed after 100 days. Finally, systemic corticosteroid therapy drastically altered the phenotype of eosinophils in patients with GVHD, but not in those without GVHD. Thus, corticosteroid-treated aGVHD and cGVHD patients' eosinophils had significantly lower levels of the surface molecules CD9, CD11c, CD44, CD49d, and CCR3, as well as lower relative counts of blood eosinophils. In addition, decreased levels of CD18 were seen in steroid-treated cGVHD patients.

Summary / Conclusion: Eosinophils are likely to play a role in GVHD since they display an activated phenotype. Moreover, the different phenotypes exhibited by eosinophils in acute and chronic GVHD suggest that blood eosinophils receive different signals of activation from the tissues in these two forms of GVHD. Possibly, eosinophilic phenotypes could be used to facilitate the diagnosis of GVHD.

B1668

THE PREVALENCE AND PROGNOSTIC VALUE OF CONCOMITANT EOSINOPHILIA IN CHRONIC GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

K Mortensen[1,2*], T Gerds[3], O Bjerrum[2], A Lindmark[2], H Sengeløv[2], C Andersen[2,4]
[1]Faculty of Health Sciences, University of Copenhagen, [2]Department of Hematology, Copenhagen University Hospital, [3]Department of Biostatistics, University of Copenhagen, Copenhagen, [4]Department of Hematology, Roskilde Hospital, Roskilde, Denmark

Background: Chronic graft-versus-host disease (cGVHD) is a common and often severe condition affecting long-term survivors of allogeneic hematopoietic stem cell transplantation (ASCT). New theories suggest that impaired thymic function with defective immune reconstitution may contribute to cGVHD by a defective peripheral immune regulation with cytokine dysregulation and a succeeding imbalance in the T helper cell (Th) cytokine secretion pathways. In this context, cGVHD has been associated with an activation of the Th2 pathway where certain Th-type 2 cytokines, e.g. interleukin (IL)-5, also act as potent eosinophilopoietic factors. Hence, eosinophilia, which may be present at the time of cGVHD diagnosis, might act as a surrogate marker of activation of the Th2 pathway, which has been proposed to be associated with a more favorable prognosis among cGVHD patients. Though several studies have focused on the prognostic impact of eosinophilia on transplant outcome, the prognostic significance of eosinophilia after myeloablative ASCT and the relationship between cGVHD and concomitant eosinophilia remain to be established.

Aims: The primary objective of this study was to identify pre-transplant factors associated with the development of cGVHD with concomitant eosinophilia. Secondly, to determine the prevalence and clinical impact (overall survival, non-relapse mortality and relapse incidence) of the condition in a large population of patients who have undergone myeloablative ASCT with a long follow-up.

Methods: Data were collected retrospectively from 142 patients, all of whom developed cGVHD after having received myeloablative ASCT with unmanipulated grafts. An absolute eosinophil count of $\geq 0.5\times10^9$/L was defined as eosinophilia (EO) and analyzed at the time of cGVHD onset.

Results: There were 28 EO+ patients (19.8 %) at the time of cGVHD onset. The median follow-up time starting at the onset time of cGVHD was 5.8 years [CI: 3.2 – 6.8 years]. Relapse was observed for 27 patients. Twenty-five patients died from other causes than relapse. The remaining 90 patients were event-free at the end of follow-up. We identified significant differences among disease-, cytomegalovirus serostatus-, cGVHD onset-, and "ongoing steroid treatment"-groups at the time of cGVHD diagnosis. We observed no significant association between eosinophilia and the grade of cGVHD; neither when assessed according to the revised Seattle criteria nor when the high risk features of thrombocytopenia and extensive skin involvement were analysed. Importantly, we observed no significant association between cGVHD with concomitant eosinophilia and long-term clinical outcomes. Furthermore, subgroup analyses performed in order to assess the influence of ongoing steroid treatment at the time of cGVHD onset revealed a considerable confounding effect. Therefore, we suggest that positive results found in previously published studies may have been the result of the confounding effect of ongoing steroid treatment on both eosinophilic levels and clinical outcomes.

Summary / Conclusion: Based on this study we advocate that conclusions regarding the prognosis of cGVHD with concomitant eosinophilia after ASCT should be drawn with caution.

INFECTIOUS COMPLICATIONS FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) AND PROPOSAL OF EVIDENCE-BASED KOREAN GUIDELINES FOR PREVENTING INFECTIOUS COMPLICATIONS IN HSCT RECIPIENTS.

Y Kim[1*], I Kim[2], Y Lee [2], D Lee [3], M Lee [4], C Min[3], N Chung [3], J Won[5], S Kim[6], S Kim[4], C Choi[7], Y Park[7], W Lee[8], Y Joo[8], H Kim [9], M Park [10], J Park [11], Y Do [12], H Yhim [13], H Lee [14], H Yi [15], J Moon [16], S Koh [17], Y Park [3], J Lee [9], J Eom [18], H Kim[1], D Han[1], H Jang[1]
[1]Chonnam National University Hwasun Hospital, Jeollanam-do, [2]Seoul National University College of Medicine, [3]The Catholic University of Korea, School of Medicine, [4]Konkuk University College of Medicine, [5]Soonchunhyang University College of Medicine, Seoul , [6]Dong-A University College of Medicine , Busan, [7]Korea University College of Medicine, Seoul , [8]Inje University College of Medicine, Busan, [9]University of Ulsan College of Medicine, Ulsan, [10]Wonkwang University College of Medicine, Iksan, [11]Gachon University Medicine and Science, Incheon, [12]Keimyung University School of Medicine, Daegu, [13]Chonbuk National University Medical School, Jeonju, [14]Kosin University College of Medicine, Busan, [15]Inha University School of Medicine, Incheon, [16]Kyungpook National University Medical School, [17]Yeungnam University College of Medicine, Daegu, [18]Hallym University College of Medicine, Chuncheon, Korea, Republic Of

Background: Infectious complications are a major issue after HSCT and remain a major cause of transplant related morbidity and mortality.

Aims: We analyzed the recent trends of infectious complications following HSCT based on a Korean Blood and Marrow Transplant Registry (KBMTR) data and proposed Korean guidelines for preventing infectious complications in HSCT recipients.

Methods: We collected 36 previous guidelines (9 international and 27 Korean individual HSCT centers) and reviewed their qualities. We also investigated incidence and causative organisms of infectious complications in1,667 patients (1,145 alloHSCT, 522 autoHSCT) undergoing HSCT in Korea during recent 5 years. On the basis of these data, 9 PICO questions were confirmed.

Results: Median follow-up time was 14 ms (0-66 ms). There were 768 episodes of infection in 456 patients after HSCT. Bacteria accounted for 59.6% of the major causative pathogens (fungus: 21%, virus: 17% and TBc: 2.2%). Infectious complications comprised 52.4% of the cause of death after HSCT. G(-) Bacterial infection is the most common cause of death in all HSCT patients G(-) bacteria: 25.1%, G(+): 21.2%, fungus: 24.7%, virus: 2.7%, TBc: 1.6%, unspecified infection: 24.7%. Routine antimicrobial prophylaxis is recommended for all adult HSCT patients. In Korea, 6.0% of HSCT recipients and 3.0% of donors had HBV infection before HSCT. Almost 5% of recipients new-

ly developed HBV infection after HSCT. Routine screening for HBV viral status in donor and recipient is recommended and tests should be repeated during follow-up for recipients. In all alloHSCT patients, 2.4% showed EBV-related PTLD. Routine screening and follow-up test for EBV viral load should be considered. Viral-associated hemorrhagic cystitis occurred in 2% of HSCT patients (87.9% BK/12.1% adenovirus-related). Almost 2% of HSCT patients had a history of active (n=12) or previous TBc (n=22) infection before HSCT and 0.8% of recipients newly diagnosed as TBc after HSCT. Korean HSCT centers revealed to have several different strategies for the vaccination after HSCT. A considerable rate of vaccine-preventable diseases such as varicella zoster or influenza viral infections occurred in HSCT patients, especially in adults. Therefore, we recommend routine immunization schedule with available vaccines for HSCT patients.

Summary / Conclusion: Infection is still one of the main complications after HSCT and highly contributes to mortality in HSCT recipients. Proposed guidelines may help to reduce the infectious complications after HSCT patients.

B1670

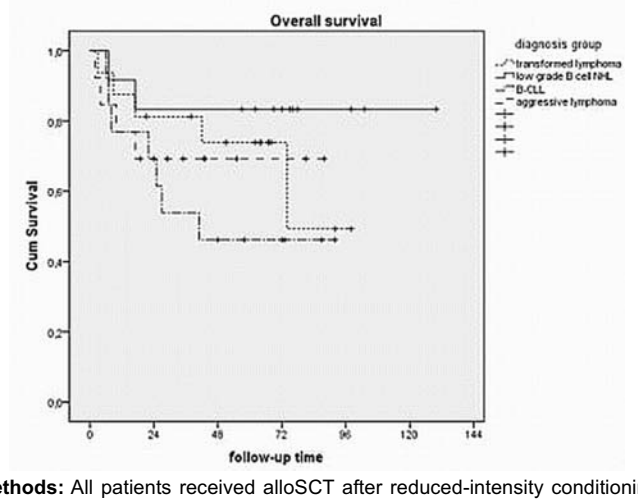
ALLOGENEIC TRANSPLANTATION AFTER REDUCED INTENSITY CONDITIONING WITH FLUDARABINE/CYCLOPHOSPHAMIDE IS FEASIBLE AND EFFECTIVE FOR HIGHLY RESISTANT INDOLENT AND AGGRESSIVE LYMPHOID MALIGNANCIES.

M Wondergem[1*], F Dijkstra[1], O Visser[1], S Zweegman[1], G Ossenkoppele[1], B Witte[2], J Janssen[1]

[1]hematology, [2]epidemiology and biostatistics, VU university medical center, Amsterdam, Netherlands

Background: Allogeneic stem cell transplantation (alloSCT) is a potentially curative treatment strategy for relapsed lymphoid malignancies.

Aims: We studied outcomes of 54 patients with relapsed or refractory indolent as well as aggressive lymphoid malignancies, who received alloSCT after reduced intensity conditioning in our center. Although the patient group reported here is heterogeneous as to lymphoma type and previous treatments, all patients had at least stable disease before transplantation and received the same conditioning regimen consisting of fludarabine and cyclophosphamide.



Methods: All patients received alloSCT after reduced-intensity conditioning with fludarabine and cyclophosphamide between July 2001 and November 2010 at the VU University medical center. AlloSCT was applied because of relapse after autologous stem cell transplantation (autoSCT) or because no further therapy was expected to lead to cure or a meaningful remission. The conditioning regimen consisted of fludarabine 25 mg/m^2 i.v. and cyclophosphamide 500 mg/m^2 i.v., both from day -7 until -3. Patients received an unmanipulated peripheral blood stem cell graft, targeting at a minimum of 4.0x10^6 CD34+ cells/kg patient body weight at day 0. Data were collected using retrospective chart review and analyzed using the SPSS statistical package (version 20.0). Overall survival (OS) and event free survival (EFS) were estimated using the Kaplan Meier method and compared using the log-rank test.

Results: A total of 54 patients were treated between July 2001 and November 2010. Median follow up of all patients alive at last follow up is 67 months (range 19-130 months). Patients were diagnosed with B-CLL (n=13), indolent B cell lymphoma (n=12), aggressive lymphoma (n=13) and 16 had DLBCL classified as transformation of indolent lymphoma. Thirty-two patients (59%) previously received rituximab. Immediately (in the first 0-3months) after conditioning and transplant, remission status had improved in 21 patients, all without donor lymphocyte infusions (DLI). During follow up six additional patients achieved CR without further therapy. Four patients relapsed within 6 months, and seven relapsed more than 6 months after transplant (range 9-58 months). Five patients required DLI during follow-up, all because of disease persistence or progression, resulting in remission in four patients. Analysis per disease category revealed a 4-year OS for B-CLL of 46% (95%CI: 19-73%), 83% for indolent B-cell lymphoma (95%CI: 62-100%), 69% for aggressive lymphoma (95% CI:44-94%) and 74% for transformed lymphoma (95%CI: 52-96%). (NS, P=0.28, see Figure 1). Four-year EFS was 46%, 75%, 55% and 67% respectively (95%CI: 19-73%, 51-100%, 24-87% and 44-91% respectively, NS, P=0.54). OS was not significantly different between patients with (n=16) and without (n=38) previous autologous stem cell transplantation. One year non relapse mortality was 11%, increasing to 16% after two years. (95%CI: 2.2-20% and 5.7-26% respectively)**Summary / Conclusion:** Reduced intensity conditioning with fludarabine cyclophosphamide is feasible with acceptable toxicity and effective for both highly resistant indolent and aggressive lymphatic malignancies, even after previous autoSCT. Due to the excellent anti-B-cell/lymphoma activity, fludarabine-cyclophosphamide decreases tumor load during alloSCT, gaining time for the development of a graft versus lymphoma effect, which was also apparent after DLI.

B1671

IMPROVED OUTCOME AND NON-RELAPSE MORTALITY AFTER ALLO-HSCT FOR CHILDREN AND ADOLESCENTS WITH HEMATOLOGICAL DISEASES: A THREE DECADE ANALYSIS FROM A SINGLE INSTITUTION

E Brissot[1*], F Rialland[1], X Cahu[2], M Strullu[1], N Corradini[1], C Thomas[1], N Blin[1], X Rialland[1], E Thebaud[1], P Moreau[1], P Chevallier[1], N Milpied[3], J Harousseau[4], F Mechinaud[5], M Mohty [6]

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) is a curative treatment for many pediatric patients with hematologic malignancies, bone marrow failure syndromes, and some inherited disorders. Over the past decades, major landmarks and advances have been achieved in the field of allo-SCT with respect to conditioning regimens, choice of stem cells source, as well as supportive care.

Aims: With this background, we conducted a study to assess the outcome of pediatric transplanted in a single institution over a 3 decades period.

	Total	1983-1999	2000-2010	p

MUD	67 (27%)	11 (11%)	56 (38%)	

Methods: All patients who received allo-SCT in our pediatric hematology department between 1983 and 2010 were included in this analysis. This period was *a priori* divided into two parts namely 1983-1999 and 2000-2010, the latest period corresponding to the initiation and development of cord blood allo-SCT and introduction of the so-called reduced-intensity conditioning (RIC) regimens in some subgroups. The main characteristics of the patients and the most relevant aspects of allo-SCT are shown on Table 1. The use of a myeloablative conditioning (MAC) regimen was predominant between 1983 and 1999 while RIC regimen represented 16% of the procedures after 2000 (P=9.10^{-5}).Bone marrow was the major stem cell source between 1983-1999 compared to 2000-2010 (96% vs 65%, P=2.10^{-10}). After 2000, cord blood was introduced as stem cell source for 25% of cases and peripheral blood stem cell for 9%.

Results: Overall survival (OS) was significantly higher in the second period (64% versus 52%, P=0.03). Also, non-relapse mortality (NRM) at 5 years was significantly lower after 2000 (29% versus 9%, P=0.0002). The cumulative incidence of relapse was 25% between 1983-1999 and 34% between 2000-2010 (P=0.11). Concerning the cumulative incidence of mortality due to relapse or progression was not statistically different between the 2 periods (20% vs 26%, P=0.26). Finally, between the 1983-1999 period and the 2000-2010 period, the cumulative incidence of death related to GVHD was significantly reduced (13% versus 3%, P=0.001).

Summary / Conclusion: In conclusion, this large analysis performed over a 3 decades period confirms that major advances in terms of outcome were achieved over the time in the pediatric allo-SCT population. The safety of the

procedure and the overall outcomes have significantly improved, despite the increasing use of alternative stem cell sources such as cord blood cells and HLA-matched unrelated donors.

B1672

THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION – A RETROSPECTIVE ANALYSIS OF 31 CASES

S von Harsdorf [1*], N Kloevekorn[1], H Döhner[1], D Bunjes[1], M Bommer[1]
[1]University of Ulm, Ulm, Germany

Background: Transplantation associated thrombotic microangiopathy (TA-TMA) can be a devastating complication of allogeneic hematopoietic stem cell transplantation (aHSCT). The incidence of TA-TMA in aHSCT recipients is reported to be very variable. This is mainly caused by the lack of a standardized definition of disease and the broad variability of the severity of TMA. Currently, the mechanisms causing this disease are still not well known. Treatment guidelines are not available.
Aims: The aim of our analyses was to evaluate the efficacy of different treatment strategies for TA-TMA.
Methods: We retrospectively analyzed 31 (f/m = 11/20) cases with TA-TMA. All patients received allogeneic hematopoietic stem cell transplantation at our hospital between 1997 and 2011. Patients suffered from AML (11), ALL (8), CML (6), NHL (3), Multiple Myeloma (2) and CLL (1). Follow up period was closed on 31.12.2012. Median follow up after transplantation was one year (range 86 to 2460 days). TMA has been defined as follows: elevated LDH, thrombocytopenia below 50 G/L or reduction of platelets of more than 50% and fragmentocytes in the peripheral blood smear.
Results: Median time for occurrence of TMA after aHSCT was 138 days (range 16 to 1862). Median duration of TMA was 72 days (range 11 to 238). Most of the patients (27/31; 87%) were treated with calcineurin – inhibitors before TMA occurred. Eight patients (26%) died from TMA, but in our cohort only two patients (6%) survived until the end of surveillance period. Most of them died from relapse, infectious complications or chronic GvHD. Treatment modalities used were plasmapheresis, defibrotide, rituximab or combinations of each. In all cases calcineurin-inhibitor treatment was stopped. Four patients were treated with supportive care only. Remission rates for defibrotide, plasmapheresis, rituximab and supportive care were 43%, 40%, 50% and 100% respectively. Median duration of TMA was 68 days (defibrotide), 168 days (rituximab), 61 days (plasmapheresis) and 70 days (supportive care). Achieving remission of TMA, duration of TMA and survival was not statistically different compared in the three treatment groups except the fact that TMA duration was longer in the rituximab group (mean 137 vs. 75 days, P=0.0246, unpaired t-test). This may be caused by the fact, that rituximab was used late in the treatment course (median 38 days (rituximab) vs. 10 days (defibrotide) vs. 8 days (plasmapheresis) after onset of TMA).
Summary / Conclusion: Treatment of TA-TMA is still challenging. None of the treatment regimens used can be considered as standard treatment. If there is no organ complication stop of calcineurin inhibitors may be sufficient, but for patients with life-threatening complications this may not be appropriate. According to the existing literature plasma exchange is no longer recommended except in patients with - very rarely found - ADAMTS13 activity below 5%. Rituximab seems not to be useful as a rescue medication. Only defibrotide may be able to shorten the course of TMA, but has no influence on inducing remission or survival. Elucidation of the pathophysiology of TA-TMA is mandatory. Especially the role of complement activation may be a cornerstone for defining new treatment options.

B1673

KIR AND CYTOKINE GENE POLYMORPHISMS AS INFLUENCE FACTORS FOR EARLY AND LATE COMPLICATIONS AFTER HAEMATOPOIETIC STEM CELL TRANSPLANTATION

D Bratu[1*], I CONSTANTINESCU[2], A MOISE[2]
[1]Haematology, [2]Immunology, Clinical Institute Fundeni, Bucharest, Romania

Background: Immunology of transplant is very complex and yet not well known.
Aims: This involve polymorphism of HLA, minor histocompatibility antigens , KIR (activatory and inhibitory) allele, cytokine(homeostatic ,inflammatory, anti-inflamatory) ,chemokines and their receptors.other non-HLA encoded genes.HLA matching can have dualistic effect on transplant outcome:it reduces rejection but conversely,it may promote other HLA-restricted mechanisms of allograft injury.
Methods: We have assesed eight pairs for allogeneic bone marrow transplantation for hematological malignancies..All related donors and recipients had 100% HLA alleles match(HLA A,B,C,DRB1,DQB1,DPB).All pairs were investigated for their cytokine gene polymorphisms and KIR haplotypes as long term prediction factors for graft versus host disease acute and chronic,complication of vascular origin(veno-oclusive disease,thrombotic microangiopathy) ,recurrence of the disease and develope of a second malignancy. HLA typing was performed by high resolution sequence specific primers(SSP) method using Dynal (KIR Genotyping SSP Kit)high resolution SSP.HLA alleles ambiguities were resolved by Sequencing Based Typing(SBT)Allele SEQR,ABBOTT.Cytokine gene polymorphisms were performed by Dynal(Cytokine Genotyping SSP Kit)PCR SSP9(IL1 alpha,IL1 beta,IL1R,IIL1R alpha,IL2,IL4,IL4Ralpha,IL6,IL10,IL12,gammaIFN,TGF beta and TNFalpha).KIR genotyping for both donors and recipients were revealed using PCR SSP (Dynal)We try to correlate with leukocytes ,platelets recovery presence of schistocytes,appearence of reccurrence.
Results: Short,our results:-following genes were identified: IL1alpha,IL1beta,IL1ra,gammaIFN,TGFbeta1,IL4,IL6,IL10;44%TNF alpha and IFN gamma,56%TGFbeta.-KIR genotype: B in 12 patients,A,in 4 patients. HLA typing at 4 and 8 digits reveal as alleles secreted but not stable at the cell surface,find at soluble form,allel which contains a mutation outside the coding region (null allele) or low expresed allele at the cell surface.
Summary / Conclusion: These differences in "perfect" matches,KIR genotype, the presence and fluctuation of cytokine influence the appearence and gravity of GVHD acute or chronic,vascular injury ,leucocyte and platelets recovery,recurrence of disease and a late second malignity.Of course,thats depends also from disease,conditioning regimen ,treatments before and after transplant.

B1674

IS SYMPTOM ASSESSMENT OF VALUE IN LYMPHOMA SURVIVORS AFTER AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT)?

T Ionova[1*], D Fedorenko[1], N Mochkin[1], K Kurbatova[2], G Gorodokin[3], A Novik[1]
[1]National Pirogov Medical Surgical Center, Moscow, [2]Multinational Center for Quality of Life Research, Saint-Petersburg, Russian Federation, [3]New Jersey Center for Quality of Life and Health Outcome Research, NJ, United States

Background: AHSCT offers effective control and potential cure of lymphoma patients but is accompanied by adverse effects and long-term complications, which have a negative impact on patient's quality of life (QoL). Self-reported symptom assessment may be a useful tool to identify patient benefits and risks of AHSCT at long-term follow-up.
Aims: We aimed to evaluate the symptom profile in lymphoma patients in complete remission after AHSCT at long-term follow-up and study its interference with QoL.
Methods: A total of 68 patients with lymphomas(non-Hodgkin lymphomas – 33, Hodgkin lymphoma –35) in complete remission after AHSCT with the follow-up of at least 12 months were enrolled in the study. Median follow-up period was 18 months. Mean age – 37 yrs (SD=12); male/female 33/35. For symptom assessment the Comprehensive Symptom Profile for patients with Lymphomas (CSP-Lym) was used. The CSP-Lym is developed to assess the profile of 41 lymphoma specific symptoms. Symptom severity and percentages of patients with moderate-to-severe (ratings 3-5) symptoms were evaluated. QoL was measured by the SF-36 questionnaire. For comparisons Mann-Whitney test was used.
Results: The majority of patients experienced fatigue (75%), decreased work energy (66.6%), feeling of constant tiredness (62.5%), shortness of breath (62.5%), and sleepiness (58.3%). Other common symptoms were exertion sweatiness (54.2%), insomnia (50%), numbness (45.8%), rapid heartbeat (45.8%), and concentration loss (45.8%). In most cases these symptoms were mild (ratings 1–4). Twenty five percent of patients experienced at least one moderate-to-severe (ratings 3-5) symptom; half of them suffered from moderate-to-severe fatigue. A small proportion of patients (8.3%) exhibited more than 7 moderate-to-severe symptoms. QoL parameters were significantly lower (P<0.001) in the patient group with moderate-to-severe symptoms as compared with the ones who did not have moderate-to-severe symptoms.
Summary / Conclusion: Lymphoma patients in complete remission after ASHCT with the follow-up of at least 1 year experience treatment-related symptoms. In the majority of cases they were of mild severity. The subgroup of patients with moderate-to-severe symptoms was identified; these patients experienced significant QoL impartment. Clinical self-reported symptom assessment in lymphoma patients in complete remission after ASHCT provides an important opportunity to promote proactive management of transplant-related side effects and maintain or improve their QoL.

B1675

BUSULFAN/CYCLOPHOSPHAMIDE VS. BUSULFAN/FLUDARABINE CONDITIONING FOR ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AML/MDS: A SINGLE-CENTRE RETROSPECTIVE ANALYSIS

I Song [1*], H Ryu[1], Y Choi[1], H Lee[1], H Yun[1], S Kim[1], D Jo [1]
[1]Department of Internal Medicine, School of Medicine, Chungnam National University , Daejeon , Korea, Republic Of

Background: There has been some controversy over whether busulfan/fludarabine (BuFlu) can be a substitute for busulfan/cyclophosphamide (BuCy) conditioning for allogeneic haematopoietic stem cell transplantation (allo-HSCT) in patients with acute myeloid leukaemia (AML) and myelodysplastic syndrome (MDS). In many earlier retrospective, nonrandomised studies, BuFlu was less

toxic and resulted in similar or better survival compared with BuCy. In a recent randomised controlled study, however, BuFlu conditioning was associated with inferior survival outcomes and no benefit in non-relapse mortality.
Aims: We compared these two myeloablative conditioning regimens in patients with AML and MDS.
Methods: Patients with AML/MDS who underwent allo-HSCT between 2002 and 2012 at Chungnam National University Hospital were enrolled. Between 2002 and 2006, patients received busulfan (3.2 mg/kg per day for 4 days) plus cyclophosphamide (60 mg/kg per day for 2 days). Between 2007 and 2012, patients received busulfan (same dose and schedule) plus fludarabine (40 mg/m^2 per day for 5 days). Primary end points were survival outcomes and secondary end points were toxicities.
Results: Eighteen and 56 patients received BuCy and BuFlu, respectively. The median age was 40.5 years (range, 19-51) and 46 years (range, 18-63), respectively, and the median follow-up duration was 63 months (range, 1-148) and 21.5 months (range, 4-64), respectively. Primary graft failure was not observed in either group. During the follow-up period, no statistically significant differences in overall survival (OS), relapse-free survival (RFS) or event-free survival (EFS) were observed between the two groups (OS at 5 years, 72.2% *vs.* 77.0%, *P*=0.580; RFS at 5 years, 70.6% *vs.* 81.1%, *P*=0.322; EFS at 5 years, 66.7% *vs.* 68.0%, *P*=0.692). Stem cell source, donor type and HLA matching did not influence OS. Acute graft-versus-host disease (GVHD) was less common in the BuFlu group (27.8% *vs.* 3.6%, *P*=0.002), whereas incidence of chronic GVHD was similar in the two groups (77.8% *vs.* 73.2%, *P*=0.700). Hepatic sinusoidal obstruction syndrome (SOS) was less common in the BuFlu group (16.7% *vs.* 1.8%, P=0.015). Non-relapse mortality (NRM) did not differ between the two groups (NRM at 5 years, 15.0% *vs.* 15.1%; *P*=0.529).
Summary / Conclusion: BuFlu conditioning has similar efficacy compared with BuCy conditioning and is associated with fewer cases of acute GVHD and SOS in patients with AML/MDS.

B1676
NEW PROPOSED GUIDELINES FOR FASTER IDENTIFICATION OF SUCCESSFUL MYELOID AND ERYTHROID ENGRAFTMENT IN HEMATOPOIETIC STEM CELL TRANSPLANTATION
K Han[1*], S Yang[2], W Min[2], B Cho[3], J Lee[3], W Lee[3]
[1]Laboratory Medicine, [2]Hematology, [3]Pediatrics, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: After hematopoietic stem cell transplantation (HSCT), prediction of engraftment relies on recovery of peripheral blood cell counts. Over the past decades, the performance of hematologic analyzers has evolved with improved sensitivity and creation of new cellular parameters, and better resolution of various cell populations in the blood. Since these new parameters are directly correlated to the presence of immature elements in the blood, their main proposed application has been evaluating the level of hematopoiesis. Previous studies have demonstrated earlier increases in immature reticulocyte fraction (IRF) by 48 hours on average prior to days required for ANC to reach the cut-off value of 500/μL in patients with successful engraftment. However, these studies did not address the question of possible false positive results in the cases without engraftment using that specific cutoff value and did not identify lineage specific engraftment.
Aims: The objective of this study is to identify possible improved laboratory guidelines for confirming engraftment post-HSCT and identify lineage specific parameters that could predict myeloid and erythroid engraftments, separately. Another objective of this study is to analyze the effect of various clinical characteristics to the myeloid and erythroid engraftment day.
Methods: We evaluated blood cell parameters including complete blood count (CBC), differential counts, and various reticulocyte parameters every work day in 115 patients who received HSCT (allogeneic, n=93; autologous, n=22) in the purpose of identifying possible improved laboratory guidelines for engraftment prediction. The analyzed reticulocyte parameters were reticulocyte count (%), mean reticulocyte volume (MRV), immature reticulocyte fraction (IRF), high light scattering reticulocyte (HLR), and absolute count of HLR (#HLR). The earliest engraftment guidelines for confirming erythroid and granulocytic lineage specific engraftment separately were searched. Using these guidelines, we analyzed the effect of various clinical characteristics including graft type, conditioning regimen, ABO compatibility and disease types to the myeloid and erythroid engraftment day.
Results: Days to while blood cell (WBC) count over 100 cells/μl with more than 2 fold increase from nadir after transplantation (proposed new WBC guideline) preceded absolute neutrophil count (ANC)>500 cells/μl by 1.7 days. Among erythroid parameters, the earliest marker for erythroid engraftment was High light Scattering Reticulocyte (HLR)>0.1 (proposed new red blood cell guideline), which preceded RET>1% and IRF>0.5 by 3.9 and 1.6 days, respectively. Among the clinical parameters compared, those with statistically significant influence on myeloid engraftment were donor type (P=0.009) and conditioning intensity (P=0.009). As for erythroid recovery, ABO incompatibility was the only significant factor. The erythroid engraftment days after HSCT from ABO major mismatched donor were 20.7±17.1 days and delayed than that from minor mismatched donor (P=0.004) and ABO matched donors (P=0.001). Especially, the erythroid engraftment days from ABO major mismatched donors to blood type O recipients were much more delayed to 45.9±37.8 days. All 2 cases which did not show engraftment after HSCT by conventional parameters did not show engraftment by the new guidelines also.

Table 1. Clinical factors showing significant difference in time of achieving granulocytic and erythroid engraftment by new WBC (>100/ μL plus > 2 fold increase from nadir after D0) and RBC guidelines (HLR>0.1).

Clinical factors	N	Days to achieve new WBC guideline mean ± S.D. (median, range)	ANOVA	Multiple comparison by T-test*	Days to achieve new RBC guideline mean ± S.D. (median, range)	ANOVA	Multiple comparison by T-test
Donor type (n=100)							
Conventional (conv)	61	10.7 ± 1.9(.8-16)	0.009	conv vs. alter 0.870	14.2 ± 10.4(.8-64)	0.564	
Alternative (alter)	27	10.3 ± 1.6(.8-13)		alter vs. auto 0.063	13.7 ± 6.3(.8-34)		
Autologous (auto)	22	9.3 ± 1.7 (3-13)		conv vs. auto 0.007	11.7 ± 2.5(.7-19)		
Conditioning intensity							
MAC	46	10.7 ± 1.7(.8-15)	0.009		14.8 ± 9.5(.8-64)	0.498	
RIC	42	10.5 ± 1.8(.8-16)		RIC vs. Auto 0.034	13.6 ± 9.0(.8-63)		
Auto	22	9.4 ± 1.7(.8-15)		MAC vs. RIC 0.007	11.7 ± 2.5(.7-19)		
ABO incompatibility			0.001			0.001	
Autologous	22	9.4 ± 1.7(.8-15)		match vs. auto 0.001	11.7 ± 2.5(8-34)		major vs. auto 0.003
Minor incompatibility	21	9.9 ± 1.6(.8-13)		match vs. minor 0.034	12.0 ± 4.5(.7-29)		major vs. match 0.005
Major incompatibility	19	10.2 ± 2.3(.8-16)			20.7 ± 17.1(.9-64)		major vs. minor 0.004
Compatible	48	11.1 ± 1.6(.8-15)			12.4 ± 4.0(.7-19)		

Summary / Conclusion: In conclusion, our guidelines may ensure engraftment a few days earlier than the conventional parameters, which may help clinicians for decision-making on rescue therapy earlier.

B1677
THE EFFECT OF SIROLIMUS BASED REGIMEN ON IMMUNE RECONSTITUTION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION
S Park[1*], J Yun[1], S Kim[1], C Kim[1], H Kim[1], D Hong[1], J Won[2], H Park[2]
[1]Hematology Oncology, Soonchunhyang University Bucheon Hospital, Bucheon, [2]Hematology Oncology, Soonchunhyang University Hospital Seoul, Seoul, Korea, Republic Of

Background: Reconstitution of the immune system following allogeneic stem-cell transplantation (allo-SCT) is a complex process that requires successful engraftment of the hematopoietic stem cell, as well as adequate thymic function. Although GVHD control, improvements in antibiotic spectra, and circumspection in the use of immunosuppressants have helped, too many patients still die of infections because of insufficient immunologic recovery. Sirolimus has been used alone and in combination with calcineurin inhibitors for prevention of allograft rejection after solid organ transplantation. In the field of hematopoietic stem cell transplantation, the combination of sirolimus and tacrolimus has also resulted in a low incidence of acute GVHD and reduced transplant-related toxicity.
Aims: We evaluated the effect of sirolimus and tacrolimus as a acute GVHD prophylaxis on the immune reconstitution after allogeneic stem cell transplantation compared to a historical control.
Methods: This study included 24 patients received the combination of sirolimus and tacrolimus and 21 patients received the combination of tacrolimus and methotrexate (MTX) for historical control. They were received G-CSF mobilized peripheral blood stem cells after myeloablative conditioning with intravenous busulfan and fludarabine.
Results: The incidence of acute GVHD in patients with sirolimus based regimen was lower. And the incidence of CMV or EBV reactivation in the same group was higher. The recovery of CD4$^+$ T cells and natural killer (NK) cells seemed to be more delayed in recipients with sirolimus based regimen compared to those in patients with tacrolimus and MTX at 1 month after transplantation (8.8±1.6 vs 14.9±5.8 for CD4$^+$ T cells, 35.7±6.4 vs 53.4±19.6 for NK cells). However, there was no significant difference between in the recovery of CD4$^+$ T cells and NK cells at 3 months after transplantation. In the aspect of humoral immunity, there was a trend to be lower in immunoglobulin-A and IgM levels during 1 month and 3 months after transplantation in patients with sirolimus based regimen. These differences were overcome around post-transplant 6 months. And regulatory T cells (CD4+CD25+Foxp3+) seemed to be higher in patients with sirolimus based regimen.
Summary / Conclusion: The sirolimus based regimen is associated with well-controlled acute GvHD. Although the correlation between the increased risk of infection and delayed immune reconstitution was not confirmed, the regimen might be cause of increasing the risk of opportunistic infection. Therefore we need an effort of early tapering of immunosuppressants and a careful monitoring for opportunistic infections in patients received sirolimus based regimen.

B1678
HIGH–DOSE THERAPY WITH AUTOLOGOUS TRANSPLANT SUPPORT IN 176 PATIENTS WITH MULTIPLE MYELOMA (MM) OVER 12 YEARS (1.999 – 2.011)
R Hamladji[1*], M Benakli[1], R Nacer[1], ATalbi[1], F Harieche[1], R Belhadj[1], F Mehdid[1], N Rahmoune[1], S Akhrouf[1]
[1]Hematology and Bone Marrow Transplantation, Pierre and Marie Curie Cen-

ter, Algiers, Algeria

Background: High dose therapy (HDT) with autologous hematopoietic stem cell (HSC) is still effective treatment of MM in young pts under 65 years of age. On 12 years period (January 1999 to December 2011), 176 pts with MM underwent HDT with autologous HSC that represent 39% of all autologous transplantation (176/449) in our center during this period.
Aims: This retrospective study analyzes the results of 176 pts.
Methods: It includes 88 males and 88 females (sex-ratio: 1); median age 52 years (24-65). Durie and Salmon stage III is observed in 155 pts (88%) with stage IIIB in 27 pts (15%), one pt with plasma cell leukemia; the distribution of monoclonal protein type IgG 105 pts (88%), IgA 38 pts (21,5%) light chain 23 pts (13%), no secretion 6 pts (3,5%), IgD 2 pts and no determined 2 pts. Initial standard therapy include 4 to 6 cycles of VAD in 152 pts; association Thalidomide–Dexamethasone (TD) in 11 pts; CTD in 6 pts, Velcade –Thalidomide 6 pts. Complete remission (CR) was observed in 67 pts (38%), partial response in 74 pts (42%) and refractory disease in 35 pts (20%). Two HDT regimen was used: MEL200 protocol (Melphalan 200 mg/m²) for 125 pts (71%) and BU-MEL (Busulfan 12mg/kg, Melphalan 140mg/m²) for 51 pts (29%). Peripheral HSC was collected by cytapheresis after mobilization by G-CSF alone, median CD34 + cells infused was4, 22 x 10^6/kg (0, 65 – 19). Median follow up is 42 months (6 -153)
Results: Early deaths accured in 9 pts (5%) about whom 7 by TRM. Within 167 appraisable pts, 132 pts (79%) observed CR, 31 pts (18,5%) a good response and 4 pts (2,5%) still on refractory disease after graft. HDT with autologous transplant improve CR rate from 38% to 79%. Also refractory disease rate decrease from 20% to2,5%. Progression disease observed in 121 pts (73%) during follow up with 74 pts (61%) at first 24 months after graft and the same frequency is noted with the two protocol regimen of HDT (MEL 200 and BU-MEL): 68,5% and 61% respectively. 81 pts (48,5%) are alive : 46 pts (27,5%) with persistent response and 35 pts (21%) with relapse; 86 pts (51%) died, of progression disease for 82 pts and other reason for 4 pts. The estimated overall survival is 46% at 5 years and 22, 5% at 12 years with a median survival at 58 months.
Summary / Conclusion: Our results are comparable with others studies who treat with VAD and found median survival at 55 months.

B1679
SEQUENTIAL INTENSIFIED CONDITIONING FOLLOWED BY EARLY TAPERING IMMUNOSUPPRESSANTS AND DONOR LYMPHOCYTE INFUSION IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR REFRACTORY/RECURRENT LYMPHOBLA
M Dai[1], H Zhou[1], F Huang[1], Y Zhang[1], Z Fan[1], X Guo[1], N Xu[1], J Sun[1], Q Liu[1*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Adult T lymphoblastic lymphoma is an aggressive form of non-Hodgkin lymphoma occurring in predominantly adolescent and young adult men. High-dose chemotherapy followed by autologous or allogeneic hematopoietic stem cell transplantation (allo-HSCT) as consolidation for patients in first complete remission is controversial. Refractory/recurrent T lymphoblastic lymphoma has poor response to conventional chemotherapy.
Aims: To prospectively evaluate the efficacy of sequential intensified conditioning followed by early tapering immunosuppressants and donor lymphocyte infusion (DLI) in allo-HSCT as salvage therapy for refractory/recurrent T lymphoblastic lymphoma.
Methods: Fourteen patients with refractory/recurrent T lymphoblastic lymphoma (male in 12 cases and female in 2 cases) from September 2010 to December 2012 were enrolled in this prospective study, with median age 33 (range 16-42) years. Twelve patients received related and 2 unrelated donor transplantation, and 13 patients received HLA-matched and 1 HLA-mismatched transplantation. The sequential intensified conditioning included fludarabine 30mg/m^2/d and cytarabine 2g/ m^2/d (on days -10 to -6),4.5 Gy total body irradiation/day (on days -5 and -4), cyclophosphamide 60 mg/kg/d and etoposide 10mg/ kg/d (on days -3 and -2). Cyclosporine A was rapidly withdrawn in a stepwise fashion if acute graft-versus-host disease (aGVHD) did not develop at day +30. Granulocyte colony-stimulating factor (G-CSF) mobilized donor lymphocytes (absolute neutrophil count: 1.0×10^6/kg, once a month, 4 doses totally) would be infused in patients without II° or more than II° aGVHD by day + 60 post-transplantation. Once patients developed GVHD after DLI, DLI would stop and methylprednisolone was added to the regimen.
Results: All patients achieved complete remission by day +30,and none of patients died of regimen-related toxicities. With a median follow-up of 26 months post-transplantation (range: 2-29 months), 3 patients relapsed and one died of relapse. Till now, 13 patients were alive and one died. The 2-year cumulative overall survival and disease-free survival post-transplantation were 65% and 51%, respectively. The 2-year cumulative incidence of relapse was 14%.
Summary / Conclusion: Our data indicate that sequential intensified conditioning and rapid tapering immunosuppressants as well as DLI in the early stage after allo-HSCT might be an effective method for refractory/recurrent T lymphoblastic lymphoma.

B1680
MYELOABLATIVE OR NON-MYELOABLATIVE? TIME TO ENGRAFTMENT UNYIELDING
K Halaburda[1*], A Ropielewski[2], G Basak[1], E Snarski[3], M Tormanowska[3], M Paluszewska[1], E Urbanowska[4], A Gronkowska[3], W Jędrzejczak[1]
[1]Department of Hematology, Oncology and Internal Medicine, [2]Medical University of Warsaw, [3]Department of Hematology, Oncology and Internal Medicine, Public Central Teaching Hospital, [4]Hematology, Oncology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland

Background: It is commonly felt that non-myelablative conditioning before stem cell transplantation leads to less profound myelosupression and faster engraftment than it is observed after classical myeloablative conditioning. Published results indicated faster engraftment after non-myeloablative conditioning in some selected cohorts of patients.
Aims: We performed a retrospective study to compare engraftment times in unselected patients undergoing allogeneic stem cell transplantation after myeloablative and non-myeloablative conditioning. The question was if type of conditioning determines time to engraftment in clinical practice.
Methods: We retrospectively studied group of 76 patients transplanted in the period from 2009 to 2012 in our institution. 45 patients received myeloablative (MAC) and 31 non-myeloablative (nMAC) conditioning. All but 1 transplantation were performed using peripheral blood as stem cell source. Patients receiving myeloablative reduced intensity conditioning (eg. Fludarabine/Busulfan 12.8 mg/kg or Fludarabine/Treosulfan) were not included the study. Conditioning regimen most frequently used in MAC was Busulfan 12.8 mg/kg with cyclophosphamide 120 mg/kg. In nMAC two most common regimens were Fludarabine 150 mg/m^2 plus Busulfan 6.4 mg/kg or Fludarabine 150 mg/m2 with Melfalan 140 mg/m^2. All patients undergoing transplantations from unrelated donors received antilymphocyte globulin at total dose of 7.5 mg/kg. Prevailing graft versus host disease prophylaxis regimen in both groups consisted of cyclosporine and short course methotrexate. Median age was 35.1 years for MAC and 48.7 years for nMAC. The MAC and nMAC groups were identical in terms of the number CD34+ cells transplanted. They were also comparable in proportion of unrelated donors, stage of the disease at transplantation (early vs. late) and proportion of patients receiving G-CSF after transplantation.
Results: Time to neutrophil engraftment was 18 (17.8) days in MAC and 17 (16.9) days in nMAC (P=0.39). Platelet engraftment was observed on day 13 in MAC and on day 14 in nMAC group (P=0.82). The number of days with leucopenia < 1.5 G/L was 16.3 days in MAC and 16.6 days in nMAC (P=0.82). Age of the patients in the whole population as well as in MAC and nMAC groups had no influence on time to neutrophil and platelet engraftment or duration of leucopenia.
Summary / Conclusion: Our data show identical time to engraftment after myeloablative and non-myeloablative conditioning in patients receiving hematopoietic stem cell transplantation for hematologic malignancies. In clinical setting type of conditioning does not influence engraftment time.

B1681
OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HCT) FOR PATIENTS WITH ACUTE LYMPHOID LEUKEMIA (ALL) WITH ACTIVE DISEASE: EXPERIENCE OF A SINGLE EUROPEAN INSTITUTION
R De Mello[1*], C Pinho-Vaz[2], I Carvalhais[3], R Branca[2], F Campilho[2], M Rosales[4], S Roncon[4], A Campos-Júnior[2]
[1]Bone Marrow Transplantation and Medical Oncology, [2]Bone Marrow Transplantation , Portuguese Oncology Insititute, [3]Clinical Hematology, Centro Hospitalar São João, [4]Cell Therapy, Portuguese Oncology Insititute, Porto, Portugal

Background: In primary refractory or advanced relapsed ALL, allogeneic-HCT is associated with three-year leukemia-free survival rates of 12 to 23 %.This is clearly superior to chemotherapy alone, which achieves no cures at this stage of the disease. Treatment options for these patients (pts) are limited and a HCT may provide a realistic chance for long term disease remission.
Aims: We report the outcome of ALL pts with active disease treated with Allogeneic-HCT.
Methods: A retrospective cohort from including clinical registries' databases for pts with diagnosis of relapsed/refractory ALL, with 31 fulfilled inclusion criteria pts from 1990 to 2011. Outcomes of interest were transplant-related mortality (TRM), incidence of acute and chronic graft-versus-host disease (GVHD), incidence of relapse and overall survival (OS) - which were estimated from the date of transplant. Parametric and non-parametric tests were used appropriately. Kaplan Meir curve was used for OS assessment. Statistical analysis was carried out using SPSS v19.0 for Mac (IBM, 2010, USA) and statistical significance was considered for P<0.05.
Results: The median age was 17 (range 2 – 48) years. Median follow up for alive pts was 6 months (08 pts; range 0.373 – 11.627). The cumulative incidence of 90-days, 1 year, and 3 years TRM was 75%, 12.5%, and 12.5%, respectively (P<0.059). 39.4% of patients developed grade II-IV acute GVHD and 23.3 % suffered from chronic GVHD. The actuarial incidence of relapse was 68.4% at 1 year and 21.1% at 3 years and 10.5% at 5 years. Actuarial OS was

estimated to be 63.6 % at 1 year, 21.2% at 3 years, and 15.2% at 5 years (P<0.001).
Summary / Conclusion: In summary, TRM and acute GVHD in first years after HCT remains considerable, but HCT in this setting seems to be a good choice for ALL pts with active disease. Indeed, actuarial OS 3 years post HCT in our cohort seems to encourage this approach in this setting.

B1682
EFFICACY OF HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (AUTO-HSCT) IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA (PMLBCL)
N Tyurina[1*], O Pavlova[1], M Vernyuk [1], E Karpenko[1], A Chervontseva[1]
[1]BMT, Hertcen Moscow Scientific Research Oncology Center, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMLBCL) is a unique type of B-cell lymphoma the WHO classification of Lymphoid Malignancies. It constitutes 6–10% of all diffuse large B-cell lymphomas (DLBCL), occurring more often in young females. PMLBCL has been postulated arisefrom a putative thymus medulla B-cell. PMLBCL is characterized by a locally invasive anterior mediastinal mass, often producing cough, chest pain, dyspnea, and superior vena cava syndrome. Most PMLBCL patients have stage I–II, bulky disease, with pleural or pericardial effusions in third of cases. In the absence of prospective studies, the optimal treatment of PMBCL is still a matter of debate. Uncertainties exist with regard to the intensity of primary chemotherapy, the role of consolidating involved-field radiotherapy, high-dose chemotherapy and the impact of an additional treatment with rituximab.
Aims: To evaluate the role of an early treatment intensification (induction CHT, autoHSCT and RT) in patients with primary PMLBCL presenting with adverse prognostic factors.
Methods: We analyzed outcomes of first-line chemotherapy, including first-line CHT with Rituximab (R-MACOP-B) and auto-HSCT in patients with PMLBCL. 38 patients with PMLBCL (13 m. and 25 f.), admitted to Hertcen Oncology Center from 2006 to 2012 are included in this study. The average age of PMLBCL patients was 34,3 years (20-64, median 37). In all cases the diagnosis was confirmed by immunomorphology. Samples were obtained by mediastinotomia (N15), percutaneous needle biopsy (N12), thoracotomy (N6) or neck/supraclavicular lymph node biopsy (N3), partial or total excision of mediastinal tumor (N2). At the time of diagnosis 32 patients had I-II stage disease, 5 - had stage III and 1 patient had VI stage disease according to Ann Arbor staging system.Local infiltration of adjacent tissues and organs was defined in the majority of patients (47%>lungs, 58%>pleura, 22%>thoracal wall), 44% presented hydrothorax and/or hydropericard. Superior vena cava syndrome observed in 69% of patients, thrombosis in 64%. Bone marrow involvement was not observed. Elevated LDH levels were found in 42% of patients. First-line chemotherapy including Rituximab received 27 patients (R-CHOP-1, R-CHOEP-1, R-MACOP-B-25), treatment without Rituximab (MACOP-B) – 9 patients. Patients with partial remission (N19) received radiotherapy on residual tumor. HDCT followed by autoHSCT was performed in 14 patients with PMLBCL to consolidate the first partial/complete remission. The source of hematopoietic progenitors was peripheral blood in all patients. The number of CD34+ cells in the autograft averaged 17.5x10^6/kg (4.3-52.1x10^6/kg). Pretransplantation conditioning was carried out according to BEAM protocol. After HDCT followed by autoHSCT 10 PMLBCL patients received radiation therapy on residual disease.
Results: Currently 32/38 (84,2%) patients with PMLBCL remain in first prolonged complete/partial remission. Average time of observation is 42,3 months (from 3 to 78). One early and two late relapses occurred after HDCT followed by autoHSCT. One patient died from concurrent disease in partial remission during radiotherapy. One patient had refractory disease.
Summary / Conclusion: The optimal treatment of PMBCL is still under investigation. Intensive CHT regimens combined with RT and treatment with Rituximab could possibly hold over the use of HDCT with autoHSCT in the low risk patients. In the high-risk group of patients, achieving partial remission, early intensification treatment including HDCT and autoHSCT could result in higher frequencies of complete remissions and improve patients survival. In patients with refractory disease autoHSCT is not considered to be sufficiently effective.

B1683
DOES SIZE MATTER? RESULTS OF ALLOGENEIC TRANSPLANTS AT A SMALL NEW ZEALAND CENTRE.
P Ganly[1*], S Cole[2], A Trengrove[1], A Butler[1]
[1]Haematology, Christchurch Hospital, [2]Medicine, University of Otago at Christchurch, Christchurch, New Zealand

Background: Reduced intensity conditioning (RIC) protocols for allogeneic haematopoietic stem cell transplants have become commonplace treatments for patients with haematological disease during the last fifteen years, extending allogeneic transplant to older or less fit patients. Outcomes in patients with different diseases and with different schedules vary. Doctors and patients want to know what they can expect in the centre where treatment is undertaken and that outcomes are equivalent to published results, especially if transplant activity is at the minimum level required by FACT.
Aims: We aimed to examine our total allogeneic transplant activity in adults and outcomes of that activity since RIC protocols were first introduced in our centre.
Methods: Clinical and Laboratory data were collected on all adult patients who received allogeneic SCT at Christchurch Hospital during 2000 – 20012. A programme of tandem auto/RIC allo transplant for patients with myeloma in first response who had sibling donors was active during this period. Outcomes including overall survival (OS) and time to treatment failure due to relapse or death in remission were compared between patients receiving myeloablative conditioning (MAC) and RIC protocols.
Results: Over 12 years between 4/2000 and 5/2012, 118 adult patients had allografts, 55 with MAC, 63 with RIC. The annual allograft rate was 1 per 100,000 of the population. During the same period 296 patients received autografts. The mean age of patients receiving MAC (35 years, range 18.2-55.8) was lower than that of those receiving RIC (49.8 years, range18.5-63.6). More MAC patients had acute leukaemia than RIC patients (71% v 23%) and fewer had myeloma (5% v 37%). 25% of patients in both groups had unrelated donors. Fewer MAC patients received peripheral blood stem cells rather than bone marrow stem cells (56% v 92%). MAC and RIC patients had similar comorbidity scores whereas EBMT score was 1 – 2 points higher for RIC patients. There was no difference between the two groups in the incidence of graft versus host disease requiring systemic treatment. 5yr OS and 5yr failure free survival was greater for MAC patients than for RIC patients (71% v 48%, P=0.02; 67% v 32% P=<0.01). Relapse rates were reduced in MAC patients, whereas there was no difference in the rate of death in remission between the groups. Within each conditioning group, OS was poorer in patients older than the median age for that group. OS was reduced in those with higher EBMT scores and there was a trend for poorer OS with increasing HSCT comorbidity index. OS was unaffected by donor source or patient/donor CMV status. The sub group of older MAC patients had the same mean age as the sub group of younger RIC patients and had the same outcome.
Summary / Conclusion: Allograft activity is lower in our centre compared with Australasia generally but meets the FACT activity level standard. RIC protocols have been followed by long term survival in many patients ineligible for MAC protocols. Results at our centre are comparable with international outcomes. Our patient outcomes correlate with their age, rather than with their conditioning protocol.

B1684
MESENCHYMAL STEM CELLS TRANSFUSION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: RESULT OF A SINGLE CENTER
Y Lu[1*], Y Zou[1], X Li[1], Y Hu[1], Z Liu[2]
[1]the third Affiliated Hospital of Sun Yat-Sen University, [2]Guangdong Cord Blood Bank, Guangzhou, China

Background: Patients may present with different kinds of refractory complications after allogeneic hematopoietic stem cell transplantation (allo-HSCT), including graft-versus-host disease(GVHD), poor graft failure(PGF) , bronchiolitis obliterans(BO) and so on. In recent years, mesenchymal stem cells(MSCs) transfusion becomes a potential treatment for allo-HSCT patients.
Aims: The aim of this work is to analyse the outcome of patients treated in our institution with MSCs after allo-HSCT .
Methods: Eight patients were included in this study and median age was 25 years(range 14-44). Two patients were diagnosed of severe aplastic anaemia(SAA) and the remaining were haematological neoplasias(4 acute leukemias, 1 lymphoma and 1 myelodysplatic syndrome). Patients with haematological neoplasia were in the state of complete remission (CR) when HSCT was carried out and all the 8 patients received graft from HLA-identical relative donors.The indication for MSCs use was refractory acute GVHD-1, refractory extense chronic GVHD-4, PGF-2 and BD-1. Patients received bone marrow derived MSCs from a third party donor at a dose of 1×106/kg for 2 to 3 cycles, with an interval of 28 to 30 days.

Table1.

complication	complete response	patial response	no response
acut GVHD n=1	0	1*	0
chronic GVHD n=4	0	4**	0
PGF n=2	2	0	0
BD n=1	1	0	0
Total n=8	3	5	0

*This patient relapsed and died.
** Two out of patients reached PR of cutaneous and oral GVHD but no response of ocular GVHD. The patient with lymphoma developed PTLD.

Results: A total of 17 infusions have been performed and no infusion-related adverse reaction was found. Patients with cutaneous, astro-intestinal, liver and oral GVHD showed partial response, but for ocular GVHD, no response was displayed. Patients with PGF were responsive to the first infusion of MSCs within one week and their blood routine turned to normal 3 months after the second. Patient with BD obtained complete response after 2 cycles of MSCs and she didn't need to depend on oxygenotherapy any more. In the median follow-up of 19 months(3-30months), one patient with acute leukemia developed disease relapse and died, and the patient with lymphoma developed posttransplant lymphoproliferative disorders(PTLD) and gained CR after 4 cycles of rituximab Table1.
Summary / Conclusion: Administration of MSCs was safe for treatment of severe complications after allo-HSCT. MSCs may be a promising therapy for refractory cutaneous , astro-intestinal, liver and oral GVHD, PGF and BD, but ocular GVHD.

B1685

POOR PREDICTION OF POST-INFUSION HEMOGLOBIN RISE IN PEDIATRIC RECIPIENTS OF UNMANIPULATED BONE MARROW HARVEST

S Martin[1,2], M Goodyer[1*], P Lynam[1], O Smith[1,2], A O'Marcaigh[1,2]
[1]Our Lady's Children's Hospital Crumlin, [2]Trinity College, Dublin, Ireland

Background: Hemopoietic stem cell transplantation is a commonly undertaken and potentially curative procedure for many children with underlying benign and malignant disorders. Matched sibling donors are preferred but when this option is unavailable a matched unrelated donor is commonly selected from adult bone marrow registries. In children, bone marrow harvest rather than peripheral stem cell collection is often favored, as there is a lower risk of graft versus host disease. The combination of a larger donor and bone marrow as the source of stem cells results in a relatively high cell dose with an excess of red cells, particularly in younger children. Provided there is no recipient-donor major ABO mismatch, these units are often infused un-manipulated, and the recipient risks iatrogenic polycythemia with potentially deleterious consequences. As a result, we use the formula outlined below to predict the increment in hemoglobin concentration based on the recipient's weight and the quantity of red cells in the product. If the predicted Hb rise is >4g/dL red-cell reduction is undertaken pre-infusion. To date, this formula has not been validated in the literature.
Aims: Our aim was to compare the predicted rise in hemoglobin concentration with the actual value measured in recipients in order to ascertain the robustness or otherwise of the formula.
Methods: Patients' age, gender, weight, baseline hemoglobin and bilirubin were recorded, along with marrow volume and hematocrit and the predicted hemoglobin increment calculated according to the following formula: Predicted Hb rise = (Marrow Vol [mls]/Recipient Wt [Kg] x 3) x (Marrow Hct/0.6). We then measured post-infusion hemoglobin at 24 and 48 hours, and compared this to the predicted increment. A post-infusion bilirubin was also checked to exclude hemolysis as an explanation for any discrepancy. The predicted versus actual increment was statistically compared using the independent t-test. 42 patients were included in the study, 29 males and 13 females. The patients were aged from 4 months to 18 years old (median 7.5 years). The patients weighed from 5.8kg to 82.0kg (median 25.9kg). All patients received un-manipulated bone marrow.
Results: The average pre- and post-infusion hemoglobin were 9.6 g/dL and 11.5 g/dL respectively. The average measured increment in hemoglobin concentration was 1.95 g/dL. The average predicted increment in hemoglobin concentration was 2.89 g/dL, a difference approaching 1 g/dL. No patients had clinically significant rises in serum bilirubin to explain a discrepancy between predicted and measured hemoglobin increments. No statistically significant correlation was demonstrated between observed and predicted Hb increment.
Summary / Conclusion: In pediatric recipients of bone marrow harvest from allogeneic donors, the above formula does not accurately predict for post-infusion hemoglobin concentration and may lead to unnecessary red-cell depletion pre-infusion. Further analysis is required to modify this formula to improve its predictive value.

B1686

THE EFFECT OF NUMBER OF APHERESIS SESSIONS REQUIRED TO ACHIEVE STEM CELL DOSE ON EARLY AND LONG TERM ENGRAFTMENT IN AUTOLOGOUS STEM CELL TRANSPLANT FOR LYMPHOMA

S Gangatharan[1*], J Kuruvilla[1], A Keating[1], V Kukreti[1], M Crump[1]
[1]Department of Medical Oncology and Hematology, Princess Margaret Cancer Center, Toronto, Canada

Background: The dose of CD34+ peripheral blood stem cells (PBSCs) infused during autologous stem cell transplantation (ASCT) correlates with time to engraftment. The number of apheresis sessions required to achieve a minimum cell dose varies between patients, affected by factors such as peripheral blood CD34 count, previous lines of chemotherapy, therapy with nucleoside analogues and radiation. It is unknown whether engraftment differs among patients whose stem cells have been difficult to mobilize, and require multiple days to collect.
Aims: To examine the effect of the number of apheresis sessions required to achieve a stem cell dose for reinfusion, on short-term and long-term engraftment in ASCT
Methods: The ASCT database at Princess Margaret Hospital was interrogated to identify lymphoma patients with stem cell collections between 2007-2011. Data were collected retrospectively on patient characteristics, cell dose, number of days required for stem cell collection, days to engraftment and blood counts at day 100 and 1 year post-transplant. Patients were excluded if they did not proceed to or relapsed within 1 year of ASCT or did not have cell counts available at PMH at follow-up.
Results: 143 patients were included with relapsed/refractory Hodgkin Lymphoma (n=54), aggressive B and T cell lymphomas (n=60), and Mantle Cell Lymphoma (MCL) in first remission (n=29). 71% of patients received 2 prior lines of therapy and 21% received radiotherapy prior to stem-cell collection. Intensive therapy for relapsed HL/NHL included high dose etoposide and melphalan; patients with MCL age <61 years also received total body irradiation (TBI). An adequate PBSC collection needed to proceed to ASCT was >2 x 10^6 CD34 cells/kg: 67% of patients required 1 apheresis to collect sufficient cells. Median peripheral blood CD34 count prior to collection was 85 CD34 cells/uL (range 4-1112). Median PBSC dose infused was 7.05x10^6 CD34 cells/kg (range 2.56-30.22). Median number of days to engraftment of neutrophils (>0.5x10^6/uL) and platelets (>20x10^6/uL unsupported by transfusion) was 11 and 12 days respectively. At day 100, proportion of patients with haemoglobin, neutrophils and platelets below normal were 67%, 29%, 36% respectively. At 1 year, patients with low haemoglobin, neutrophils and platelets were 15%, 20% and 34% respectively. Univariable analysis demonstrates PBSC dose, peripheral blood CD34 count, age and number of aphereses significantly influenced early neutrophil and platelet engraftment, and most counts at Day 100 and 1 year. Number of prior lines of therapy influenced only platelet engraftment, but not later counts. Peripheral CD34 counts strongly correlated with stem cell dose collected. The addition of TBI did not influence early or late engraftment. On multivariable analysis PBSC dose significantly influenced early neutrophil and platelet engraftment as well as haemoglobin and platelet counts at day 100, but only neutrophil count 1 year post-ASCT. Number of aphereses to obtain adequate PBSCs did not affect engraftment time or blood count recovery at any of the later time points evaluated. Time to early neutrophil and platelet engraftment predicted counts at day 100, which in turn predicted counts 1 year post-ASCT.
Summary / Conclusion: We conclude stem cell dose is the most important factor influencing early and late blood counts post-ASCT regardless of the number apheresis required to achieve this. Neutrophil and platelet counts demonstrate a temporal relationship with early engraftment predicting higher counts at Day 100, and in turn 1 year.

B1687

HEALTH-RELATED QUALITY OF LIFE AMONG EGYPTIAN CHILDREN RECEIVING AUTOLOGOUS STEM CELL TRANSPLANTATION.

Y Al-Tonbary[1*], R El-Ashry[1], M Sarhan[1]
[1]Pediatrics, Mansoura University, Mansoura, Egypt

Background: Stem cell transplantation (SCT) is an aggressive medical procedure associated with high mortality and morbidity rates. It is the best line of therapy after disease relapse or failure of the conventional treatment. It may add a severe stress to the patient with profound disruption for the entire family. Thus, it places each family member at risk for psychological maladjustment and decrease in quality of life.
Aims: The aim of this study was to describe the quality of life and behavioral adjustment of receivers of autologous stem cell transplantation and their family members before the procedure and six months after transplantation.
Methods: It compromised 27 children with age range of 4-18 years (19 male and 8 female). Sixteen patients had Hodgkin's lymphoma, 5 patients had Non-Hodgkin lymphoma, 2 patients had acute myeloid leukemia, one patient with Wilm's tumor and another one with metastatic neuroblastoma.
We used peds QL cancer module-child report version 3 and 4 for assessment of health related quality of life (HRQOL) of children and QOL scale-family for assessment of HRQOL of the parents.
Results: Many children and adolescent have been found to exhibit decline in social competence and self-concept or to experience social isolation and other emotional difficulties that require psychological intervention.
Symptoms of psychological distress usually appear immediately after SCT and increase reaching the peak during the period of hospitalization and then improve gradually. Stem cell recipients showed variable degree of life satisfaction after stem cell transplantation, while their parents appeared more anxious and stressed after the procedure.
Summary / Conclusion: Assessment of Quality of life is an important indicator to the patient's psychosocial aspects after the procedure.

B1688

PRE-EMPTIVE TREATMENT OF CYTOMEGALOVIRUS INFECTION IN PEDIATRIC PATIENTS WHO UNDERWENT HEMATOPOIETIC STEM CELL TRANSPLANTATION

D Atay[1*], G Ozturk[2], SAnak[2], A Akcay[3], D Tugcu[3], M Garipardic[4], O Devecioglu[2], Z Karakas[2], A Unuvar[2], L Agaoglu[2]
[1]Pediatric Hematology Oncology, S.B. Okmeydani Education And Research Hospital, [2]Pediatric Hematology Oncology, Istanbul University Istanbul School Of Medicine, [3]Pediatric Hematology Oncology, Istanbul Kanuni Sultan Suleyman Education And Research Hospital, [4]Pediatric Hematology Oncology, Van Yuzuncuyıl University, Istanbul, Turkey

Background: Cytomegalovirus (CMV) remains a serious problem after hematopoietic stem cell transplantation (HSCT). It's associated with significant morbidity and mortality if not treated promptly.
Aims: To investigate the incidence of CMV infection and outcome we retrospectively analyzed 79 pediatric patients received HSCT monitored by CMV polymerase chain reaction (PCR) and CMV pp65 antigenemia. The influence of recipient and donor CMV serostatus on the risk for development of CMV disease was studied. The characteristics of patients with CMV infection and their outcome were described.
Methods: All consecutive patients, who underwent miyeloablative allogeneic (n=60) or otolog (n=19) stem cell transplantation were included in this analysis. Data were available on demographic characteristics, underlying diseases, donor and recipient CMV serostatus, occurrence of GVHD and treatment (i.e. initiation, duration, type and dosage of drugs used) and the ganciclovir formulation (i.e. valganciclovir or ganciclovir), CMV DNA load, CMV pp65 antigenemia measurements and general laboratory parameters. Patients were routinely screened 1 or 2 times a week using CMV pp65 antigenemia and quantitative CMV-PCR for CMV DNA. CMV monitoring begins on day -9 pre HSCT until day 120 and thereafter at any time point when the patients attended the outpatient clinic until immunosuppression was discontinued. Patients with 2 positive results for CMV DNAemia received induction therapy using ganciclovir at a dose of 5 mg/kg twice daily for 7–14 days and continued until 2 consecutive negative results were obtained. If antigenemia decreased or converted to negative, maintenance therapy with ganciclovir was given at 5 mg/kg/day for another seven days. If antigenemia still remained positive after 7–14 days, ganciclovir was continued until the antigenemia test became negative. Acyclovir prophylaxis was withheld during ganciclovir treatment. If the patient must continue the therapy at home then the therapy was switched to valganciclovir.
Results: A total of 79 patients (47 male / 32 female) at risk of CMV reactivation were analyzed. The median age was 107 months (range= 9-241 months). Patients had acute leukemia (n=29), chronic myelogenous leukemia (CML) (n=7), solid tumor (n=13), haemoglobinopathy (n=11), primary immune deficiencies (n=2), hystiocytic disorders (n=6), metabolic disorders (n=2), aplastic anaemia (n=9). The median age of patients at the time of transplant was 107 months (range= 9-241 months). All allogeneic transplant patients received grafts from a matched sibling donor. The source of stem cell was peripheral blood cells in 14 cases, bone marrow in 64 cases. All stem cell products were infused without T-cell depletion. The median follow-up time was 32 months (min 1- max 80) post transplant. Graft-versus-host disease was positive in 26 patients (acute:20, chronic:2, acute+chronic:4). 96% of patients were CMV seropositive before transplantation (recipient or donor seropositive); in 3 cases, both the recipient and the donor were CMV seronegative. CMV infection was detected in 9 patients (11.5%). Both CMV antigenemia and PCR were positive in 9 patients; in 2 patients a positive CMV PCR together with negative antigen assay was found. The median time for CMV reactivation was 45 days (min 30 – max 162) post HSCT. The median value of pp65 antigenemia and CMV copies on start of GCV treatment was $10/2x10^5$ PBLs (range:2-98/$2x10^5$ PBLs) and 1650 copies/10^6 PBLs(range: 619-18700 copies/10^6 PBLs). All patients obtained a complete clearance of antigenemia and/or CMV DNA. None of them developed CMV disease. The median time to the first CMV antigenemia and DNA negativity was 22 and 21 days. CMV infection relapsed in 2 patients. One of these patients (hyperimmunglobulin M syndrome +chronic GVHD) relapsed 74 days after the completion of the treatment and succumbed to bronchiolitis obliterans and multiorgan failure. The second patient (CML+chronic GVHD) relapsed 150 days after the completion of the treatment and succumbed to cryptococcus meningitis.
Summary / Conclusion: CMV reactivation and disease remains a major problem in high-risk patients undergoing allogeneic HSCT. Prophylactic acyclovir and pre-emptive ganciclovir treatments to prevent CMV disease are effective in children. Valganciclovir (VGC) has increasingly been used as prophylaxis against CMV infection after solid organ transplantation, but it's efficacy in pediatric hematopoietic stem cell transplant patients has been studied poorly. Novel prophylactic measures such as immunotherapy and valganciclovir prophylaxis need to be considered in this specific group of patients especially to prevent prolonged hospitalization.

B1689

REAL-LIFE CML PATIENTS REFERRED TO STEM-CELL TRANSPLANTATION IN TKI ERA: A SINGLE-CENTRE EXPERIENCE.

F Pavesi[1*], F Lunghi[1], S Malato[1], S Claudiani[1], M Carrabba[1], C Corti[1], M Marcatti[1], J Peccatori[1], M Bernardi[1], F Ciceri[1]
[1]Hematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milan, Italy

Background: Tyrosine Kinase Inhibitors(TKIs) are first-line standard treatment for adult patients with Chronic Myeloid Leukemia (CML). Allogeneic Stem Cell Transplantation (alloSCT) is indicated for patients (pts) who do not tolerate or develop resistance to TKIs. Outcome of alloSCT in active Blastic Phase (BP) of CML remains, however, still poor.
Aims: In this retrospective study we intend to evaluate the outcome of alloSCT in a monocentric consecutive series of pts referred to alloSCT for CML in chronic or more advanced phases.
Methods: Between 2005 and 2012, 2 CML patients out of 46 patients followed in our Institution under TKI and 8 patients referred from other centers received alloSCT: 8 were in BP, 1 in chronic phase (CP) refractory to imatinib,1 in second CP after dasatinib. All patients had received TKIs treatment before transplant±associated to chemoterapy. Seven out of 8 patients in BP received allotransplant in presence of active disease; 1/8 achieved a complete hematologic response (CHR) before alloSCT. Donor sources were: 1 HLA identical sibling, 2 matched unrelated donor (MUD), 6 mismatched related donor (Haplo), 1 double Unit Cord Blood (CB). All patients received treosulphan based myeloablative conditioning. Graft versus Host Disease(GvHD) phrophylaxis administered was Rapamycin/Mycophenolate in 7 patients, Cyclosporin (CSA) in 1 patient, CSA/Methotrexate in 1 patient and Rapamycin/Cyclophosphamide in 1 patient. Table 1 summarizes pts and transplant characteristics at transplant.
Results: Median follow up of our pts is 7 months (range 2 – 45 months). Eight pts were transplanted in active BP. Four of them died for transplant-related complications (2 GvHD, 2 infections). Two of these 8 pts are alive at last follow up (1 in Complete Molecular Response (CMR) after 12 months from transplantation, 1 in relapse after 20 months).Two other pts were lost at follow-up, disease status at the last visit (5 and 9 months after transplantation) was CHR and CMR respectively. Notably, at day +30, 6/8 pts transplanted in BP 6 achieved disease remission: 3 reached CMR, 1 showed a Major Molecular Response (MMR), 1 obtained a Complete Cytogenetic Response (CCyR) and 1 had a CHR, that became a MMR at day+60.
Both patients that underwent alloSCT while in CP are still alive and in CMR.
Donor Lymphocyte Infusion (DLI) and TKI combination treatment (in one case systemic and intrathecal chemotherapy was associated) was used as a strategy to treat 2 cases of relapse after aSCT and 1 case of refractory disease. No clinically signs of GvHD and no increase of TKIs toxicity were reported. All three patients responded achieving: 2 CMR (3 months after and 2 months after) and 1 MMR (2 months after). One of these three pts experienced a recurrency 6 months after.**Summary / Conclusion:** AlloSCT can rescue a minority of pts with active BP-CML. A combination of immunotherapy and TKIs administration need more investigation strategy after alloSCT.

B1690

THE LEVELS OF TOTAL AND VIABLE CD34+ STEM CELLS DO NOT DECREASE STATISTICALLY WHEN THEY ARE CRYOPRESERVED AT -80OC AFTER OVERNIGHT STORAGE AT REFRIGERATOR

A Donmez[1], AYilmaz[1*], N Soyer[1], B Arık[1], S Cagırgan[1], M Tombuloglu[1]
[1]ege university faculty of medicine, izmir, Turkey

Background: Although peripheral blood stem cells (PBSC) which are cryopreserved at -80ºC after overnight storage at refrigerator are used for stem cell transplantation, the efficacy of this method is not searched in prospective studies.
Aims: In this study we tried to identify the levels of viable and total CD34+stem cells and the effect of this on stem cell transplantation.
Methods: 43 patients (median age: 52, female/male: 20/23) with 80 PBSC products were analyzed prospectively. Total and viable CD34+ stem cells levels of the products were determined immediately after leukapheresis (group 1), after overnight storage at refrigerator (group 2) and post-thaw periods (group 3). The levels were analyzed by flowcytometry method (BD FACSAria cell sorter, BD Biosiences). We tried to determine the effect of the results on neutrophil and thrombocyte engraftments after stem cell transplantation.
Results: The levels of total CD34+ cells were not statistically different (P<0,5) between the group 1 ((664.5 [20.76 – 8420] /µL), group 2 (614.5 [21 – 7982] /µL) and group 3 (582.3 [17.04 – 4062] /µL). Also we did not find any statistical difference (p:0,08) between the groups when we compared the viable CD34+ cell levels (group 1:632 [20.12 – 8420] /µL; group2: 602.5 [21.80 – 7978] /µL; group 3: 526.8 [4.1 – 3880 /µL). Reverse relation was documented between neutrophil (12 days [9 – 19]) and thrombocyte (12days [0– 35]) engraftment periods and group 1(r=-0.41, P=0.02; r=-0.36, P=0.04,respectively) and group 3 (r=-0.51, P=0.005; r=-0.41, P=0.02, respectively) viable CD34 + cell levels but not group 2.
Summary / Conclusion: Since we did not find any statistical difference between total/viable CD 34+ stem cells and groups, freezing directly at -80ºC

after overnight storage at refrigerator method could be used safely and effectively. Group 1 and group 3 viable CD34+ stem cells levels should be evaluated carefully before stem cell transplantation because we can predict any engraftment delays by these results.

B1691

THE EXAMINATION OF CELL CHIMERISM AS A NONSPECIFIC MARKER IN POST-TRANSPLANT PERIOD BY MOLECULAR GENETICS METHODS

M Holicka[1*], K Pegova[1], S Nadvornikova[1], P Hrabakova[1], D Brezinova[1], M Stankova[1], H Cechova[1]
[1]The Institute of Hematology and Blood Transfusion, Prague2, Czech Republic

Background: Allogeneic bone marrow or peripheral blood stem cell transplantation (allo-HSCT) is an important medical procedure in the treatment of malignant and nonmalignant disorders in children. After the transplantation it leads in the recipient to the development of chimerism (cells from genetically different individuals coexist in one body). The detection of only donor´s genotype in blood cells is called the complete chimerism (CC). The coexistence of recipient's and donor's haematopoiesis in different proportions (mixed chimerism – MC) augments the risk of relapse.
Aims: The early detection of mixed chimerism or microchimerism (less than 1% of recipient´s genotype) is important for individual approach to the patient care. The ability to detect early the recurrence of recipient's haematopoiesis followed by disease depends on the sensitivity of the used method.
Methods: The most of the samples are quantitatively determined by the short tandem repeat polymerase chain reaction (STR-PCR). Currently, sex-specific loci and a method based on SNP (Single Nucleotide Polymorphism) or short insertion and deletion (indel) are also used; less frequently the length polymorphisms of VNTR type (Variable Number of Tandem Repeats) are determined. The sensitivity of the used methods is the following: VNTR 1-5%, STR 1% and SNP or indels 0.01%.We have regularly received the samples of pediatric patients after allo-HSCT from The University Hospital Motol since 1992. Informed consents were obtained from all patients, or from their legal guardian.
Results: The informativity was determined in 356 children´s patients indicated for allo-HSCT during the years 1992-2012, including 112 cases of acute lymphoblastic leukemia (ALL), 49 cases of acute myeloid leukemia (AML), 58 cases of aplastic anemia, 26 cases of chronic myeloid leukemia (CML), 40 cases of immunodeficiency, 41 cases of myelodysplastic syndromes (MDS) and 30 cases of other diagnoses. It was also investigated 23 cases of maternal engraftment and 2 detections of twins zygocy. In total, 67% of transplantations were provided from unrelated donors and 33% from related donors. Patients achieved CC in a median of 21 (range, 7-543) days after allo-HSCT, 9% of all patients never reached CC and they still have MC. Altogether, 77% of all monitored patients survive and they are constantly monitored, while 23% of all patients died. Five years after HSCT 80% of patients with CC and 74% of patients with MC continue to survive. Relapse was the cause of death in 37%, infection in 23%, graft versus host disease (GVHD) in 16%, organ failure in 13% and the other causes in 11%. In 29 patients who died because of relapse MC was detected in 20 of them (69%). In the other 9 patients with relapse CC was detected. These patients died before the year 2005 when the samples were analysed only by VNTR polymorphisms, that´s sensitivity is 1-5%. According to the selected examples of the patients who died because of relapse the increasing of cell chimerism corresponds with the other results (increasing of blast number).
Summary / Conclusion: Analysis of individual haematopoietic chimerism in the time period after transplantation is a nonspecific marker for post-transplant haematopoiesis for all diagnoses and it provides diagnostic evidence for clinical decisions. With this analysis it is possible to predict negative events, such as graft rejection or relapse in the early stage of disease. Subsequently quick therapeutic intervention can efficiently reduce the number of autologous cells before clinical manifestation of the disease.

B1692

OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA WITH ACTIVE DISEASE: EXPERIENCE OF A SINGLE EUROPEAN INSTITUTION

R De Mello[1*], C Pinho-Vaz[2], I Carvalhais[3], R Branca[2], F Campilho[2], M Rosales[4], S Roncon[4], A Campos-Júnior[2]
[1]Medical Oncology/Bone Marrow Transplantation, [2]Bone Marrow Transplantation, Portuguese Oncology Insititute, [3]Clinical Henatology, Centro Hospitalar de São João, [4]Cell Therapy Service, Portuguese Oncology Insititute, Porto, Portugal

Background: Allogeneic hematopoietic stem cell transplantation (AHSCT) represents a potentially curative approach for patients (pts) with relapsed or refractory acute myeloid leukemia (AML). However, those pts are a heterogenous population with long-term survival rates after AHSCT ranging from 40 % to less than 5%.
Aims: We report the outcome of relapsed/refractory AML pts treated with AHSCT.
Methods: A retrospective cohort from including clinical registries' databases for pts with diagnosis of relapsed/refractory AML, with 61 fulfilled inclusion criteria pts from 1994 to 2012. Outcomes of interest were transplant-related mortality (TRM), incidence of acute and chronic graft-versus-host disease (GVHD), incidence of relapse and overall survival (OS) - which were estimated from the date of transplant. Parametric and non-parametric tests were used appropriately. Kaplan Meir curve was used for OS assessment. Statistical analysis was carried out using SPSS v19.0 for Mac (IBM, 2010, USA) and statistical significance was considered for $P<0.05$.
Results: The median age was 38 (range 1 – 65) years. Median follow up for alive pts was 8 months (17 pts; range 3.26 – 12.73). The cumulative incidence of 90-days, 1 year, and 3 years TRM was 50%, 45%, and 5%, respectively ($P<0.001$). 42.6% of patients developed grade II-IV acute GVHD and 76.5% suffered from chronic GVHD. The actuarial incidence of relapse was 37.2% at 1 year and 25% at 3 years and 66.7% at 5 years. Actuarial OS was estimated to be 41.7% at 1 year, 50% at 3 years, and 8.3% at 5 years ($P<0.001$). OS of pts age < 45 years or >= 45 years was 52.9% versus 47.1% for all pts ($P=0.549$).
Summary / Conclusion: In our study, TRM and GVHD in first years after AHSCT remains considerable, but AHSCT in this setting seems to be a good choice for AML pts with active disease. However, new approaches are needed to reduce TRM and relapse in this cohort of patients.

B1693

TREATMENT OUTCOME IN THE PATIENTS WITH LARGE-B-CELL LYMPHOMA (LBCL) AFTER HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

N Tyurina[1*], O Pavlova[1], M Vernyuk [1], E Karpenko[1], A Chervontseva[1]
[1]BMT, Hertcen Moscow Scientific Research Oncology Center, Moscow, Russian Federation

Background: Diffuse large B-cell lymphomas (DLBCL) are the most common lymphoid neoplasms. The International Prognostic Index (IPI), and even more, age-adjusted IPI (aaIPI), has proved valuable for risk stratification of patients, particularly to "tailor" more intensive therapy such as high-dose therapy (HDCT) followed by autologous hemopoietic stem cell transplantation (autoHSCT). Despite the striking advances in the treatment of DLBCL, a group of patients with high risk factors still have a poor prognosis (long-term survival estimated at only 50%). In the absence of prospective studies, the optimal treatment for high-risk patients is still a matter of debate. Uncertainties exist with regard to the intensity of primary chemotherapy, the impact of rituximab and the role of high-dose chemotherapy.
Aims: To evaluate the effectiveness of high-dose chemotherapy and autologous stem cell transplantation in large-B-cell lymphoma patients with unfavorable prognosis.
Methods: 38 patients with large B-cell non-Hodgkin's lymphoma (24 patients with diffuse large B-cell lymphoma (DLBCL) and 14 patients with primary mediastinal large-B-cell lymphoma (PMLBCL), admitted to Hertcen Moscow Scientific Research Oncology Center between 2006 and 2013, were treated with HDCT followed by autoHSCT. There were 13 men and 25 women, most of PMLBCL patients were young women (79%). The average age of DLBCL patients was 38 years (17-60, median 38), PMLBCL patients – 32 (20-43, median 32). In all cases the diagnosis was confirmed by immunomorphology. All DLBCL patients had 2 or more adverse prognostic factors according to IPI. Most PMLBCL patients (69%) had localized stage II-E. Local infiltration of adjacent tissues and organs was defined in all PMLBCL patients, bone marrow involvment was not observed. HDCT followed by autoHSCT was performed in 16 patients with DLBCL and 13 patients PMLBCL to consolidate the first partial/complete remission; 3 patients with relapsed DLBC and 6 patients with stable refractory diseases also received HDCT followed by autoHSCT. The source of hematopoietic progenitors was peripheral blood in all patients. In most cases (79%) mobilization and collection of HSC was performed after DHAP, Dexa-BEAM, mini-BEAM or ICE chemotherapy. The number of CD34+ cells in the autograft averaged $18.3x10^6$/kg ($3.4-98.1x10^6$/kg). Pre-transplantation conditioning was carried out according to BEAM protocol. After HDCT followed by autoHSCT 10 PMLBCL patients received radiation therapy on residual disease.
Results: Currently 31/38 (81,5%) patients with LBCL remain in first prolonged-complete/partial remission, including 16 DLBCL patients and 11 PMLBCL patients to whom HDCT followed by autoHSCT was performed to consolidate complete/partial remission. Prolonged remission after HDCT followed by autoHSCT is also achieved in 3 relapsed patients. First prolonged remission achieved the only one patient with refractory disease. Observation time varies from 3 to 78 months (mean 43 months). Early refractory relapses after HDCT followed by autoHSCT occurred in 4/5 patients with stable refractory disease. One patient died from other causes 30 months after autoHSCT in complete remission.In 3 PMLBCL cases recurrent disease was found after HDCT and autoHSCT.
Summary / Conclusion: Treatment of B-large cell lymphoma requires a differentiated approach. In the group with adverse prognostic factors patients achieving complete/partial remission should receive early intensification treatment including HDCT and autoHSCT. In patients with refractory disease

autoHSCT is not considered to be sufficiently effective. Treatment of these patients is advisable to carry out as part of research protocols in clinical trials.

B1694

FAVORABLE OUTCOMES OF REDUCED-INTENSITY CONDITIONING REGIMENS FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHILDREN WITH ACUTE LEUKEMIA

K Koh[1*], J Seo[1], E Choi[1], H Im[1], J Seo[1]
[1]Pediatrics, ASAN MEDICAL CENTER, Seoul, Korea, Republic Of

Background: Reduced-intensity conditioning (RIC) has been successfully adopted for allogneneic HSCT for older patients or those with medical comorbidities, while experiences in children are limited.
Aims: This study was performed to evaluate the safety and efficacy of RIC for children with acute leukemia.
Methods: We retrospectively evaluated 17 patients aged ≤ 18 years with acute leukemia who received allogeneic HSCT with RIC from 2008 to 2012 in Asan Medical Center Children's Hospital. In our pediatric HSCT program, eligibility criteria for allogeneic HSCT with RIC included unresolved infection at HSCT, co-morbidity or poor performance status, a history of prior HSCT, and infants. Performance status was scored according to Karnofsky scale in patients aged 16 years and older, and Lansky scale in patients less than 16 years. Organ toxicity was evaluated according to Common Terminology Criteria for Adverse Events (CTCAE) v4.0.
Results: The median age at HSCT was 13 years (range, 0.7-16 years), and 3 were younger than 1 year old at HSCT. Indications for RIC were unresolved infection at HSCT (N = 10), performance scores < 90% (N = 3), infancy (N = 3), and a prior history of allogeneic HSCT (N = 1). The diagnoses were AML (N = 13) and ALL (N = 4). Disease status was first complete remission (CR) in 13, ≥ CR2 in3, and partial remission in 1. RIC regimens were TBI-based in 7 (fractionated TBI 800 cGy, fludarabine 150 mg/m^2, cyclophosphamide 120 mg/kg) or busulfan-based in 10 (intravenous busulfan 6.4 mg/kg with fludarabine 150 mg/m^2 and rabbit-ATG 7.5-9 mg/kg with or without cyclophosphamide). Donors were matched sibling donors in 6 and unrelated donors in 11. Grafts were mobilized-peripheral blood in 16, and cord blood in 1. Sixteen achieved neutrophil engraftment at a median of 13 days (range, 10-20 days), and platelet engraftment at a median of 19 days (range, 13-30 days), while one patient, who received a cord blood graft, failed engraftment and subsequently received rescue transplantation from a haploidentical donor. Median duration of absolute neutrophil count (ANC) < 0.1 × 10^9/L was 6 days (range, 2-21 days). Full donor chimerism was achieved in all but one who failed engraftment. No CTCAE grade III or higher toxicity was observed in the kidneys, lungs, heart, mucosa and nervous system, while grade III hepatic toxicity was observed in one patient, who experienced a moderate degree of hepatic sinusoidal obstruction syndrome. None experienced documented bacterial or fungal infection. Six patients experienced CMV reactivation, while no patients developed CMV disease. No TRM was observed. Cumulative incidence of acute GVHD at day 100 and chronic GVHD at 1 year were 37.5% and 36.5%, respectively. At a median follow-up of 25 months, the 2-year overall survival (OS) was 68.6% and the 2-year relapse incidence (RI) was 29.4%. OS and RI were not different between the patients with AML and ALL. Analyzing the outcomes of risk-based subgroups in AML, 2-yr OS were 33.3% in intermediate-risk group and 83.3% in poor-risk group. OS, RI, and GVHD incidence were not different between a busulfan- and TBI-based regimen, while days to neutrophil and platelet engraftment and duration of ANC < 0.1 × 10^9/L tended to be longer in a TBI-based regimen (*P*=0.124, 0.066, 0.001, respectively).
Summary / Conclusion: These results suggest that RIC is a feasible approach with low morbidity and TRM for children with acute leukemia. A long-term follow-up study in a larger population is warranted to evaluate the efficacy and long-term safety of RIC in children.

B1695

HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MYELOFIBROSIS: A COMPARISON BETWEEN MYELOABLATIVE AND REDUCED INTENSITY CONDITIONING

V Funke[1*], V Fiorini[1], G Santos[1], T Fagundes[1], L Sinamura[1], C Sola[1], D Setubal[1], L Medeiros[1], R Pasquini[1], M Malvezzi[1]
[1]Hematology, Federal University of Parana, Curitiba, Brazil

Background: Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) is indicated for patients with intermediate or high risk primary Myelofibrosis (MF), and also in patients with Policitemia Vera or Essential Thrombocythemia who have progressed to high risk MF. The results for allogeneic HSCT with myeloablative conditioning seem to be better for patients younger than 45 years, determining low risk to recidivate. However, Reduced Intensity Conditioning (RIC) for patients between 45 and 65 years-old has shown to be promising.
Aims: This study aims describing a series of patients diagnosed with myelofibrosis, transplanted in the Hospital de Clínicas (HC) from the Federal University of Paraná and Hospital Nossa Senhora das Graças (HNSG) (Curitiba, Brazil).
Methods: From 1984 to 2011, fourteen patients with MF were submitted to HSCT, eleven from the HC and three from HNSG. The median of age was 42 years (10-51). There were ten males and four females. In average, five blood transfusions were done per patient (0-61). Five male patients received the graft from a female donor, and two patients were submitted to non-related HSCT. The median of duration of the disease was 20 months (2-150). According to Dupriez Classification, all the patients were of intermediate and high risk. Five patients did the myeloablative conditioning (Busulfan plus Cyclophosphamide – n=4 – Cyclophosphamide plus Total Body Irradiation – n=1) while nine did the RIC (Fludarabine 150mg/m2 plus Melphalan 140mg/m2 –n=6– Fludarabine plus Melphalan plus Antithymocyte Globulin -n=2- Fludarabine 180mg/m2 plus Bulsufan 10mg/m2 plus Antithymocyte globulin 5mg/kg –n=1).
Results: In the myeloablative conditioning group (n=5), all the patients presented marrow engraftment; one recidivated MF later. Three patients presented grade II-IV acute graft versus host disease, and four evolved with severe extensive chronic graft versus host disease. Four patients expired, and the only survivor was 10 years-old. Median survivor was 479 days. In RIC group (n=9), engraftment didn't occur in one patient (which had splenomegaly of 18 cm at the time of transplantation), and another three had had the disease recidivated. The other seven patients remained alive, with median survival of 750 days (34-1872; P=0,000123).
Summary / Conclusion: In spite of the limited number of patients in this study, data suggest that RIC utilization can improve mortality in HSCT for myelofibrosis, even with greater risk to recidivate.

B1696

USE OF PROTON PUMP INHIBITORS IN HEMATOPOIETIC STEM CELL TRANSPLANTATION DOES NOT INCREASE THE FREQUENCY OF FEBRILE NEUTROPENIA

M Comert[1*], A Donmez[1], A Arslan[2], M Tombuloglu[1]
[1]Hemathology, [2]Internal Medicine, Ege University, School of Medicine, Izmir, Turkey

Background: Despite the proton pump inhibitor (PPI) use is a risk factor for infections in heterogeneous groups of patients, the studies related to PPI use and febrile neutropenic episodes (FNE) in hematopoietic stem cell transplantation (HSCT) are limited.
Aims: Identifying whether PPI use is a risk factor for febrile neutropenia at HSCT.
Methods: One hundred fifty-three HSCTs' data from 145 patients who was underwent HSCT at the Ege University, Adult Hematology Transplant Center between 2005 and 2012 were analyzed retrospectively. We analyzed the relationship between PPI use and febrile neutropenic episodes, culture results, viral antigenemia and fungal infections. For this purpose, the described variables were calculated using the multivariate test (logistic regression). 111 HSCT were autologous and 42 were allogeneic. Median age was 49 years. The study subjects consisted of patients with multiple myeloma and primary amyloidosis (n=60), lymphomas (Hodgkin's or non-Hodgkin's [n=49]), acute leukemia's (lymphoblastic or myeloid [n=28]), and other diseases (n=8). The patients were composed of 83 (57.2%) males and 62 (42.7%) females. 8 males were retransplanted. 94 (61.4%) of the HSCTs was performed with central venous catheter. All of the HSCTs were performed with peripheral blood stem cell. Considering the duration of PPI use; 69 (54.8%) patients were used PPI with the beginning of the HSCT conditioning regimen until >+14 days of HSCT. Chronic PPI use was determined in 57 (45.2%) patients.
Results: One hundred thirty-one (85.6%) of the HSCTs was complicated with FNEs and in 22 (14.4%) HSCT FNEs was not observed. The median neutropenia period was 9.27 days. Blood cultures were positive in 25 (16.3%) samples. Ten (40%) of them were gram-negative and 15(60%) were gram-positive microorganisms. There was no statistically significant difference between gram-positive and gram-negative microorganism positivity with PPI use blood cultures. On multivariate analysis, PPI use was not significantly associated with FNEs (odds ratio [OR]2,10; 95% Confidence Interval [CI] 0,63 -6,94; P=0,225) and bacterial culture positivity (OR 0,99; 95% CI 0,35 -2,80; P=0,984).
Summary / Conclusion: Our study have been revealed that in the patient group which was consist of majorly with chronic PPI use does not propose any additional risk for FNE and bacterial culture positivity at transplanted patients.

B1697

LYMPHOCYTOSIS WITH CD3CD8 PREDOMINANCE ASSOCIATED WITH CHRONIC GRAFT-VS-HOST DISEASE

A Piekarska[1*], W Prejzner[1], A Hellmann[1]
[1]Department of Hematology and Transplantology, Gdansk, Poland

Background: Chronic graft-vs-host disease (cGvHD) is the most important non-relapse complication that affects long-term survivals of allogeneic hematopoietic cell transplantation (HCT). Clinical symptoms often mimic certain autoimmune diseases and worsen the quality of life. Infectious complications related to GvHD and immunosuppression may be fatal.
Aims: Patients with acute GvHD (aGvHD) history have higher incidence rate of cGvHD but it is difficult to predict who will actually develop cGvHD.
Methods: We analyzed clinically and with the use of flow cytometry the cases

of living 16 patients who developed lymphocytosis >5 G/l after HCT performed between 2003-2012 due to hematological malignancies. Median age at HCT was 41 (range 23-60).The donor was sibling in 7 cases, 10/10 matched unrelated in 7 cases and unrelated with 1 locus mismatch in 2 cases. 14/16 patients developed aGvHD (3 in grade 3-4; 10 in grade 1-2). 14 patients had confirmed cGvHD diagnosis in their medical history. We classified 4 as mild, 2 as moderate and 8 cases as severe cGvHD, including 4 with sclerotic features.
Results: Lymphocytosis > 5 G/l first time appeared between 5-51 month after HCT (median 15 months) with maximal achieved value from5,15-10,66 G/l. It was not related to infection or EBV replication (excluded by PCR). In 5 (31%) cases increased lymphocyte count preceded cGvHD symptoms or cGvHD exacerbation, while in 6 (37.5%) was accompanying cGvHD symptoms. In 12/16 patients lymphocytosis maintained for median 10-month-period (range 3-65 months). 4 patients are still under surveillance because of lymphocytosis (lasting <= 4mc). Lymphocytes T predominance was confirmed in 12 (75%) cases. Inverted CD4/CD8 ratio was present in 14/16 analyzed patients. The ratio range varied from 1:2 to 1:25. LGL cells>10% in peripheral blood were present in 14/16 cases.
Summary / Conclusion: 1. Significant CD3CD8 lymphocytosis >5 G/l with the presence of NK cells may appear prior to or correspond with exacerbation of cGvHD clinical symptoms and therefore should be treated as important laboratory finding. This population of lymphocytes may contain alloreactive donor-derived cells with cytotoxic properties. 2. As a majority of patients in the analyzed group had a history of aGvHD that may lead to destruction of the thymus, it could explain the low output of CD3CD4 cells with extrathymic expansion of CD3CD8 cells leading to inverted CD4/CD8 ratio.

B1698
COMPARISON OF TOXICITY AND EFFECTS OF CONDITIONING SCHEME USING BUSULPHAN AND CYCLOPHOSPHAMIDE AS MODIFIED BUCY WITH CYBU IN PATIENTS TREATED WITH HEMATOPOIETIC CELL TRANSPLANTATION.
M Dutka[1*], M Bieniaszewska[1], H Dahm[2], O Bielska[2], P Klimont[2], A Hellmann[1]
[1]Hematology and Transplantology, [2]Medical University of Gdańsk, Poland, Gdańsk, Poland

Background: Conditioning treatment is important issue that affects course of hematopoietic stem cell transplantation, bothshort-term andlong-term results. One of the common ways of preparation for transplantation is chemotherapy based on busulphan and cyclophosphamide. Recently there is a EBMT recommendation to use rather the altering drug combination CyBu then original conditioning BuCy. The reasons for thischange are results of animal and then clinical studies, which demonstrated less hepatic toxicity including a decreased number of VOD incidents and early transplantation related mortality. Using busulphan as a first drug affects cyclophosphamide's metabolism and increases the level of its toxic metabolites by reducing the level of glutathione. In theory, the impact of toxic metabolites causes liver damage and high levels of proinflammatory cytokines: IL-2, TNF-alpha that could be of importance in the development of aGvHD. The other way to reduce the risk of VOD is the modification of BuCy conditioning with one day break between those two drugs and implementation of leucovorin supply after methotrexate dose, which we implemented in our unit in 2011.
Aims: The aim of our study was to compare the hepatotoxicity and its severity, the number and severity of VOD incidents and associated mortality, engraftment and aGvHD in cohort treated with modified, in a way described above, BuCy and the CyBu conditioning.
Methods: From May 2012 10 patients underwent transplantation with conditioning CyBu (60 mg/m^2 i.v. on days -7 to -6; 0,8mg/kg every 6 hours -5 to -2) . Data were compared with patient treated in 2011-2012 with BuCy (0,8mg/kg every 6 hours -8 to -5; 60 mg/m^2 i.v. on days -3 to -2) conditioning. In both groups immunosuppression therapy was similar consisted of cyclosporine (from -1) and methotrexate on day1,3,6, 11 (in BuCy cohort with intravenous lecovorin support) with thymoglobulin in case of MUD. The following parameters were estimated: liver toxicity (bilirubin, ALT level), the incidence and severity of VOD, aGvHD and engraftment.
Results: The characteristic of both groups (CyBu / BuCy): women 50% v 62% and men 50 % v 38% respectively, the medianage (and range) at the transplantation point was 36 (19-57) and 45 (31-62). Almost all patients were treated with myeloproliferative disease: AML 80% v 77%; CML 10% v 15% and because of MDS 10% v 8%. In each casewas the firstgraft. Donors were HLA – identical siblings (50% v 46%); matched (30 % v 31%) and unmatched (10% v 15%) unrelated donor; autologous transplantation was made in 10% and 8% of patients respectively. Stem cells source in CyBu cohort was PSC in 70% cases and BM in 30%, no BM was given in BuCy. Pretransplant EBMT risk score was similar in both groups – average 4. At the baseline liver function tests was similar with slightly increase of bilirubin in two patients in each group (median2,2 mg/dl). Also one patient at anyof the groups had HBV infection in history but with negative DNA HBV before transplantation. Values of bilirubin observed in period of transplantation showed a higher level in CyBu than in BuCy cohort [median2,74 (1-7,36) v1,74 (1-3,5) mg/dl] but alanine amino transferase were not statistically significantly higher in BuCy [median 87,5 (62-735) v 120 (50-656) U/l]. Reporteddeviationsoccurred earlier in BuCy cohort [average day 3] than in CyBu [average day 5] but resolved the same after 12 days. No VOD incidence was observed. One patient in CyBu cohort died before engraftment because of infections reasons. Times to myeloid engraftment were in BuCy cohort median 17 days (renge 13-24) vs CyBu cohort median 26 days (range 20-29). aGvHDappeared amongBuCycohort in 53% of cases with median range of severity 2 (1-4) compared to CyBu cohort in 20% with severity 2 and 1 in each cases.
Summary / Conclusion: Modified conditioning regiment BuCy with one day break between intravenous Bu and Cy with supportive care of leucovorin after methotrexate use could be more safe with less liver toxicity than CyBu conditioning but with more incidence of aGvHD.

B1699
T CELL REPLETE HAPLOIDENTICAL TRASPLANTATION. A FEASIBLE ALTERNATIVE WITH ENCOURAGING SURVIVAL FOR PATIENTS WITHOUT MATCHED SIBLING IN DEVELOPING COUNTRIES. 34 TRANSPLANTS IN ONE CENTER IN COLOMBIA
A Karduss[1*], Y Coll[1], L Gomez[1], A Jimenez[1], P Reyes[1], R Perez[1], H Deossa[1], L Hurtado[1]
[1]Bone Marrow Transplant, Instituto de Cancerología , Medellin, Colombia

Background: The use of matched unrelated donor or cord blood as a CD34 source are the usual alternatives for patients without a sibling matched donor, however their cost and the difficulty in their consecution are important barriers for being a real solution in countries with limited economic resources. In the other hand haploidentical transplant has the advantage of an easy, timely and not expensive form of procurement a donor
Aims: We would like to present our experience with haploidentical transplant using T cell replete peripheral blood as a CD34 source, a reduce intensity conditioning regimen and alemtuzumab or cyclophosphamide for prevention of GVHD, graft rejection and management of T cell alloreactivity
Methods: Regimen 1 :(29 transplants): Cyclophosphamide (cy) 500 mgs/m2, and fludarabine (flu) 30 mgs/m2 from d-5 to –2, five ptes received busulfan or thiotepa on d -6 and twenty TBI 200-400 cGy on d – 1. GVHD prophylaxis: alemtuzumab 0.2 mgs/kg/IV d-4 to cero, mycophenolato (MMF) and cyclosporine from D – 3 to + 45 and + 180 respectively
Regimen 2: (5 transplants): Busulfan 4-6 mgs/kg, cy 30 mgs/kg, flu 150 mgs/m2, TBI 400 cGy. GVHD prophylaxis: Ciclophosphamide 50 mg/kg d+3 and d+4, MMF and Cyclosporine from d+5 to + 90 and +180 respectively
Results: 26 ptes received 29 transplants with regimen 1(R1) (3 needed a second transplant after engraftment failure of the first one) and 5 were transplanted with regimen 2 (R2). Median age was 24 y (7-50), 10 had AML, 6 LLA, 6 Fanconi Anemia, 3 aplastic anemia, 2 myeloproliferative disorders, 2 CML and 2 other disease. The CD34 cells were obtained from peripheral blood and infused without manipulation, the median transplanted dose was 12 million/kg (8-20), the median time for neutrophil recovery was 11 days (9-14) for R1 and 14 (13-15) for R2, the platelet recovery was at day +12 (9-50) after R1 and d +14 after R2. The cumulative incidence of engraftment was 88% for R1 and 100% for R2, The incidence of aGVHD (G II-III) was 27% for R1 and it occurred in 2 out of 5 after R2, the incidence of cGVHD was 40%, all limited, after R1 and cero after R2. The median follow up for R1 is 540 days(100- 1.620,) the day 100 mortality is 17.2% and the actuarial 50 months survival is 50%. The median follow up for R2 is shorter, 5 months, range 3-10, all patients are alive and without recurrence of their disease
Summary / Conclusion: Haploidentical transplant using the protocols previously described is feasible, produce a fast and reliable engraftment, low incidence of aGVHD, low day 100 mortality and an encouraging survival. taking into account the low cost and easy form of procurement the donor, it is a very good alternative for patients without matched sibling in countries with limited economic resources.

B1700
THE ATG BASED MYELOABLATIVE CONDITIONING REGIMEN IS EFFECTIVE IN PATIENTS WITH RELAPSED OR HIGH-RISK T CELL LYMPHOMA
y jun[1], w chun[1], y shike[1], j jieling[1], w liping[1], c yu[1], y jun[2*]
[1]hematology, [2]hematolog, Shanghai Jiaotong University affiliated Shanghai First People's Hospital, shanghai, China

Aggressive T-cell lymphomas (ATCLs) represent 10% to 15% of non-Hodgkin's lymphomas (NHLs) in adults. Patients with relapsed or refractory disease are generally considered incurable with conventional therapies. ATG had been used in the conditioning regimen to reduce the incidence of Graft-versus-host disease □GvHD□for a long time especially in the matched unrelated donor HSCT. The early experiment result in our hospital showed that ATG inhibited the proliferation of lymphoid tumor cells in a dose-dependent manner especially in the T cell tumors.
Aims: We used the ATG as the part of the conditioning regimen in the all patients and to evaluate the long-term anti-leukemia effect, the safety and complication in the patients with relapsed or high-risk T cell lymphomas.
Methods: 12 patients(male6, female 6) were enrolled into this study. Median patient age at the time of transplantation was 27 years (range, 16–36 years).

At the time of transplant, 3 patients reached CR, 4 patients had a partial response (PR), 2 patients had relapsed disease and 3 patients had primary refractory disease. Donors were 10/10 HLA matched related (3), 10/10 matched unrelated (2) 8/10 matched unrelated (6) and mismatched related (1). The median number of CD34+ cells within the allografts was 9.31/kg body weight (BW) (range, 4.6–24.85/kg BW). All patients underwent myeloablative conditioning. Rabbit antithymocyte globulin (ATG 2.5 mg/kg×3-4 days) was used in all 12 patients. Eight patients underwent the conditioning regimen that included cyclophosphamide (120 mg/kg), VP 16 30-40mg/kg and total-body irradiation (10 Gy in five fractions). Conditioning regimens were cyclophosphamide and total-body irradiation (Cy–TBI) in 2 patients; VP16 and TBI in one patient; and CTX and fludarabine in one patient. GVHD prophylaxis was cyclosporine based, usually in combination with methotrexate. Quantitative chimerism analyzes were performed using short-tandem-repeat-based polymerase chain reaction techniques at regular intervals for every 4 weeks after transplantation in bone marrow at the first six months.

Results: All patients achieved a complete remission after allogeneic HSCT. At a median follow-up time of 21 months, nine(75%) patients are alive. OS at three years was 64% Three patients were died after transplant, two from relapse and one from treatment related complication. Acute GvHD grades I-II occurred in eight patients and grades III-IV in two patients. Eight out of ten patients with acute GvHD are currently alive and free of disease. Five of them developed chronic GvHD(4 limited, 1 extensive). One patients suffering from acute GvHD grade IV died due to treatment-related complications. One patient who suffering from acute GvHD grade I relapsed after decay of GvHD symptom. Eleven patients had suffered from CMV viremia in the first three months after transplant. And two of them gradually evolved into viral haemorrhagic cystitis. One patient suffered from aspergillus pneumonia while another two suffered from bacterial pneumonia. But, there was no patient dying from infectious complications.

Summary / Conclusion: Conditioning with ATG, TBI, CTX or VP16 is a feasible and effective alternative for patients with relapsed or high-risk T cell lymphomas.

HEMATOPOIETIC CELL TRANSPLANT CO-MORBIDITY INDEX IN DIFFUSE LARGE B-CELL LYMPHOMA: SINGLE EXPERIENCE

G Catania[1*], F Monaco[2], M Corsetti[2], F Zallio[3], S Tamiazzo[3], M Pini[1], B Anna[3], D Pietrasanta[2], L Depaoli[3], A Levis[3], F Salvia[2]

[1]Ematologia, Ospedale SS Antonio e Biagio e Cesare Arrigo, [2]Ematologia, SS. Antonio e Biagio e Cesare Arrigo, [3]Ematologia, Ospedale SS. Antonio e Biagio e Cesare Arrigo, Alessandria, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common lymphoid malignancy in adults in western countries. The combination of anti-CD20 monoclonal antibody rituximab and CHOP chemotherapy every 14 or 21 days, is the standard treatment for DLBCL patients. The high-dose chemotherapy supported by autologous stem cell transplantation (HDC / ASCT) is recommended in young relapsed patients or in patients who have not achieved a complete remission (CR) after first-line chemotherapy.

The International Prognostic Index (IPI) end the revised version in the post-rituximab era (R-IPI) are the benchmarks of prognosis DLBCL. However, this system does not evaluate the comorbidities, that can influence the outcome of HDC.

Aims: The hematopoietic cell transplantation-specific comorbidity index (HCT-CI) was developed to assess the pretransplant comorbidities that may predict nonrelapsae mortality (NRM) and overall survival (OS) in patients undergoing allogeneic bone marrow transplantation.

Methods: We conducted an analysis on the prognostic role of HCT-CI on a group of DLBCL patients submitted to BEAM-conditioned ASCT for relapse or refractory disease to first line chemotherapy from 2001 to 2012. According to HCT-CI patients were classified as: low risk (no comorbidity), intermediate risk (1-2) and high risk (= or> 3). Furthermore, we considered as potential confounding prognostic factors both the pre-ASCT status and sex. OS and NRM were evaluated by Kaplan-Meier method.

Results: 57 patients were considered. The median age of the patient population was 53 years (range 20-71 years) and 31 (54 %) were male. HCT-CI was 0 in 17 (30 %), 1-2 in 31 (54%), and ≥ 3 in 9(16%). The pre-ASCT status was: progressive disease 16% , partial response 39%, and complete response in 45 %. The median follow-up time was 36 months (2-145 months). At 60 months the OS was 72 % and NRM was 6 %. The OS by HCT-CI was: low risk 90%, intermediate risk 59%, high risk 89% respectively (P<0.05). The OS was 72% both in men and women group. The OS according to pre-ASCT status was: 33% in progressive disease, 69 % in partial response and 90 % in complete response (P<0.05). The NRM by HCT-CI was: 0 % in low risk, 12 % in intermediate risk and 0% in high risk (P>0.05). The NRM was 8 % in men and 4% in women. The NRM by pre-ASCT status was: 11% in progressive disease, 5% in partial response and 3 % in complete response (P>0.05).

Summary / Conclusion: Our retrospective study confirms that pre-ASCT status has an important prognostic role. In this group aren't able showing a significant role of HCT-CI. This is possibly due to the low number of patients and the low number of events. An evaluation a larger number of patients is needed.

B1702

CAPILLARY LEAK SYNDROME IN HAEMATOLOGICAL PATIENTS: MANAGEMENT AND TREATMENT RETROSPECTIVE EVALUATION

M Postorino[1*], R Rossi[2], A Zizzari[3], F Marchesi[4], I Provenzano[1], L Franceschini[1], L Pupo[1], M Rizzo[1], L Gianni'[1], S Gumenyuk[1], G De Santis[1], D Renzi[4], G Guiducci[1], E Fiorelli[3], F Coniglione[2], R Puliti[2], A Berrini[2], MmDauri[2]

[1]Haematology, [2]Anesthesiology, [3]SIMT, Policlinico Tor Vergata, [4]Haematology, Campus Biomedico, Rome, Italy

Background: Capillary leak syndrome (CLS) is an uncommon (< 10%) early complication of hematopoietic stem cell transplantation (HSCT) or intensive chemotherapy caused by the injury of the cytokines against the vascular endothelium, with loss of sodium, albumin and fluids into the interstitial space. The clinical features of CLS are: weight gain (>4% in 24h), generalized edema, hypotension and renal insufficiency of pre-renal origin. The CLS is related to a high risk of mortality due to frequent progression towards the multiorgan failure.

Aims: In order to treat early this syndrome, we designed a prospective protocol: all patients undergoing autologous or allogeneic HSCT or intensive chemotherapy for acute leukemia or bulky lymphoma.

Methods: From January 2004 to January 2013, 12 patients met the diagnostic criteria for CLS (HSCT: allogeneic n=2, autologous n=3; bulky NHL: n= 3; AML: n=3; AITL: n=1). All patients were monitored every 6 hours for weight, arterial pressure and fluid balance until 16 days after the end of intensive chemotherapy or pre-transplant conditioning. In presence of > 2% weight gain and/or 1000 cc positive fluid balance at 6 h, furosemide was given at dose of 0.4 mg/kg. After 1 hour, if patient didn't respond to furosemide, 100 cc of 18 % mannitolo and after 30 minutes 125 mg of furosemide were administered. In case of a persisting negative response, we began CLS therapy consisting of dopamine (4ug/kg/min), prednisolone (1 gm/kg) and furosemide (250 mg by continuous infusion) for 24 hours. The day after, if the response to therapy was positive,the pt continued the same therapy until the normalization of clinical parameters; in the other case we began the continuous hemofiltration until the normalization of clinical parameters.

Results: The 5 transplanted patients responded to the treatment with dopamine and prednisolone (PDN) with resolution of all symptoms within 24 hours. Two of 3 chronic myeloid leukemia (AML) patients and only one with angioimmunoblastic T-cell lymphoma (AITL) not responding to dopamine and PDN underwent hemofiltration within 24 hours with complete resolution of symptoms after a median time of 72 hours (range 48-96 h). One patient affected by LNH, currently hospitalized in the intensive care unit, seems respond to dopamine/prednisolone treatment and probably not need hemofiltration. Instead the other 3 patients (2 LNH and 1 AML), not responding to the first line therapy, for clinical and logistic reasons, underwent hemofiltration later than 24 h: all 3 patients progressed towards the MOF and died.

Summary / Conclusion: Altought limited to a small number of cases, from our experience we can draw the preliminary conclusion that our protocol seems to be effective 1) in monitoring patients at risk for developing CLS and 2) in permitting an early diagnosis and treatment of CLS. Furthermore, our study suggests that hemofiltration within 24 hours could be a crucial intervention for patients not responding to the first line therapy.

B1703

ZARZIO PLUS CHEMOTHERAPY AS PERIPHERAL BLOOD STEM CELL MOBILIZATION STRATEGY IN PATIENTS WITH HEMATOLOGICAL DISEASES CANDIDATED TO AUTOLOGOUS STEM CELL TRANSPLANTATION

V Pavone[1*], M Morciano[1], A Mele1, F Mariapaola[1], C Daniela1, G Greco[1], S Sibilla[1], R De Francesco[1], B Rossini[1], C De Risi[1], A Ostuni[1]

[1]Department Of Haematology And Trasfusion Medicine, Hospital C G Panico, Tricase, Italy

Background: Biosimilar granulocyte colony-stimulating factor (G-CSF) has been recently approved for mobilization of peripheral blood stem cell (PBSC).

Various recent reports describe a comparable efficacy as original G-CSF with a significant reduction of costs.

Aims: In this study we assessed safety and efficacy of Zarzio (Zarzio® Sandoz Biopharmaceuticals) in order to mobilize PBSC in patients (pts) with hematological malignancies and to ensure an optimal engrafment capability.
Methods: From June 2011 to December 2012, a cohort of 44 pts was studied. All pts received disease specific chemotherapy plus Zarzio at a dose of 5µg/kg body weight twice daily. Programmed CD34+ cells target dose was $4x10^6$/kg for pts with non-Hodgkin and Hodgkin Lymphomas, Leukemia and $6x10^6$/kg for Multiple Myeloma. Plerixafor was used in predicted poor mobilizer pts. Amicus Fenwal separator was used in all leukapheresis procedures.

Table 1 Patients' demographic characteristics

	N	%
N of patients	44	
Age	49,8	
Gender M/F	29/15	66/34
Diagnosis		
NHL/HD	22 /9	50 /20
MM	11	25
Acute Leukemia	2	4
Status of disease to mobilization*		
CR	17	38,6
PR	14	31,8
VGPR	5	11,4
NHL/HD	3 /3	6,8 /6,8
Previous stem cell transplantation	3	11,4
N° of previous chemotherapy regimen		
1 /2	27/7	61,4 /15,9
3	7	15,9
Mobilization chemotherapy regimen		
DHAP	20	45,5
HD-EDX	10	22,7
EDEV	9	20,5
Other	5	11,4
Mobilization failed	6	13,6
Mobilization failed after Zarzio plus Plerixafor	2	4,5
Mobilization achieved with Zarzio plus Plerixafor	7	15,9

Table 2 Patients' collection data

	median	range
Collection timing (days)	14	8 - 24
Pre-apheresis data		
CD34+/µL pool	38,3	10 - 303,5
WBC x10^6/ml	14,9	2,2 - 43,8
PLT x10^6/ml	28,8	11,8 - 348
HGB g/dL	10,5	7,9 - 13,9
Leukapheresis data (efficiency)		
CD34+(%)	79,2	33 - 99,8
MNC (%)	43,9	33,2 - 98,1
PLT depletion(%)	13,2	
Graft characteristics		
WBC x10^6/ml	119,8	42,1 - 212,9
MNC%	72,2	30,9 - 94,3
CD34+ x10^6/ml	2,7	0,3 - 13,8
CD34+ viability %	98,9	97,4 - 99,3

Results: Patients' demographic characteristics are listed in table 1. Median time of Zarzio administration was 8.2 days; 38 pts (86%) reached the target dose to perform ASCT with an average number of apheresis of 1.45. Collection data are in table 2. Poor mobilization was documented in 13 pts (29%), mainly of them received more than 3 chemotherapy regimens previously. Six pts failed mobilization, two of them even after the administration of Plerixafor. Among pts who have mobilized, 21 (55.3%) were submitted to high-dose chemotherapy followed by autologous (18) or allogenic (3) PBSC infusion. Median of $CD34x10^6$/kg infuse and viability were 4.3 $x10^6$/kg (0.8-6.2) and 75.3% (51.4-88.2), respectively. Engraftment occurred in all pts. The median time to absolute nucleated cells >500 and to platelets >20 000 was 12 days (10-23) and 14 (10-33) after CD34+ infusion, respectively.
Summary / Conclusion: Biosimilar G-CSF, such as Zarzio, may represent an effective strategy for PBSC mobilization and collection after chemotherapy in terms of CD34+ cell dose and timing of collection. A study of comparison will be necessary to establish advantages in terms of cost.

B1704
FREQUENCY OF CHRONIC GRAFT VERSUS HOST DISEASE AND THE FACTORS FOR DEVELOPMENT OF CHRONIC GRAFT VERSUS HOST DISEASE
E Uzer[1*], I Oner[2], A Serin[3], G Zararsız[4], A Unal[1], M Cetin[1]
[1]Haematology, [2]Internal Medicine, Faculty of Medicine,University of Erciyes, Kayseri, [3]Gastroenterology, Faculty of Medicine,University of Ege, Izmir, [4]Biostatistics, Faculty of Medicine,University of Erciyes, Kayseri, Turkey

Background: Graft Versus Host Disease (GvHD) is a most common complication after allogeneic haematopoietic stem cell transplantation (AHSCT). Chronic GvHD (cGvHD) deteriorates quality of life.
Aims: To investigate frequency and factors related with development cGvHD.
Methods: A total of 100 patients who underwent AHCST in University of Erciyes, Faculty of Medicine, Haematopoietic Stem Cell Transplantation Unit were investigated, retrospectively. All transplantation procedures were performed from fullmatch donor and Seattle regimen was used for GvHD prevention. The frequency of cGvHD and factors related with development of cGvHD including recipient age, donor age, recipient gender, donor gender, recipient-donor gender match, blood group compatibility, amount of CD34+ given, conditioning regimen and prior acute GvHD (aGvHD) were investigated.
Results: The diagnosis of the patients were as follows: acute leukemia in 67 patients (69.1%), aplastic anemia in 7(7.2%), non-Hodgkin lymphoma in 6(6.2%), other diseases in 17(17.5%) (Hodgkin lyphoma, myelofibrosis, myelodysplastic syndrome, chronic myelogenous leukemia, chronic lymphocytic leukemia, paroxysmal nocturnal hemoglobinuria). 36 of patients were female (36%) and 64 patients were male (64%). 57 (58.8%) of patients were given non containing total body irradiation (TBI) conditioning regimen, 40(41.2%) of patients were given total body irradiation (TBI). The mean age of 100 patients was found 33.3 years (±11.04). The frequency of cGvHD was 26% (26 patient). No statistically significant difference was determined among development of cGvHD and patient age, diagnosis, recipient age, donor age, recipient gender, donor gender, recipient-donor gender match, blood group compatibility, amount of CD34+ given, conditioning regimen and prior aGvHD. The cGvHD percentage were 43.8% while female donor-female recipient, 11.8% while male donor-female recipient, 35% while female donor-male recipient, 20% male donor male recipient. It was seemed that the proportions were higher when donors were female. However the differences between these proportions were not found statistically significant (P=0,110).
Summary / Conclusion: Transplantation performed between female donor-female recipient and female donor-male recipient may increase risk of cGvHD development.

B1705
DEVELOPMENT OF A FAST PCR PROTOCOL ENABLING RAPID AND HIGH QUALITY STR BASED CHIMERISM ANALYSIS AFTER ALLO-HSCT
H Liu[1*], Q Niu[1], F Wang[1], W Teng[1], Y Wang[1], T Chunrong[1]
[1]Ludaopei Hematology & Oncology Center, Beijing, China

Background: Chimerism analysis based on microsatellite (STR) genotyping is the standard method for donor cell engraftment monitoring after allogeneic hematopoietic stem cell transplant (allo-HSCT). Traditional STR-PCR amplification require approximately 3 to 3.5 hours, contributing a significant portion of the time required in chimerism analysis. So the PCR amplification time is an important rate-limiting aspect in clinical chimerism analysis and report. When using conventional Taq polymerase, the PCR products often incomplete adenylated due to DNA quality is not good enough or other reasons, thus sometimes interfere with the STR genotyping and accurately calculation of chimeric proportion.
Aims: We aimed to develop and validate a fast PCR protocol that enables rapid and high quality STR genotyping, and to shorten the chimeric analysis and clinical report time.
Methods: Peripheral blood, bone marrow and fingernail samples were collected from healthy donors and patients. Simulate mixed chimerism samples with different proportion of donor and recipient cells (1:2,1:4,1:8,1:16, 1:32,1:64,1:128) were prepared by white blood cell count and fold dilution. The AB Identifiler Kit including primer set and STR allelic ladders for 15 STR loci was used. Amplitaq Gold polymerase provided within the Identifiler kit and standard PCR cycling conditions were performed as control. Three newly bio-engineer modified fast polymerase MyTaq, Phusion and Q5 were used with each corresponding rapid cycling conditions. The amplification products were capillary electrophorese detected by using AB3500XL, and STR genotyping and chimerism as analyzed by using GeneMapper IDX software.
Results: All the four kinds of polymerase can be used for STR-PCR and genotyping. For the analysis of simulate mixed chimerism samples, the observation value were all in good consistency with expectations values for all of the four polymerase. . The STR-PCR cycling time for MyTaq, Phusion and Q5 were about 30 minutes, considerably less than 3 hours when using Amplitaq Gold polymerase. For the 3 kinds of fast polymerases, the Q5 polymerase showed the best balanced amplification efficiency for all of the 15 STR loci. The amplification product of Phusion and Q5 polymerases don't have the non-template addition "A" tail due to lack of adenylate activity, thus theoretically completely eliminated the problem of incomplete adenylation. But the corresponding allelic ladders without "A" tail needed for STR genotyping, which must be specially made. The MyTaq polymerase has extremely efficient of adenylate activity and showed complete adenylation in all of 8 crude DNA samples extracted from fingernail, actually fully resolved the problem of incomplete adenylation when compared with Amplitaq Gold polymerase.
Summary / Conclusion: We developed a fast STR-PCR protocol using MyTaq polymerase that enables rapid and high quality STR genotyping, decreased the STR-PCR time from 3 hours to 30 minutes and resolved the problem of incomplete adenylation. It could significantly shorten the chimeric analysis and clinical reports time.

THE EXPERIENCE OF PEDIATRIC ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RESULTS FROM A SINGLE CENTER AT MIDDLE ANATOLIA, TURKEY
T Patıroğlu[1*], M Karakukcu[1], E Unal [1], F Mutlu[1], B Isık[1], E Yılmaz[1], B Isık[1], M Ozdemir[1]
[1]Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: HLA matching plays a major role in determining the outcome of the hematopoetic stem cell transplantation (HSCT). An optimal donor for an allogeneic HSCT is genotypically HLA identical sibling of the patient. If the patient has no siblings, an extended family typing may identify HLA phenotypically matched relatives. Such donors usually share on haplotype with the patient and another one is matched or partially matched with the patient.
Aims: We would like to share our allogeneic HSCT experince at Pediatric

HSCT unit of Erciyes University.
Methods: Clinical and laboratary finding of our cohort is revisited
Results: During the last 2 years 35 allogeneic HSCT were performed in our clinic. Out of 35 patients, 10 with aplastic anemia (3 of them Fanconi), 6 were with thalassemia, 5 with AML, 4 with ALL, 2 with mucopolysaccaridosis type-I, 2 with familial hemophagocytic lymphohistiocytosis, 2 with CML, 2 with primary immune deficiency (1 ADA deficiency, 1 CD4 lymphopenia associated with NHL), 1 with Griscelli syndrome, 1 with relapsed Hodgkin's disease, respectively.Three of 35 HSCT were sibling umbilical cord blood transplantation, 3 haploidenitical transplantation (1 from mother, 2 from father), 1 unrelated donor with 1 mismatch allel of HLA-A. Related donors were one mother, one aunt, three fathers, and 22 siblings respectively. However, each of the two sibling donors had 1 mismatch allel of HLA-DR. All of patients except one transplanted from unrelated donor had myeloid engraftment at the median days of 18 (range: 12-35) and platelet engraftment at the median days of 32 (range: 20-51). In 4 patients mixed chimerism was detected in early period of HSCT but was soon followed by full donor chimerism. The patient with relapsed ALL and graft failure underwent alfa-beta T cell depleted haploidentical HSCT from father two months after the first unrelated HSCT. Although a patient with Griscelli syndrome died because of pneumonia, all the others survived.
Summary / Conclusion: In conclusion, we observed that allogeneic HSCT is a good substitution for relapsed hemato-oncological malignancies. Alfa-beta T cell depleted haploidentical can be a suitable source for patients with high risks.

B1707

THE FEASIBILITY OF ALLOGENEIC STEM-CELL TRANSPLANTATION IN THERAPY RELATED MYELOID NEOPLASMS: A RETROSPECTIVE ANALYSIS OF A SINGLE CENTRE EXPERIENCE

BVannata[1*], L Laurenti[1], N Piccirillo[1], F Sorà [1], P Chiusolo[1], J Bajer[2], M Voso[1], G Leone[1], S Sica[1]
[1]Hematology, [2]Università Cattolica del Sacro Cuore di Roma, Roma, Italy

Background: Therapy-related myeloid neoplasms (t-MN) include, according to the 2008 WHO classification, acute myeloid leukemia (t-AML), myelodisplastic syndrome (t-MDS) and myelodysplastic/myeloproliferative neoplasms occurring after chemo- and/or radiotherapy administered to treat a previous neoplasm or a non-neoplastic disorder. t-MN display a 5-year overall survival (OS) of less than 10%, worse than the *de novo* counterpart. The only curative option in suitable patients (pts) is allogeneic stem cell transplantation (aSCT). Literature data demonstrate an emerging role for hypomethylating agents instead of chemotherapy as a bridge to aSCT in *de novo* MDS and low-blast count AML, but scanty data is available for t-MN.
Aims: Our retrospective study has the purpose to analyse the feasibility of aSCT in t-MN, which are characterized by unfavourable clinical and biological prognostic features and to investigate the role of induction therapy before aSCT.
Methods: Our analysis includes 18 t-MN pts (11 females, 7 males) of a median age of 52.5 years (range 29-64), observed at our Hematology Department, who underwent aSCT between September 1999 and June 2012. All pts were treated for a primary neoplasm with chemo- and/or radiotherapy (median 2 lines of treatment). Primary neoplasms consisted of 7 hematologic malignancies (2 B-CLL/SLL, 1 low-grade NHL, 3 DLBCL, 1 HL) and 11 solid tumors, mainly breast cancer (8/11). The median time from the first treatment to t-MN was 33 months (range, 12-144 months). Eight pts had a t-AML, 9 t-MDS and 1 Ph+ t-ALL. Karyotype was available for 15/18 patients: 5 had a normal karyotype, 2 abnormalities of chromosome7, 2 complex karyotypes, 1 monosomy16/+13, 1 del(11)(q14;q23), 1 t(9;22), 1 t(9;16), 1 del(20) and 1 was hypodiploid. Median hematopoietic cell transplantation-comorbidity index (HCT-CI) was 3 (range 3-5), 7/18 pts had an HCT-CI >3. Fourteen pts received an induction treatment before aSCT, consisting of chemotherapy (10 pts) , 5-azacitidine (3 pts), or both (1 pt). Six pts (33.3%) were in complete remission (CR) at the time of aSCT. The conditioning regimen was myeloablative (MA) in 27.7% of pts (BuCy2). GVHD prophylaxis included cyclosporine, Methotrexate and MMF. All 10 pts receiving matched unrelated donor (MUD) aSCT were treated with additional immunosuppressive therapy.
Results: Three pts died within one month after aSCT (16.6%). Early deaths were attributable to infectious complications and acute GVHD. In 15 pts surviving at least 100 days after aSCT the response rate was 80%. Two pts relapsed at 6 and 12 months after aSCT, respectively, and both died with active disease, similar to two pts with refractory disease. Five pts died due to infectious complications (4/15) and GVHD (1/15) later than 100 days post-aSCT, respectively. At a median follow-up of 20.5 months from the diagnosis (range 9-149), 6 pts are alive in cCR (33.3 %). When analysing OS only status at transplant (responders, refractory and untreated) resulted significant (P=0.03), while other factors, as cytogenetic risk, conditioning regimen, source of stem cell, type of primary neoplasia, number of previous lines of therapy, disease status at aSCT did not play a significant role.
Summary / Conclusion: Our study confirm that aSCT is the only curative option in t-MN, although a better patient selection may reduce early transplant mortality. Of note, our data show that 60% of pts who underwent transplant in CR or were previously untreated for t-MN are alive and in CR at median of 102 months (range, 16-132 months).

B1708

G-CSF BIOSIMILAR (ZARZIO®) MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

A Zabalza[1*], P Anton[1],M Antelo[1], S Zalba[1], M Aznar[1], E Vicente[1], I Aoiz[1], E Olavarria[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Recently, a new G-CSF biosimilar (Bio-filgastrim, Zarzio®, Sandoz) has been approved by the European Medicines Agency for autologous PBSC mobilization. However, this authorization was based on comparable safety and efficacy to the reference product (Neupogen®) in the management of chemotherapy-induced neutropenia, with no data available regarding PBSC mobilization in patients with Hematological Malignancies.
Aims: Since 2011, Zarzio® has been approved in our institution for all authorized indications including PBSC mobilization in autologous SCT. A total of 36 patients mobilized with bio-filgastrim were included in this retrospective study, and were compared with the previous 36 patients mobilized with reference filgastrim.
Methods: Neupogen® was given at a dose of 10 µg/kg/day while Zarzio® was given at a dose of 5 or 10 µg /kg/day (depending on the CD34 target). Both were given during 5 or 6 days with the first apheresis scheduled for day 5. The target CD34+ cell dose was 2 x 10^6/kg recipient body weight in Lymphomas and 4 x 10^6/Kg in Myelomas.
Results: Median age was 57 years (range 19 - 72). The median duration of G-CSF treatment was 5 days (5-6) and the median number of apheresis was 1 (1-3) in both groups equally. Zarzio® seemed to have been well tolerated with no long-term adverse events reported in our series. Side effects included mild bone/muscle pain in both groups. There were no significant differences in mobilization outcomes between groups receiving the bio-filgastrim or reference filgastrim. The median number of circulating CD34+/L at day 5 was 41.4x10^9 (range 3.2 - 256.5) and 19.6 x 10^9 (range 1.8 - 119.1) respectively (P=0.01). The median number of CD34+/kg was 4.64 x 10^6 (2.04 -13.42) and 3.38 x 10^6 (1.04 -10.98) in both groups (P=ns). All 36 patients (100%) in the bio-filgastrim group achieved the target CD34 cell dose compared to 28/36 (78%) patients in the control group (P<0.001). To date, 26 patients mobilized with bio-filgastrim and 27 with reference filgastrim, have undergone autologous SCT. All patients engrafted within a median of 13 days (10 - 19) for the bio-filgastrim group and 11 days (10-17) for the control group. Platelet engraftment was at 19 and 18 days respectively.
Summary / Conclusion: In our group of patients, our findings suggest that Zarzio® is well tolerated and safe when compared with Neupogen® for PBSC mobilization before autologous SCT in patients with Hematological Malignancies. However, further studies are required to assess longer-term safety of G-CSF biosimilars.

B1709

G-SCF-ASSOCIATED ADVERSE EVENTS IN PATIENTS WITH MULTIPLE MYELOMA DURING STEM CELL MOBILIZATION

M Nareyko[1*], O Pokrovskaya[1], L Mendeleeva[1], I Galtseva[1], I Kostina[1], E Parovichnikova[1], V Savchenko[1]
[1]National Research Center for Hematology, Moscow, Russian Federation

Background: High-dose chemotherapy followed by autologous stem cell transplantation is the standard care for multiple myeloma (MM) patients fit enough to undergo the procedure. Granulocyte colony-stimulating factor (G-CSF) alone or combined with cyclophosphomide is commonly used to mobilize blood progenitor stem cells to support high-dose therapy with melphalan.
Aims: To define G-CSF-associated adverse events in pts with MM during stem cell mobilization. Also we present here a 60 y.o. male patient with MM who developed a rare complication - acute exacerbation of gout during stem cell mobilization.
Methods: We have analyzed adverse events during stem cell mobilization in 198 pts with MM treated in our center from November 2000 to February 2013. There were 105 male, and 93 female, median age 52,5 (range 26-68). In mobilization procedure pts received CY 4-6 g/m2 followed by daily administration of G-CSF 5 mcg/kg or G-CSF 10 mcg/kg alone.
Results: The most common G-SCF-associated adverse events were bone pain (46%), myalgia (32%), low-grade pyrexia (24%) and vascular events (8,3%). One pt developed ischemic stroke on the third day of G-CSF administration due to thrombosis of medial cerebral artery. 4 pts (2%) had a previous history of gout and only 1 pt developed acute exacerbation of gout during stem cell mobilization. A 60 y.o. man was diagnosed with MM Bence-Jones lambda in June 2012. At the time of diagnosis blood chemistry analysis revealed increased level of uric acid (up to 495 mkmol/l). The pt was treated with 7 cycles of bortezomib+cyclophosphomide+dexamethasone (VCD) and after induction therapy achieved very good partial response. After the 1 VCD cycle the first episode of gouty arthritis had appeared. Pain and swelling developed at the 1st left metatarsophalangeal joint. The pt received allopurinol and non-steroidal anti-inflammatory drugs with success. During stem cell mobilization marked swelling of both feet developed on the second day of G-CSF administration. On examination his feet were red, swollen and sharply painful. He had had high-

grade pyrexia for 5 days. Deep vein thrombosis and sepsis were excluded. X-rays of feet revealed minor osteoarthritic changes at the 1st metatarsophalangeal joint of both feet but no chondrocalcinosis. During this period increased levels of uric acid had never been registered. Therapy with non-steroidal anti-inflammatory drugs and allopurinol was prescribed again. General relief of symptoms of gouty arthritis was registered on day 10 of the therapy. Stem cells were successfully collected and in February 2013 autologous stem cell transplantation was performed.
Summary / Conclusion: Acute gout can manifest in context of normal uric acid levels, precipitated by several factors such as dehydration, diet, trauma and drugs. Gout should enter the differential of acute joint pain in pts receiving G-CSF for stem cell mobilization.

B1710
PEG-FILGRASTIM AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION: A SINGLE-CENTRE EXPERIENCE
F Grimaldi[1*], E Madonna[1], S Avilia[1], F Pane[1], A. Risitano[1], G De Rosa[1]
[1]Hematology division, Federico II University, Napoli, Italy

Background: High – dose chemotherapy followed by autologous peripheral blood stem cell transplantation (auto-PBSCT) is considered the standard of care for patients affected by multiple myeloma or relapsing Hodgkin (HL) or Non Hodgkin lymphoma (NHL) with chemosensitive disease. Severe pancytopenia and subsequent febrile neutropenia are well recognized complications of autologous-PBSCT: therefore recombinant hematopoietic colony-stimulating factors (CSF) are currently used to accelerate cellular engraftment after stem cell reinfusion.
Aims: Peg-filgrastim (Peg-G-CSF) is a long-acting pegylated form of filgrastim, that is commonly used after myelosuppressive chemotherapy as single subcutaneous injection, with comparable effect to non Peg-G-CSF. Moreover, several studies have shown activity of Peg-filgrastim on neutrophil recover both after conventional chemotherapy and after auto-PBSCT. For these reasons we performed a retrospective analysis of safety and efficacy of Peg-GCSF in patients who received auto-PBSCT for NHL in our institution from April 2004 to January 2013.
Methods: Fifty-five patients (25 M; 30 F), with a median age of 45 years (r.21–65), were treated with Auto-PBSCT for relapsed NHL. Conditioning schemes used were: BEAM (BCNU 300 mg/m^2 day-6, Ara-C 400 mg/m^2 day -6→-3, VP-16 200 mg/m^2 day -6→-3, Melphalan 140 mg/m^2 day -2) in 28 patients, TEAM (Thiotepa 10 mg/Kg day-7) in 4 patients, FEAM (Fotemustine 150 mg/m2 day -8, -7) in 4 patients and BTM (BCNU 300 mg/m^2 day-6, ThioTepa 150 mg/m^2 day-5→-3, Melphalan 140 mg/m^2 day-2) in 19 patients. All patients received Peg-G-CSF as a single subcutaneous injection at day +1 after stem cell reinfusion. Antimicrobial prophylaxis consisted of levofloxacin 500 mg once daily and fluconazole 400 mg once daily from the first day of chemotherapy; antiviral prophylaxis consisted of acyclovir 5 mg/kg from day +1 and a single infusion of immunoglobulin at a dose of 500 mg/kg on day+1. Neutropenic fever was defined as a temperature >38° on 2 consecutive readings or >38,5° on a single reading. Empirical antibiotic therapy, red blood cell and platelet transfusions were given according to our institutional guidelines. The recovery of platelets (PLTs) and neutrophils (ANC) was considered if superior to 1x10^3/mmc and 20x10^3/mmc, respectively,on two consecutive determinations.
Results: The median time to ANC recovery was 10 days (5–13) and to PLTs engrafment was 13,5 days (4–48); 2 units was the median number of PLT or blood cell transfusions per patient (r.1-10 and 1–5, respectively). Neutropenic fever was observed in 20 patients, and bloodstream infection was documented in 5 of them (3 Gram+/ 2 Gram-). The median number of days of fever was2,5 (r.1–7), with a median time of intravenous antibiotic therapy of 10,5 days (3-21). Two patients died within 100 days from Auto-PBSCT (1 for pulmonary embolism and 1 for blood sepsis due to E. Coli). Oral mucositis was observed in 6 patients, while gastrointestinal mucositis was observed in 24 patients. The median time of hospitalization was of 18 days (r.15-30).
Summary / Conclusion: In our hands, Peg-G-CSF was safe and effective in the management of post auto-PBSCT neutropenia. We did not observe increased incidence of infectious episodes or delayed ANC recovery compared to literature references. However, prospective randomized trials comparing pegylated vs non pegylated G-CSF are needed to finally asses which form of G-CSF should be used in this particular setting of patients.

B1711
AML WITH MYELODYSPLASIA RELATED CHANGES: IMPACT OF CYTOGENETIC ABNORMALITIES ON TRANSPLANT OUTCOME
M Calbacho[1*], S Gómez-Rojas[2], M Blanchard[2], A Vallés[2], P Herrera[2], J García-Gutiérrez[2], J López-Jiménez[2]
[1]Hospital Ramón y Cajal, Madrid, Spain, [2]Hematology, Hospital Ramón y Cajal, Madrid, Spain

Background: Acute myeloid leukaemia with myelodysplatic features (MRC-AML) is a 2008 WHO classification new category which includes both acute myeloid leukemias with morphological features of myelodysplasia and those with a prior history of myelodysplastic syndrome. Compared to other AML types, MRC-AML has a lower rate of complete remission and a poor prognosis. Association with high risk cytogenetic abnormalities seems more significantly related to poor outcome than myelodysplastic features. Role of cytogenetic abnormalities on transplant outcome is not established for MCR-AML patients.
Aims: We report a single centre retrospective analysis of 17 patients who received a stem cell transplant for MRC-AML from 2000 to 2012.
Methods: Male/Female ratio: 13/4. Median age at transplant: 43 years. Type of transplant: autologous: 4/17(24%), allogeneic: 13/17(76%). Donor: sibling: 53,8% (7/13), matched unrelated: 46,2% (6/13) Cytogenetic data: normal: 7 (41%), abnormal: 8 (47%), not available: 2 (12%). Abnormalities: del 5q (3), t(2;3) (1), t(3;11) (1), del Y (1), complex karyotype (1), t(6;19) (1). Patients with del5, del7, t (6;9), complex kariotype, t (2;3) and t (3;11) were assigned to the High Risk group (HR) whereas Standard Risk group (SR) included normal kariotype and del Y. Both groups were comparable except in the type of transplant: all HR patients received alloSCT, meanwhile half SR patients received an alloSCT and the other 50% an autoSCT.
Results: Patients without available cytogenetic analysis were excluded. HR group: 7 (46.6%); SR group: 8 (53.3%). Median follow up from SCT: 8 months (2-96). OS at Day 100 was 70.5% for HR and 62.5% for SR (P=0, 71). Median PFS was 9 months. To date, only 35% remain alive. In HR 2 of 7 patients are alive, 1 with relapsed disease and other in complete remission, both with a follow up of 5 months. In the SR group 4 of 8 patients are alive and with no evidence of disease progression: 2 received allogeneic SCT (follow up of 16 and 7 months) and 2 received an autologous SCT (follow up of 71 and 9 months). Global relapse rate was 13%.
Summary / Conclusion: Cytogenetic abnormalities are one of the most important prognostic factors in MRC-AML. Our review suggests that cytogenetic risk is crucial for a transplant satisfactory result. Outcome in HR cytogenetic patients, even treated with alloSCT, remains dismal. Autologous transplant could be a therapeutic approach in selected MRC-AML with favorable cytogenetic.

B1712
G-CSF BIOSIMILAR (ZARZIO®) STEM CELL MOBILIZATION IN SIBLING HEALTTHY DONORS
M Antelo[1*], A Zabalza[1], P Anton[1], S Zalba[1], M Aznar[1], E Vicente[1], I Aoiz[1], E Olavarria[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: G-CSF mobilized peripheral blood stem cells (PBPC) have became the major source of hematopoietic stem cells for transplantation. Recently, a new G-CSF biosimilar (Bio-filgastrim, Zarzio®, Sandoz) has been approved by the European Medicines Agency for autologous and allogeneic PBSC mobilization. However, this authorization was based on comparable safety and efficacy to the reference filgastrim, (Neupogen®, Amgen) in the management of chemotherapy-induced neutropenia, with no data available regarding PBPC mobilization in healthy donors.
Aims: We present our experience with 9 HLA-identical sibling donors mobilized with Bio-filgastrim that were compared with the previous 9 donors mobilized with filgastrim. Both drugs were given at a dose of 5µg/kg/day for 4 or 5 days with the first apheresis performed on day 5. The target CD34+ cell dose was 5 x 106/kg recipient body weight.
Methods: Both drugs were given at a dose of 5µg/kg/day for 4 or 5 days with the first apheresis performed on day 5. The target CD34+ cell dose was 5 x 106/kg recipient body weight.
Results: Donor median age was 48 years (range 17 - 77). Median duration of G-CSF treatment was 5 days (5-6) and the median number of apheresis was 1 (1-2) in both groups. Side effects included mild bone/muscle pain all patients with no differences between the 2 groups. No immediate serious adverse effects were detected in either group. Bio-filgastrim seemed to have been well tolerated with no long-term adverse events reported.
There were no significant differences in mobilization outcomes between groups receiving the biosimilar or reference filgastrim. The median number of circulating CD34+ cells at day 5 was 69.09 x 10^9/L (24- 114) and 75.2 x 10^9/L (42.3-146.4) respectively. No mobilization failure was observed in either group. The median number of CD34+ cells/kg harvested was 6.8 x 10^6 (4-9.2) and 8.5 x 10^6 (6-14.3) respectively (P=0.12). Seven patients have received PBSC mobilized with bio-filgastrim with no significant side-effects during the infusion. All patients engrafted at a median of 23 days (18 - 28) for the bio-filgastrim group compared with 19 days (12-28) for the reference filgastrim group (P=0.11). Platelets engraftment occurred at 26 and 24 days respectively.
Summary / Conclusion: Our findings suggest that Zarzio® is well tolerated and safe as compared with Neupogen® for PBSC mobilization of HLA-Identical siblings before allogeneic SCT. Given the similar effectiveness and their reduced costs, G-CSF biosimilars may represent a cost-effective alternative for PBSC mobilization. However, further studies are required to assess longer-term safety of G-CSF biosimilars.

B1713

CLINICAL AND LABORATORIAL CHARACTERISTICS PREMOBILIZATION, DURING THE HARVEST AND IN RELATION WITH THE AUTOLOGOUS STEM CELL TRANSPLANTATION OF ALL PATIENTS MOBILIZED USING PLERIXAFOR IN OUR CENTRE

I Orden[1*], J Lozano[1]
[1]Hematología y Hemoterapia, Hospital Universitario Miguel Servet de Zaragoza, Zaragoza, Spain

Background: Plerixafor (AMD3100, Mozobil®) is a CXCR4 antagonist, receptor in the hematopoietic stem cells and its block releases them into the peripheral blood circulation. Plerixafor is the last drug in the list of movilizing agents and has been approved for steady-state mobilization with G-CSF for patients with high risk of mobilization failure.
Aims: Analyze the clinical and laboratorial characteristics before the mobilization and during the autologous hematopoietic stem cell transplantation (autoHSCT), and those in relation with the harvest in all patients mobilized using Plerixafor in our hospital.
Methods: Observational and retrospective study of the patients have been mobilized with Plerixafor in our centre (n=14). We have revised the medical notes of all these patients assessing these parameters: underlying hematological disease, premobilization factors associated with risk of mobilization failure (previous failure, advanced age, bone marrow infiltration by tumor cells, previous chemotherapy with Fludarabine, Melphalan or Lenalidomide, extensive radiotherapy to bone marrow sites and thrombocytopenia), time drug was administered, number of doses, adverse effects, total CD34 cells collected and amount after using Plerixafor, CD34 cells collected by apheresis session after G-CSF alone and after Plerixafor, complications during the product infusion in patients undergoing autoHSCT, time to platelet engraftment and discharge day. Mobilization regimen with G-CSF alone was 20 /kg daily. Plerixafor was administered at the standard dose of 0.24 mg/kg at 12±2 h before apheresis and concurrently with G-CSF.
Results: The underlying hematological disease was NHL (n=3), HD (n=4) and MM (n=7). Eleven (78%) showed premobilization factors associated with risk of mobilization failure. The total number of apheresis cycles after Plerixafor was 17 because three patients needed two apheresis cycles to collect the CD34 /kg goal. The time when this drug was administered was pre-emptive treatment in first apheresis (n=6), rescue during first apheresis (n=3), pre-emptive in second apheresis (n=7), and rescue during second apheresis (n=1). The average number of Plerixafor doses per apheresis cycle was 1.7 (range: 1-3). Only two administrations (11%) produced adverse effects and both were slight. The median CD34/kg collected in all apheresis sessions, including mobilization with G-CSF alone, was 1.9 (0.3-8.1). The median amount of CD34 cells per apheresis cycle collected after Plerixafor was 94% (47-100). Using G-CSF alone the median of CD34 per apheresis session was 0.3 (0.05-0.7) and after Plerixafor use 0.8 (0.3-8.1). One patient (7%) didn't get enough product to go to autoHSCT. In patients (n=12) undergoing autoHSCT nine (75%) suffered from complications during the product infusion, six (66%) were slight and three (33%) mild. The median time to platelet engraftment was 13 days after infusion (10-29), and the median time to the discharge was 17 days (14-31). One patient died during the autoHSCT and so these data are not avalaible.
Summary / Conclusion: Plerixafor is an effective and safety drug to mobilize patients with high risk of mobilization failure or after previous mobilization failure with any regimen. The amount of CD34 cells collected in this kind of patients after Plerixafor undergo the same volume leukapheresis seems to be higher than G-CSF alone. In spite of the clinical characteristics of these patients the engraftment and the discharge time doesn't seem to be later after autoHSCT compared to that patients mobilized with G-CSF alone althought no current data are available.

B1714

INVESTIGATION ON THE VARIATION OF PERIPHERAL BLOOD CD34+ CELLS DURING THE HEMATOPOIETIC STEM CELL MOBILIZATION AND ITS INFLUENCE ON THE COLLECTION: DATA ANALYSIS IN A CHINESE POPULATION

Y Tan[1], X Liu[1], C Wang[1], S Gao[1*], W Li[1]
[1]Tumor center, Fisrt Hospital of Jilin University, changchun, China

Background: Effective mobilization and collection of hematopoietic stem cells were the key factors in peripheral blood hematopoietic stem cell transplantation. The number of $CD34^+$ cells number as well as mononuclear cells was the usual indicator used to predict the acquisition effect and to seize the right time of collection. But there were few reports about the variation of $CD34^+$ cells number during the course of the mobilization in Chinese population.
Aims: To investigate the variation of peripheral blood $CD34^+$ cells during the hematopoietic stem cell mobilization in Chinese population, and to determine its influence on the collecting timing and acquisition effect.
Methods: 27 cases of peripheral blood hematopoietic stem cell mobilization and collection from 2011 April to 2011 December were analyzed, including 13 autologous cases mobilized with chemotherapy combined with granulocyte colony-stimulating factor (G-CSF) 10 $\mu g \cdot kg^{-1} \cdot d^{-1}$, and 14 cases of healthy donor mobilized with only G-SCF 7.5 $\mu g \cdot kg^{-1} \cdot d^{-1}$. Peripheral blood $CD34^+$ cells count was monitored, and its correlation with the yield of mononuclear cells (MNCs) and $CD34^+$ cells were analyzed. Informed consent was obtained before the start of the mobilization.
Results: $6.59\pm2.26\times10^8$/kg/recipients body weight MNCs and $4.38\pm2.47\times106$/kg/recipient body weight $CD34^+$ cells were obtained in healthy donor, $6.58\pm3.72\times10^8$/kg MNCs and $3.98\pm3.06\times10^6$/kg $CD34^+$ cells were obtained in autologous cases, there was only 1 failure in autologous cases. The peak of peripheral blood $CD34^+$ cells in autologous cases was appeared in day 4 after the treatment of G-CSF, and in healthy donors the count of peripheral blood CD34+ cells on fifth day was still in ascendant phase. The percentage and absolute value of peripheral blood CD34+ cells were the only indicators positive correlated with the $CD34^+$ cells/kg in the collection products. The cases ratio of $CD34^+$ cells$\geq2\times10^6$/kg in the products of single collection was up to 76%(16/21) in the cases with peripheral blood $CD34^+$ cells absolute value greater than 20/μL.
Summary / Conclusion: The peripheral blood $CD34^+$ cells count was good monitoring indicators in hematopoietic stem cell mobilization and collection, $CD34^+$ cell absolute value≥20/μl could be used as collection threshold.

B1715

LONG-TERM DISEASE-FREE SURVIVAL IN MANTLE CELL LYMPHOMA (MCL) PATIENTS FOLLOWING REDUCED INTENSITY CONDITIONING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (RIC ALLO-HSCT)

V Constantinou[1], I Batsis[1*], P Kaloyannidis[1], D Mallouri[1], E Yannaki[1], M Iskas[1], I Sakellari[1], A Anagnostopoulos[1]
[1]Hematology-BMT Unit, George Papanikolaou General Hospital, Thessaloniki, Greece

Background: MCL represents an aggressive and difficult to cure disease. Current practice for patients with chemosensitive MCL includes high-dose therapy followed by autologous hematopoietic rescue (autologous HSCT). However, this treatment modality does not offer long-term survival since the majority of patients will experience a, very poor prognosis, relapse. Allogeneic HSCT appears to be the only curative approach for MCL, however, this outcome is being compromised by the greater risk of non-relapse mortality.
Aims: Given the limited evidence existing for the role of RIC allo-HSCT as consolidation therapy for MCL patients, we retrospectively analyzed the outcome of RIC-HSCTs performed at our center, during 2001-2011, in 8 MCL patients. RIC-HSCT was administered either as consolidation therapy in selected patients in first complete remission (CR1) or in chemosensitive relapse, aiming to provide the benefit of the reported, although still conflicting, graft versus MCL (GvMCL) effect.
Methods: All patients (n=8) were males who presented with advanced disease stage at diagnosis (stage IV, 8/8 / bone marrow involvement, 7/8). The median age at diagnosis was 47.5 years (37-63). They all received multi-agent chemotherapy as induction therapy and achieved complete remission (CR1). They were transplanted at a median time from diagnosis 19.5 months (9-41), in CR1(4/8) or CR2 (4/8). Two of the patients transplanted in CR2 had previously received autologous HSCT as consolidation therapy at CR1 and relapsed, 11 and 18 months post auto-HSCT. The median age at allo transplant was 48.5 years (40-64) and the median HCT comorbidity index (HCT-CI) 1 (0-1). All patients received reduced intensity conditioning (fludarabine and cyclophosphamide) and they were grafted with peripheral blood stem cells (8/8) from sibling (6/8) or matched unrelated donors (2/8) (MUD). Patients who had sibling donors received cyclosporine + mycophenolate mofetil (MMF) as anti-graft versus host disease (GvHD) prophylaxis, whereas MUD recipients received tacrolimus + MMF.
Results: With a median follow up of 74.5 months (15-122) after allo-HSCT, none of these patients relapsed and 7/8 are alive (disease free survival and overall survival 87.5%). The patient who died succumbed to, refractory to many lines of therapy, chronic GvHD, 15 months post transplant (TRM 12.5%). Two patients developed steroid-responsive acute GvHD (2/8), whereas all of them developed extensive chronic GvHD (100%). In 4/7 alive patients, chronic GvHD resolved after therapy, but three patients are still under immunosuppressive therapy.
Summary / Conclusion: Despite the limited number of patients in this study, our results suggest that RIC-HSCT is a potentially suitable treatment modality for selected MCL patients with chemosensitive disease. Especially in young patients in CR1 and with low HCT-CI, RIC-HCT could become the preferred postremission consolidation therapy, since a strong GvMCL effect is implicated and the survival rates seem to override the rates of non relapse mortality. Safer conclusions for the efficacy of RIC allo-HSCT in the treatment of MCL, however, can be only drawn by large prospective randomized trials.

B1716

FOTEMUSTINE BASED PLATFORM AS CONDITIONING REGIMEN IN RELAPSED NON HODGKIN'S LYMPHOMA PATIENTS ELIGIBLE FOR AUTOLOGOUS STEM CELL TRANSPLANT

F Saltarelli[1*], A Ferrari[1], M Bianchi[1], M Piedimonte[1], V Naso[1], R Porrini[1], B Veggia[1], E Conte[1], M Cox[1], E Montefusco[1]

[1]Hematology, S.Andrea Hospital, "Sapienza" University, Rome, Rome, Italy

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) represents currently the standard of treatment for patients with relapsed/refractory and chemosensitive non Hodgkin's lymphoma (NHL).
Aims: The most used conditioning regimen in NHL is the carmustine containing protocol BEAM. Chemotherapy toxicity is associated with early and late onset complications. Fotemustine is a third generation chloroethyl-nitrosurea that in previous studies showed a better toxicity profile and good results in terms of survival compared to carmustine.
Methods: In our study, we used a fotemustine based regimen as conditioning pre ASCT in 6 patients with relapsed NHL. 3 patients were affected by aggressive NHL and 3 patients were affected by follicular lymphoma. Salvage chemotherapy was R-DHAP in 5 patients and R-IEV in 1 patient. After salvage treatment 4 patients were in complete remission (CR) and 2 patients were in partial remission (PR). All patients received FEAM regimen according to the following schedule: fotemustine 150 mg/m2 on days -7, -6, etoposide 200 mg/m2 and aracytin 400 mg/m2 on days -5, -4, -3, -2 and melphalan 140 mg/m2 on day-1. In all patients CD34+ cells source was peripheral blood and the median number of infused cells per patient was 2.75 x 10^6 CD34+/Kg (range 2-5.5).
Results: Median time to neutrophil recovery (>500 x 10^9/l) was of 8.5 days (range 5-11), median platelets recovery (>20.000 x 10^9/l) was of 9 days (range 4-20).All patients required platelets support and 2 patients also received RBCs infusions. 3 out of 6 patients experienced G3/G4 mucositis. Neutropenic fever occurred in 5 patients due to bacterial sepsis. Median follow-up was 10.5 months (range 4-13). Transplant related mortality at 100 days was 0%. Currently, 5 patients are in CR and 1 patient is in PR.
Summary / Conclusion: In our experience, fotemustine containing regimen showed an acceptable acute toxicity profile. In all patients, hemopoietic engraftment occured within the expected timing. Considering the short follow-up of our study, FEAM efficacy in terms of long term outcome and survival will require a longer observation to be evaluated.

B1717

EFFICACY AND TOXICITY OF BUMEL CONDITIONING REGIMEN IN AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA

I Lucea[1*], M Tenorio[1], I Saavedra[1], N Revilla[1], P Herrera[1], M Blanchard[1], V Garcia-Gutierrez[1], M Calbacho[1], J Lopez-Jimenez[1]
[1]Hematology, Ramon y Cajal, Madrid, Spain

Background: Autologous stem cell transplantation (SCT) is still the standard treatment for patients with multiple myeloma (MM) who are candidates for high dose chemotherapy regimens. The classic conditioning regimen is Melphalan 200 mg/$m^{2.}$ The combination of Melphalan and oral Busulphan leads to increased disease-free survival with the counterpart of a greater toxicity, being sinusoidal obstruction syndrome (SOS) the most limiting complication. Intravenous Busulphan appears to maintain good responses whilst decreasing the toxicity associated with the oral formulation.
Aims: To evaluate the security of Busulphan-Melphalan (BUMEL) intravenous combination as a conditioning regimen for autologous stem cell transplantation (ASCT) in patients with multiple myeloma.
Methods: Conditioning regimen: BUMEL (Melphalan 140 mg/m^2 day -2 plus Busulphan 3.2 mg/Kg once daily days -5, -4 and -3). Patients: n=10. Average age: 56 years (range 39-66). First ASCT: 1; second ASCT: 9. Status pre-ASCT: complete remission (CR): 1 (10%), very good partial response (VGPR): 2 (20%), partial response (RP): 6 (60%), EE: 1 (10%). All of them received pegilated G-CSF on day +5. Stem cells were obtained after G-CSF mobilization. Average CD34+ cells: 2.24x10^6/Kg (range: 1.9-3.5).
Results: Neutrophil and platelet engraftment time were 11 (range: 10-13) and 13(range: 10-15) days respectively, with nil engraftment failures. TRM was 0% and OS at 375 days was 100%. The regimen had good tolerability (table 1). The only grade 3-4 toxicity found was mucositis which affected 3 patients (43%). Other important complications included 2 proven IFI (29%). Average length of hospitalization was 25 days (range: 16-44). Disease status evaluation at day +90 in 8 patients showed: 2 CRs (pre-ASCT status was PR and VGPR), 4 CR and 2 PR.
Summary / Conclusions: BUMEL conditioning regimen with unique daily dose of intravenous Busulphan was a safe option, even for patients submitted to a second ASCT. Our experience agrees with the published literature data revealing an effective and poor toxicity regimen. However, overall survival evaluation of BUMEL in prospective studies is still pending.

B1718

SALVAGE HEMATOPOIETIC STEM CELL TRANSPLANTATION WITHOUT CONDITIONING REGIMEN FOLLOWED BY CYCLOPHOSPHAMIDE AND MESENCHYMAL STEM CELLS (MSC) AS GRAFT-VERSUS-HOST DISEASE (GVHD) PROPHYLAXIS

M Drokov[1*], E Parovichnikova [2], L Kuzmina [1], G Galstian [3], E Urnova[1], A Pavlova[1], G Klyasova[4], V Savchenko[1]
[1]Bone Marrow Transplant Department, [2]National Research Center for Hematology, Moscow, Russian Federation, [3]Intensive care unit, [4]Microbiology department, National Research Center for Hematology, Moscow, Russian Federation

Background: Sometimes in clinical practice we have to break the canonical laws of HSCT regarding conditioning regimens, immunosupression protocols and inclusion criteria (f.e., absence of full blow infections). Transplant related mortality is strictly associated with these rules. But nowadays, new options appeared (such as cyclophosphamide (CY) as single agent for GVHD prophylaxis: Luznik et al., 2010) allowing us to be more flexible and confident in critical decisions.
Aims: We report here a 51-years-old man in 1st molecular CR of acute myeloid leukemia (AML) with t(8;21) who developed extremely severe and prolonged bone marrow aplasia (WBC<0.05x10^9/L more than 25 days), confirmed by threphanobiopsy, after consolidation with intermediate dose of Ara-C (1g/m^2 bid 1-3 d) and Mitoxantrone (10 mg/m^2 3-5 d) During that period he developed poorly controlled invasive aspergillosis (treated with voriconazole and caspofungin), Pseudomonas aeruginosa's sepsis.
Despite severe infections as salvage-therapy, he was transplanted from his HLA-identical sibling donor on day 30 after consolidation course. Bone marrow was infused in intensive care unit where the patient was transferred due to altered consciousness. There was no conditioning regimen and standard immunosuppression during post transplant period, except CY given at dose 50 mg/kg on day +3 after HSCT.
Results: WBC recovered at day +19. On day +20, 1*10^6/kg of MSC were infused for acute GVHD prophylaxis. At day +30 85% of donor chimerism was detected in the bone marrow. His infection complications slowly regressed and at day + 30 the patient had no fever.
At day +48 after BMT the patient developed aGVHD with skin and liver involvement (stage 2). After initiation of cyclosporine A (CSA) all aGVHD signs fully regressed. At day + 90 the patient was discharged from the hospital with full donor chimerism.
Summary / Conclusion: So, our case demonstrates, that 1) HSCT without conditioning regimen is possible if the patient has prolonged and profound aplasia after chemotherapy; 2) only WBC recovery due to HSCT made it possible to control infection; 3) CY and MSC as sole GVHD prophylaxis can be very effective in patients in whom standard immunosuppression is contraindicated.

B1719

CORD BLOOD TRANSPLANTATION FOLLOWING HAPLOIDENTICAL DONOR LYMPHOCYTE INFUSION IN A CASE OF REFRACTORY T-CELL ACUTE LYMPHOCYTIC LEUKEMIA; A NEW CONCEPT

H Yagasaki[1*], M Kato[1], H Shichino[1], M Chin[1], H Mugishima[1]
[1]Pediatrics, Nihon University, Tokyo, Japan

Background: Although a potent graft-versus-leukemia (GVL) effect is expected to work in haploidentical stem cell transplantation, fatal alloreactive complications such as graft-versus-host disease (GVHD) remain major obstacles in such patients. In contrast, relapse is a major concern in patients who receive cord blood transplantation (CBT).
Aims: To improve the outcome in chemo-refractory pediatric leukemia, we developed a new method incorporating haploidentical donor lymphocyte infusion (DLI) prior to CBT. The study was approved by the institution review board of Nihon University Itabashi Hospital.Written informed consent was obtained for parents of the patient in accordance with the Declaration of Helsinki.
Methods: The patient was a 5-year-old boy with T-cell acute lymphocytic leukemia who relapsed just before commencing maintenance therapy. He did not respond to various types of chemotherapy, and thus, a potent GVL effect was deemed necessary. Our new concept in the current study is to cause a short-term pure GVL to eradicate the leukemic cells using haploidentical lymphocytes, and then replace them with less alloreactive cord blood. The first conditioning step consisted of fludarabine (30 mg/m^2/day, day -15 to -12), cytarabine (2 g/m^2/day, day -15 to -12) and cyclophosphamide (60 mg/kg/day, day -11). At day -9, the patient received unmanipulated DLI from a HLA 3 loci mismatched related donor (father). The infused CD3+ T-cell number was 2.7 x 10^7/kg. At days -2 and -1, the patient received the second conditioning with total body irradiation (3 Gy/day) and dexamethasone to eliminate the haploidentical donor lymphocytes and prevent rejection of the stem cell graft. At day 0, the patient underwent HLA 1 locus (DR) mismatched CBT. The infused cell number was 6.5 x 10^7/kg. Cyclosporine A (CsA) with short-term methotrexate was used for GVHD prophylaxis.
Results: At 3 days following DLI, he developed a high-grade fever, severe diarrhea and skin eruption, symptoms similar to acute GVHD. Thereafter, his general status worsened and he developed disseminated intravascular coagulation. At day -2, haploidentical donor lymphocytes were present in the bone marrow (donor type: 12.2%, recipient type 87.8%) and peripheral blood (donor type: 23.5%, recipient type 76.5%). After the second conditioning, his general status and laboratory data immediately improved. Since no alloreactive signs such as acute GVHD were found after CBT, CsA was tapered off at day 17. Donor-type neutrophil engraftment was observed at day 22; however, a leukemic blast emerged at the same time. Thereafter, the leukemic blast count increased rapidly and the patient died at day 56.
Summary / Conclusion: Our method was similar to the 2-step technique pre-

viously reported by Grosso D et al. Since the patient achieved donor-type engraftment and showed no post-transplant complications, the method was deemed feasible. Nevertheless, the anti-leukemic effect was insufficient to eradicate the malignant clone in this patient. This short-term GVL effect (from days -9 to -3) might therefore have been too short to kill the residual blasts, but since the haploidentical lymphocytes induced severe GVHD-like organ damage, elongation of the incubation time seemed dangerous. The efficacy of this new approach requires detailed evaluation in more patients.

B1720

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN RELAPSED OR REFRACTORY AGGRESSIVE NON HODGKIN LYMPHOMA WITH ACTIVE DISEASE

A Stasia[1*], S Bozzani[1], M Parma[2], P Pioltelli[2]
[1]Ospedale San Gerardo Monza, Università Milano Bicocca, [2]Ospedale San Gerardo Monza, Monza, Italy

Background: According to the current guidelines an autologous hematopoietic stem cell transplant (HSCT) is considered the best choice as salvage for aggressive non Hodgking lymphomas relapsed or refractory (r/r) to standard treatment. Allogeneic approach seems to be harmful in fact it's proposed as a second line treatment, due to presence of GvHD and a heavier transplant related mortality (TRM) now its role is limited as a third line for the restricted number of patients still eligible after a long history of aggressive chemotherapy. Nevertheless Autologous HSCT requires a useful stem cell harvest and is precluded for the poor mobilizers, accounting for the 25% of the candidates; moreover though it can rescues 45% of chemo-sensitive patients its effectiveness falls to 10-20 % for the refractory ones. The disease status at transplant is the most relevant factor influencing the disease free and overall survival: patients with active disease usually die early (within 6 months) due to progression or relapse. For these r/r patients an early allogeneic HSCT could be the better choice.
Aims: We report a small series of patients (n=9) with r/r aggressive non Hodgkin lymphoma that undergo allogenic HSCT with active disease.
Methods: Our series included 4 diffuse large B cell (DBLCL), one of them was HIV+, 2 peripheral blood T cell (PTCL), 1 mediastinal lymphoblastic B cell,1 mantle cell (MCL), 1 T Angioimmunoblastic. All the patients were refractory or relapsed after standard treatment and have a relevant disease burden assessed by clinical or histological features and CT-PETscan, 4 patients previously undergone autologous-SCT. Five patients received a reduced intensity conditioning course (Tiothepa-Flu-Cy with or without rituximab) and the other 3 received a myeloablative course (BuCy or BuFlu or Tiothepa-BuCy). Patients were allografted from HLA identical donors related (n=5) or unrelated (n=2) or haploidentical related donor (n=1).
Results: All patient experienced III-IV degree of mucositis and 1 patient had a major infectious episode, nevertheless all reached a good engraftment and were in complete remission (CR) at the hospital discharge. The mediastinal lymphoma patient relapse early after the transplant and died due to relapsed disease. Two patient (1 PTCL and the HIV+ DBLCL) relapsed early too but were rescued with tapering of immunosuppressive treatment, without chemotherapy nor DLI infusion.After a median follow up of 18 months (range 2-33 months) 6 patients are alive in CR, 2 patients died, in CR, due to hemorrhagic cystitis and cerebral hemorrhage. Only one patient developed a chronic GvHD with sclerodermic features but limitated. The ORR is 100% (9/9 CR).
Summary / Conclusion: We didn't find any difference in toxicity among patients that previous undergone or not autologous SCT. Despite the short follow-up and the small number, the clinical course of our patients enlighten a major role of the immunological pathway to induce and maintain the disease remission by a graft versus lymphoma effect. It suggests that allogeneic transplant is a suitable and feasible choice as second-line treatment in relapsed or refractory lymphoma, instead of autologous HSCT.

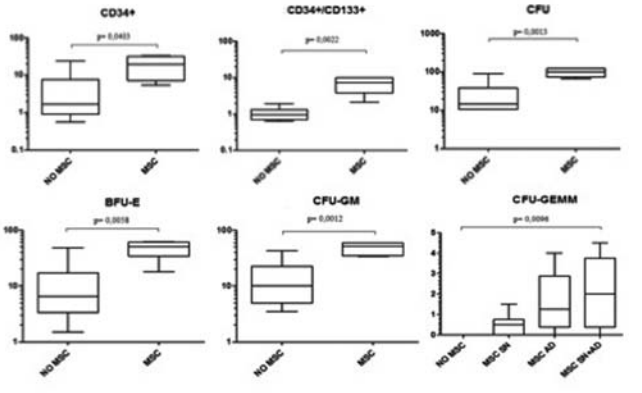
Hematopoiesis, stem cells and microenvironment

B1721

COMBINED EFFECTS OF MESENCHYMAL STROMAL CELLS (MSC) AND STIMULATORY CYTOKINES ON THE *ex vivo* GROWTH OF UMBILICAL CORD BLOOD HEMATOPOIETIC PROGENITOR CELLS (UCB-HPC).

A Di Palma[1*], S Perucca[1], A Neva[2], R Verardi[2], C Skert[1], R Ribolla[1], M Malagola[1], S Braga[2], A Bianchetti[2], C Bergonzi[1], F Cattina[1], E Alghisi[1], V Cancelli[1], S Bernardi[1], M Marini[2], C Almici[2], D Russo[1]
[1]Chair of Haematology, Unit of Blood Diseases and Cell Therapies, University of Brescia, [2]Laboratorio Manipolazione e Criopreservazione delle Cellule Staminali, A.O. Spedali Civili, Brescia, Italy

Background: Mesenchymal stromal cells (MSC) are a component of the hematopoietic niche. Due to their ability to support UCB-HPC expansion, MSC can be used for *ex vivo* experiments, in order to enhance the engraftment of adult patients who underwent UCB allogeneic stem cell transplantation (UCB-allo-SCT).
Aims: To set-up MSC and UCB-HPC co-culture experiments in order to better support UCB-allo-SCT in adult patients.
Methods: We have analyzed six previously frozen units of UCB. Cells were cultured in a serum free medium containing three different cytokines: granulocyte colony-stimulating factor (G-CSF), stem cell factor (SCF) and thrombopoietin (TPO), either with or without a layer of human bone marrow MSC. After 10 days we have evaluated the expansion rate of harvested cells grown with MSC both in suspension and directly adherent to the mesenchymal layer, and also of those grown without MSC. We have studied the immunophenotype of each population with a flow cytometry panel of CD45-FITC, CD34-PE, CD133-APC and 7-AAD. Furthermore the clonogenic capacity of these populations has been evaluated after a further 14 days culture in methylcellulose.



Labels:
NO MSC: colture of UCB-HPC in presence of cytokines only
MSC: co-colture of MSC+UCB-HPC in presence of cytokines
MSC SN: supernatant fraction of the co-colture MSC+UCB-HPC
MSC AD: adherent fraction of the co-colture MSC+UCB-HPC
MSC SN+AD: superanatant and adherent fraction of the co-colture MSC+UCB-HPC

Results: Ten days after seeding, a2,27-fold increase (range 0,80-15,93) in CD34+ cells and a1,04-fold increase (range 0,22-8,75) in CD34+/CD133+ cells have been obtained by cells cultured in absence of MSC. On the other hand, in cells co-cultured with MSC we have obtained a 17,14-fold increase (range7,77-33,26) in CD34+ cells and a4,87-fold increase (range1,94-9,86) in CD34+/CD133+ cells. Clonogenic assay confirms our data: we have registered a higher number of colony forming units (CFU) in UCB cells co-cultured with MSC, in comparison with cells grown without the MSC layer (respectively median of 100,3, range 65-123, and median of 14,8, range 10,5-91; P=0,0013). These data are confirmed in each kind of CFU subpopulation: BFU-E, CFU-GM and CFU-GEMM. No immature CFU have been detected in the cells grown without MSC, in comparison with the large number registered in the cells grown in presence of the MSC layer (P=0,0096). Moreover we have noticed that the number of CFU-GEMM was higher in the population of cells grown adherent to the MSC layer, in comparison with the number of CFU-GEMM registered in the population of cells grown in the supernatant fraction of the co-culture.
Summary / Conclusion: Our study strongly suggests that MSC act in a synergic manner on UCB-HPC expansion, thereby the co-culture of UCB-HPC with MSC and specific cytokines could represent a good approach to overcome the problem of the limited number of UCB-HPC in adult UCB-allo-SCT.

B1722

INDIVIDUAL PECULARITIES OF MULTIPOTENT MESENCHYMAL STROMAL CELLS DERIVED FROM BONE MARROW OF HEALTHY DONORS

N Petinati[1], I Shipounova[1*], N Sats[1], L Kuzmina[2], E Parovichnikova[2], V Savchenko[2], N Drize[1]

[1]Physiology of Hematopoiesis laboratory, [2]Bone marrow transplantation department, National Hematology Research Centre, Moscow, Russian Federation

Background: Multipotent mesenchymal stromal cells (MMSCs) are widely used for immunomodulation in the treatment of autoimmune diseases and graft versus host disease. The effect of such treatment varies significantly. The efficiency of the MMSCs could depend on the individual features of these cells.
Aims: The aim of the study was to investigate the individual characteristics of healthy donors' MMSCs.
Methods: Bone marrow samples were collected from healthy donors during the aspiration for allogeneic hematopoietic stem cell transplantation after informed consent. MMSCs from 50 donors (24 females and 26 males, age 13 – 59, median 32.5 years) were cultured in MEM alfa media supplemented with 10% fetal calf serum. Cumulative MMSCs production was counted after 5 passages. Colony forming unit fibroblast (CFU-F) concentration in bone marrow samples was analyzed in 14 days as additional characteristic of stromal cells. Gene expression level in 1st passage MMSCs was estimated by real-time PCR. The relative expression levels were calculated using the $\Delta\Delta C_t$ meth

Gene	Relative expression level (Mean ± standard error)				
	All	Male	Female	Younger than 32	Older than 32
BMP-4	1.1 ± 0.2	0.9 ± 0.7	1.3 ± 0.0	1.1 ± 0.3	1.0 ± 0.3
FGFR1	0.8 ± 0.1	0.8 ± 0.1	0.8 ± 0.1	0.8 ± 0.1	0.7 ± 0.1
FGFR2	1.7 ± 0.3	1.9 ± 0.4	1.4 ± 0.2	2.2 ± 0.3	1.2 ± 0.3
SPP1	0.8 ± 0.3	0.8 ± 0.6	0.8 ± 0.3	1.0 ± 0.6	0.6 ± 0.3
PPARg	0.5 ± 0.1	0.4 ± 0.1	0.5 ± 0.1	0.3 ± 0.1	0.6 ± 0.1
IL6	3.9 ± 0.8	3.9 ± 1.0	3.9 ± 1.5	4.8 ± 1.5	3.2 ± 1.0
CFH	0.9 ± 0.2	0.8 ± 0.3	1.1 ± 0.4	1.2 ± 0.4	0.7 ± 0.3
IDO1	2.1 ± 0.6	2.2 ± 0.9	1.9 ± 0.9	1.7 ± 0.7	2.3 ± 1.0
PTGES	2.2 ± 0.2	2.4 ± 0.2	1.8 ± 0.3	2.4 ± 0.3	2.1 ± 0.3
CSF1	0.9 ± 0.1	0.8 ± 0.1	0.9 ± 0.2	1.0 ± 0.2	0.7 ± 0.1
PDGFRα	1.0 ± 0.1	1.0 ± 0.2	1.0 ± 0.2	1.0 ± 0.2	1.0 ± 0.2

Results: There were no significant differences between concentration of CFU-F and cumulative MMSCs production in male and female donors. The age of MMSCs donor appeared to be very important for CFU-F concentration and MMSCs cumulative production. The concentration of CFU-F was 2.5 fold higher (P=0.02) and MMSCs production was increased 4 fold (P=0.01) in bone marrow of donors younger than 32 years. The expression level of FGFR2 was about 2 fold higher (P=0.02) in MMSCs of young donors (Table). It suggests the importance of this gene for growth characteristics of MMSCs. The expression level of other factors participating in cell growth genes (BMP4, FGFR1, PDGFRa) did not depend on donors' age and sex. As MMSCs population is heterogenic the genes marking the maturation rate were studied in MMSCs not induced to differentiation. The marker of adipose differentiation (PPARg) was 2 fold lower in young donors (P=0.02) without associations with sex. Osteogenic differentiation marker (SPP1) was higher in young donors, especially in males, but the difference was not significant. The expression level of immunomodulating genes varied individually but independently of sex and age.
Summary / Conclusion: MMSCs population is heterogeneous. There are significant individual variations in growth parameters and genes' expression in MMSCs of different peoples. Some of these characteristics could be important for therapeutic action of these cells.

B1723

OSTEOGENIC MESENCHYMAL STEM CELLS ARE ABLE TO PROMOTE THE PRESERVATION OF CD34+CD38- POPULATION OF HEMATOPOIETIC STEM CELLS

O Kulemina[1*], R Dmitrieva[2], P Butylin[1], A Zaritskey[1]

[1]Institute of Hematology, [2]Institute of Molecular Biology and Genetics Laboratory of Cell Biology, Almazov Federal Heart, Blood and Endocrinology centre, St. Petersburg, Russian Federation

Background: Hematopoietic progenitor/stem cell (HPSC) transplantation is the treatment of choice for a variety of malignant and nonmalignant diseases. To improve the therapeutic outcomes of transplantation one potential strategy is *ex vivo* expansion of HPSC.
in vivo HPSC are located in the specialized bone marrow (BM) niche that is supposed to support HPSC proliferation, differentiation and maintain their quiescence. Despite numerous studies, mechanisms of cell–cell interaction between HPSC and niche microenvironment remain unclear. For this reason, no methodology for successful expansion of HPSCs that could support efficient hematopoiesis has yet been established.
Aims: To estimate the impact of stromal feeder layer on the functional, phenotypic, and clonogenic parameters of HPSC at different oxygen tension conditions.
Methods: We investigated the interaction of CD34+ HPSC (obtained from healthy donor BM mononuclear cells and enriched with CD34+ fraction) with mesenchymal stem cells (MSC) without induced differentiation (ndMSC) or MSC stimulated into osteogenic differentiation (osteoMSC) in cytokine – based coculture system (IL-3 50ng/ml, SCF 150ng/ml, Flt-3L 150ng/ml). In view of critical role of oxygen in stem cell quiescence, coculture proceeded upon hypoxic (pO_2=5%) and normal oxygen conditions. HPSC parameters such as expansion, phenotypic and clonogenic characteristics were evaluated separately for suspensive and adhesive fraction of HPSC after5, 10 and18 days of coculture. The most significant immunophenotypic characteristic for both fractions was the presence of $CD34^+CD38^-$ primitive population and its preservation during long term coculture.
Results: Total multiplication of HPSC cocultured with osteoMSC versus ndMSC was 2.6±0.5 vs 1.12±0 fold after 5 days; 40.2±6.4 vs 33.6±9.6 fold after 10 days; 147.8±58.1 vs 153.2±20.2 fold after 18 days.The expansion of primitive $CD34^+CD38^-$ fraction in HPSC during co-culture with osteoMSC was on 5th day 2.4±0.5 fold, 10th day 31.2±7.0 fold, 18th day 22.5±14.8 fold vs coculture with ndMSC-4.5±2.5, 40.6±19.5, 22.9±17.4 fold, accordingly. Expanded suspensive and adhesive fractions were evaluated for their ability to preserve primitive population. The maximum increment of $CD34^+CD38^-$cells in suspensive fraction was observed on 10th day coculture and did not depend on differentiation of MSC, while osteoMSC demonstrated better preservation $CD34^+CD38^-$ population in adhesive fraction (Figure 1.). CFU-frequency evaluated on 10000 seeded HPSC on 5th day coculture with ndMSC in suspensive fraction was 875±219 colonies, in adhesive fraction-661±366 colonies versus 1053±283 colonies (in a.o. erythroid colonies) and 190±0 after coculture with osteoMSC, accordingly. Total expansion of HPSC cocultured with ndMSC under atmospheric oxygen conditions was higher than at hypoxic conditions and was 157.2±27.0 vs 67.6±16.0 fold on 18th day (P<0.05, n=3). Preservation of total CD34+CD38- fraction upon hypoxic conditions and normal oxygen tension was comparable and was better in suspensive fraction in both cases. After 5 days of coculture, HPSC grown under hypoxic and normoxic conditions were able to give CFU-GM and CFU-GEMM in equal ratios. Upon hypoxia adhesive fraction of HPSC was induced to give predominantly erythroid colonies on long term coculture.

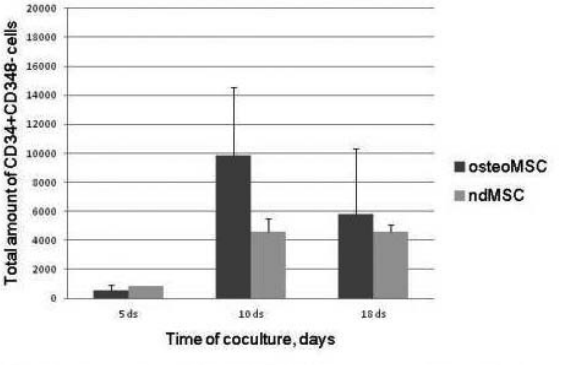

Fig.1. Dynamic of $CD34^+CD38^-$ increment in adhesive fraction during coculture with ndMSC and osteoMSC

Summary / Conclusion: OsteoMSC demonstrated better preservation $CD34^+CD38^-$ population in adhesive fraction. Low oxygen tension favored to increase erythroid progenitors from adhesion fraction of HPSC.Further investigations required.

B1724

BONE MARROW ENDOTHELIAL CELLS, PROGENITOR AND MATURE, IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA, SOLID TUMORS AND IMMUNE CYTOPENIAS

G Martimianaki[1], C Perdikogianni[1*], S Kyriakopoulou[1], M Pesmatzoglou[1], E Stiakaki[1]

[1]Pediatric Hematology-Oncology, University of Crete, Heraklion Crete, Greece

Background: The role of endothelial progenitors (EPC) and mature cells (EC) in angiogenesis of malignant and blood diseases has been the focus of many recent studies.
Aims: The quantitation and immunophenotypic characterization of EPC and EC subpopulations in the bone marrow (BM) of children with acute lymphoblastic leukemia (ALL), solid tumors (ST) and immune cytopenias.
Methods: BM cells from children with ALL at diagnosis (ALLd, n=15), day 15 (ALL15d, n=12), day 33 of treatment when remission is achieved (ALL33d, n=11), at consolidation (ALLct, n=22), at the end of treatment (ALLet, n=21), solid tumors without BM involvement at diagnosis (ST, n=11) and under treatment (STth, n=11) and immune cytopenias (n=10) were studied. The putative

antigenic phenotypes of EPC and EC were assessed using a 4-color flow cytometry in the CD45negative cell subpopulation.
Results: The highest levels of EPC subpopulation immunophenotypically characterised by CD45negCD133$^+$CD34$^+$VEGFR-2$^+$ were estimated at diagnosis of ALL
with statistically significant differences compared with ALL33d (0.0869±0.0571 vs 0.01±0.0067, P=0.023), ALLet (0.0869±0.0571 vs 0.0185±0.0130, P=0.024) and cytopenias (0.0869±0.0571 vs 0.0051±0.0033, P=0.039). As far as ST is concerned, the highest levels of the triple combination of EPCs were determined at diagnosis (0.0176±0.0069). The levels of CD45negCD133+VEGFR-2+EPCs were also higher in ALLd (0.1144±0.0398) with statistically significant differences compared with ALL33d (0.1144±0.0398 vs 0.0473±0.0339, P=0.031) and ST (0.1144±0.0398 vs 0.028±0.0066, P=0.043). In addition, the highest levels of CD45negCD34+VEGFR-2+EPCs were determined in ALLd (2.6197±2.5522) with statistically significant differences compared with ALL33d (2.6197±2.5522vs 0.0436±0.0277, P=0.031), and ST (2.6197±2.5522 vs 0.0227±0.0065, P=0.032). For both the above EPCs subpopulations, there were found to be higher in ST under treatment compared to diagnosis.The highest levels of intermediate maturity combinations such as CD45negCD146+CD34+ were observed in ALLd with statistically significant differences compared with ALL33d (0.216±0.0569 vs 0.0460±0.0177, P=0.014) and the CD45negCD146$^+$CD34$^+$VEGFR-2$^+$ was also found to be highest at diagnosis of ALL (0.0288±0.0199) compared to low levels at ALL33d (0.0037±0.0035). The more mature EC subpopulation CD45negCD31$^+$CD34$^+$VEGFR-2$^+$ was estimated to be highest in the group of ALL15d (0.0263±0.0104) and ST under treatment (0.024±0.0186) followed by ALL at diagnosis (0.0152±0.0064). Statistical analysis revealed significant differences between ALL15d vs ALL33d (P=0.011) ALL15d vs ALLct (P=0.016) ALL15d vs ST (P=0.042).The levels of CD45negCD31+VEGFR-2+subpopulation were also higher in ALL15d with statistically significant differences compared with ALL33d (0.1542±0.0480 vs 0.0642±0.0293, P=0.037). This subpopulation was also found to be high in immune cytopenias (0.1589±0.0737).
Summary / Conclusion: At diagnosis of ALL the levels of both progenitor and more mature endothelial cells seem to be highest. Induction of remission is associated with the lowest levels of EPC and EC subpopulations. At solid tumors the progenitor endothelial cells' subpopulations were found to be more prominent while in immune cytopenias the levels of more mature ECs were found to be higher than EPCs one. The precise role of these findings warrants further investigation.

B1725

NEUTRALIZATION OF VASCULAR ENDOTHELIAL GROWTH FACTOR-C INDUCES THE EXPRESSION OF FMS-LIKE TYROSINE KINASE 3 IN INTERLEUKIN 1-BETA-STIMULATED ADULT HUMAN DERMAL FIBROBLASTS

T Matsuo[1*], R Shirasaki[1], Y Oka[1], N Shirafuji[1]
[1]Department of Hematology/Oncology, Teikyo University Schiio Of Medicine, Tokyo, Japan

Background: We previously reported that human interleukin 1-beta (IL-1-b) stimulated bone-marrow stromal myofibroblasts to express CD34 molecule. We also reported that when adult human dermal fibroblasts (HDFs) were cultured with IL-1-b and erythropoietin (EPO), hematopoiesis-related molecules were induced to express (17th EHA). And, when HDFs were cultured in knockout (k/o) DMEM and IL-1-b, lymphatic duct neogenesis-related genes expressed, and vascular endothelial growth factor (VEGF)-C was produced significantly (74th JSH, and 54th ASH).
Aims: To understand better the hematopoiesis and lymphangiogenesis, we observed effects of anti-VEGF-C-neutralizing antibody (Ab) when HDFs were cultured with IL-1-b.
Methods: HDF were purchased, and cultured in k/o DMEM with 20% KSR and recombinant human IL-1-b for two weeks with or without anti-human VEGF-C Ab. The morphological changes and the expressions of hematopoietic and lymphangiopoietic molecules were analyzed time-dependently. Then, HDFs were further cultured in DMEM/F12 with hematopoietic cytokines, and were characterized biologically.
Results: When HDFs were cultured with human IL-1-b for 2 weeks, the cellular morphology changed to the filamentous appearance. RT-PCR analyses revealed that the culturing cells expressed Prox-1, VEGF receptor type-3, Smad7, and PAI1; however, when anti-human VEGF-C Ab was added to the cultures, these lymphduct-neogenesis genes were down-regulated, and fms-like tyrosine kinase (FLT) 3 was expressed significantly. When HDFs were further cultured in DMEM/F12 with human stem cell factor, IL-6, FLT3 ligand, EPO, and granulocyte colony-stimulating factor, CD45 was induced to express, and these cells formed hematopoietic colonies.
Summary / Conclusion: When HDFs were cultured in k/o DMEM, a growth-condition for an embryonic stem cell, and with IL-1-b, several molecules relating to a lymphangiogenesis expressed, and they were down-regulated when VEGF-C neutralizing Ab was added to the cultures. By the addition of VEGF-C Ab FLT3 expressed in HDFs, and, when HDF were further cultured with hematopoietic cytokines, hematopoietic markers including CD45 were induced to express significantly. Currently we are validating the precise molecular mechanism on the expression of FLT3 in IL-1-b-stimulated HDFs in the presence of VEGF-C Ab using a microarray analysis, and also characterize the generated cells *in vivo* using an immunodeficiency murine transplantation-model.

B1726

THE RELATIONSHIP BETWEEN OXIDANT INJURY AND INSULINE RESISTANCE IN PATIENTS WITH FANCONI APLASTIC ANEMIA

E Erduran[1*], A Bahadir[1], D Albayrak[2], Y Aliyazicioglu[1], M Buyukavci[3], S Demir[1]
[1]Karadeniz Technical University, Trabzon, [2]Ondokuz Mayis University, Samsun, [3]Ataturk University, Erzurum, Turkey

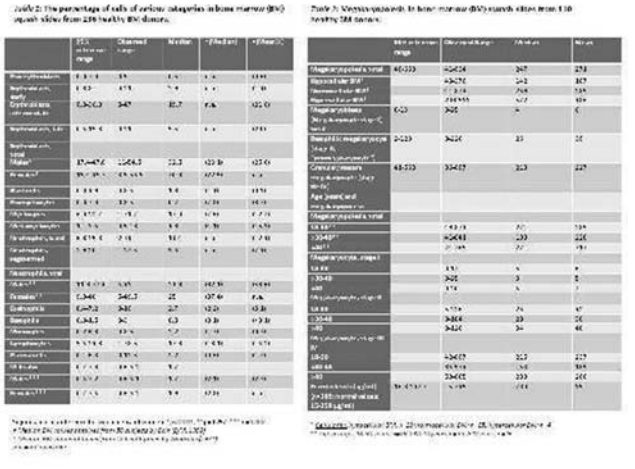
Background: Fanconi aplastic anemia (FAA) is an autosomal recessive chromosome instability disorder characterised by bone marrow failure. DNA repair mechanism is impaired in FAA and FA cells are intolerant of oxidative stress. Reactive oxygen species (ROS) could damage DNA and inability to repair of FAA hematopoeitic stem/progenitor cells (HCPCs). Diabetes is a common comorbidity associated with FAA. ROS have been proposed to play a causative role in insulin resistance (IR). Another cause of type 2 diabetes in FAA is elevated serum ferritin level. Increased serum ferritin concentration causes IR.
Aims: To investigate the relationship between oxidative injury, IR and iron load in patients with FAA. In addition, to indicate the risk factors to play a role in developing of IR in FAA patients.
Methods: Twenty-three patients (11 girls, 12 boys) ages between 4-19 years-old with FAA and 10 controls who were healthy ages between 4-17 years-old were included in the multicentre study. Samples for determination of complet blood count (CBC), alanin aminotransferase (ALT), aspartat aminotransferase (AST), gamma glutamiltransaminase (GGT), C-reactive protein (CRP), fasting blood glucose and simultaneous insulin, hepcidin, ferritin, 8-Oh deoxyguanosine (8-OHdG), protein cabonyl groups, malondialdehyde (MDA) and HOMO-IR were drawn in the patients and controls. The serum ferritin levels were performed monthly in the patients with high serum ferritin level and receiving iron chelating therapy. All tests were repeated when the serum ferritin level was decreased by at least 25% according to a previously determined serum ferritin level. Chromosomal breakages were investigated by incubation with diepoxybutane (DEB) of the peripheral lymphocytes of all patients, in-vitro. The patients with a positive DEB test were received as FAA, those with a negative DEB test were received as non-FAA. Statistical analyses were done with 'SPSS 13 (Statistical Package for Social Screnu) for Windows©' program.
Results: DEB test was positive in 16/23 patients.Bone marrow transplantation was done in seven patients.Three cases who were transfusion-dependent were receiving a chelating agent (Deferisirox) for iron overload. IR was present in 12 cases. 8-OH dG and MDA levels in FAA patients were significantly higher than those in controls (P=0.001 and P=0.002, respectively). There were no statistically significant differences between the serum hepcidine and the protein carbonyl levels in FAA and controls, separately (P>0.05). Serum ferritin level and IR were higher in FAA patients than controls (P=0.000, P=0.002). IR was significantly higher in patients with DEB test positive (10/16 patients) than those in patients with DEB test negative (2/7 patients) (P=0.03).There were not significant differences between serum ferritin, hepcidine, MDA, protein carbonyls, CRP and 8-OH dG levels in DEB tests positive and negative patients, separately (P>0.05). Five FA patients had transfusion-dependent and they were received packed red blood cell transfusions every 3-6 weeks. Four for five patients had IR and serum ferritin levels of the patients were 435-6702 ng/ml, serum ALT levels were 21-110 IU and serum GGT levels were 29-31 IU. There were significant differences between 8-OHdG, ferritin and MDA levels in patients with IR and without IR, separately (P=0.009, P=0.001 and P=0.013, respectively). There was a good correlation at the rate of 56.8 % between IR and ferritin level (P=0.05). The mean serum ferritin levels were 168.8±27.9 ng/ml in patients without IR and 1586,6±2436,7 ng/ml in patients with IR. There were no a good correlation between IR and hepcidine level and between ferritin and hepcidine levels (P=0.48 and P=0.95, respectively). There were not statistically significant correlation between serum ferritin and serum hepcidine, protein carbonyl, 8-0H dG, MDA levels, IR in 21 patients having serum ferritin levels lower than 1000 ng/ml, separately (P>0.05).
Summary / Conclusion: Lipid peroxidation and DNA oxidation due to increased ROS have been developed in FAA. FAA patients are under the risk of IR and diabetes mellitus followed by oxidative injury. There is a good correlation between IR and serum ferritin level in FAA. Body iron load and serum ferritin level play an important role to develop IR and diabetes mellitus in FAA in addition to oxidative stress.

B1727

NEW ASPECTS OF NORMAL BONE MARROW VALUES FOR MEGAKARYOPOIESIS FROM 110 HEALTHY BONE MARROW DONORS AND NORMAL BONE MARROW VALUES FROM 236 HEALTHY BONE MARROW DONORS

S Parmentier[1*], M Kramer[1], S Weller[1], U Schuler[1], R Ordemann[1], G Rall[2], M Schaich[1], M Bornhäuser[1], G Ehninger[1], F Kroschinsky[1]
[1]Medical Department I, University Hospital Dresden , Dresden, [2]DKMS, Tübingen, Germany

Background: In 1974, M.M. Wintrobe described a differential count of bone marrow (BM) aspirates from 12 healthy men. Twenty years later, Barbara Bain assessed the percentage of cells in BM films of 50 healthy subjects. Until today most laboratories rely on these normal BM values obtained from only small numbers of healthy subjects. Bain also described a varying number of megakaryocytes (6-77, mean 31) on wedge-spread BM films. Kenneth Kaushansky describes a prevalence of 20% megakaryoblasts, 25% basophilic megakaryocytes and 55% mature megakaryocytes within a normal BM (Wintrobe´s Clinical Hematology, 12th edition).
Aims: We gathered BM squash slides from over 400 healthy BM donors harvested over a 4 year period at our institution to investigate normal hematopoiesis.
Methods: BM squash slides from 236 healthy unrelated BM donors were examined independently by three experienced morphologists for normal BM values and 110 slides for megakaryopoiesis.. All volunteers underwent predonation health check-up about four weeks prior to the harvest. During the BM harvest, samples for this study were taken from the first aspiration.
BM cellularity, megakaryocyte numbers and morphology were assessed by examination at a 20fold magnification. Morphology of myeloid and erythroid cells was assessed using a x100 objective and cells being counted in the trails behind the particles. Each morphologist had to do a 200 differential cell count. Megakaryopoiesis was assessed for total counts and differentiated between megakaryoblasts, basophilic megakaryocytes and mature megakaryocytes. BM preparation and assessment was performed according to WHO, ICSH guidelines and the ELN recommendations (*Zini et al., 2010*).
Results: Normal values obtained from a 600 cell count are described in *T*able 1 together with the median values described by Bain and Wintrobe, respectively. Peripheral blood counts were in the normal range.



Compared to results described by Bain and Wintrobe, relevant differences can only be seen for the promyelocyte count. In contrast, significant differences between male and female donors were seen with regard to the M:E ratio and the percentage of erythroblasts , as formerly described by Bain, but not for the percentage of neutrophils. Megakaryopoiesis showed a high variety depending on cellularity with a mean of 271 for total megakaryopoiesis (Table 2). The percentage of megakaryoblasts accounted for 2%, promegakaryocytes 14% and mature megakaryocytes 84%, respectively. In donors between the age of 30-40 years, megakaryopoiesis appears to be less compared to younger or older ones.
Summary / Conclusion: According to our data, most of the formerly described normal BM values by Bain and Wintrobe were confirmed by a much larger cohort. The total median megakaryocyte counts seen in our study differ significantly from those described by Bain which might be explained by the fact that megakaryopoiesis was evaluated in BM squash slides and the larger cohort in which megakaryopoiesis was evaluated. According to our data, the prevalence of different maturation states also differ significantly compared to the data of Kaushansky, which might be due to the fact that megakaryopoiesis was evaluated primarily on trephine biopsies.

B1728

EXPERESSION AND REGULATION OF ERYTHROID DIFFERENTIATION RELATIVE FACTOR (EDRF) IN ERYTHROD DIFFERENTIATION

Y Tan[1], C Wang[1*], G Wang[1]
[1]Tumor center, Fisrt Hospital of Jilin University, changchun, China

Background: Erythroid differentiation relative factor (EDRF), also called Human α-hemoglobin stabilizing protein (AHSP), was an erythropoiesis related factor expressed only in erythroid cells. It played important roles in the production of Hemoglobin A by stabilizing free alpha-globin. But how it was regulated in erythropoiesis was still not very clear.
Aims: To investigate the expression of EDRF during erythropoiesis and to explore the mechanism of its regulation.
Methods: The expression of EDRF in mice fetus liver tissue and in erytholeukemia cell line HB22.2 which was deficient in erythroid differentiation was detected by Northern blot method, the DNA transmutation was detected by Southern blot method. The change of EDRF expression during erythoid differentiation was observed by using erythroleukemia cell line HB60-5 which could be induced to differentiation to mature erythrocytes by changing culture condition with different combination of several cytokines. And the regulation of EDRF expression by erythroid transcription factor GATA-1, NF-E2 and Fli-1 was detected with transgenic method.
Results: EDRF was high expressed in normal erythroid tissue, however the high expression of EDRF was greatly suppressed accompanied with the block of erythroid differentiation in erythroleukemia cells, and the abnormal of EDRF was not caused by DNA aberration. The expression of EDRF was gradually evaluated during the erythroid differentiation of HB60-5 cells. The transfection of NF-E2 into HB22.2 cells could restore the expression of EDRF and the transfection of GATA-1 into HB60-5 cells could promote EDRF expression, however, the transfection of Fli-1 into HB60-5 cells suppressed EDRF expression.
Summary / Conclusion: EDRF was an erythroid specific factor. It was related with erythoid differentiation and was highly expressed in normal Hematopoietic tissue. The regulation of EDRF maybe controlled by varies erythroid transcription factor such as GATA-1, NF-E2 and Fli-1.

B1729

PRESENCE OF ANEUPLOIDY CLONES IN CULTURED MESENCHYMAL STEM CELLS AND CHARACTERISTICS OF ANEUPLOIDY IN BONE MARROW CELLS WITH HEMATOLOGIC MALIGNANCIES

S Kim[1*], S Park[2], J Kwon[2], J Kim[1], Q Choi[1], S Hwang[1], D Lee[1,2]
[1]Department of Laboratory Medicine, [2]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic Of

Background: Emergence of aneuploidy during in vitro culture of cells is occasionally observed, but the significance of aneuploidy is not elucidated yet. We quantitatively assessed the aneuploidy of mesenchymal stem cells using multiple fluorescent in situ hybridization (FISH) probe panels and investigated the pattern of aneuploidy in stem cells.
Aims: The aim of this study was to comparison of the pattern of aneuploidy in stem cells with those of aneuploidy found in bone marrow cells from patients with hematologic malignancies, to have a guidance for assessing the significance of aneuploidy clones.
Methods: For the quantitative detection of aneuploid clones, we performed interphase FISH on 13 kinds of mesenchymal stem cells and 3 kinds of mesenchymal stem cell lines. Among hematologic diseases, we analyzed 77 patients with hematologic/non-hematologic diseases showing numerical chromosomal abnormalities.
Results: Interphase FISH showed variable proportions of cells with tetrasomy (0.5% to 10.5%) among various mesenchymal stem cells and the patterns of tetrasomy were asymmetric. However, numerical chromosomal abnormalities was absent in all of the 3 kinds of mesenchymal stem cell-lines. Diagnoses of 77 patients with hematologic diseases included, 22 acute lymphoblastic leukemia, 18 acute myeloid leukemia, 25 mature lymphoid neoplasms including 14 myeloma cases, 5 myelodysplastic syndrome (MDS), and 7 cases with anemia without definite evidence of hematologic malignancies. Of 77 cases, 48 cases showed < 10% of tetraploidy clones (5 acute leukemia, 5 myeloma, and 3 with mature lymphoid neoplasm). Higher tetraploidy clones and variability between percentage of tetraploidy clones were related to dysplastic features in MDS. Meanwhile, BM with erythroid hyperplasia and no definite malignancy usually showed <10% of tetraploidy clones with symmetric tetraploidy pattern.
Summary / Conclusion: Present study showed variable cell populations of tetraploidy among mesenchymal stem cells with asymmetric pattern. In contrast, patients without evidence of hematologic malignancy showed presence of tetraploidy with symmetric pattern. Presence of tetraploidy clones might mean the presence of senescent cell population or actually transforming cells into tumor. Evaluation of tetraploidy with its pattern might help in differentiation of active cellular hyperplasia and malignancies.

B1730

THE URGENT NEED OF PRIMARY PREVENTION OF STROKE IN CHILDREN WITH SICKLE CELL DISEASE IN SAUDI ARABIA USING TRANSCRANIAL DOPPLER

S Jaouni[1*], R Hammad[2], N Qarni[2], I Raffa[2]
[1]Hematology Department, Consultant of Hematology King Abdul Aziz University , [2]Hematology Department, Resident in Pediatric Hematology/Oncology at King Abdul Aziz Hospital , Jeddah, 21589, Saudi Arabia

Background: Stroke is a devastating clinical complication with increase morbidity among young patient with sickle cell disease (SCD). Limited data is available regarding stroke incidence in pediatric SCD in Saudi Arabia.
Aims: To determine the prevalence of stroke in pediatric SCD patient, and the recommendation to implement screening by Transcranial Doppler.
Methods: A retrospective study on pediatric patients with SCD treated at King Abdul Aziz University Hospital (KAUH), between January 2006 and December 2012. Stroke were diagnosed based on clinical and diagnostic radiology.
Results: A total of 203 patients with SCD were identified. Twenty eight patients (13.8%) were diagnosed with stroke. Fifteen patients (53.6%) were males and 13 patients (46.4%) were females, age range from 1-18 years (mean 8.46 years). Seventeen patients (61%) diagnosed with stroke were younger than 7 years. The clinical presentations of those diagnosed with stroke; 10 patients (35%) with hemiparesis, 6 patients (21%) were asymptomatic, 5 patients (17%) with headache, 4 patients (14%) with convulsions, 2 patients (7.1%) were irritable and 1 patient (3.5%) with meningeal signs
Summary / Conclusion: Children with SCD are at increase risk of stroke as early as infancy. Stroke prevention in SCD is needed as a routine before the age of 1 year.

Signalling, transcription and apoptosis

B1731

CHOLESTEROL SYNTHESIS INHIBITION INDUCES LEUKEMIA-SPECIFIC CYTOPROTECTIVE AUTOPHAGY VIA SUPPRESSION OF THE AKT/MTOR SIGNALING PATHWAY

M Bosnjak[1*], A Bogdanovic[2], I Markovic[3], A Isakovic[3], V Trajkovic[4], V Bumbasirevic[1], U Vilimanovich[1]
[1]Institute of Histology and Embryology, [2]Institute of Hematology, [3]Institute of Medical and Clinical Biochemistry, [4]Institute of Microbiology and Immunology, University of Belgrade School of Medicine, Belgrade, Serbia

Background: High dose statins exhibit anti-leukemic properties *in vitro*. This is due to the suppression of the mevalonate pathway which is responsible for the synthesis of cholesterol and prenyl moieties required for the farnesylation and geranylgeranylation cell signaling proteins. We have shown that statin treatments at physiologically attainable and tolerable doses also have specific anti-leukemic activities. Low dose statin treatments induce autophagy in leukemic cells but not normal human lymphocytes, this is dependent upon the inhibition of cholesterol synthesis, not inhibition of protein farnesylation or geranylgeranylation. Inhibition of autophagy in leukemic cells reveals a remarkable apoptosis-inducing effects of low, non-cytotoxic doses of statins. This effect is mimicked by the inhibition of cholesterol synthesis, but not by the inhibition of prenylation, and is not observed in normal human lymphocytes. However, the mechanisms of statin and cholesterol synthesis inhibitor-induced autophagy are currently unknown.
Aims: Our aim was to examine the involvement of the Akt/AMPK/mTOR pathways in statin and cholesterol synthesis inhibitor-induced cytoprotective autophagy in leukemic cells.
Methods: The human leukemic cell lines REH, K562 and JVM-2, as well as PBMCs isolated from leukemic patients and healthy volunteers were used. Cells were treated with lovastatin (LS), simvastatin (SS) and atorvastatin (AS), the cholesterol synthesis inhibitor Ro-48-8071, and FTI-277 or GGTI-2133. Cell viability was determined by acid phosphatase assay. Apoptotic responses were analyzed by Western blotting for active caspase-3, and by flow cytometry using annexin V-FITC and propidium iodide for phosphatidylserine externalization and DNA fragmentation. Activation of Akt, AMPK, S6K, and mTOR were determined by Western blot analysis for the phosphorylated protein forms. Autophagy was determined by electron microscopy and Western blotting for the appearance of the LC3II. Inhibition of autophagy was performed by use of bafilomycin A1 and by RNA interference knockdown of the beclin-1 and LC3II proteins.
Results: Treatment with low dose LS, SS, and AS all reduced leukemic cell viabilities without the induction of cytotoxicity. Statins and Ro-48-8071 induced an autophagic response in a time dependent manner in leukemic cells patients, which peaked at 72h post treatment. Ro-48-8071 induced LC3II protein accumulation with faster kinetics than statins. Western blotting for activated Akt, AMPK, mTOR and S6K proteins showed that statins and Ro-48-8071 inhibited Akt, mTOR, and S6K phosphorylation with kinetics overlapping those of the appearance of LC3II, while phospho-AMPK levels remained unchanged after all treatments. None of these effects were observed after FTI-277 or GGTI-2133 treatment or in normal human lymphocytes. Akt inhibition by perifosine mimicked the effects of statin and Ro-48-8071 treatment in leukemic cells, but not normal lymphocytes.
Summary / Conclusion: Our study confirms that mevalonate pathway inhibition by low dose statins induces cytoprotective autophagy dependent specifically on the inhibition of cholesterol synthesis. Autophagy induced by cholesterol synthesis inhibition seems to be dependent upon the inhibition of Akt activity and not AMPK activation. The inhibition of Akt activation by cholesterol synthesis inhibitors leads to the inhibition of mTOR, and the induction of autophagy in leukemic cells but not normal human lymphocytes. Our results lend further credence to the idea that selective cholesterol reducing therapies in combination with autophagic inhibition warrant further exploration as potential candidates for selective anti-leukemic therapy.

B1732

RNA IN RETICULOCYTES IS NOT A WASTE BUT A FINAL MESSENGER TO BECOME RBCS

E Lee[1], H Choi[1], E Baek[1*]
[1]clinical pathology, Hanyang University Kuri hospital, Guri-si, Gyeonggi-do, Korea, Republic Of

Background: Reticulocytes represent the last stage of erythropoiesis before full maturation to red blood cells (RBCs) and initially contain both RNA and micro-organelles. Even though some hemoglobin and membrane-bound proteins are additionally synthesized in reticulocytes, the remnant RNA is regarded as waste material, and its importance has not been demonstrated.
Aims: Here we explore whether the small amount of residual RNA is essential for reticulocytes to become erythrocytes.
Methods: Fresh human or mouse peripheral blood samples with high reticulocytes were incubated with RNase or RNase inhibitor for 24~48 hr. Then, sur-

vival of reticulocytes, maturation states, viability, cell morphology, and changes of mRNA expression were analyzed compared to the control groups. Also, fresh reticulocytes were incubated in a methionine-free media to inhibit new protein synthesis.
Results: When we abruptly removed remnant RNA, reticulocytes could not survive or mature into RBCs in human and mouse. However, reticulocytes treated with an RNase inhibitor were able to form normal donut shaped cells with more preserved mitochondria and plasma membrane consistency. Furthermore, when we blocked protein synthesis, reticulocytes could not survive. To elucidate the relevant signals, we analyzed differentially expressed RNAs in human reticulocytes compared to terminally matured erythroblasts cultured from cord blood CD34+ stem cells. We found that several exocytosis, metabolism, and transduction related signals are relatively more expressed in reticulocytes.
Summary / Conclusion: Taken together, these results suggest that RNA in reticulocytes must be translated into neo-protein, which might then help to preserve mitochondria and maintain cell membrane consistency until maturation to erythrocytes. These results enhance the previously poor understanding of final erythropoiesis and low survivability of *in vitro* generated reticulocytes.

B1733
APOPTOSIS AND CXCR4 EXPRESSION IN CHILDHOOD LEUKEMIA AND SOLID TUMORS
M Pesmatzoglou[1], G Martimianaki[1], C Perdikogianni[1*], E Stiakaki[1]
[1]Pediatric Hematology-Oncology, University of Crete, Heraklion Crete, Greece

Background: The chemokine receptor CXCR4 is expressed on leukemic and hematopoietic stem cells and has been shown to play a crucial role in chemotaxis and homing.
Aims: The study of CXCR4 expression in marrow leukemic blasts and hematopoietic stem cells in solid tumors with and without marrow involvement, as well as the apoptosis of the CXCR4 population at diagnosis and remission in acute lymphoblastic leukemia.
Methods: BM cells from children with acute lymphoblastic leukemia at diagnosis (ALL, n=7) and on day 33 (ALLd33, n=6) of treatment when remission is achieved, as well as with solid tumors at diagnosis without (ST) and with BM involvement (STinv) (n=10 and n=4, respectively) were studied. Flow cytometry was performed to assess the expression of chemokine receptor CXCR4 in $CD34^+$ blasts or hematopoietic stem cells as well as the percentage of apoptotic subpopulations of these cells stained by PI/Annexin.
Results: The percentage of bone marrow leukemic blasts expressing CXCR4 at diagnosis of ALL was estimated to be 65.26% and only 5.61% of this population is apoptotic. On day 33 of treatment the apoptosis of $CD34^+$ marrow hematopoietic stem cells that express $CXCR4^+$ mounted up to 24.05% (P=0.035 compared to diagnosis). In solid tumors without BM involvement the percentage of $CD34^+$ marrow hematopoietic stem cells that express $CXCR4^+$ was calculated to be 60.01% whereas the same percentage for the group of ST with BM infiltration was 80.25%, a difference that was not found to be statistically significant. The apoptosis of $CD34^+$ marrow hematopoietic stem cells that express $CXCR4^+$ in the case of ST with BM infiltration was 3.93%, statistically significantly lower than the relevant percentage in ST without BM involvement (22.69%, P=0.014).
Summary / Conclusion: The above results point out that the apoptosis of $CD34^+$ marrow hematopoietic stem cells that express $CXCR4^+$ at remission is higher compared to diagnosis of ALL. The expression of CXCR4 on $CD34^+$ marrow hematopoietic stem cells in ST with BM infiltration seems to confer to resistant to apoptosis. These results warrant further investigation of the implication of CXCR4 in the mechanism of apoptosis.

B1734
ELEVATION OF CAMP LEVELS INHIBITS ARSENIC-INDUCED APOPTOSIS IN ACUTE PROMYELOCYTIC LEUKEMIA CELLS
M Safa[1*], K Mousavizadeh[2]
[1]Hematology, [2]Oncopathology Research Center and Department of Basic Medical Sciences, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: Acute promyelocytic leukemia (APL) is the most frequently curable subtype of acute myeloid leukemia. Most patients are treated with all-trans retinoic acid (ATRA) and its combination with anthracycline-based chemotherapy. More recently, another natural compound, arsenic trioxide (As2O3), was integrated into APL treatment, showing high efficacy and tolerability in APL patients.
Aims: The aim of this study was to evaluate the effect of activation of cAMP signaling system on As2O3 -induced apoptosis in acute promyelocytic leukemia cells.
Methods: Cultured acute promyelocytic leukemia NB4 cells were exposed to As2O3 in the presence or absence of cAMP-increasing agent forskolin for 24h and then cells were subjected to apoptosis analysis by flow cytometry. Analysis of cell cycle was also performed by flow cytometry. Western blot method was used to analyze phosphorylation state of p53 protein, total p53, p21, cyclin-D1, and the levels of other proteins which were involved in arsenic-induced apoptosis.
Results: These results indicate that elevation of cAMP in acute promyelocytic leukemia cells profoundly inhibit the apoptotic response to As2O3. Analysis of the cell cycle distribution showed that NB4 cells significantly accumulated at the G0/G1 phase under forskolin treatment alone or when As2O3 and forskolin treatments were combined, but not in the presence of As2O3 alone. This inhibitory effect of cAMP was reversed by PKA inhibitor H89. Our results showed a dramatic increase of p21 without any change in p53 protein levels during forskolin treatment of NB4 cells. Increased cAMP levels also decreased arsenic-induced caspase-3 activation in acute promyelocytic leukemia cells.
Summary / Conclusion: As2O3 has dose-dependent dual effects on APL cells: triggering cell apoptosis at high concentration and inducing partial differentiation at low concentration. This study shows that elevation of cAMP levels in acute promyelocytic leukemia cells can inhibit apoptosis induced by high concentration (1-2 μM) of As2O3.

B1735
THE PROLIFERATION ARREST OF PRIMARY BONE MARROW TUMOR CELLS DURING CULTURE IS PRECEDED BY DOWNREGULATION OF MKI67 AND NUMEROUS MITOTIC AND TRANSCRIPTIONAL GENES
Y Cohen[1*], O Garach-Jehushua[2], A Bar-Chaim[3], N Rahimi-Levene[1], M Izak[1], K Hertzog [1], O Gutwein[1], I Esterlis[1], A Kornberg[1]
[1]Hematology, [2]Hematology laboratory, [3]Biochemistry laboratory, Assaf Harofeh Medical Center (Affiliated to Sackler Faculty of Medicine, Tel Aviv University), Be'er Yacob, Israel

Background: To identify the gene subset in bone marrow (BM) tumor cells which is controlled by the natural microenvironment we recorded recently the changes acquired in gene expression profile (GEP) after removal of the cells out of their niche. The results revealed prompt and sustained switch in the expression of numerous genes which started immediately following aspiration and persisted for at least 11 hours. It addition, most of the prominent changes were common to all types of tumors examined and the constitutive overexpression of master genes and tumor suppressor genes could account for the short survival of aspirated tumor cells *ex vivo*. Nevertheless, the almost complete regression of the above GEP changes under culture conditions that resumed cell-cell-matrix contact in vitro indicated that other factors are responsible for the proliferation arrest ensued.
Aims: To identify the factors responsible for the proliferation arrest of primary multiple myeloma (MM) and acute myeloid leukemia (AML) cells in culture.
Results: Despite the tremendous biological differences between MM and AML the post-aspiration switch in GEP regressed equally during culture and de novo changes appeared which were overlapping to large extent irrespective of the culture duration or the tumor type. The reproducible GEP changes appearing in culture compared with the expression recorded from the corresponding fresh samples included **Downregulated Genes:** Irrespective of the underlying tumor MM or AML, the aspirated BM cells showed significant downregulation of dozens of genes during culture (lasting between 1 to 29 days). However, the most interesting finding was the downregulation of a major subset of genes which had in common established roles in mitosis or during transcription. The combined downregulation of plenty of genes which are all function in the machinery of replication seems to represent the best explanation for the invariable proliferation arrest limiting culture of primary tumor cells.
Upregulated genes: The upregulated gene subset predominated by extracellular protein coding genes which included a variety of extracellular matrix (ECM) proteins (SPP1, FN1) and angiogenic factors (IL8, CCL2, CXCL5, FN1, MMP14, MT1G). Thus, the induction seemed to be oriented purposely towards angiogenesis and matrix enrichment.
Summary / Conclusion: In analysis of the various GEP changes evolved during culture the proliferation arrest could be best attributed to the excessive downregulation of mitotic and transcriptional genes. The latter insult in turn could be secondary to the loss of vital signals or direct contact with a feeder niche component not existing in the culture flasks. In this regard, the overexpressed extracellular genes pointed towards the angio-matrix tissue as the best candidate for being the missing feeder structure required for proliferation. The suggested relationships might therefore direct future antitumor treatments towards interruption of the feeder signals (which are not known yet) or to target the angiogenic/ECM recruitment factors (i.e., IL8, osteopontin, proteases) as alternatives to traditional cytotoxic drugs. In summary, our results encourage the future assessment of non-cytotoxic niche modifying agents, directed against IL8, osteopontin and certain proteases in various combinations as well as against amphiregulin and COX2 which are probably adding to tumor expansion.

SANGIVAMYCIN-INDUCED APOPTOTIC INDUCTION IN HL-60 CELL LINE

S Kim[1*], I Nassour[2], C Lee[3]
[1]Department of Surgery, University of Pittsburgh, Pittsburgh, [2]Department of Surgery, Johns Hopkins University, Baltimore, United States, [3]Department of Pharmacy, Hanyang University, Ansan, Korea, Republic Of

Background: Sangivamycin (SGV) has shown a potent antiproliferative activity against a variety of human cancers. However, little is known about the mechanism of action underlying its antitumor activity in leukemia.
Aims: This study aimed to show the anti-leukemia effect of SGV on the HL-60 human acute myeloid cell line and to investigate the underlying molecular mechanisms governing these effects in terms of apoptosis.
Methods: To investigate the effects of Sangivamycin on cell cycle in HL-60 cells, cell viability were tested with MTT assay and we measured theDNA content of HL-60 cells using flow cytometry. In addition, TUNEL assay was used to examine apoptotic induction in treated cells, and the effects of Sangivamycin on the expression of apoptosis-associated proteins were examined by Western blot.
Results: This study showed that SGV inhibited the proliferation of HL-60 cells in a concentration- and time-dependent manner as measured by the MTT assay. Treatment of HL-60 cells with an IC50 of SGV resulted in morphological changes typical of apoptosis. Flow cytometric analysis of PI indicated that SGV-induced apoptosis in HL-60 cells occurs in a time-dependent manner. Tunnel assay was utilized to investigate the apoptosis induced by SGV. The pro-apoptotic activity of SGV was attributed to its ability to modulate, in a concerted manner, the expression of Bcl-2 and Bax proteins, which were down- and up-regulated, respectively. Caspase-9 and -3 were subsequently activated, however caspase-8 was not.
Summary / Conclusion: These results prove that SGV effectively induces programmed cell death and suggests that SGV-induced apoptosis in the HL-60 cells is mediated by the regulation of Bid cleavage and the activation of caspase-9 and -3.

HIGH FREQUENCY OF NQO1 C609T VARIANT GERMLINE POLYMORPHISM IN MDS/AML WITH TRISOMY 8

S Zachaki[1*], C Stavropoulou[1], T Koromila[2], M Kalomoiraki[1], A Daraki[1], D Koumbi[1], A Athanasiadou[3], K Manola[1], P Kollia[2], C Sambani[1]
[1]NCSR "Demokritos", [2]University of Athens , Athens, [3]G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Clues to the etiology of myeloid malignancies are expected to be gained through the study of genetic susceptibility in candidate genes. Models for MDS development suggest the role of cumulative genetic and toxic environmental factors in genetically predisposed individuals. The NAD(P)H:quinone oxidoreductase 1 (NQO1) enzyme detoxifies a number of endogenous and exogenous quinones, protecting cells against oxidative damage. The corresponding gene is subject to a single-nucleotide germline polymorphism ($C^{609}T$) resulting in a lowering of enzyme activity. Individuals homozygous for the mutant allele (T/T) completely lack NQO1 activity, whereas heterozygotes (C/T) present approximately threefold decreased enzyme activity.
Aims: Considering the critical role of the NQO1 enzyme in detoxification mechanisms implicated in MDS pathogenesis, the aim of the present study was to investigate whether the *NQO1* germline polymorphism influencing the NQO1 activity, confers susceptibility to MDS development and/or promotes certain chromosomal changes.
Methods: We conducted a case-control study to evaluate the *NQO1* genotype in a large series of 330 Greek patients with primary MDS (217 males, 113 females, median age 68 years) and 416 gender and age matched healthy individuals (270 males, 146 females, median age 66.5 years). Bone marrow specimens from patients and peripheral blood samples from healthy donors were used for DNA extraction and subsequent genotypic analysis. The *NQO1* gene status was also evaluated in relation to patients' characteristics and cytogenetic findings. Focusing on specific cytogenetic aberrations recurrently found in MDS/AML, we retrospectively analysed the *NQO1* genotypic distribution in a cohort of 566 patients with -5/del(5q), -7/del(7q), trisomy8, del(20q) and -Y. Among them, 199 cases showed -5/del(5q), 153 had -7/del(7q), 202 presented +8, 51 cases had del(20q) and 65 cases exhibited loss of the Y chromosome (-Y). The *NQO1* $C^{609}T$ SNP genotyping was performed by a Real-Time PCR method using Taqman technology.
Results: Our case-control study revealed no differences in the frequencies of the *NQO1* variant genotypes between patients and healthy donors. The higher incidences of variant *NQO1* genotypes observed in MDS patients with +8, prompted us to analyse the *NQO1* gene status in a large number of MDS/AML patients carrying certain specific abnormalities. Interestingly, the results showed that patients with either +8 or del(20q) exhibited a 1.8-fold increased risk of carrying at least one variant T allele, as compared to the allele frequencies of the control population (P=0.032, χ^2=10.526, df=4). Particularly, genotypic analysis revealed significantly increased frequencies of heterozygotes (C/T) among patients with del(20q) and homozygous variant individuals (T/T) among patients with +8, as compared to either healthy donors or other cytogenetic groups (P=0.001, χ^2=27.503, df=8).
Summary / Conclusion: Our case-control study, that represents the largest series of patients with primary MDS ever evaluated for the *NQO1* $C^{609}T$ gene polymorphism, showed no differences in the frequencies of the *NQO1* variant genotypes between patients and healthy donors. The result suggests that *NQO1* polymorphism does not correlate with susceptibility to MDS. The increased frequency of homozygous variant genotype (T/T) in patients with +8 might suggest a potentially causative role of lack of NQO1 protein in the pathogenesis of trisomy 8 in MDS/AML.

B1738

AN IMPROVED REAL-TIME QUANTATIVE PCR PROTOCOL FOR DETECTING VARIANT-TYPE PML-RARA FUSION TRANSCRIPTS

H Liu[1*], F Wang[1], W Teng[1], T Wang[1], C Tong[1]
[1]Ludaopei Hematology & Oncology Center, Beijing, China

Background: The variant-type PML-RARA (PML-RARA-V) transcript is typically refers to that the breakpoint of PML gene located in exon6 and sometimes accompanied by insertion of small pseudo exon sequences derived from RARA-intron2. The Europe Against Cancer Program (EAC) reported sets of reverse transcript quantitative PCR (RQ-PCR) protocols including PML-RARA-V type in 2003 and were widely referenced. But we find that the EAC2003 protocol couldn't efficiently detect 4 of the 11 PML-RARA-V transcripts identified in our laboratory.
Aims: To design a new RQ-PCR primer, in order to efficiently detect the PML-RARA-V fusion gene.
Methods: PML-RARA-V sequences were got by a longer fragment PML-RARA amplification and Sanger sequencing in 4 patients whom PML-RARA-V gene failed detected by using EAC-2003 primer set. Sequences were analyzed and new forward primer was designed and tested.

Results: Cases and PML-RARA-V sequences information are following: Case 1: The PML partial retained the first 110bp of exon6, with an 'AG' insertion; Case 2: Retained the first 112bp of PML-exon6, with a 63bp insertion; Case 3: Retained the first 115bp of PML-exon6, with a 9bp insertion, morphology and immunophenotype of the leukemia cells manifested as atypical APL with lack of granules and Auer rods; Case 4: Retained the first 172bp of PML-exon6, with a 36bp insertion, the leukemia cells showed normal chromosome karyotype but PML-RARA fusion signal can be detected by fluorescence in situ hybridization. Insertion fragments of the later 3 PML-RARA transcripts were all derived from RARA-intron2. All of the 4 patients were sensitive to all-trans retinoic acid and arsenic trioxide treatment. These 4 out of 11 PML-RARA-V transcripts were all failed to be detected by EAC2003 protocol due to the forward primer affected by their breakpoints. By combining use the newly designed forward primer 'GAGGGGAAGGAGGCAAGGTT' and EAC2003 forward primers, we could efficiently detect all of the 11 PML-RARA-V transcripts identified in our laboratory.
Summary / Conclusion: We propose combining use of a newly designed forward primer and EAC2003 forward primer to detect PML-RARA-V transcripts more efficiently.

B1739
DELETION OF 14Q IN COHORT OF 560 PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA
L Dostalova[1*], V Hodslavska[1], T Sablaturova[1], M Stoklasova[1], A Strnkova[1], B Drevojankova[1], A Burdova[1], M Brejcha[2], D Klodova[2], M Wrobel[2], Y Brychtova[3], H Francova[3], V Heinzova[4], J Zivna[5], N Rytikova[6], C Bodzasova[7], J Zuchnicka[7]
[1]Laboratory of Medical Genetics, Laboratore AGEL a.s., [2]Hospital Novy Jicin a.s., Novy Jicin, [3]University Hospital Brno, Brno, [4]Silesian Hospital Opava, Opava, [5]Hospital Hranice a.s., Hranice, [6]Hospital Krnov, Krnov, [7]Faculty Hospital Ostrava, Ostrava, Czech Republic

Background: Deletion of 14q is rare but recurrent aberration in B-cell malignancies, especially in chronic lymphocytic leukaemia (CLL). A limited number of studies focused on characterization of patients with del(14q). Reindl *et al*. (2010) suggested that del(14q) is associated with short time to treatment. We analysed CLL patients from Czech republic by conventional cytogenetic analysis, fluorencence *in situ* hybridization (FISH) and molecular methods and characterized the cases with del(14) in detail.
Aims: The purpose of the current study was to focus on del(14q) in cohort of 560 CLL patients, to evaluate the incidence and to analyse additional cytogenetic abnormalities, *IGVH* mutation status and clinical outcomes.
Methods: In a period between 2008 to 2012, 560 cases with CLL were investigated. Conventional cytogenetics was performed on peripheral blood or bone marrow samples cultured in medium with CpG-oligonucleotides and IL-2 for 72 hours. I-FISH was performed on unstimulated cells for detection of *IGH@* rearrangement, + 12, del(11q), del(13q) and del(17p). The range of del(14q) was determined by multicolor banding. For analysis of the *IGVH* mutation status, monoclonal immunoglobulin rearrangements were amplified by PCR from cDNA. PCR products were purified in agarose gel and analysed by direct sequencing.
Results: A total of 519/560 (92,7 %) cases were succesfully stimulated for metaphase analysis. Del(14q) was detected in 12 cases (12/519,2,3 %) and it was mostly intersticial (11/12). It showed variable size but clustered at specific chromosomal bands. FISH revealed loss of 3´*IGH@* flanking sequences (8/12). In 5 cases del(14q) was found as sole abnormality, whereas additional aberrations were identified in 7 cases. Two cases had complex karyotype. *IGHV* status was unmutated in 9/11 cases.
Summary / Conclusion: Cytogenetic results are highly relevant in defining the prognosis of CLL patients. I-FISH is standard method for detection of important chromosomal aberrations. However, metaphase cytogenetic analysis reveals another abnormalities which may change the prognosis of patients defined by FISH. Our results are consistent with those of other studies. We confirmed the low occurence of del(14q), association with unmutated *IGVH* and the presence of additional aberrations together with del(14q).

B1741
MOLECULAR CHARACTERIZATION AND PRENATAL DIAGNOSIS OF FAMILIAL HEMOPHAGOCYTIC LYMOPHOHISTOCYTOSIS IN EGYPTIANS
S Elsayed[1*], E Elsobky[1], E Ragab[1], V Grandin[2], N Lambert[3], G de Saint Basile[3]
[1]Children's Hospital, Ain Shams University, Cairo, Egypt, [2]CEDI, Hôpital , Necker Enfants Malades, [3]CEDI, Hôpital , Necker Enfants Malades, Paris, France

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is a rare, autosomal recessively disease with a clinical manifestation during infancy in 70%–80% of the patients. Previous genetic studies in FHL revealed an extended genetic heterogeneity. The high rate of consanguinity in Egyptians makes this rare recessive disease relatively common.
Aims: To study molecular characteristics of the Egyptian patients with FHL and to find any potential genotype phenotype correlation
Methods: The study included 15 families presenting to the Medical Genetics Center for genetic counseling as one or several children had clinical and laboratory criteria consistent with FHL. Molecular diagnosis was done in 9 families by segregation analysis of polymorphic markers of *PRF1* (FHL2), *UNC13D* (FHL3), *STX11* (FHL4), and *STXBP2* (FHL5) genes. Sequencing of *PRF1* gene was performed to another 3 parents as their affected children were already deceased at presentation. Prenatal diagnosis was done for 2 mothers with previously detected mutations
Results: Mutations in FHL causing genes were detected in 5 patients (2 in the same family). This included homozygous Del218-224 mutation and compound heterozygous for G218A/C1304T mutation in the *PERF1* gene, homozygous 284delC mutation in the *STX11* gene and homozygous C1430T mutation in the *STXBP2* gene (one family). Prenatal diagnosis revealed normal fetus in *STX11* family while an affected fetus was detected in a family of *PRF1* gene.
Summary / Conclusion: The mutation spectrum of the FHL in the Egyptian children is expected to be heterogeneous due to the wide ethnic variation. The severity and the rapid progression of the disease was an obstacle in molecular diagnosis in many families as most families presented after death of one or several children. Molecular analysis should be further extended for carrier testing to define the actual frequency of this rare disease

B1742
ASSOCIATION OF GSTP1 POLYMORPHISM AND CHROMOSOME ABERRATIONS IN ACUTE MYELOID LEUKEMIA
A Daraki[1,2*], F Rosmaraki[1,2], K Kakosaiou[1,2], S Zachaki[2], M Kalomiraki[2], V Aleporou[1], C Sambani[2], G Pantelias[2], P Kollia[1], K Manola[2]
[1]National and Kapodistrian University of Athens, [2]NCSR "DEMOKRITOS", Athens, Greece

Background: The role of cytogenetics in determining the biologic basis of Acute Myeloid Leukaemia (AML) is widely recognized. Different cytogenetic abnormalities and normal karyotype have been described in AML, although aetiology of AML remains unknown. However, interactions between environmental exposure and genetic background postulated to be a possible cause of AML development. The GSTP1 gene implicated in the detoxification pathways of many genotoxic xeniobitics and the single-nucleotide polymorphism ($A^{313}G$) abolished GSTP1 enzymatic activity. Thus, homo-/hetero-zygotes (G/G, A/G) for the mutant allele present decreased enzymatic activity.
Aims: Our study aimed to investigate the potential implication of GSTP1 polymorphism in AML susceptibility and AML-specific chromosomal abnormalities.
Methods: Chromosome studies were performed on 184 AML patients. Patients were classified according to FAB classification. GSTP1 genotyping was performed by PCR-RFLP assay in all patients and 370 sex and age matched unrelated healthy controls.
Results: FAB classification was available in 102 patients with M2 (32.5%) as the most common subtype. Cytogenetic analysis was successful in 97.3% of patients. Abnormal karyotype was found in 62.6% of patients and among them, 32.1% were complex while 20.5% satisfied the requirements of the monosomal karyotype definition. The most common chromosome aberrations were +8 (21.4%), -7/del(7q) (20.5%), -5/del(5q) (13.4%), abnormalities of 11q23 (12.5%), t(15;17) (9.8%), t(8;21) (8.0%), -Y (8%), +22 (7.1%) and inv(16) (6.25%). The *GSTP1* genotypic distribution in patients and controls was significantly different($P<0.0001$). An increased frequency of heterozygotes A/G was observed in M2 (70.8%) and M4 (65%) subtypes. Interestingly, a higher frequency of homozygous mutant G/G in AML patients with normal karyotype was observed compared to the abnormal karyotype ($P=0.056$). Furthermore, a higher frequency of heterozygotes A/G was revealed in AML patients with -Y, -7/del(7q) and +22.
Summary / Conclusion: Our results suggest that the GSTP1 $A^{313}G$ polymorphism may be a predisposing factor for the development of AML-specific abnormalities. Moreover, homozygosity of the GSTP1 polymorphism seems to be associated with development of AML with normal karyotype.

B1743
EXTERNAL QUALITY ASSESSMENT OF KIT D816V MUTATION TESTING IN MASTOCYTOSIS
S Scott[1*], J Clark[1], A Jack[1], L Whitby[1], D Barnett[1], J Reilly[1]
[1]UK NEQAS for Leucocyte Immunophenotyping, Sheffield, United Kingdom

Background: Mastocytosis is frequently associated with the somatic activating mutation D816V in the *KIT* gene; this results in constitutive activation of *KIT* tyrosine kinase activity, and provides resistance to tyrosine kinase inhibitors such as Imatinib. It is a minor criterion for classification of Systemic Mastocytosis (SM) according to the 2008 WHO Classification of Tumours of Haematopoietic and Lymphoid Tissues. The *KIT* D816V mutation is detectable in 95% of patients with SM but mutation load is often low, with previous studies showing a median 0.9% mutant versus wildtype. UKNEQAS LI, an international provider of External Quality Assessment (EQA)/Proficiency Testing (PT) services, has a commitment to improve laboratory testing quality through standardisation and education in haemato-oncology diagnostics.
Aims: To assess and improve the quality of diagnostic testing for *KIT* D816V mutation testing UKNEQAS LI have recently initiated a pilot scheme for *KIT*

D816V mutation.
Methods: Two vials of lyophilised cell-lines were distributed to 28 participants for *KIT* D816V mutation analysis. The samples were manufactured to contain a minority of *KIT* D816V mutated cells with a substantial background of unmutated cells, to mimic mutation levels typically seen at diagnosis in SM. Based on cell composition the level of mutation in the two samples was 1% and 2.5%, respectively, when analysing genomic DNA.
Results: 20/27 (74.1%) participants found a *KIT* D816V mutation in both samples issued. Six participants did not find a *KIT* D816V in either sample. One participant found a mutation in the 1% sample but not in the 2.5% sample and another participant found a mutation in the 2.5% sample but not in the 1% sample. This indicates a potential false negative rate of around 25% in clinical samples. Eleven participants used Sanger sequencing as part of their testing pathway. Interestingly, of the 8 participants who did not find a *KIT* D816V mutation in one or both of the samples, 7 used Sanger sequencing as part of their testing pathway, with 5 of these using it as their sole technique.
Summary / Conclusion: Direct Sanger sequencing has a sensitivity of 15-20% which is not adequate to detect low level *KIT* D816V mutations typically found in SM unless, perhaps, highly purified mast cells are analysed. Other more sensitive techniques such as nested PNA-PCR or real time PCR should be employed to provide optimal SM diagnosis and treatment.

B1744
SUBMICROSCOPIC DELETIONS OF 3'-CBFB GENE PORTIONS IN ACUTE MYELOID LEUKEMIA WITH INV(16): A COMPREHENSIVE DIAGNOSTIC APPROACH USING HIGH RESOLUTION MICROARRAY AND LONG DISTANCE-PCR
J Yang[1*], S Oh[2], E You[3], H Lee[1], W Lee[1], S Baek[4], H Yoon[4], E Cho[5], C Meyer[6], R Marschalek[6], T Park[1]
[1]Department of Laboratory Medicine, School of Medicine, Kyung Hee University, Seoul, [2]Department of Laboratory Medicine, Inje University College of Medicine, Busan, [3]Laboratory Medicine, [4]Department of Hematology-Oncology, School of Medicine, Kyung Hee University, Seoul, [5]Greencross Reference Laboratory, Yongin-city, Korea, Republic Of, [6]Institute of Pharmaceutical Biology, ZAFES, Diagnostic Center of Acute Leukemia, Goethe-University of Frankfurt, Frankfurt/Main, Germany

Background: Submicroscopic deletions in leukemia occurs in rearrangements such as *BCR-ABL1*, while 3'-*CBFB* gene deletions in AML with inv(16) are rarely reported with the incidence ranging from 2% to 7.7% estimated by fluorescence in situ hybridization (FISH).
Aims: As almost all other reports were based on FISH analysis alone, we focused on the comprehensive molecular analysis of 3'-deletion of *CBFB* in AML with inv(16), obtained from bone marrow specimen of a male AML patient. Identifying the extent of submicroscopic deletion and involved genes could provide an understanding of presumably an inferior prognosis of such patients with submicroscopic deletion.
Methods: Workup included karyotyping, FISH, multiplex reverse transcriptase polymerase chain reaction (RT-PCR), long distance-PCR (LD-PCR), and high resolution microarray studies. A chromosomal microarray experiment using Cytoscan 750K array (Affymetrix, Santa Clara, CA) was conducted to confirm the presence of the submicroscopic deletion. To reconfirm the deleted regions, high resolution microarray was conducted using a customized Agilent Human aCGH Microarray 1x1M designed to include 698K probes of chromosome 16 (Agilent Technologies, Palo Alto, CA).
Results: Cytogenetic analysis resulted in the karyotype 46,XY,inv(16)(p13.1q22) in 19 out of 20 metaphases we analyzed. FISH analysis using Vysis LSI *CBFB* dual-color break-apart probe (Abbott Molecular/Vysis, Des Plaines, IL) also resulted in split signals in 94.5% of the analyzed cells. A notable finding was the loss of the green 3'-*CBFB* telomeric signal which indicated for a 3'-*CBFB* deletion, namely a submicroscopic deletion. The subsequent multiplex RT-PCR using Hemavision (DNA Technology, Aarhus, Denmark) revealed a *CBFB-MYH11* rearrangement. From LD-PCR analysis, *CBFB-MYH11* fusion gene was found to have been generated from a recombination event that occured within intron 5 of *CBFB* and intron 32 of *MYH11*. Microarray result was arr16p13.11(15,822,415-16,289,059)x1,16q22.1(67,122,027-68,312,149)x1 (Human Genome Build 37.2; http://genome.ucsc.edu). The deletion at 16p included the 5'-portion of the MYH11 gene and several genes located centromeric to *MYH11*. High resolution microarray resulted in arr 16p13.11(15,815,138-16,291,017)x1,16q22.1(67,123,219-68,307,465)x1 and gave a more detailed information of the deletion that occurred at 16p13.11 and 16q22.1 (Figure 1). Interestingly, the high resolution aCGH analysis revealed another deletion (exon 28-32) that occurred telomeric to the *MYH11* gene remnant at 16p13.11 identified and led to the deletion of the overlapping *NDE1* gene (exon 8).
Summary / Conclusion: Analysis of submicroscopic deletions in AML patients can be of great benefit for comprehension of patients' clinical courses and their corresponding genetics. Reports on submicroscopic *CBFB* deletions in AML patients with inv(16) are yet limited and require further studies to characterize the additional genetic lesions of these patients. The best strategy would be the use of commercially available SNP microarrays (Affymetrix, Santa Clara, CA) and customized aCGH arrays (Agilent Technologies, Palo Alto, CA) for chromosome 16 to systematically characterize more deletions in AML patients with inv(16). Deletion of the *NDE1* gene located centromeric to the *CBFB-MYH11* breakpoint was recently described to be disrupted in at least of 90% of inv(16)-positive AML cases. Since *CBFB-MYH11* fusion gene produces a large variety of alternatively spliced fusion transcripts (n~10), we recommend using the established genomic breakpoint analysis for the molecular characterization of inv(16) leukemia patients. In addition, genomic breakpoint analysis enables prompt diagnosis and confirmation of specific gene rearrangements in leukemia and even solid tumors. The combination of different molecular and array technologies will aid the understanding of cancer-based mechanism, and moreover, to translate this knowledge into clinical trials to improve cancer treatment in the future.

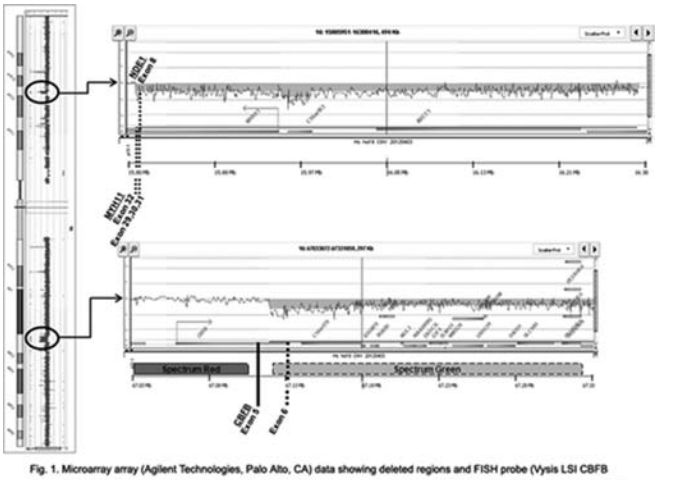

Fig. 1. Microarray array (Agilent Technologies, Palo Alto, CA) data showing deleted regions and FISH probe (Vysis LSI CBFB dual-color break-apart probe, Abbott Molecular/Vysis, Des Plaines, IL) binding sites on chromosome 16. At 16p, the 5'portion of MYH11 gene (exon 1-32) and overlapping 3'-portion of NDE1 gene (exon 8) were deleted. At 16q, region extending from intron 5 of CBFB to probe-binding site (3' CBFB green telomeric signal) was deleted.

B1745
MOLECULAR FACTORS ASSOCIATED WITH BONE INVOLVEMENT IN GAUCHER PATIENTS
K Lukina[1*], I Fevraleva[1], V Mamonov[1], E Sysoeva[1], G Yatsyk[1], A Sudarikov[1], E Lukina[1]
[1]Hematology Research Center of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Gaucher disease is one of the most common glycolipid storage disorders caused by mutations in the gene (GBA) which encodes human acid-β-glucosidase. Bone involvement is typical for Gaucher disease and varies from asymptomatic osteopenia to irreversible orthopedic defects. Bone marrow infiltration by Gaucher cells, impaired regulation of bone metabolism and ischemic osteonecroses are currently considered to be the main pathogenic mechanisms of bone involvement. However, the cause of exceptional heterogeneity of bone disease still remains unclear.
Aims: To study genetic factors possibly associated with severity of bone involvement in type I Gaucher patients: the most common GBA mutations and mutations causing a predisposition to thrombophilia.

Methods: The study group included 100 adult patients (36 males and 64 females aged from 18 to 79 years) with the diagnosis of type I Gaucher disease verified by enzyme assay. Patients (pts) were divided into 4 groups based on the severity of bone involvement: extremely severe (3 pts), severe (25 pts), moderate (58 pts) and mild (14 pts) bone involvement. The assessment of bone involvement was based on the severity of osteoporosis, presence of pathological fractures, avascular necroses of hips, osteonecroses, bone marrow infiltration assessed by MRI and X-ray examinations.
Allele-specific real time polymerase chain reaction enabling the identification of single nucleotide substitution in certain DNA segments was used to screen the pts for: 1) the most common GBA mutations (amino acid substitution N370S, G - insertion (84 GG), amino acid substitution L444P and inversion IVS2+1G>A); 2) mutations causing a predisposition to thrombophilia (G1691A Factor V Leiden, G20210A prothrombin, C677T MTHFR mutations and 4G/5G polymorphism of PAI-1).
Results: The most common mutation was N370S revealed in 93% of the total number of alleles, followed by L444P found in 22% of alleles. The method allowed to identify both mutant alleles in 39% of pts: the genotype N370S/N370S was revealed in 17% of pts, N370S/L444P – in 19%, N370S/IVS2+1 – in 2%, L444P/84GG – in 1% of pts. Only one mutant allele was identified in 57% of pts: the genotype N370S/Other mutation was found in 55%, L444P/Other mutation – in 2% of pts. None of the 4 analyzed mutations was found in 4% of pts. No correlation between the GBA genotype and sever-

ity of bone involvement was found in our group of patients.
We also searched for the markers of other hereditary diseases and predispositions among Gaucher patiens. Homozygous C677T MTHFR mutation was found in 7 (7%) of pts, heterozygous factor V Leiden mutation – in1, heterozygous G20210A prothrombin mutation – in 1; 4G/4G PAI-1 polymorphism – in 30 (30%) of pts. It should be noted that all 3 pts with extremely severe bone involvement carry molecular markers of thrombophilia: 1 pt – G20210A prothrombin mutation, 2 pts – 4G/4G PAI-1, however correlation with bone involvement is not statistically significant.
Summary / Conclusion: We found no association between the severity of bone involvement and GBA genotype. To assess correlation between thrombophilia markers and severity of bone involvement further research is needed.

B1747

CLINICAL SIGNIFICANCE OF PREVIOUSLY CRYPTIC COPY NUMBER ALTERATIONS AND LOSS OF HETEROZYGOSITY USING THE COMBINED ARRAY CGH AND SNP MICROARRAY ANALYSIS IN CHILDREN WITH AML AND MDS

K Koh[1*], J Lee[2], J Seo[1], H Shin[1], E Seo[2], H Im[1], J Seo[1]
[1]Pediatrics, [2]Laboratory Medicine, ASAN MEDICAL CENTER, Seoul, Korea, Republic Of

Background: Although cytogenetic analysis provides essential information for diagnosis and prognosis in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS), a significant proportion of patients lacks cytogenetic aberrations on metaphase cytogenetics (MC). The combined array comparative genomic hybridization and single-nucleotide polymorphism microarray (CGH+SNP microarray) platform can allow the simultaneous detection of copy number alterations (CNA) and copy neutral-loss of heterozygosity (CN-LOH), which cannot be detected by MC, in high-resolution without the need to run two separate microarray experiments. Whole-genome scanning studies using array CGH and SNP microarray are not sufficient in pediatric AML and MDS, and their clinical and biological implications are still to be investigated in pediatric population.
Aims: This study was performed to detect simultaneously cryptic CNA and CN-LOH by CGH+SNP microarray, and to characterize the clinical significance of the submicroscopic defects in childhood AML and MDS.
Methods: A total of 18 patients with AML (n = 15) or MDS (n = 3) younger than 18 years of age at diagnosis were included in this study. DNA extracted from frozen bone marrow (n=17) or peripheral blood (n=1) samples at diagnosis were used for CGH + SNP microarray analysis. LOH regions >5 Mb was regarded as significant. All samples were analyzed with Agilent CGH+SNP 180K kit microarrays (Agilent Technologies, Santa Clara, CA, USA). Data were analyzed using Agilent CytoGenomics 2.0.6.0 with an ADM-2 algorithm (threshold 8.0). The results were analyzed according to the genome build Hg19.
Results: CGH+SNP microarray revealed CNAs at 14 regions (7 gains, 7 losses) in 9 patients, while MC detected 11 regions (5 gains, 6 losses) in 8 patients. All genomic imbalances detected by MC were recognized by CGH, whereas 2 gains and 1 loss revealed by CGH were undetectable by MC. In addition, an accurate gain region, which was erroneously detected by MC, was corrected by CGH. With CGH+SNP microarray, LOHs larger than 5Mb were detected at 12 regions in 8/18 (44%), LOHs larger than 10 Mb were detected at 6 regions in 5/18 (28%), and LOHs, which were larger than 10 Mb and involved terminal regions or whole chromosome, were detected at 3 regions in 3/18 (17%). LOH affected the following chromosomal arms of 1p, 5q, 9p, 7q, 13q,6,15q, 18q, Xp, Xq, and recurrent LOH was observed at 1p33-p32 (n = 2). Of 5 patients with normal karyotype, CGH+SNP microarray revealed cryptic LOH with or without CNA in 3 patients. Of 13 patients with abnormal MC, CGH+SNP microarray detected additional cryptic CNAs (n = 2), and LOHs (n = 5) in 6 patients. In total, 9 patients were shown to have additional aberrations including CNAs (n = 3) and/or LOHs (n = 8). Certain segmental LOH or CNA regions included candidate genes responsible for leukemogenesis, such as *CDKN2C* (1p), *CDKN2A* (9p), *JAK2* (9p), *PAX5* (9p), *BEX1* (Xq), *ETV6* (12p), *IRF4* (6p), *DEK* (6p), and *FLT3* (13q). Of 15 patients with AML, 3 patients with terminal LOH larger than 10 Mb showed significantly inferior relapse-free survival rate (*P*=0.041), whereas interstitial LOH larger than 5Mb or those larger than 10 Mb did not influence the outcome.
Summary / Conclusion: This study showed that CGH+SNP microarray allowed simultaneous detection of previously cryptic CNA and LOH in the patients with abnormal karyotypes as well as normal karyotype. The results showed that CGH+SNP microarray can be used complimentarily with the conventional cytogenetics to delineate the genetic aberrations of childhood AML and MDS. In addition, segmental LOHs harboring oncogenes or tumor suppressors associated with leukemogenesis may imply pathobiological significance. To refine the prognostic impact and biologic implications of hidden genetic aberrations in childhood AML and MDS, a prospective study on larger pediatric population with matched DNA sample is warranted.

B1748

HYPOXIA INDUCIBLE GENES, ERYTHROPOIETIN AND VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION IN RENAL CELL CARCINOMA

B Beleslin-Čokić[1*], B Ilić[1], K Mirković[1], C Noguchi[2], V Čokić[3], S Damjanović[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, Belgrade, Serbia, [2]Molecular Cell Biology Section, Molecular Medicine Branch, NIDDK, National Institutes of Health, Bethesda, United States, [3]Laboratory of experimental hematology, Institute for Medical Research, Belgrade, Serbia

Background: More than 90% of kidney cancers are of epithelial cells origin, referred to as renal cell carcinoma (RCC). RCC can be familiar or sporadic, often associated with distinct genetic mutations with the most prominent being von Hippel-Lindau (VHL) gene mutations. The germ line mutation in the VHL gene is usually associated with familiar RCC and VHL syndrome. The VHL protein is a component of an E3 ubiquitin ligase complex that regulates hypoxia-inducible factor (HIF). If VHL is inactivated, then a defective VHL protein is produced and HIF is not degraded.
Aims: Accumulation of HIF induces over-expression of hypoxia related genes including erythropoietin (EPO), vascular endothelial growth factor (VEGF) and platelet-derived growth factor (PDGF), thus promoting angiogenesis, proliferation and tumorogenesis. The aim of this study was to examine hypoxia related genes in RCC.
Methods: We analyzed the tumor and surrounding healthy tissue in 10 patients who had radical nephrectomy because of RCC. We analyzed mRNA expression of VEGF and two VEGF receptors, VEGFR-1 (Flt-1) and VEGFR-2 (Flk-1, KDR) in tumors vs. surrounding healthy tissue by real time quantitative PCR. In addition, we determined EPO and EPO receptor (EPOR) mRNA expression in tumors compared surrounding tissue. DNA was isolated from blood and from tumor and surrounding healthy tissue for sequencing of VHL gene. Also, DNA methylation of VHL gene was analyzed in tumors.
Results: We found that VEGF was induced several folds in all examined tumors compared to healthy tissue.VEGF binds with high affinity to two receptors, VEGFR-1 (Flt-1) and VEGFR-2 (Flk-1, KDR),and we found that VEGFR-2 was induced several folds in tumors compared to healthy tissues, while VEGFR-1 was not induced. However, EPO expression was only detected in 4 out of 10 tumor samples, suggesting dependence of tumor localization in the kidney, since only peritubular fibroblasts produce EPO. Erythropoietin receptor (EPOR) was detected both in tumor and healthy tissues with no difference in expression.DNA was isolated from the blood of all examined patients before radical nephrectomy and was used for sequencing of the VHL gene, checking for sporadic and hereditary forms of RCC. Only one patient had a substitution of leucine to proline at position 25 (P25L) as a polymorphism of the VHL gene. Using sequencing, we demonstrated two different mutations in VHL gene, one was deletion of a nucleotide in codon 147 of exon 2 and second was deletion of 22 nucleotides in codon 99 of exon 1. Since sporadic RCC goes with inactivation of the VHL, either through hypermethylation or mutation, the other 7 tumor samples showed no increase in DNA methylation of VHL gene.
Summary / Conclusion: These results suggest that defective production of VHL protein and accumulation of HIF, EPO and VEGF partially explains the angiogenesis, proliferation and tumorogenesis of sporadic RCC.

B1749

PRODUCTION OF PLASMID CONTROL REAGENTS FOR MOLECULAR MONITORING OF ATYPICAL BCR-ABL1 FUSIONS

H White[1,2*], V Hall[1], G Gerrard[3], L Foroni[3], M Müller [4], A Hochhaus [5], N Cross[2,6]
[1]National Genetics Reference Laboratory (Wessex), Salisbury NHS Foundation Trust, Salisbury, [2]Faculty of Medicine, University of Southampton, Southampton, [3]Molecular Pathology, Centre for Haematology, Faculty of Medicine , Imperial College London, London, United Kingdom, [4]III. Medizinische Klinik, , Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, [5]FZL Dept. Hematology/Oncology, Universitätsklinikum Jena, Jena, Germany, [6]National Genetics Reference Laboratory (Wessex), Salisbury District Hospital, Salisbury, United Kingdom

Background: Approximately 97-98% of CML patients express e13a2 and/or e14a2 *BCR-ABL1* fusion transcripts resulting from translocation breakpoints that fall within the major breakpoint cluster region of *BCR* and a large region upstream of *ABL1* exon 2. Residual disease after therapy for these cases is typically monitored by qRT-PCR using a single primer/probe set. The remaining 2-3% of CML patients express atypical *BCR-ABL1* fusions, the majority of which are accounted for by five variants: e1a2, e6a2, e8a2, e13a3, e14a3, e19a2. These atypical transcripts cannot be monitored by qRT-PCR using standard methodologies and for most of these cases no molecular monitoring option is available.
Aims: To facilitate molecular monitoring for patients with atypical *BCR-ABL1* transcripts we sought to develop five plasmid constructs containing *BCR-ABL1* transcripts e1a2, e6a2, e8a2, e14a3, or e19a2 along with the three principal controls genes *ABL1*, *BCR* and *GUSB*. Construction of plasmids containing the *BCR-ABL1* variant and the control genes allows the same plasmid standard to

be used for both targets.
Methods: The e6a2, e14a3, and e19a2 transcripts were PCR amplified from patient blood samples to produce amplicons upstream of the *BCR* breakpoint to *ABL1* exon 10. E1a2 was amplified in a similar fashion from the SD1 cell line. The e8a2 transcript was also amplified from patient leukocytes from *BCR* exon 8 to *ABL1* exon 5 and included a 55bp inverted insertion between the two genes that was derived from ABL1 intron 1. Three transcripts (e6a2, e14a3, e19a2) were cloned into pCR2.1 (Invitrogen). e6a2 and e19a2 (HindIII/XbaI) fragments were subcloned into a previously constructed vector pUC18_GUSB_BCR (HindIII/XbaI) and e14a3 (HindIII) was subcloned into pUC18_ABL1_BCR_GUSB (HindIII). E8a2 and e1a2 were amplified using primers with SalI tags and subcloned into pUC18_BCR_GUSB (SalI). Plasmid sequences were verified by sequencing the cloned insert and then plasmids were linearised using HindIII (e6a2, e19a2), EcoRV (e1a2, e8a2) and SalI (e14a3). Each plasmid was quantified and the copy number determined. Ten-fold serial dilutions were prepared in 0.1xTE buffer containing 50µg/ml tRNA and analysed using real time PCR with transcript specific forward primers and the Europe Against Cancer reverse primer and probes ENR561 and ENP541 (e1a2, e6a2, e8a2, and e19a2) and ENR1063 and ENP1043 (e14a3).
Results: Copy numbers were assigned to each plasmid and their performance evaluated on replicate serial dilutions. Standard curves showed acceptable gradients: -3.33 (e1a2), -3.33 (e6a2), -3.36 (e8a2), -3.45 (e14a3), and -3.36 (e19a2) and all had an r^2 above 0.99.
Summary / Conclusion: We conclude that this set of 5 plasmids are suitable for calibrating residual disease in patients with atypical *BCR-ABL1* transcripts. Because of the rarity of these fusions, we suggest that molecular monitoring is performed in a very limited number of centres to facilitate cost effective, quality controlled analysis.

B1750
COMPARISON OF CONVENTIONAL CYTOGENETICS, MULTIPLEX RT-PCR, NPM AND FLT3 MUTATION FOR THE DETECTION OF GENETIC ABNORMALITIES IN ACUTE MYELOID LEUKEMIA
J Kim[1*], D Cho[2], S Koo[1], Y Park[1]
[1]Laboratory Medicine, [2]Hemato-Oncolology, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: Acute myeloid leukemia (AML) is a clonal disorder resulting from genetic alterations. Although conventional cytogenetic analysis is a most common method to detect many genetic abnormalities, it requires time for dividing cells and 40 to 50% of AML show normal karyotype. For these limitations, new molecular methods such as multiplex reverse transcriptase-polymerase chain reaction (RT-PCR) and gene mutations have been implemented in characterization of AML to determine diagnosis, prognosis and treatment.
Aims: We studied the clinical usefulness of each method as a routine diagnostic practice.
Methods: We collected data of 104 newly diagnosed AML patients between January 2010 and December 2012. Cytogenetic analysis was performed on unstimulated 24- and 48-hour cultures of bone marrow and multiplex RT-PCR was performed using Hemavision system (DNA Technology A/S, Aarhus, Denmark) to detect 28 different translocations. In addition, *FLT3*-ITD mutations and *NPM1* mutations were analyzed by PCR and sequencing.
Results: Of 104 bone marrow specimen, 57 (54.8%) had clonal abnormalities in cytogenetic analysis and 26 (25.0%) were positive for multiplex RT-PCR. There was no case with more than 1 translocation in multiplex RT-PCR. Among 26 multiplex RT-PCR positive cases, 24 cases had same translocations in cytogenetic analysis. But cytogenetic analysis missed translocations in 2 cases and false negative rate of cytogenetic analysis was 7.7% (2/26). One case with t(9;11) showed normal karyotype in cytogenetic analysis and 1 with t(10;11) had no abnormalities of chromosome 10 and 11 except i(17). Among 57 cases with cytogenetic abnormalities, 32 cases had genetic aberrations not targeted by multiplex RT-PCR but 1 with t(15;17) showed false negative for multiplex RT-PCR due to very low RNA quantity (9.8 ng/µL). So false negative rate of multiplex RT-PCR was 3.7% (1/27). The *NPM1* mutations were identified in 19 (18.3%) of the 104 AML and in 18 (40.0%) of the 45 AML showing normal karyotype and negative multiplex RT-PCR. And type A *NPM1* mutations were 15 (78.9%). The *FLT3*-ITD mutations were found in 6 (13.3%) of the 45 AML with normal karyotype and were a sole detected genetic abnormality in 4 cases.
Summary / Conclusion: In AML, genetic changes could be detected in 76.9% using cytogenetic and molecular analysis including gene mutations. Cytogenetic analysis has the extensive capacity to detect chromosomal abnormalities. Multiplex RT-PCR has an advantage in detecting cryptic translocations missed by cytogenetic analysis and gene mutations provide additional prognostic data. Therefore, combination of cytogenetic and molecular analysis should be used at the time of diagnosis routinely.

B1751
CLINICAL AND MOLECULAR FINDING IN MACEDONIAN FAMILY WITH NIJMEGEN BREAKAGE SYNDROM
S Kocheva[1*], K Martinova[1], S Glamocanin[1], Z Antevska-Trajkova[1], B Coneska-Jovanova[1], A Eftimov[2], N Matevska[2], A Dimovski[2]
[1]Hematology and Oncology, University Children's Hospital, Medical Faculty, University "St. Cyril and Methodius", Skopje , [2]Molecular laboratory, Faculty of Pharmacy, University "St. Cyril and Methodius", Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Nijmegen breakage syndrome (NBS) is a rare autosomal recessive chromosomal instability disorder characterized by microcephaly, immunodeficiency, radiosensitivity and a very high predisposition to malignancy. The gene responsible for NBS, NBS1, is located on chromosome 8q21 and encodes a protein called nibrin. This protein is a component of the hMre11/hRad50 protein complex, suggesting defective DNA double strand break (DSB) repair or cell cycle checkpoint function in NBS.
Aims: In this report we describe two patients with the NBS in Macedonian family. To our knowledge this is the first family with NBS reported from Macedonia.
Methods: Clinical and laboratory examinations with regard to lymphoma and NBS. Mutation detection using genomic DNA was performed by PCR with specific primers for the human *NBS1* gene, followed by automated DNA sequence analysis
Results: Both children presented with microcephaly, syndaktylia and by the development of T cell non Hodgkin lymphoma at the age of 7 and 10 years, respectively. Molecular analysis showed homozygositye for 657del5 mutation in the NBS1 gen. The parents were heterozygotes and they had no knowledge of consanguineous relationship. The first child was treated with BFM-NHLprotocol and achieved a complete remission which lasted for 21 months. A subsequently, he developed a medullar relapse with hiperleukocytosis and died due to lethal CNS complications. The second child was treated according to AIOP-BFM ALL 2009 protocol. The remission was not achieved in this patient and she passed away after a very brief and severe episode of gram-negative sepsis and SIRS during bone marrow aplasia after the intensive chemotherapy block in the induction phase for bone marrow transplantation.
Summary / Conclusion: Because of increased sensitivity to radiation therapy and chemotherapy, the treatment of malignancies in patients with NBS can be difficult. The ability to diagnose disease at the molecular level allows prenatal diagnosis in families at risk to having a child with NBS which is warranted in these families.

B1752
A MULTIPLEX REAL TIME QUANTITATIVE PCR METHOD TO DETECT THE CO-EXPRESSION OF WT1 AND MDR1 GENE EXPRESSION IN ACUTE LEUKEMIA PATIENTS
B Xu[1*], X Song[1], P Shi[1], X Guo[1], J Li[1], S Zhou[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: The interaction between Wilms tumor gene 1 (*WT1*) and the promoter region of the multidrug resistance-1 (*MDR1*) gene has been previously reported but the clinical significance of the coexpression of *WT1* and *MDR1* in acute leukemia *(*AL*) is still largely unknown*. So correlative studies of *MDR1* and *WT1* expression in leukemia cells may ultimately contribute to a better understanding of the relationship of *WT1* and *MDR1* gene expression and elucidate the clinical significance.
Aims: To establish a multiplex real-time quantitative PCR (RQ-PCR) method to detect the co-expression of *WT1* and *MDR1* in acute leukemia patient.
Methods: Total RNA was extracted from k562 cell line and was revrerse transcribed to cDNA by the outer primers of *WT1* and *MDR1* respectively. The cDNA of *WT1* and *MDR1* were purified and digested by BamHI and BglII, and then the two fragments were ligated to form the recombinant fragment *WT1+MDR1*.The outer forward primer of *WT1* and outer reverse primer of *MDR1* were used to amplify the recombinant fragment *WT1+MDR1*.The PCR product was purified and connected with pMD18-T vector, and then transferred into Ecoil DH-5α. A new kind of *WT1-MDR1*-contained plasmid was gained from the positive colony. The recombinant plasmid was verified by digestion with restriction enzyme and PCR amplification. A multiplex real time quantitative PCR method was set up with FAM-labeled *MDR1* probe and VIC-labeled *WT1* gene in one reaction tube. The absolute copy numbers of these two genes were calculated according to their own standard curve. positive plasmid and 47 acute leukemia(AL) patients were tested by this method.
Results: The recombinant plasmid was confirmed by EcoR1 digestion and PCR amplification. The multiplex RQ-PCR technique can catch the sensitivity of *WT1* gene and *MDR1* to 10 copy/µl. The standard curve slope were 0.998 and 0.999. The expression results were the same tendency with route RQ-PCR method. The *WT1* and *MDR1* expression levels of *de novo* AL patients were significantly higher as compared to the controls P<0.001. The *WT1* and *MDR1* expression correlated to the clinical outcome, the AL patients with *WT1* and *MDR1* expression levels significantly decreased after chemotherapy and retained in a low range had a favorable outcome, while patients with high *WT1* and *MDR1* expression levels persistent or increased significantly predicted an adverse prognosis.
Summary / Conclusion: A multiplex real time quantitative PCR method to detect *WT1* and *MDR1* gene were constructed successfully, and it could be used to detect the expression levels of *WT1* and *MDR1* genes simultaneously. The expression of *WT1* and *MDR1* may provide useful information for AL patients prognosis.

B1753
UNUSUAL CONSTITUTIONAL ANOMALY T(11;12;20) IN A CASE OF MULTIPLE MYELOMA
T Boneva[1*], A Asenova[1], L Mitev[1]
[1]Cytogenetics, Military Medical Academy, Sofia, Bulgaria

Background: It is accepted that constitutional structural chromosome aberrations are associated with cancer predisposition. The cytogenetic investigation of these anomalies could be of major importance for identification of the molecular events responsible for the initiation steps in oncogenesis. However, because of insufficient data, the main question, are constitutional chromosome aberrations a part of the multistep malignant process has not been as yet clarified.
Aims: . In this report we describe a new constitutional rearrangement in a case of multiple myeloma. The aim of our study is to investigate is there a link between the constitutional anomaly and the tumor clone.
Results: The patient a 71-year old female was presented with lower back pain, X-rays data of multiple loci of osteolysis in the pelvis, mild anemia (Hb 114 g/l), elevated serum monoclonal protein concentration (35g/l; IgA/kappa), kappa light chain in the urine and 30 percent plasma cells in the bone marrow (BM). Cytogenetic examination of phytohemagglutinin stimulated peripheral blood (PB) established 12 cells (50 cells analyzed) with the following three-way reciprocal translocation 46,XX,t(11;12;20)(p11.2;q21.32;q11.1). Fluorescent in situ hybridization (FISH) of PB with whole chromosome probes for 11 (WC11) and 20 (WC20) confirmed the translocation. Cytogenetic study of BM with G-banding method revealed pathological clone with different numerical and structural anomalies. The clonal aberrations are summarized in the following composite karyotype: 80-81,XX,+1,+1,+2,+2,+3,+3,+4,+4,+5,+5,+dic(5;?;9)(5pter->5p12::?::9p11-9qter),+6,+6,+8,+10,+10,+11,+11,+13,robt(14;15)(p11;p11),+15,+der(17)t(17;?)(p13;?),+18,+18,+19,+19,del(20)(p11.1p11.2),+21,+21,+22,+22,+3mar,dmin.[cp5]. The remaining 18 cells analyzed showed normal diploid karyotype 46,XX. Constitutional anomaly t(11;12;20) or some of the constitutional derivative chromosome №№11, 12, 20 are not presented in the malignant clone. Fish analysis of BM with WC11 and WC20 did not find constitutional rearrangements in chromosome 11, 12 and 20, but demonstrated that the deleted segment 20p11.1-11.2 is inserted in the dicentric chromosome between the parts of chromosome 5 and 9. Split assay with DNA specific probes for IgH region at 14q32 and DNA specific probes for 1q21/1p36, p53 showed normal FISH signals. DNA specific probe for 13q14 indicated clone with monosomy 13 – nuc ish(DLEUx1,13qterx1)[10/100]. In conclusion, the pathological clone in our case has not been originated from the cells with constitutional anomaly and the both are independent cytogenetic events.
Summary / Conclusion: In conclusion, the pathological clone in our case has not been originated from the cells with constitutional anomaly and the both are independent cytogenetic events.

Drug resistance and pharmacology

B1754
EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1 INCREASES DRUG-RESISTANCE THROUGH ENHANCED PKD
J Kim[1*], W Kim[2], C Park[1]
[1]Samsung Biomedical Research Institute, [2]Div. of Hematology/Oncology, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Epstein-Barr virus (EBV)-encoded latent membrane protein-1 (LMP1) is a transmembrane protein essential for EBV-induced immortalization and transformation of B cells. Protein kinase D (PKD, also called PKCmu) as a serine/threonine kinase processes important to cancer development, including cell growth, apoptosis, motility, and angiogenesis.
Aims: We sought to identify molecular targets of LMP1 and examined the effects of a specific LMP1 target on the chemo-susceptibility of EBV-infected B cells.
Methods: To investigate the effect LMP1 on B cell, we compared gene expression profile according to the LMP1 expression, using commercially available cDNA microarray. Additionally, we examined that LMP1 and PKD co-localize in cytoplasm by confocal microscopy and interact by immunoprecipitation. Cytotoxicity assay was determined whether LMP1-induced PKD drug resistance by promoting cell survival.
Results: LMP1 induces expression of endogenous PKD in B cell specific manner. LMP1 and PKD were co-localized interaction in cytoplasm. We verified that NF-*K*B binding is required for LMP1-induced enhancement of PKD expression. Furthermore, PKD was required for LMP1-induced B cell survival. First, PKD expression enhanced the survival of durg-treated BJAB cells. Second, inhibition of PKD expression by siRNA (siPKD) and GÖ6983 effectively suppressed LMP-1-induced cell survival. Third, PKD mutation and other PKC isoform decreased LMP1-induced drug resistance.
Summary / Conclusion: PKD is a downstream target cellular target of LMP1 via NF-kB and co-localized interaction in B cells. These finding suggest that PKD may be a candidate for new therapeutic interventions aimed at EBV-associated B cell lymphoma.

B1755
TRIPTOLIDE, A CHINESE HERBAL EXTRACT, SENSITIZES RESISTANT LEUKEMIA CELL LINES THROUGH DOWN-REGULATION OF HIF-1A AND NRF2
B Xu[1*], F Chen[1], Y Liu[1], P Shi[1], X Guo[1], S Wang[1], R Li[1], J Zha[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Emergence of cancer cells resistance might be responsible for relapse of leukemia while addition of another cytotoxic drug into the chemotherapy regimen commonly leads to more side effects. Thus, it is challenging to find a novel chemotherapy sensitizer which could be used in a relative lower dosage. Triptolide (TPL) is the extract of old Chinese medicine that has recently been indicated to show cytotoxicity to multiple cancers. However, its application is limited by its narrow therapeutic window. Previous studies have demonstrated that it could re-sensitize resistant cancer cells however the mechanism remains unclear. HIF-1α and Nrf2 are two transcriptional factors which was reported to be related to chemo-resistance.
Aims: To investigate the ability of TPL to re-sensitize HL60/A cell line to Adriamycin (ADM) and K562/G to Imatinib(IM) and related mechanism.
Methods: HL60/A and K562/G cells were subjected to different treatments and thereafter MTT assay, flow cytometry and Western blot or RT-PCR were used to determine IC_{50}, apoptotic status and expression of Nrf2, HIF-1α and their target genes.
Results: Cytotoxic effect of TPL to HL60/A and K562/G cell line were assayed using MTT assay after being exposed to a serial concentration of TPL for 48h. TPL demonstrated a high toxicity to HL60/A and K562/G with IC_{50}= 43.064±1.064 nM and 55.142±5.220 nM respectively. MTT assay showed that a relatively low dose of TPL (IC_{20}: 14nM for HL60/A and 25nM for K562/G) enhanced the cytotoxicity of ADM (IC_{50}:14.36±2.23 vs. 7.9±0.33μM, 1.82 fold; *P* =0.008) to HL60/A and IM (IC_{50}: 62.54±4.33 vs. 53.11±0.57μM, 1.18 fold; *P* =0.02) to K562/G. Results of combination index showed that TPL and anticancer agents had synergistic effects when fraction affected was below 70% (ADM) and 90% (IM). Moreover, apoptotic ratio of cells treated by ADM or IM together with TPL was significantly increased compared to cells treated by ADM or IM alone (ADM: 19.55±1.70% vs. 72.62±4.83, *P* =0.000; IM: 24.78±1.12 vs. 77.52±7.75, *P* =0.000). To further explore the mechanism, Nrf2 and HIF-1α expression was detected by western blotting and RT-PCR with down-stream genes being assessed after HL60/A and K562/G cells being exposed to indicated drugs (ADM 7μM plus TPL 14nM; IM 50μM plus TPL 25nM respectively). In combination with TPL, both ADM and IM down-regulates Nrf2 and HIF-1α expression in HL60/A and K562/G cells at both protein and mRNA levels with Down-stream genes of Nrf2 e.g NQO1, GSR and HO-1 as well as target genes of HIF-1α such as BNIP3, VEGF and CAIX also down-reg-

ulated at mRNA level.
Summary / Conclusion: In conclusion, our study demonstrated that TPL reverses chemo-resistance of HL60/A and K562/G in vitro through down-regulation of Nrf2 and HIF-1α. This work indicates a new role for TPL in cancer therapeutics.

B1756
CHANGES IN GENE EXPRESSION PROFILES IN RESPONSE TO APIGENIN IN IMATINIB SENSITIVE AND RESISTANT CHRONIC MYELOID LEUKEMIA CELLS
Y Baran[1*], A GOKBULUT[1], Z CINCIN[2], B CAKMAKOGLU[2], I KOZANOGLU[3]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, Izmir, [2]Department of Molecular Medicine, Istanbul University, Institute of Experimental Medical Research, ISTANBUL, [3]Department of Hematology, Baskent University, Adana Teaching and Medical Research Center, Izmir, Turkey

Background: Chronic Myleoid Leukemia (CML) results from BCR-ABL gene which is the fusion product of a reciprocal translocation between chromosomes 9 and 22. Currently,tyrosine kinase inhibitors (TKIs) such as imatinib, nilotinib and dasatinib, are generally used for the treatment of CML. Although these inhibitors have significant therapeutic efficacy, the development of resistance is a major problem in terms of patient benefit. Many novel compounds are currently being investigated preclinically and clinically in terms of their therapeutic potentials to overcome imatinib resistance. Apigenin (4',5,7- trihydroxyflavone), a plant dietary flavonoid, has anticancer effects on various cancer types. However, there is no information about the precise mechanisms by which apigenin exerts its antileukemic effects.
Aims: The aim of this study is to obtain comprehensive gene expression profiles altered by apigenin in imatinib-sensitive and imatinib resistant, Philadelphia-positive K562 CML cells.
Methods: K562 and 3 micromolar imatinib resistant K562 cells (K562/IMA-3) cells were treated with 100 μM apigenin for 72 h. Then, total RNA was isolated and converted to cDNA by reverse transcription reaction. Gene expression profiles were determined using Human HT-12v4 beadchip (Illumina, whole genome expression beadchip). Quality control of raw data was performed with the Genome Studio software (Illumina). We performed network and pathway analysis using Ingenuity Pathway Analysis (IPA) software.
Results: Cellular development, hematological system function and hematopoesis were the highest rated Networks in K562 cells as compared to K562/IMA-3 cells. Moreover, hematological disease (p-value:2,78E-04) and cancer (p-value:3,34E-02) were the most statistically significant biofunctions in K562 cells treated with 100 μMapigenin as compared to K562/IMA-3 cells. We also found that the expression levels of 17 genes were statistically affected in both cancer and hematologic disease pathway (p value=.6,44E-03) after apigenin treatment in K562 cells and we determined that these genes are responsible for the development of chronic leukemia. Human serine/threonine protein kinase B-raf proto-oncogene, human non-receptor tyrosine kinase proto-oncogene (FYN), non-polymorphic integral membrane protein (CD74) and interleukin-8 genes are downregulated while programmed cell death-1-ligand-2 and mir-15 genes are upregulated in 100 μM apigenin-treated K562 sensitive cells as compared to untreated controls. ADAMTS5 matrix-metalloproteinase and tumor necrosis factor receptor-associated factor-5 and interleukin-15 receptor alpha genes are upregulated in 100 μM apigenin-treated K562/IMA-3 cells. Downregulated genes in K562/IMA-3 include FOXA2 (Fork-head box) and CYP4Z1 (a cytochorome P450 enzyme) as compared to untreated controls.
Summary / Conclusion: Our results demonstrated that apigenin affected the expression of a large number of genes that are related to the development of CML, cell survival and physiologic behaviors in both cell types. This may help to determine the molecular mechanisms by which apigenin exert pleiotropic effects on K562 and K562/IMA-3 cells. Furthemore, this information could be investigated for the development of chemopreventive and/or therapeutic strategies for CML treatment.

B1757
VARIATION IN LEVELS OF SERUM IMMUNOGLOBULINS AND ITS RELATIONSHIP WITH THE DEVELOPMENT OF SERIOUS INFECTIONS IN PATIENTS TREATED WITH RITUXIMAB
R Martos[1*], J Queizan[1], L Bermejo[1], I Cano[1], B Rosado[1], C Olivier[1], R Fisac[1], A Mateo[1], S Valencia[1], J Hernandez[1]
[1]Hematology and Hemotherapy, HOSPITAL GENERAL DE SEGOVIA, SEGOVIA, Spain

Background: Rituximab is a chimeric monoclonal antibody directed toward CD20, a pan B-cell surface marker that has been proven effective in depleting normal and malignant B cells *in vivo*. Rituximab has demonstrated in combined with chemotherapy and stem cell transplantation, is an effective therapeutic option in the treatment of B lymphoproliferative disorders who expressing CD20. Recent studies have indicated that patients treated with Rituximab, have an increased risk of developing hypogammaglobulinemia, which can increase risk of infectious processes with clinical relevance. However this observation has notthe same significance for all patients, so there must be other factors that have influence in the development of hypogammaglobulinemia (hGM) and severe infections. In this sense, FCGR3A-158V/F polymorphism and its relationship with serum immunoglobulin levels after treatment with Rituximab has been reported as a possible risk factor for developing these complications.
Aims: We report initial data of a study in which we evaluate the impact on variations IG levels in patients treated with Rituximab and its influence on the development of clinically relevant infections.
In a second phase (ongoing) we will analyze the presence/absence of the FCGR3A-158V/F polymorphism in blood samples; from two groups of patients, with and without hypogammaglobulinemia.
Methods: Retrospective study conducted between, January 2008/Maye 2012, which includes all patients who received treatment with Rituximab in our hospital. We analyze demographic parameters (age, sex), hematologic pathology, IG values (pre and post treatment), defining the hypogammaglobulinemia according to the following cutoffs: IgG ≤750mg/dl, IgA ≤80mg/dl and IgM ≤45mg/dl, and its association with the presence of clinically relevant infections (such as reason for hospital admission) and analyzed in respect of type of infection, causing germ and final outcome. Statistical analysis was performed using SPSS v.15: Test of homogeneity for comparison two proportions (Z test for comparing).

	Patients	Infection	Site of infection	Germ	Exitus
hGM	n=41 (45%)	n=26 (63%)	Respiratory n=11 Bacteremia n=13 Others n=2	GNB n=19 CG+ n=4 Virus n=3	hGM with infection n=11 (66%) hGM without infection n=1 (6%)
IG-n	n=51 (55%)	n=15 (29%)	Respiratory n=2 Bacteremia n=8 Others n=4	GNB n=3 CG+ n=2 Others n=10	n=6 (33%)
Differences	---	**p<0,01**	---	---	**p<0,01**
Total	n=92	n=41 (44,5%)	---	---	n=18 (19,5%)

Results: Included 92patients [54%♂/♀ 46%], median age of 63 years (range:18-85). Pathologies distribution was: Chronic Lymphocytic Leukemia (CLL)(12%) Follicular Lymphoma (FL)(38%), Diffuse Large Cell Lymphoma (DLCL)(36%), Mantle Cell Lymphoma (MCL)(4%),Burkitt Lymphoma (BL)(4%), Immune Thrombocytopenic Purpura (ITP)(3%), and others (3%). According IG serum (IgG, IgM, IgA), pretreatment, only 15patients (16%), had values below the normal range at the expense of mainly IgG. Administered once treatment with Rituximab, 41patients (45%) also showed predominantly hGM IgG (47%), followed by IgM (44%) and IgA (9%). 41patients (45%) had an infectious event from the start of therapy until end. The analyzed data are shown in Table 1.
Summary / Conclusion: In our series, Rituximab has been associated with a high incidence in developing hGM, being charge or a greater number of infections (63%vs.29%)(p <0.01) vs. patients without alterations in IG basal levels. We found no differences in the site of infection or germ, compared to patients without hGM. For the number of deaths in our study, is higher in patients with infection associated hGM vs. IG patients in the normal range (61% vs.39%)(p <0.01) were statistically significant difference despite the small sample size. These results will be completed and checked in the future with the determination of FCGR3A-158V/F polymorphism. Second phase is ongoing, and results will be presented as soon as possible.

B1758
EFFECTS OF APIGENIN ON IMATININ-SENSITIVE AND RESISTANT CHRONIC MYELOID LEUKEMIA CELLS
Y Baran[1*], S SOLMAZ[2], A GOKBULUT[1], I KOZANOGLU[3], H OZDOGU[2]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, Izmir, [2]Department of Hematology, Baskent University, Adana Teaching and Medical Research Center, Adana, [3]Department of Hematology, Baskent University, Adana Teaching and Medical Research Center, Izmir, Turkey

Background: Chronic myeloid leukemia (CML) is characterized by a reciprocal translocation between BCR and ABL genes. The resulting BCR-ABL1 oncogene encodes the chimeric BCR-ABL1 protein with constitutive kinase activity. In the clinic, tyrosine kinase inhibitors, especially imatinib, are used for CML therapy. Despite its therapeutic efficacy, not all patients benefit from imatinib because of the development of resistance. Many novel compounds are currently being investigated preclinically and clinically in terms of their therapeutic potentials to overcome imatinib resistance. Apigenin (4',5,7- trihydroxyflavone), a common plant dietary flavonoid, has been paid attention as an alternative anticancer compound.
Aims: The aim of this study is to examine antiproliferative, cytostatic and apop-

totic effects of apigenin on imatinib-sensitive and imatinib resistant K562 CML cells.
Methods: Growth-inhibitory effects of apigenin on K562 and 3 micromolar imatinib resistant K562 cells (K562/IMA-3) were determined by MTT cell proliferation assay. Apoptotic effects of apigenin were determined by changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential (MMP), and Annexin-V staining by flow cytometry. Cytostatic effects of apigenin were examined using DNase-free RNase and propidium iodine by flow cytometry.
Results: There were significant decreases in proliferation of both K562 and K562/IMA-3 cells in a dose- and time dependent manner. IC50 values of apigenin were found to be 65- and 63 μM for K562/IMA-3 cells for 48- and 72 hours, respectively, while it was 16- and2,5 μM for K562 cells, respectively. Increasing concentrations of apigenin triggered apoptosis in both cell types. There were 160- and 320% increases in apoptotic K562 cell population in response to 50-, and 100 μM apigenin as compared to untreated cells, respectively. On the other hand, 50- and 100 μM apigenin caused 10- and 20% increases in apoptotic K562/IMA-3 cell population as compared to untreated cells. Apigenin caused the loss of MMP in both sensitive and resistant cells exposed to same concentrations of Apigenin. The loss of MMP were 30-, 70-, 110-, and 130% in K562 cells treated with 5-, 10-, 50-, and 100 μM apigenin, respectively. The same concentrations of Apigenin led to 18-, 19-, 30-, and 41% increases in loss of MMP in K562/IMA-3 cells, respectively. Moreover, there were increases in caspase-3 enzyme activity in response to Apigenin in a dose-dependent manner in both K562 and K562/IMA3 cells. Treatment of K562 cells with Apigenin resulted in small increases in the percentage of cells in the G2/M phase at 5 to 20 μM Apigenin but in response to 100 μM Apigenin, there was a significant increase. There was no significant effect of Apigenin on G2/M phase of K562/IMA-3 cell cycle. However, K562/IMA-3 cells arrested in S phase especially at 100 μM apigenin.
Summary / Conclusion: Our results, in agreement with each other, showed that apigenin has cytotoxic, apoptotic and cytostatic effects on both cell types in a time- and dose- dependent manner. However, K562/IMA-3 cells were still more resistant to apigenin than K562 cells. But comparing the imatinib resistance, K562/IMA-3 cells demonstrated less resistance to Apigenin.

B1759

A CLINICAL MICRODOSE STUDY WITH 14C-ELACYTARABINE IN HEALTHY MALE SUBJECTS TO GENERATE MASS BALANCE DATA TO SUPPORT REGULATORY SUBMISSION: AN INNOVATIVE MICROTRACER APPLICATION

I Shaw[1*], A Gianella-Borradori[2], P Hals[2], F Myhren[2], T Veiteberg[2], S Mair[1], L Stevens[1], S Sweet[1], S Dueker[3], H Dirven[2]
[1]Quotient Clinical, Nottingham, United Kingdom, [2]Clavis Pharma, Oslo, Norway, [3]Eckert & Ziegler Vitalea Science, Davis, United States

Background: Obtaining human mass balance data for a cytotoxic drug product has always been regarded as a challenge. While it is not feasible to perform a conventional mass balance study at clinical doses in healthy volunteers, it is difficult to subject severely ill patients to the rigours of prolonged residency in a clinical unit and to the comprehensive excreta collection and blood sampling that is required. Notwithstanding these challenges, regulatory authorities do ask pharmaceutical companies to describe the routes and rates of elimination for cytotoxic drug molecules as a minimum description of drug metabolism in the registration packages for new drug products.
Elacytarabine is a novel, lipid derivative of the anti-cancer drug cytarabine commonly used in the treatment of acute myeloid leukemia. The drug is in the final stages of a phase 3 study in relapsed or refractory AML. Elacytarabine is a stable ester of elaidic acid and cytarabine.
Aims: This paper describes an open label, single-dose study to assess the mass balance recovery of an intravenous microdose of ^{14}C-elacytarabine in healthy male subjects. The study requirement was driven by a specific request from the US Food and Drug Administration (FDA) to provide supporting information on the routes of elimination of total radioactivity and total recovery. The study synopsis was reviewed by the FDA before implementation.
Methods: The program of work from the radiosynthesis of the ^{14}C API through to the final study report was delivered as a synthesis-to-clinic package. The clinical study design comprised a single intravenous administration of 50μg ^{14}C-elacytarabine containing not more than 270nCi of ^{14}C to a single cohort of 6 healthy male subjects. The subjects remained resident in the clinical unit for 7 days post dose and returned for 24 hour visits on Days 10 and day 14. Blood, urine and faecal samples were collected through the residential periods and samples were submitted for total ^{14}C analysis by accelerator mass spectrometry.
Results: Average urinary mass balance recovery in excess of 85% (draft data) in the first 48 hours post-dose was achieved. The complete cumulative mass balance recovery will be presented together with the conclusions drawn about routes of elimination.
Summary / Conclusion: This study demonstrated the validity of a microdose approach to generate mass balance data to support regulatory submission for a drug where obtaining the data by traditional methods was not possible.

B1760

ROLE OF VKORC1 AND CYP4502C9 POLYMORHISM IN RESISTANCE TO WARFARIN THERAPY AMONG EGYPTIAN PATIENTS

A Ahmed[1*], H Goubran[1], M Farha[1], M Yacoub[1], S Amin[2]
[1]Hematology, Kasralainy, [2]Professor of clinical pathology, Kasralainy school of Medicine, Cairo, Egypt

Background: Warfarin is still considered the principal oral anticoagulant. Its effect is subjected to a maltitude of factors among which are the VKORC1 and CYP4502C9 SNPs. Resistance to warfarin therapy is an emerging clinical problem especially that other oral anticoagulants do not cover completely the spectrum of anticoagulation indications. Pharmacogenetic testing has been approved for dosing calculation though its routine use was not recommended. The role of warfarin pharmacogenetics and pharmacogenomics had not been widely tested.
Aims: To screen Egyptian warfarin treated patients for various VKORC1 and CYP4502C9 polymorphisms
To stratify the warfarin effect regarding the genotype of the patient in order to spot any racial or ethnic variations between Egyptians and the previously published international data. To spot any relation between patient genotype and resistance to warfarin therapy.

	VKORC1	CYP4502C99		N	Minimum	Maximum	Mean	Std. Deviation
control	GG	1*/1*	dose	6	2	12	7.50	3.406
			INR	6	2	5	2.93	1.237
		1*/2*	dose	1	5	5	5.00	.
			INR	1	2	2	2.00	.
		1*/3*	dose	4	5	6	5.25	.500
			INR	4	2	4	3.32	.922
	GA	1*/1*	dose	9	3	10	5.78	2.587
			INR	9	2	5	2.68	.967
		1*/2*	dose	7	3	12	6.29	3.352
			INR	7	2	7	3.05	1.889
	AA	1*/2*	dose	1	6	6	6.00	.
			INR	1	2	2	2.00	.
case	GG	1*/1*	dose	12	16	20	18.67	1.303
			INR	12	1	1	1.08	.122
		1*/2*	dose	3	20	20	20.00	.000
			INR	3	1	2	1.23	.252
		1*/3*	dose	4	18	25	20.75	2.986
			INR	4	1	2	1.28	.222
	GA	1*/1*	dose	11	18	25	19.73	2.005
			INR	11	1	2	1.24	.150
		1*/2*	dose	1	30	30	30.00	.
			INR	1	1	1	1.00	.
		1*/3*	dose	4	18	20	19.00	1.155
			INR	4	1	1	1.25	.173
		3*/3*	dose	1	18	18	18.00	.
			INR	1	1	1	1.20	.

Methods: We performed a case-control study. Informed consent was obtained from each participant. We enrolled patients failing to reach a target INR of 2-3 after using large doses of warfarin (more than 15mg PO daily) as cases (n=36). Age and sex matched patients successfully reached target INR with usual doses were considered as controls (n=28). Both groups were screened for VKORC1 -1629G>A and CYP4502C9 variants after at least 8 weeks of therapy.
Inclusion Criteria:
- Informed consent
- Indication for longterm coagulation

Exclusion Criteria:
- Extremes of age (>70y and <18y)
- BMI >25
- Disturbed baseline AST, ALT, Bilirubin, Albumin, PT, APTT, CBC
- Drug intake other than warfarin and LMWH
- Current or history of malignancy

Results: On analyzing our results, we found more males among the control group (53.6% males compared to 46.4% females) though statistically insignificant (p value 0.44), while among cases females were more encountered (58.3% females compared to 41% males) which reached statistical significance (p value 0.02). On testing for VKORC1 mutations, we found 47.2% of cases with mutant allele, all heterozygous. On testing the control group for the same mutation, we found 60.7% of subjects (n=17) with mutant allele, 3.6% (n=1) was homozygous (AA) genotype, though not achieving statistical significance (p value = 0.27). On testing for mutations affecting CYP4502C9 allele, we found 36.1% (n=13) of cases with mutant alleles, 11.1% (n=4), 22.2% (n=8) and 2.8%(n=1) with 1*/2*, 1*/3* and 3*/3* respectively. Regarding controls, we detected mutations in 46.4% (n=13) of which, 32.1% (n=9) had 1*/2* and 14.3 (n=4) had 1*/3* alleles, though not achieving statistical significance (p value = 0.15). On correlating VKORC1 genotype with mean INR among controls, GG variants achieved a higher INR of 2.99 followed by genotype GA (INR=2.84)

and the least with genotype AA (INR=2) at a relatively constant warfarin dose (p value 0.05). On correlating CYP4502C9 genotype with mean INR among controls, the wild genotype 1*/1* was associated with the lower INR of 2.78, followed by the genotype 1*/2* (INR=2.82) the genotype 1*/3* (INR=3.32) with the same median warfarin dose of 5 mg per day (p value = 0.02). Same correlation was demonstrated among cases. When combined genotype possibilities were correlated to the mean INR we found the highest INR with the genotype GG/1*/3* (INR=3.32) and the lowest with AA/1*/2* (p value=0.014). We found that patients carrying at least one wild type allele needed higher doses of warfarin.

Summary / Conclusion: Our study confirmed the relation between warfarin pharmacogenetics and dosing although our patients needed higher warfarin doses than internationally reported one. We did not prove any relation between VKORC1 and CYP4502C9 SNPs and resistance to warfarin therapy.

B1761

EVALUATION OF CHEMICAL STABILITY OF ROMIPLOSTIM IN STERILE WATER

L Simeone[1*], F Chiurazzi[1], V Russo[1], C Candido[1], F Pane[1]
[1]Hematology, University "Federico II" Naples, Italy, Naples, Italy

Background: Romiplostim is an Fc-peptide fusion protein (peptibody) that signals and activates intracellular transcriptional pathways via the TPO receptor (also known as cMpl) to increase platelet production. Romiplostim is indicated for adult chronic immune (idiopathic) thrombocytopenic purpura (ITP) splenectomised patients who are refractory to other treatments (e.g. corticosteroids, immunoglobulins). Romiplostim can be considered as second line treatment for adult non-splenectomised patients where surgery is contra-indicated. The overall platelet response rate was noted in 88% of non-splenectomised and 79% of splenectomised patients (Kuter et al., Lancet 2008). Romiplostim is supplied as powder (Nplate, Amgen Dompè®) to be reconstituted with sterile water. After reconstitution, drug solution is considered stable, and may be consequently used within 24 hour when protected from light and kept in the original vial. The expected average annual expense per patient is about 47000€ .
Aims: to evaluate the chemical stability of Romiplostim after 24 hours
Methods: Spectrophotometric analysis was performed using a UV spectrophotometer Shimadzu RF-1501, in the range of wavelength between 200 and 800 nm. Chemical stability of romiplostim was evaluated immediately, after reconstitution of the powder with the correct volume of sterile water for injection, and then at day1,4, 7 and 10. After reconstitution, samples were kept in the dark at °4C.
Results: The results obtained do not show spectrophotometric changes of the samples over time.In particular a maximum peak of absorption at 280 nm was observed in all analyzed samples and no changes attributable to derivatives with different optical characteristics were observed.
Summary / Conclusion: Spectrophotometric analysis shows that Romiplostim is stable after reconstitution in sterile water for 10 days at 4°C. Romiplostim reutilization after reconstitution could allow cost reduction whereas the retail price of the bottle of 250µg is € 994,37. For example, a 70 kg patient receiving 3µg of product, draws 0.42 ml and threws 0.08 ml of romiplostim corresponding to € 159 that is € 7632 annual. From microbiological point of view further studies could better define the sterility of romiplostim solution over time.

B1762

SIROLIMUS EFFICIENCIES ON PEDIATRIC HEMATOLOGY PATIENTS

O Avar[1], N Ozdemir[1], G Tuysuz[1], T Celkan[1*]
[1]Pediatric Hematology-Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: *Sirolimus (rapamycin)* is a macrolide immunosupresant which has a distinct mechanism of action by allostherically inhibition of the mammalian target of rapamycin (m TOR), a central controller of cell growth and proliferation.
Aims: To evaluate sirolimus effect on different childhood diseases.
Methods: In our Pediatric Hematology-Oncology Clinic we used sirolimus in fourteen patients aged 1-13 (group 1: arteriovenous malformation AVM, group 2: autoimmune lymphoproliferative syndrome ALPS and group 3: tuberosclerosis TS) after failing multiple other therapies.
Results: *Group 1:* Sirolimus is given to seven patients who have AVM resistant to corticosteroid, propranolol interferon and thalidomide treatments. Especially one of them showed marked improvement. This case had been diagnosed as blue rubber bleb syndrome by cutaneous lesions at birth and gastrointestinal hemorrhages after age1, who needed multiple blood transfusions, 1-2 times per week. His lesions and symptoms were resistant to corticosteroid, propranolol, interferon and thalidomide treatments. Four months after the beginning of the sirolimus treatment, blood transfusions were needed only 2 times and his cutaneous lesions reduced markedly. Similarly, marvoious response has been realized in other six patients' symptoms and cutaneous lesions. *Group 2:* Sirolimus is given to three patients two of whom are siblings, with ALPS at the dosage of 1.6 mg/m^2/day after failure of corticosteroids or due to adverse effects of it. One of them, has been using sirolimus regularly since2,5 years. The other , who was diagnosed and treated erroneously. as diffuse T cell lymphoma, got the true diagnosis after 2 years period when clinically relapsed. After sirolimus treatment, hepatosplenomegaly and lymphadenopaties were disappeared and his blood counts returned to normal. His sister with the same complainments were easily diagnosed as ALPS when she was 3 months old. *Group 3:* Four patients, two of whom are siblings, were diagnosed as tuberosclerosis with intracranial masses and got sirolimus treatment. After sirolimus, intracranial masses showed mild regression in two of them and had no new epileptic attacks. However; the other sibling couple although getting sirolimus treatment regularly since1,5 years had no clinical improve
Summary / Conclusion: In our Pediatric Hematology- Oncology Department, sirolimus efficiency and safety are assessed in 3 groups of patients (AVM, ALPS and TS). These patients showed significant improvement in their clinical status with no side effects. The siblings with tuberosclerosis and intracranial masses, who are still getting sirolimus, have not shown enough recovery and they still have convulsions. No side effects except indefinite discomfort in an infant with arteriovenous malformation have been distinguished. The oral form of the medicine made the dosage adjustment and easy usage available. We think that with the efficiency on different diseases, it's tolerable side effects and easy usage, sirolimus will have a place in childhood diseases treatment regimens in future.

B1763

ACCURACY OF PHARMACOGENETIC ALGORITHMS FOR THE PREDICTION OF ACENOCOUMAROL STABLE DOSES IN ANDALUSIAN POPULATION

J Varo[1*], C Garre[1], A Gómez[2], V Aguilera[3], C Hernández[4]
[1]Pharmacy Service. Pharmacogenetic Unit., Complejo Hospitalario of Granada. Virgen de las Nieves University Hospital, [2]University of Granada, [3]Statistics, [4]Pharmacy Service chief, Complejo Hospitalario of Granada.Virgen de las Nieves University Hospital, Granada, Spain

Background: There is high risk of bleeding and thrombus in initiation acenocoumarol treatment. Currently, initial dose of acenocoumarol is prescribed based only on clinical variables. Clinical and genetic variables have an influence of approximately 50-60% on the required dose to achieve stable anticoagulation. Several pharmacogenetic algorithms to improve the prediction of acenocoumarol stable dose in European and Spanish patients. The EU-PACT pharmacogenetic algorithm includes the variables: age, male sex, weight, height, amiodarone, CYP2C9 (rs1057910 and rs1799853) and VKORC1 (rs9923231) genotypes. The Spanish pharmacogenetic algorithm by Borobia et al. was developed in Madrid and includes additional clinical and genetic variables: inhibiting/inducting concomitant drugs, pathologies, smoking status, CYP4F2 (rs2108622) and ApoE (rs7412) genotypes to improve prediction of acenocoumarol stable dose (mg/sem).
Aims: Our aim was to evaluate the accuracy in the prediction of the dose of these two pharmacogenetic algorithms in 15 patients with acenocoumarol stable dosis achieved at Virgen de las Nieves University Hospital.
Methods: Fifteen atrial fibrillation patients with acenocoumarol stable doses treated at a third level hospital of Andalusian were recruited.
Two pharmacogenetic algorithms (EU-PACT and Borobia et al) were used to calculate the predicted dose for every patient, and this predicted dose was compared to the actual stable dose received using a reliability analysis.
Results: Concordance between both algorithms and actual stable doses was moderate-low. The intraclass correlation coefficient (ICC) for the comparison of the European pharmacogenetic algorithm with stable doses received was 0.524 (p-value: 0.088), and for the Spanish pharmacogenetic algorithm, the ICC was 0.268 (p-value: 0.283).
Summary / Conclusion: The accuracy in the prediction of the doses by these two pharmacogenetic algorithms is low, at least for the Andalusian population studied. Therefore, pharmacogenetic algorithms developed to predict acenocoumarol doses should be tested before applying in different populations. In some cases, it could be necessary to develop a predictive pharmacogenetic model adapted to specific populations.

Genomics and proteomics

FC GAMMA RECEPTOR POLYMORPHISMS IN PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANAEMIA

M Pavkovic[1*], S,Terzieva-Trpkovska[1], R Angelkovic[1], T Sotirova[1], GAmzai[1], O Karanfilski[1], M Spiroski[2], L Cevreska[1], A Stojanovic[1]
[1]Univeristy Clinic for Hematology, [2]Institute for Immunobiology and human genetics, Medical Faculty, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Autoimmune hemolytic anemia (AIHA) is a second most common autoimmune blood disorders. AIHA may occur as primary (idiopathic) or secondary to other lymphoproliferative or immune disease. The etiology of AIHA remains unclear, but both genetic and environmental factors are thought to play role in the development of the disease. The aim of our study was to investigate a possible role of two polymorphisms in the Fc gamma receptor 2A and 3A (FCGR2A and FCGR3A) in the development of AIHA.FCGR2A is polymorphic and has two alleles, FCGR2A-H131 and FCGR2A-R131. This polymorphic variation of FCGR2A is due to a single base substitution of nucleotide adenine for guanine in position 494. The allele FCGR2A-H131 has a higher affinity for human IgG2, comparing to FCGR2A-R131. The gene for FCGR3A has also two polymorphic variant alleles: 158 valine (V158) and phenylalanine (F158) due to single base substitution of timidine to guanine at nucleotide position 559. This polymorphism influences ligand binding and FCGR3A-158V allele variant has higher affinity for Fc fragment of IgG1 and IgG3 than 158F variant. These Fc gamma receptor polymorphisms may influence antibody-mediated phagocytosis and antigen presentation activity.
Aims: The aim of our study was to investigate a possible association of these two single nucleotide polymorphisms in Fc gamma receptor genes (FCGR2A +494A/G) and (FCGR3A +559T/G) with autoimmune hemolytic anemia.
Methods: We have analyzed 70 adult patients with AIHA; 35 patients with idiopathic AIHA and 35 patients with secondary AIHA and chronic lymphocytic leukemia (CLL). Controls were 120 healthy individuals. DNA was isolated from peripheral blood mononuclear cells with standard phenol-chloroform extraction. Genotyping was performed by using PCR and RFLP methods. The distribution of genotypes and allele frequencies were compared between patients and controls using a chi-squared test or Fisher's exact test.
Results: Our results demonstrated significantly different genotype distribution for FCGR2A+494A/G in patients with AIHA (n=70; A/A=45, A/G=19, G/G=6) and controls (n=120; A/A=55, A/G=50, G/G=15), P=0.048. There was also significantly higher frequency of the high affinity FCGR2A-131H (+494A) allele in patients with AIHA comparing with controls (66.6% versus 77.8%; P=0.028). Statistical analysis of the genotype distribution for FCGR3A+559T/G showed significant difference between patients with AIHA (n=70; T/T=22, T/G=23, G/G=25) and controls (n=120; T/T=52, T/G=46, G/G=22), P=0.025. We also found significantly higher frequency of the high affinity FCGR3A-158V (+559G) allele in patients with AIHA comparing with control individuals (47.9% versus 37.5%; P=0.007).
Summary / Conclusion: Results of this study, suggest possible role of both FCGR2A and FCGR3A polymorphism in the etiology and development of autoimmune hemolytic anemia, but further larger prospective studies are necessary to confirm these results.

B1765

MOLECULAR CHARACTERIZATION OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY IN ABU DHABI DISTRICT, UNITED ARAB EMIRATES (UAE)

S Amro[1,1*], E Zaabi[1], A Aly[1], N Yosuff[2]
[1]Haematology, Mafraq Hospital, , Abu Dhabi, United Arab Emirates, [2]Cluster of Regenerative Medicine, Advanced Medical and Dental Institute (AMDI) Universiti Sains Malaysia (USM), Penang, Malaysia

Background: Glucose-6-Phosphate dehydrogenase (G6PD; E.C.1.1.1.49) is a key enzyme of the pentose monophosphate pathway, and its deficiency is the most common inherited enzymopathy and affects 400 million people worldwide with more than 140 genetic variants. Acute haemolytic anaemia and Jaundice are the main clinical symptoms, triggered by infection or ingestion of Fava beans or oxidative drugs. It is common among populations of the Arabian Peninsula, including UAE population. The objective of this study is to determine the prevalence of this enzymopathy and to clarify the molecular basis of G6PD deficiency among different age groups of individuals including newborns, children and adults in Mafraq Hospital in Abu Dhabi.
Aims: The aims of this study is to determaine the prevalence and molecular basis of G6PD deficincy within the UAN nationals and non- UAE nationals in Abu Dhabi District.
Methods: Blood samples were collected from subjects after approved by the Research Ethical Committees of Mafraq hospital. It was conducted within a period of three years, i.e. from January 2006 to January 2009. There were 15995 subjects involved in this study: 8984 males and 7011 females. From this there were 6302 UAE nationals: (2996 males and 3306 females) and 9693 were Non- UAE nationals (i.e. 5988 males and 3705 females). Five milliliters of peripheral blood samples were collected in EDTA from each individual to perform routine hematologic investigations and screening for G6PD was done using the florescent spot method followed by the quantitative G6PD assay.
Genomic DNA was extracted from peripheral blood leukocytes for 225 G6PD deficient subjects using Qiagen DNA extraction kit. PCR amplification of the G6PD gene was performed using specific primers. Analysis for the samples were then subjected to PCR-based methods using restriction enzyme digestion (RFLP), denaturing high performance liquid chromatography (DHPLC) and finally confirmation using automated gene sequencing.
Results: Among UAE nationals, the prevalence of G6PD deficiency was 466 (7.4%). From this 347 (11.6%) were males and 119 were females (3.6%). The prevalence of G6PD deficiency among non-nationals was 364 (3.8%). From this 301(5%) were males and 63 (1.7%) were females. The molecular basis of G6PD among nationals of UAE revealed the mutations Mediterranean 563C→T, Aures 143 T→C, Africa A–202G→A and Chatham 1003 G→A representing mutations frequencies 0.785, 0.118, 0.083 and 0,007 respectively. A novel mutation 1011T-G with predicated amino acid change of phe337leu was identified in exon 9 for one UAE national boy. For the non-nationals, genotyping showed the mutations Mediterranean 563C→T, Aures 143 T→C , A–202G→A and Union 1360 C–T representing frequencies 0.744, 0.122, 0.11and 0.024 respectively. PCR products digested with *Mbo*II restriction enzyme, analysis of the PCR product before and after digestion of *Mbo*II enzyme for the detection of Mediterranean mutation in G6PD gene on 2% agarose gel from left to right. The arrow shows restriction sites in normal and deficient patients. Lanes1, 10, and 12: normal samples; Lane 2: positive control, Lane 5: 100 bp ladder marker; Lanes3,4,7,8, 9, 11: G6PD Mediterranean mutation; Lane 6: PCR product, and Lane 13 free nuclease water (negative control).
Summary / Conclusion: The findings suggest that G6PD Mediterranean mutation is the most common mutation underlying G6PD deficiency in UAE which indicates the gene flow from the Indian subcontinent and other parts of the Mediterranean basin. All UAE chromosomes with the Mediterranean mutation had the polymorphic 1311T allele (*Bcl*I+). Such a Med+/*Bcl*I+ haplotype is typical for the Mediterranean region and the Middle East, while most cases from India and South East Asia are Med+/*Bcl*I−, thus suggesting independent origin of Mediterranean mutations on two different haplotype. The presence of G6PD A– is regarded as significant gene flow from sub-Saharan Africa. For the Aures mutation, it was documented as specific mutation for the central and southern part of the Arabian Peninsula thus our findings suggest that the genetic background of UAE nationals descended from authentic Arab tribes.

Novel therapeutics, targeted therapies and gene therapy

B1766

REGULATION OF HEPCIDIN TRANSCRIPTION BY K-7174

A Inoue[1*], T Ikeda[1], T Fujiwara[1,2], Y Nagasaka[1], Y Okitsu[1], N Fukuhara[1], Y Onishi[1], K Ishizawa[1,3], R Ichinohasama[4], H Harigae[1,2]
[1]Hematology and Rheumatology, [2]Molecular Hematology/Oncology, Tohoku University Graduate School of Medicine, [3]Clinical Research, Innovation and Education Center, Tohoku University Hospital, [4]Hematopathology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Hepcidin (HAMP) is the principal iron regulatory hormone, controlling the systemic absorption and remobilization of iron from intracellular stores. The expression of *HAMP* increased in patients with anemia of chronic disease. Previously, a synthesized compound K-7174 (Kowa Company Ltd., Tokyo, Japan) was identified through chemical screening as a novel inhibitor for the adhision of monocytes to cytokine-stimulated endothelial cells (Umetani et al. BBRC 2000). Interstingly, K-7174 restored anemia induced by inflammatory cytokines in mice (Imagawa et al. FASEB J 2003), implying that K-7174 might modulate hepcidin level.
Aims: To assess the impact of K-7174 on hepcidin expression based on human hematoma cell line and *in vivo* mice.
Methods: The HepG2 hematoma cell line was used for the analysis. The cells were treated with K-7174 at doses of 10 and 20 uM for 24 h.For transcription profiling, Human Oligo chip 25K (Toray) were used for K-7174-treated HepG2 cells. Western blot analysis was performed with antibody to GDF15 (abcam). GDF15 concentration in the K-7174-treated media was evaluated with ELISA (R&D systems). For *in vivo* analysis, ICR mice were injected intraperitoneally with PBS (control) or 30 mg/kg K-7174, respectively, on day 0-3 and 5-8, and the samples were taken on day 9. Serum hepcidin1 concentration was determined with LC-MS/MS method (MCProt Biotechnology, Kanazawa, Japan).
Results: We first demonstrated that K-7174 treatment in HepG2 cells significantly decreased HAMP expression in a dose- and time-dependent manner. Thus, we next conducted microarray analysis to reveal the molecular mechanism by which K-7174 inhibits the *HAMP* expression. Transcriptional profiling confirmed the downregulation of *HAMP* as well as erythropoietin. Surprisingly, we found that K-7174 strongly induced GDF15, a negative regulator of *HAMP* expression (Tanno et al. Nat Med 2007). Quantitative RT-PCR analysis, Western blot analysis as well as ELISA analysis confirmed the induction of GDF15 by K-7174 treatment, suggesting that K-7174-mediated induction of GDF15 participates in the inhibition of *HAMP* expression.
Next, we assessed if K-7174 inhibits hepcidin expression in mice. Quantitative RT-PCR analysis with liver sample from K-7174-treated mice demonstrated significant upregulation of *Gdf15* and downregulation of *Hamp* ($n = 8$, $P<0.05$). Furthermore, serum hepcidin concentration was also significantly decreased in K-7174-treated mice (Average: 138.1 and 110.4 ng/mL for K-7174-treated and control mice, respectively. $n = 8$, $P<0.05$).
Summary / Conclusion: K-7174 inhibits hepcidin expression partly by inducing GDF15. K-7174 might be considered as a potential therapeutic option to treat anemia of chronic disease.

B1767

GIVINOSTAT INDUCED APOPTOSIS IN ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

W Zhao[1*], Y Tang[1], G Zhang[1], K Patterson[1], Y Li[2], L Zhao[2], L Chen[3], Q Wang[4]
[1]Pathology, The Ohio State University Medical Center, Columbus, United States, [2]Pediatrics, The 3rd Xiangya Hospital, the South Central University, Changsha, China, [3]Internal medicine, [4]Radiology, The Ohio State University Medical Center, Columbus, United States

Background: Givinostat (ITF2357) is a histone deacetylase inhibitor with potential anti-inflammatory, anti-angiogenic, and antineoplastic activities. Givinostat is in clinical trials for Hodgkin's lymphoma, chronic lymphocytic leukemias and myelomas, and has been granted orphan drug designation in the European Union for the treatment of systemic juvenile idiopathic arthritis and polycythemia vera. The effect of Givinostat on acute lymphoblastic leukemia (ALL), an incurable disease with resistance to therapy developing in the majority of patients, is still unknown.
Aims: We examined the antitumor effect of Givinostat, being able to inhibit class I and class II histone deacetylases (HDACs), on the proliferation and apoptosis of human leukemia cell lines K562, SUP-B15, CCRF-SB, and NALM.
Methods: SUP-B15 is a precursor B-lymphoblastic with both transcripts of t(9;22)(BCR-ABL) and isoform IK6 of IKZF1, while CCRF-SB and NALM didn't. K562 derived from acute erythroblastic leukemia with t(9;22)(BCR-ABL). Cell proliferation and viability, induction of apoptosis, immunohistochemical identification of cell death signalling molecules, and pharmacological inhibition were assayed to detect the apoptotic cell death pathways. Finally, genetic mutation status of these celllines, detected by Ampliseq Version2, was correlated to the effect of Givinostat.
Results: Givinostat inhibited proliferation and induced apoptosis in all B-lymphoblastic leukemia, in a dose-dependent manner, in the sequence of SUP-B15 (IC50=180 nM) > NALM1 (IC50= 250nM) > CCRF-SB (IC50= 0.5 uM). Givinostat had no effect on K562 (IC50>4 uM). Western blot analysis showed significant reduction of pBCR/ABL, pSTAT5, and pCRK-L in SUP-B15 but not in K562. The early and late phase of apoptotic fractions determined by propidium Iodide (PI) and annexin-V staining followed by flow cytometry, in SUP-B15 (35.75% and 72.4%), and NALM1 (27.67% and 61.10%), in the presence of 250 uM Givinostat, were significantly higher than those induced in CCRF-SB (3.5% and 47.61%) and K562 (10.4% and 56.2%), with 1 uM Givinostat for 24 and 48 hrs, respectively. Accompanied with the apoptosis in SUP-B15 and NALM1 were cleavages of procaspase proteins (Casp-3 and -7) and PARP. Elevation of p21 expressions was observed in SUP-B15 and NALM1. In contrast, elevation of miR-20b, the negative regulator of p21, was present in CCRF-SB when treated with Givinostat. The molecular profiling of these four cells lines includes the presence of BCR-ABL+ (p185) and BCR-ABL+ (p210) in SUP-B15 and K562; P72R (+/+) and P72R (+/-) of TP53 in SUP-B15 and CCRF-SB; p.Q135Pfsx12 of TP53(-/-) in K562; and IKZF1 isoform IK6+ in SUP-B15.
Summary / Conclusion: Our data suggest that Givinostat might be used as a potential and effective therapy for acute lymphoblastic leukemia. The presence of BCR/ABL, IK6 isoform, and other mutation types don't alter the proapoptotic effect of Givinostat in SUP-B15. An intact p53/p21 signal pathway might be a dependent factor for Givinostat-induced apoptosis.

B1768

4SC-202: A NOVEL EPIGENETIC MODULATOR TO TARGET CANCER STEM CELLS

H Kohlhof[1*], R Baumgartner[1]
[1]Translational Pharmacology, 4SC AG, Martinsried-Planegg, Germany

Background: 4SC-202 is an orally available inhibitor of HDAC1, 2 and 3 with a unique combination of anti-cancer activities actually under investigation in a phase I clinical trial in patients with hematological malignancies.
Aims: We wanted to investigate the MoA of this novel epigenetic modulator and show its tolerability and potency as an anti-cancer drug in a phase I clinical trial.
Methods: The potency of 4SC-202 was tested in *in vitro* and *in vivo* model systems for efficacy to target 1) the cancer stem cell phenotype (anchorage independent growth, spheroid formation, migration and invasion), 2) the Wnt signalling pathway (Affymetrix Chip analysis in tumor samples from an orthotopic xenograft model), 3) tumor growth (xenograft models), 4) angiogenesis (HUVEC tube formation assay), and 5) to modulate gene and protein expression (Chip analysis, qPCR and reversed phase protein arrays). Tolerability, safety and efficacy are under investigation in an ongoing clinical trial in patients with hematological malignancies.
Results: 4SC-202s pharmacology comprises epigenetic regulation, targeting of cancer stem cells and inhibition of angiogenesis. 4SC-202 has demonstrated effective modulation of Wnt-signaling in preclinical *in vitro* and *in vivo* models. Notably, epigenetically driven Wnt-modulation results in the inhibition of cancer stem cell related properties like anchorage independent growth, formation of spheroids and prevention of migration and invasion. Additionally, 4SC-202 is highly active on a number of preclinical hematological and solid tumor models. Currently, 4SC-202 is under clinical phase I evaluation in pretreated patients with hematological tumors (TOPAS study). A biomarker program including *ex vivo* determination of HDAC activity and protein acetylation as well as gene expression analysis is implemented.
Summary / Conclusion: 4SC-202 is a selective HDAC inhibitor with a unique combination of anti-cancer activities. In the ongoing phase I clinical trial, 4SC-202 shows good PK properties, good tolerability and signs of clinical efficacy. According to the MoA and preclinical results multiple development options arise with a focus on hematologic malignancies and WNT related solid tumors.

B1769

NECROX-7 AS A NOVEL HMGB1 BLOCKADE ATTENUATES GRAFT-VERSUS-HOST DISEASE BY AUGMENTING REGULATORY T CELLS AND INHIBITING DEVELOPMENT OF TH17 CELLS

S Cho[1*], K Im[2], E Kim[3], J Lim[4], N Kim[4], J Park[5]
[1]Laboratory of Immune Regulation, Department of Hematology, Catholic Blood and Marrow Transplantation Center, [2]Laboratory of Immune Regulation, Department of Hematology, [3]Laboratory of Immune Regulation, CRCID, [4]Laboratory of Immune Regulation, [5]Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary's Hospital, The Catholic University of Korea College of Medicine, SEOUL, Korea, Republic Of

Background: Extracellular HMGB1 is the best characterized damage associated molecular pattern (DAMP) molecule, which functions as a potent innate immune mediator implicated in aGVHD.
Aims: In this study, we investigated the effects of a novel HMGB1 blockade, Necrox-7 on aGVHD model.
Methods: After allogeneic BMT, recipients (BALB/c) were given Necrox-7 injections in 2 day intervals for 2 weeks. All mice were monitored for survival and

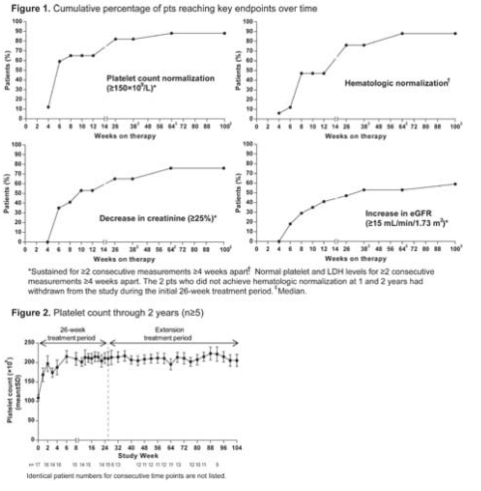
clinical signs of aGVHD. Secretion and mRNA expression of HMGB1 were confirmed by HMGB1-specific ELISPOT assay and real-time PCR. Intracellular reactive oxidative stress (ROS) production was detected by flow cytometry. Th17 and Treg cells were analyzed by the measurement of cytokine expression.
Results: Administration of Necrox-7 significantly attenuated the aGVHD-related mortality and inhibited severe tissue damages in the intestine, liver and lung. In *ex vivo* analysis, these protective effects correlated with the observed decrease in HMGB1 expression and ROS in the PB. Furthermore, administration of Necrox-7 showed the suppression of donor T lymphocyte proliferation in MLR and reduced serum levels of the pro-inflammatory cytokines. Blockade of HMGB1 signaling augments CD4+CD25+Foxp3+ Tregs reconstitution and attenuates the severity of aGVHD whereas Th17 cells reduced in spleen.
Summary / Conclusion: These results suggest that HMGB1 could be a promising target for aGVHD treatment and a critical role for the Necrox-7 as novel blockade of ROS and HMGB1 in pro-inflammatory events contribute to prevent aGVHD.

B1770
MK-2206 SENSITIZES ACUTE MYELOID LEUKEMIA CELLS TO CYTARABINE VIA APOPTOSIS INDUCTION
C Hu[1,2*], Y Lin[1], D Ou[3], C Chen[4], Y Lai[1], H Tien[4], L Lin[1,2]
[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Laboratory Medicine, National Taiwan University Hospital, [3]Oncology, National Taiwan University, [4]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan

Background: Acute myeloid leukemia (AML), a heterogeneous hematopoietic malignancy, results from various genetic abnormalities affecting proliferation or differentiation. Genetic alterations in phosphoinositide 3-kinases (PI3Ks)/AKT cascade have been linked to various human cancers, including AML, accordingly targeting the critical nodule AKT becomes expected for effective therapy. The specific allosteric AKT inhibitor, MK-2206, was developed and proved survival advantage for patients with advanced solid tumor including thyroid cancer, metastatic head and neck squamous cell carcinoma and hepatocellular carcinoma cells by single or combined usage. Previously, we elucidated the molecular mechanism of MK-2206 on leukemia cells and found that MK-2206 resulted in G_1-phase arrest and apoptosis induction in leukemia cells. In addition, downregulation of myeloid cell leukemia-1 (Mcl-1) through glycogen synthase kinase 3β (GSK3β)-mediated and proteasome-dependent protein degradation by MK-2206 was noted to be associated with apoptosis induction. However, the therapeutic potential of AML remains unclear.
Aims: To elucidate the therapeutic efficacy and therapeutic potential of MK-2206 in leukemia cell lines.
Methods: Leukemia cell lines U937, OCI/AML3, MOLM-13, and MV-4-11 were used in this study. Apoptosis and cell cycle distribution were determined by flow cytometry analysis. Expression profiles of anti-apoptotic protein family were determined by western blotting. Drug combination effects of MK-2206 with cytarabine on leukemia cells were evaluated by cell proliferation assay and combination Index (CI) values were calculated by CompuSyn software.
Results: MK-2206 represented a significant cytotoxic effect on all these leukemia cells with IC_{50}s of 0.6 mM to 2.5 mM for 72 h treatment, but with minor effect on normal peripheral blood mononuclear cells (PBMCs) from two healthy volunteers with IC_{50}s of 18.8 mM and 19.5 mM. Drug combination analysis on leukemia cells demonstrated that MK-2206 could sensitize most leukemia cell lines except U937 to cytarabine treatment, a first-line strategy for *de novo* AML treatment. The CI values of the combinations in MV-4-11, MOLM-13 and OCI/AML3 were at ED_{50} of 0.59, 0.37 and 0.38, respectively. Consistent results were observed in the ED_{50} isobologram analysis. Further analysis revealed that this sensitization was associated with induction of the cleavage of PARP. In addition, we explored that MK-2206 at physiologically plasma concentration (200nmol/L) could significantly reduce the IC_{50} of cytarabine in leukemia cells.
Summary / Conclusion: We explore the therapeutic potential of MK-2206 and strengthen the efficacy of cytarabine treatment coupled with MK-2206 in myeloid leukemia.

B1771
TIME TO HEMATOLOGIC AND RENAL IMPROVEMENTS IN AHUS PATIENTS WITH PROGRESSING THROMBOTIC MICROANGIOPATHY AFTER COMMENCEMENT AND DURING CONTINUATION OF ECULIZUMAB FOR MORE THAN 2 YEARS
P Muus[1*], R Furman[2], K Douglas[3], S Babu[4], C Legendre[5], C Bedrosian[6], C Loirat [7]
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Weill Cornell Medical College, New York, United States, [3]Beatson West Scotland Cancer Centre, Glasgow, United Kingdom, [4]Fort Wayne Medical Oncology and Hematology, Fort Wayne, United States, [5]Université Paris Descartes, Hôpital Necker, Paris, France, [6]Alexion Pharmaceuticals Inc., Cheshire, United States, [7]Assistance Publique Hôpitaux de Paris, Hôpital Robert Debré, Paris, France

Background: Atypical hemolytic uremic syndrome (aHUS) is a life-threatening disease caused by inherited and/or acquired defects of complement system regulators, resulting in chronic, uncontrolled complement activation that causes platelet activation, thrombosis, hemolysis, and thrombotic microangiopathy (TMA). Despite plasma exchange/plasma infusion (PE/PI), patients (pts) may develop end-organ damage, frequently in association with anemia, thrombocytopenia, undetectable haptoglobin levels, and/or elevated lactate dehydrogenase (LDH) levels. Up to 65% of pts develop permanent renal damage or die in the first year of diagnosis. Eculizumab (Ecu), a humanized monoclonal antibody that is a terminal complement inhibitor, binds with high affinity to the human C5 complement protein and is the first approved treatment for aHUS in pediatric and adult pts.
Aims: Investigate the cumulative percentage of pts reaching key hematologic and renal endpoints over time in a phase 2 study of Ecu in aHUS pts with progressing TMA.
Methods: Pts age ≥12 years with clinical evidence of progressing TMA (platelet count <150×10^9/L and decreased >25%, despite ≥4 PE/PI sessions in the prior week) were enrolled and received Ecu. Pts provided informed consent and the study was approved by each center's institutional review board. Data are reported up to 104 weeks.



Results: The 17 pts (median age 28 years, 71% female, 41% with prior renal transplant) had a median time from diagnosis to screening of 10 months. Hematologic parameters (mean±standard deviation [SD]) at baseline were: platelets 109.0±32.1×10^9/L, LDH 323.0±138.2 U/L, hemoglobin (Hb) 89.1±14.0 g/L, and haptoglobin 0.5±0.4 g/L. All pts presented with estimated glomerular filtration rate [eGFR] <60 mL/min/1.73 m^2, and mean±SD serum creatinine was 351.5±214.9 µmol/L. The median time to the start of platelet count normalization (first platelet count ≥150×10^9/L) was 7 days (range 1–218). Nine of the 10 pts with abnormal LDH at baseline (90%) showed LDH improvement ≤ upper limit of normal (ULN). The time to first occurrence of LDH ≤ ULN was 14 days (range 0–56) after the first Ecu dose. The cumulative percentages reaching key hematologic and renal endpoints are shown in Figure 1. Also, 76% of pts had sustained improvement in Hb levels (≥20 g/L) at 64 weeks (median), and 71% of pts had improvement in chronic kidney disease stage (≥1 stage) at 100 weeks (median). Mean platelet count (Figure 2) and renal function (as measured by creatinine levels and eGFR) rapidly improved and was sustained through 2 years of Ecu treatment. Only 2 pts (12%) required PE/PI after starting Ecu (1 pt at 10 days after discontinuing treatment due to a protocol violation, the other at 84 days). Four of 5 pts (80%) receiving dialysis at baseline discontinued dialysis; the time of discontinuation ranged from 1 to 14 days after the first Ecu dose. There were no reported deaths during Ecu treatment (28.5 patient-years).
Summary / Conclusion: The majority of pts showed improvement in hematologic and renal parameters within several months of starting Ecu. Ongoing treatment with Ecu led to sustained improvement in hematologic outcomes in nearly all pts by 2 years, including inhibition of TMA, in association with ongoing improvements in renal function. As such, Ecu may decrease mortality in aHUS patients when compared to the natural disease progression. These results provide a framework for treatment expectations with Ecu and highlight the need for early and ongoing Ecu treatment in pts with aHUS and progressing TMA.

B1772
RHTRAIL AND SURVIVIN DOWNREGULATORS AS NEW THERAPEUTIC APPROACH IN ACUTE LYMPHOBLASTIC LEUKEMIA
C Domingues[1*], J Leite[2], M Ferreira[2], P Guarino[2], R Alves[1], M Coucelo[3], L Ribeiro[3], A Gonçalves[1], M Dourado[4], J Nascimento-Costa[5], A Sarmento-Ribeiro[1]

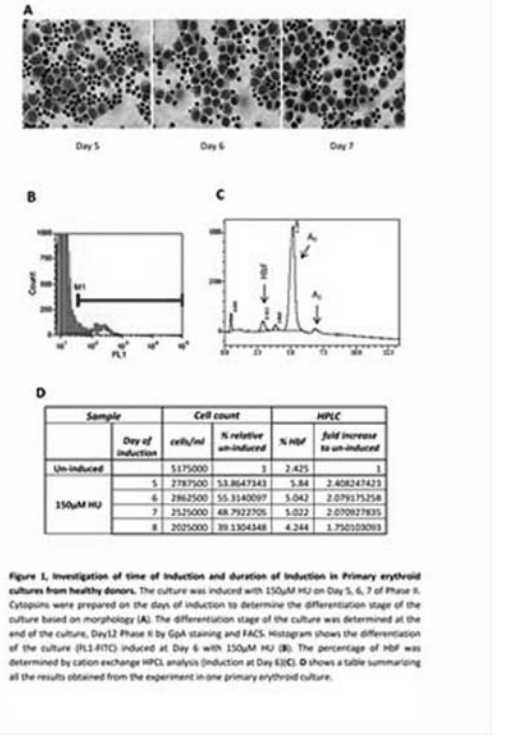
[1]Applied Molecular Biology / University Clinic of Hematology and CIMAGO, [2]Applied Molecular Biology and University Clinic of Hematology, Faculty of Medicine University of Coimbra, [3]Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHC/CHUC), [4]Applied Molecular Biology / University Clinic of Hematology / CIMAGO / Oncology and Paliative Care, [5]CIMAGO / Oncology and Paliative Care / Internal Medicine Department, Faculty of Medicine University of Coimbra, Coimbra, Portugal

Background: Acute lymphoblastic leukemia (ALL) represents a biologically and clinically heterogeneous group of hematological malignancies, which results from the abnormal proliferation and accumulation of immature lymphoid cells (blasts) within the bone marrow and lymphoid tissues. Although, chemotherapy is a hallmark treatment for ALL many patients become resistant to therapy or may relapse, requiring the development of alternative treatment strategies. Tumor necrosis factor (TNF)-related apoptosis inducing ligand (TRAIL/Apo-2L) is a type two membrane protein which selectively induces apoptosis in transformed or stressed cells but not in most normal cells. Nevertheless, in some cases treatment with TRAIL alone may not be sufficient for an effective response. Take into account, combined TRAIL therapies not only with conventional chemotherapeutic agents but also with survivin downregulators, namely gambogic acid (GA) and silibinin (SLB) have given encouraging results to restore TRAIL sensitivity.
Aims: In the present study, we aimed to explore the therapeutic efficacy of a recombinant human TRAIL (rhTRAIL) and survivin inhibitors, GA and SLB, alone and in combination with conventional chemotherapeutic agents, in ALL.
Methods: For this purpose we maintained in culture an ALL cell line established from a patient at disease presentation, the CEM cells, in absence and in presence of different concentrations of rhTRAIL, GA and SLB in monotherapy as well as in association with each other and with conventional drugs (Doxorubicin or Vincristine). Cell viability was assessed by the trypan blue assay and cell death by Optical Microscopy (May-Grunwald staining) and flow cytometry (FC) using the Annexin V/Propidium Iodide double staining. TRAIL, TRAIL-Receptors, survivin, Transferin receptor (TfR), activated caspase-3 and cytocrome *c* expression levels were also evaluated by FC using specific monoclonal antibodies. Mitochondrial membrane potential was assessed by FC using JC-1 probe.
Results: Our results show that, as single agent, rhTRAIL, GA and SLB induce antiproliferative and cytotoxic effects in a dose, time and administration type dependent manner. We observed an IC_{50}, at 72h of exposure, for rhTRAIL, of 500ng/mL. On the other hand, when CEM cells were treated with GA and SLB, the IC_{50} is reached at 24h and is approximately 400nM for GA and 100μM for SLB. Moreover, when we administrated these compounds at low concentration daily in monotherapy, as well as in a combination schedule, with each other or with conventional chemotherapy, we observed a synergist cytotoxic effect. The different therapeutic efficacy of rhTRAIL, GA and SLB, in CEM cells, may also be correlated with the major expression of TRAIL pro-apoptotic receptors than anti-apoptotic receptors, TfR and survivin basal expression levels, respectively. Furthermore, these compounds induce cell death mainly by apoptosis which may be related with membranar and mitochondrial apoptotic pathways activation.
Summary / Conclusion: Our findings suggest that rhTRAIL and survivin downregulators, in monotherapy or in combination, may constitute a new potential therapeutic approach in ALL treatment.

B1773
SCREENING AND DELINEATION OF MOLECULAR MECHANISMS OF ACTION OF NOVEL AGENTS FOR THE TREATMENT OF B-THALASSAEMIA

A Theodorou[1*], M Phylactides[1], S Thein[2], M Kleanthous[1]
[1]Molecular Genetics Thalassaemia, Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]Cancer Studies, King's College London, London, United Kingdom

Background: Beta-thalassaemia, an inherited disorder of beta haemoglobin chain production, is a global health burden. The current management is regular blood transfusions with regular iron chelation therapy. However, this is not curative and has substantial morbidity related to iron overload. Pharmacological reactivation of gamma-globin genes for the production of foetal haemoglobin (HbF) is a very promising therapeutic approach for beta-thalassaemia, as foetal haemoglobin can substitute for the absent adult beta-haemoglobin. Although clinical trials have shown notable results for some agents, these were not very encouraging for large-scale use (Perrine, 2008) due to low efficacy and specificity and high toxicity (Gambari and Fibach, 2007). Furthermore, pharmacological attempts to find suitable HbF inducers are limited since none of the mechanisms of action of these agents in activating gamma-globin expression is fully understood. Understanding how the transcriptional network causing the switch from gamma to beta-globin works will provide a new mechanism-based approach for the reactivation of HbF synthesis in beta-thalassaemia.
Aims: Based on the literature and preliminary studies, four pre-identified HbF inducers; Lenalidomide, Angelicin, 5-aza-2'-seoxycytidine (decitabine) and Mithramycin were selected with the aim to investigate their HbF inducing activity *in vitro* on primary erythroid cultures from healthy donors and the potential delineation of the molecular mechanisms of action of the agent with the best activity. In the current study, all of the four agents will be screened on K562 cell line to select the two agents with the highest inducing activity. In addition, the optimum protocol for induction of primary erythroid cultures will be determined which will be then used for screening of the two selected agents on primary erythroid cultures for selection of the agent with the best inducing activity.
Methods: K562 cell line was induced with different concentrations of each agent for five days and the HbF induction activity was determine by benzidine staining. The two-phase method originally identified by Fibach (1998) was used for preparation of primary erythroid cell cultures from peripheral blood obtained from healthy individuals. Experiments were performed to identify the best time that the agent should be added to the culture on phase II as well as the duration of induction with the agent to be investigated. The level of induction of foetal haemoglobin was detected at the protein level by cation exchange HPLC as defined by Ou and Rognerud (1993), at the mRNA level by multiplex-Real time PCR. The level of differentiation was investigated by Glycophorin A staining followed by FACs analysis and morphologically by cytospins stained with methylene blue and eosin red dyes.
Results: The two agents identified with the highest HbF inducing activity following screening in the K562 cell line were Mithramycin and Decitabine. These agents will be screened on primary erythroid cultures for identification of the most active compound. Analysis of the culture induction profiles in primary erythroid cultures showed that for optimal induction, the agents should be added to the culture at the prepro- to pro-erythroblast stage. Collection of the culture samples for analysis should be carried out when the culture reaches a plateau stage and before showing any signs of cell death, with a minimum induction period of 5 days.
Summary / Conclusion: Following induction of K562 cell line with the four agents decitabine and mithramycin were selected as the two agents with highest HbF inducing activiy. Having decided on the experimental protocol for induction on primary erythroid cultures, the two selected agents will be screened for identification of the agent with the best inducing activity and least cytotoxicity *ex vivo*. The best agent will be used in future studies for delineation of the molecular mechanisms for potential use on target-based therapeutic approaches.



Sample		Cell count		HPLC	
	Day of induction	cells/ml	% relative un-induced	% HbF	fold increase to un-induced
Un-induced		5175000	1	2.425	1
150μM HU	5	2787500	53.8647343	5.84	2.408247423
	6	2862500	55.3140097	5.042	2.079175258
	7	2525000	48.7922705	5.022	2.070927835
	8	2025000	39.1304348	4.244	1.750103093

Figure 1, Investigation of time of induction and duration of induction in Primary erythroid cultures from healthy donors. The culture was induced with 150μM HU on Day 5, 6, 7 of Phase II. Cytospins were prepared on the days of induction to determine the differentiation stage of the culture based on morphology (A). The differentiation stage of the culture was determined at the end of the culture, Day12 Phase II by GpA staining and FACS. Histogram shows the differentiation of the culture (PL1-FITC) induced at Day 6 with 150μM HU (B). The percentage of HbF was determined by cation exchange HPCL analysis (induction at Day 6)(C). D shows a table summarizing all the results obtained from the experiment in one primary erythroid culture.

HISTORICAL EVIDENCE OF SYSTEMIC MULTIORGAN COMPLICATIONS IN ATYPICAL HEMOLYTIC UREMIC SYNDROME (AHUS) PATIENTS BEFORE ECULIZUMAB THERAPY EITHER IN PROSPECTIVE TRIALS OR IN REAL-WORLD USE

P Muus[1*], C Loirat[2], C Licht[3], C Langman[4], C Bedrosian[5], C Legendre [6]
[1]Radboud University Nijmegen Medical Centre, Nijmegen , Netherlands, [2]Assistance Publique Hôpitaux de Paris, Hôpital Robert Debré, Paris , France, [3]Hospital for Sick Children and University of Toronto, Toronto, Canada, [4]Feinberg School of Medicine, Northwestern University, and Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, [5]Alexion Pharmaceuticals Inc., Cheshire, United States, [6]Université Paris Descartes, Hôpital Necker, Paris, France

Background: aHUS is a rare, systemic disease characterized by chronic, uncontrolled alternative complement pathway activation leading to thrombotic microangiopathy (TMA). Within 1 year of diagnosis, up to 65% of patients develop permanent renal damage or end-stage renal disease or die. Extra-renal involvement and overall rate of complications in the course of aHUS are poorly documented. Eculizumab is the first approved treatment for aHUS in pediatric and adult patients.
Aims: Identify and describe evidence of historical systemic complications in aHUS patients from three trials: two phase 2 clinical trials of eculizumab (002 and 003), and in a cohort of aHUS patients who were treated with eculizumab outside clinical trials.

Table. Baseline characteristics and historical incidence of complications by system

Baseline characteristics	Retrospective study (N=30)	Patients with progressing TMA[a] (Study 002) (N=17)	Patients with long duration of aHUS and CKD[b] (Study 003) (N=20)
Age, mean, years (range)	12 (0–51)	28 (17–68)	28 (13–63)
Gender, female, %	53	71	60
No identified complement mutation or autoantibody, %	53	24	30
Prior kidney transplant, %	37	41	40
LDH >ULN, %	67	59	20
Platelet count×10^9/L, mean±SD	171±83	109±32	228±78
eGFR ≥90 mL/min/1.73 m^2, %	13	0	0
Historical complications by system			
Renal, %	90	71	80
Extrarenal thrombi, %	40	6	50
Cardiovascular, %	50	94	95
Gastrointestinal, %	73	53	45
Neurologic, %	53	29	30
Pulmonary, %	50	47	40
Complications in >1 system, %	100	82	90
Complications in >2 systems, %	40	59	70
Complications in >3 systems, %	25	35	20

[a]Platelet count <150×10^9/L after ≥4 PE/PI sessions with average platelet count decrease >25% in the prior week prior to most recent TMA presentation. [b]Receiving chronic PE/PI on a stable regimen with no platelet count decrease >25% during 8-week observation period before eculizumab treatment. CKD=chronic kidney disease; LDH=lactate dehydrogenase; ULN=upper limit of normal; SD=standard deviation; eGFR=estimated glomerular filtration rate.

Methods: Medical record data were collected retrospectively for 30 aHUS patients (children, n=15; adolescents, n=4; adults, n=11) who received eculizumab treatment from 2007 to 2009 outside the setting of a controlled clinical trial. The 002 clinical trial (NCT00844844 and NCT00844845) enrolled 17 patients age ≥12 years with progressing TMA despite ≥4 plasma exchange/plasma infusion (PE/PI) sessions in the prior week. The 003 clinical trial (NCT00844428 and NCT00838513) enrolled 20 patients age ≥12 years on chronic PE/PI with no platelet count decrease >25% during an 8-week observation period prior to eculizumab. Patients/guardians provided informed consent, and the studies were approved by each center's institutional review board. Data prior to administration of the first eculizumab dose are described. All complications, not only TMA-related complications, were included in the analysis.
Results: Disease characteristics for the groups at baseline are shown in the Table. Medical records of 90% of patients in the retrospective study and 71–80% of clinical trial patients demonstrated evidence of a history of kidney disease prior to the current TMA presentation. Extrarenal, systemic organ complications were reported in the majority of patients, with up to 100% experiencing complications in >1 body system (Table). Twenty-three patients across the 3 studies (34%) experienced extrarenal thrombi, including deep vein thrombosis (n=10). In addition, cardiac morbidities occurred in 75% of patients, including cardiomyopathy (n=6), myocardial infarction (n=2), transient ischemic attacks (n=2), pulmonary embolism (n=1), and cardiac arrest (n=1). Gastrointestinal disease was seen in 40 patients (60%) and included diarrhea (n=11), vomiting (n=9), and constipation (n=8). Neurologic complications occurred in 27 patients (40%), including headache (n=8), seizures (n=4), migraine (n=3), epilepsy (n=3), and facial paralysis (n=2). Thirty-one patients (46%) had pulmonary complications, including asthma (n=5), pneumonia (n=2), and respiratory failure (n=1).
Summary / Conclusion: aHUS is a devastating and progressive disease in which TMA and the accumulation of complications from renal failure and historical treatments may be associated with sudden and potentially fatal systemic aHUS morbidities. Based on the three studies in the present analysis, extra-renal systemic organ involvement (including cardiac, gastrointestinal, neurologic, and pulmonary complications, as well as peripheral thrombi) should be expected in aHUS. Historic data from these patients confirm the need for a treatment approach outside of plasma-based therapies should systemic aHUS organ involvement occur.

VISMODEGIB – AN HEDGEHOG PATHWAY INHIBITOR INDUCES CELL DEATH IN AN ALL CELL LINE

R Alves[1,2,3], M Ferreira[1], P Guarino[1], C Domingues[1], J Leite[1], A Gonçalves[1,2,3], A Sarmento-Ribeiro[1,2,3*]
[1]Applied Molecular Biology Biology and University Clinic of Hematology, [2]CIMAGO - Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, [3]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal

Background: Conserved embryonic signaling pathways such as Hedgehog (Hh), Wingless (Wnt) and Notch, critical for stem cell self-renewal and differentiation in hematopoiesis, have been implicated in the pathogenesis of several hematological malignancies. Acute lymphoblastic leukemia (ALL) is characterized by the abnormal proliferation and accumulation of immature lymphoid cells within the bone marrow and lymphoid tissues, which can develop from the aberrant activation of the Wnt/β-catenin, Notch and Hedgehog signaling pathways. On account of that, these pathways may constitute new potential candidate targets for ALL therapy.
Aims: The main goal of this study was to evaluate the therapeutic potential of the hedgehog inhibitor, vismodegib, in an ALL cell line.
Methods: To evaluate the effect of this signaling pathway inhibitor on cell viability, we use an ALL cell line, the CEM cells, submitted to different concentrations of vismodegib (GDC-0449). The IC50 (half maximal inhibitory concentration), was determined using the blue trypan assay. The cell death was assessed by optical microscopy (May-Grunwald staining) and by flow cytometry (Propidium Iodide/Annexin V staining, BAX and BCL-2 levels and mitochondrial membrane potential). We also analysed, by flow cytometry, some proteins related with cell cycle regulation, as p53 and Cyclin D1.
Results: Our results showed that, vismodegib induced a cytostatic and cytotoxic effect in CEM cells in a time- and dose-dependent manner. The half maximal inhibitory concentration (IC50) is attainted with 150 μM, after 24h of treatment. This compound induces cell death mainly by apoptosis that may be related with the observed increase in caspases levels and decrease in BAX/BCL-2 ratio and mitochondrial membrane potential. The observed antiproliferative effect may be related with the decrease in p53 and cyclin D1 levels.
Summary / Conclusion: In conclusion, our results suggest that vismodegib (GDC-0449) may be a new potential targeted therapeutic approach that could be efficient in ALL treatment.

B1776

SELECTIVE SMALL MOLECULE AXL INHIBITOR BGB324 FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA

G Gausdal[1*], K Wnuk-Lipinska[1], E Milde[1], T Sandal[1], M Hellesoy[1], L Ahmed[1], H Haugen[1], S Loges[2], D Micklem[1], J Lorens[3], L Zhou[1]
[1]BerGenBio AS, Bergen, Norway, [2]University Hospital Hamburg-Eppendorf University Comprehensive Cancer Center II. Medical Clinic & Institute of Tumor Biology, Hamburg, Germany, [3]Department of Biomedicine and Centre for Cancer Biomarkers, University of Bergen, Bergen, Norway

Background: Axl, a member of the TAM family of receptor tyrosine kinases comprising Tyro3, Axl and Mer, has been implicated in the development and metastasis of many cancers, including haematological malignancies. A high level of Axl is associated with worse progression-free and overall survival in AML patients, and represents an independent prognostic marker. Growth arrest specific gene-6 (GAS6) is the known ligand with highest affinity for Axl. AML cells induce expression and secretion of GAS6 by bone marrow-derived stromal cells (BMDSCs), and this Gas6/Axl paracrine axis promotes proliferation, survival and chemoresistance of AML cells in the bone marrow microenvironment. Axl also contributes to the pathogenesis of *FLT3*-internal tandem duplication (*FLT3*-ITD) AML, suggesting Axl as an attractive target in AML. BGB324, a potent and selective small molecule inhibitor of Axl with low nanomolar potency in biochemical assays and exceptional kinase selectivity in cellular assays (at least 50 fold difference over Tyro and Mer), will be evaluated in a phase I clinical trial in coming months.
Aims: We aimed to explore the potential of the first-in-class Axl inhibitor BGB324 for the treatment of *FLT3*-ITD (+) AML.
Methods: The Axl inbibitor BGB324 was tested in the Mv4-11 cell line either as a single agent or in combination with chemotherapeutic agents such as Cytarabine and doxorubicin in: cell proliferation assays in the absence or presence of adherent HS-5 human stroma cells; Flow cytometric analyses of cell cycle and apoptosis; *in vivo* Mv4-11 subcutaneous xenograft and bone marrow engraftment models in NOD/SCID mice. *in vivo* target validation and PD biomarker detection were performed with Western blot, immunoprecipitation, and IHC.
Results: BGB324 treatment effectively inhibited Mv4-11 AML cell growth, induced cell apoptosis, and potentiated the killing effect of chemotherapeutic agents such as Cytarabine and doxorubicin against Mv4-11 cells. BGB324 treatment caused tumor regression, and significantly prolonged animal survival.
Summary / Conclusion: These data support further clinical evaluation of BGB324 as a single agent or in combination with established treatment regimen in AML patients.

BICYCLIC DERIVATIVES OF LIDONOJIRIMYCIN AS PHARMACOLOGICAL CHAPERONES FOR NEURONOPATHIC FORMS OF GAUCHER DISEASE

P Alfonso[1,2,3*], V Andreu[1,2], A Pino-Angeles[4], A Moya-García[3,4], M García-Moreno[5], F Sánchez-Jiménez[4,6], M Pocovi[1,3,7], C Ortiz-Mellet[5], J García-Fernández[8], P Giraldo[1,2,3, 9]

[1]Aragon Institute for Health Sciences of Aragon (I+CS), [2]Traslational Research Unit, Miguel Servet University Hospital, [3]CIBERER, Zaragoza, [4]Department of Molecular Biology and Biochemistry, University of Malaga, Malaga, [5]Department of Organic Chemistry, University of Sevilla, Sevilla, [6]CIBERER, Malaga, [7]Department of Biochemistry and Cellular and Molecular Biology, University of Zaragoza, Zaragoza, [8]Institute for Chemical Research (IIQ), CSIC-University of Sevilla, Sevilla, [9]Hematology Department, Miguel Servet University Hospital, Zaragoza, Spain

Background: Gaucher disease (GD), the most prevalent lysosomal storage disorder, is caused by mutations in the GBA1 gene encoding for lysosomal acid β-glucosidase (glucocerebrosidase, GCase). The mutant enzymes exhibit impaired cellular trafficking as a consequence of aberrant folding. Current investigational therapeutic strategies for include the development of ligands of the enzyme capable of promoting those conformational changes that are required for efficient folding and restoring trafficking. Although somewhat counterintuitive, competitiveinhibitors of this enzyme, at subinhibitory concentrations, can increase steady-state lysosomal levels of active GCase through this rescuing mechanism acting as "pharmacological chaperones". At the massive lysosomal substrate concentration, the inhibitor would be replaced from the active site of the enzyme and the metabolic activity recovered. However, most of the pharmacological chaperones under study are iminosugars that behave as broad spectrum inhibitors, inhibiting simultaneously several glucosidases, which represents a serious inconvenient for clinical applications. An additional problem is that iminosugars are not active as pharmacological chaperones for glucocerebrosidase mutations located outside the domain containing the active site and are associatedwith neurological involvement.

Aims: To develop molecules with high binding specificity towards GCase, high ratio of chaperone *versus* inhibitor activity and capable of producing an increase in the levels of GC mutants, including those with mutations located outside the catalytic domain.

Methods: Three bicyclic derivatives of L-idonojirimycin (L-idose-based sp^2-iminosugars) designed and chemically synthesized from D-glucose after *in silico* structural analysis and identification of the most favorable molecular features to interact with the glucocerebrosidase active site. Their chaperone potential was evaluated *in vitro*using stable transfectants of glucocerebrosidase mutants (N370S and L444P) in COS-7 cells and human skin fibroblasts of homozygous GD patients for these above mentioned mutations.

Results: Results showed an increase in GCase activity at various chaperone concentrations, ranging from 2-fold to 5-fold for the L444P mutant and from 2-fold to 3-fold for the N370S mutant in COS-7 cells and increases of 3-fold for the L444P homozygous GD fibroblasts.

Summary / Conclusion: The use of bicyclic L-idonojirimycin-based pharmacological chaperones could be considered as a therapeutic alternative for GD, mainly in patients with mutations located outside the GC active site and associated with neurologic involvement.

B1778

ORIDONIN UPREGULATES RETINOIC ACID RECEPTORS AND SHOWS SYNERGISTIC EFFECT WHEN USED IN COMBINATION WITH ALL-TRANS RETINOIC ACID IN T(8:21) LEUKEMIA

Y Wang[1*], T Zhen[1], C Wu[1], P Liu[1], H Wu[1], Y Lu[1], W Zhang[1], S Chen[1], Z Chen[1]

[1]Shanghai Institute of Hematology, Rui Jin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: The t(8;21)(q22;q22) translocation, which generates AML1-ETO (AE) fusion gene, is one of the most frequent chromosomal abnormalities detected in acute myeloid leukemia (AML, 12-20%), especially in FAB subtype M2 (AML-M2, 40-50%). The resultant AE fusion protein immortalizes hematopoietic progenitors and induces a myeloproliferative disorder in mice. Additional mutations are required to cooperate with full-length AE to cause full-blown leukemia. An isoform of AE with an alternatively spliced exon (exon 9a) of ETO (AE9a) could induce leukemia in mice. Therefore, AE oncoprotein plays a critical role in leukemogenesis, and agents that target AE could be useful in treating t(8;21) leukemia. Arabinosylcytosine and anthracycline-based chemotherapy has been the principal frontline treatment for t(8;21) AML, which results in a median survival of less than 2 years and a 5-year overall survival of no more than 40%. Targeted therapies against oncoproteins crucial for leukemia pathogenesis represent a new and promising approach to cancer treatment. In our previous work, oridonin, a diterpenoid isolated from the medicinal herb *Isodon rubescens*, was identified to have a relatively selective effect against t(8;21) leukemia cells. Further studies showed that oridonin specifically bound to AE, causing caspase-3-mediated cleavage of AE to generate a truncated version that acted as a tumor suppressor. Oridonin significantly prolonged life span of mice bearing t(8;21) leukemic cells. These results demonstrate the potent antileukemia efficacies of oridonin on t(8;21) leukemia which might provide benefits for patients.

Aims: To explore whether oridonin could induce differentiation besides apoptosis and the potential synergistic effect of oridonin-based combinatorial therapies in t(8:21) leukemia.

Methods: Cell growth and proliferation assays, differentiation assay, flow cytometry, quantitative RT-PCR, luciferase reporter assay, western blotting, hematopathologic analysis, murine bone marrow transplantation by tail-vein injection and *in vivo* treatment studies were performed.

Results: In this study, we show that oridonin upregulates retinoic acid receptors α2 (RARα2) and RARb2 in t(8;21) leukemia cells. Oridonin also increases the activation of retinoic acid (RA) signaling regulated by all-trans retinoic acid (ATRA). It exerts enhanced differentiation effect when ATRA was used in combination with oridonin in both t(8;21) leukemia cell line and primary leukemic cells isolated from t(8;21) AML patients. In murine models of t(8;21) AML, combined use of oridonin and ATRA synergetic prolongs the survival of leukemic mice.

Summary / Conclusion: Oridonin upregulates retinoic acid receptors and shows synergistic effect when used in combination with all-trans retinoic acid in t(8:21) leukemia, suggesting potential benefits of oridonin/ATRA combinatorial therapy for patients with t(8:21) AML.

B1779

ROLE OF LENALIDOMIDE IN MANAGEMENT OF MYELODYSPLASTIC SYNDROMES (MDS) WITH DEL(5Q) ASSOCIATED WITH PURE RED CELL APLASIA (PRCA)

C Cerchione[1*], G Cerciello[1], R Della Pepa[1], N Pugliese[1], L Marano[1], O Vitagliano[1], L Luciano[1], F Alfinito[1], F Pane[1], A Risitano[1]

[1]Hematology, AOU "Federico II", Napoli, Italy

Background: Myelodysplastic syndromes associated with PRCA is a rare condition characterized by severe anemia, transfusion dependence, reticulocytopenia, reduction of erythroid precursors and multilineage dysplasia. In PRCA erythroid precursors are nearly absent, while megakaryocytes and granulocytic precursors are usually present at normal levels. Damage to erythroid progenitors appears to be immune-mediated and in about 10% of cases acute myeloid leukemia represents the latest evolution. Conventional immunotherapy is ineffective while alemtuzumab combined with CyA seems to be a valid therapy.

Aims: Nearby 25 cases of MDS with PRCA have been described until today and 5 of them were associated with del(5)(q14q34). 2008 WHO classification defined MDS with isolated del(5q) as a syndrome characterized by bone marrow blast count < 5%, isolated del(5q) and absence of Auer rods.

Methods: Here we report 3 cases of severe transfusion-dependent macrocytic anaemia in which del(5) (q14q34) was associated with erythroblastopenia and myelodysplasia.

Results: (M/61 y.o.) with a transfusion dependence of 4 units/month, received diagnosis of PRCA and underwent 12 cycles of alemtuzumab + CyA during 3 years: transient remissions from transfusion dependence were followed by relapses; after 3 years del(5q)was evident in a bone marrow that appeared dysplastic: lenalidomide treatment was started, after few months AML merged with fatal evolution. (F/35 y.o.) received diagnosis of PRCA after 1 year treatment with steroids and transfusions (2 Units /month). She underwent three courses of CyA and alemtuzumab with short transient periods of transfusion independence: a second bone marrow investigation, performed after one year,

showed del(5q) and lenalidomide therapy was started: transfusion independence was obtained after 2 months. (M/65 y.o.) with a transfusion dependence of 4 units/month, received diagnosis of PRCA and was treated with a single course of alemtuzumab and CyA without any result, cytogenetic revision of bone marrow highlighted the presence of del(5q) and treatment with lenalidomide was started 3 months after diagnosis. No hematological improvement was observed and after 9 courses therapy was stopped. Nowadays patient is transfusion-dependent after 21 months from diagnosis.
Summary / Conclusion: Here we stress the difficulty of diagnosing PRCA within unilineage myelodysplastic syndromes and focus on the relationship among MDS with erytrhoid aplasia and del(5q) in order to speculate on the role that lenalidomide could play in such entities.

B1780
GLYCOENGINEERED ANTIBODIES MEDIATE SUPERIOR MONOCYTE/MACROPHAGE-MEDIATED PHAGOCYTIC AND CYTOTOXIC ACTIVITY COMPARED TO PARENTAL ANTIBODIES
S Herter[1], M Birk[1], C Gerdes[1], P Umana[1], C Klein[1*], M Bacac[1]
[1]pRED, Oncology DTA, Roche-Glycart, Schlieren, Switzerland

Background: Therapeutic monoclonal antibodies eliminate tumor cells by different mechanisms including blocking of receptor signaling pathways, induction of antibody dependent cellular cytotoxicity (ADCC), antibody dependent cellular phagocytosis (ADCP), complement dependent cytotoxicity (CDC), and induction of adaptive immunity.
Aims: In view of the important role of phagocytic cells in the mechanism of action of therapeutic antibodies, we analyzed the FcgR-dependent effector functions mediated by monocytes and macrophages upon treatment with glycoengineered (GE) and wild-type (WT) antibodies under different experimental conditions.
Methods: GA101 (obinutuzumab, a humanized type II, glycoengineered anti-CD20), GA201 (glycoengineered anti-EGFR) and GA601 (glycoengineered anti-HER2) monoclonal antibodies displaying enhanced binding affinity to human FcgRIIIa (CD16) were compared to corresponding parental antibodies bearing unmodified antibody Fc part for their capacity to induce monocyte/macrophage-mediated phagocytic and cytotoxic activity under several experimental conditions.
Results: GE and WT antibodies displayed comparable binding and induced similar monocyte/macrophage-mediated ADCC and ADCP in absence of competing endogenous IgGs. Interestingly, in their presence, i.e. in a situation that more closely mimics physiological conditions, GE antibodies displayed significantly superior binding and induced higher levels of ADCC/ADCP.
Summary / Conclusion: These data show, for the first time, that in addition to enhancing FcgRIIIa-dependent NK-cell cytotoxicity (ADCC), glycoengineering also enhances monocyte and macrophage cytotoxic and phagocytic activities through enhanced binding to FcgRIIIa under conditions that more closely resemble the physiological setting.

Cellular immunotherapy and vaccination

B1781
MONITORING OF T-LYMPHOCYTE SUBPOPULATIONS IN PERIPHERAL BLOOD OF PATIENTS WITH ACUTE LEUKEMIA (AL) DURING DONOR LYMPHOCYTE INFUSION (DLI) AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION (ALLO-BMT)
R Bogdanov[1*], L Mendeleeva[1], I Galtseva[1], L Kuzmina[1], E Parovichnikova[1], V Savchenko[1]
[1]Bone marrow transplantation, Research center of hematology, Moscow, Russian Federation

Background: Delayed Reconstitution of T-cell component of the immune system after allogeneic bone marrow transplantation is a risk factor for post-transplant relapse in AL patients. DLIs for inducing the "graft versus leukemia" effect to prevent and treat the relapse of the disease.
Aims: To investigate subpopulations of T-lymphocytes in peripheral blood derived from patients with AL after allo-BMT during DLI, followed by intravenous interleukin-2 (IL-2) infusion, as therapy of hematological relapse and mixed chimerism progression.
Methods: The study included 10 patients (9 - AML, 1 - ALL): 7 - male, 3 - female, aged 27 to 57 years (median age 34 years). The pre-transplant conditioning was performed by myeloablative regimen (BU + TF) in 6 patients and by low-intensity regimen in 4 pts: Flyud + BU + ATC - 3 patients, BU+Flyud+Cytosar+Idarubicin in 1 patient. All pts were recipients of bone marrow from HLA-matched related donor. The number of tranfused myelokaryocytes ranged from 2.5 to 5.4 x 10^8/kg (median 3.95 x 10^8/kg). DLI after allo-BMT were administered in the case of mixed chimerism progression (4 pts) and hematologic relapse (6 pts). The time between the allo-BMT and a statement of the growth of mixed chimerism / relapse ranged from 3 to 51 months (median 7.2 months). Pts with hematologic relapse were administered DLI during myelosupressive aplasia after reinduction chemotherapy. The median number of DLI procedures was 2 DLI (range from 1 to 4). The total number of transfused CD3+ cells ranged from 0.1 to 1.74 x10^8/kg (median 0.35x10^8/kg). Intravenous IL-2 (6 MUE) was administered after DLI in all pts.
The quantity composition of T-lymphocyte subpopulations in the peripheral blood was estimated using the method of immunophenotyping and flow cytometry (cytometry FACS Canto II, BD). Monoclonal antibodies to the following antigens were used: CD3 (PerCP), CD4 (PE), CD8 (FITC), CD 25 (FITC), CD 56 (FITC) (BD). Immunophenotypes of the following T-lymphocyte subpopulations: T-lymphocytes (absolute CD3+ count), T-helper cells (CD3+/CD4+); T-cytotoxic cells (CD3+/CD8+), regulatory cells (CD4+/CD25^{high}), T-NK cells (CD3+/CD56+) and NK-cells (CD3-/CD56+) were identified.Control points: statement of increase of mixed chimerism/relapse, then 1 time every 2 weeks for 10 weeks.
Results: Complete remission with full donor chimerism was achieved in 7 pts, in 3 pts the treatment was not effective. The median duration of response was 9 months (range 1 to 16 months). Acute GVHD occurred in 4 patients (I-II degree - 3 pts, III - IV degree - 1 pt).
The absolute number of T-helpers, T-cytotoxic cells, TNK-cells, NK-cells were reduced at the time of relapse (in 83%, 50%, 50%, 100 % of pts respectively), however the amount of T-regulatory cells remained normal at the same time. The number of T-cells subpopulations reduced in 2 weeks after the chemotherapy+1DLI in relapse pts. Normal values of those T-subpopulations gradually recovered after 6 weeks. Patients had received DLI for mixed chimerism progression have reduced number of CD3+ and T-helper cells (50% and 100% of pts respectively), and low levels maintained for 10 weeks after the first DLI.
Summary / Conclusion: DLI is an effective treatment of leukemia relapse after allogeneic BMT. Absolute number of T-helper cells, T-cytotoxic cells, T-NK cells and NK-cells were decreased at the time of relapse and after chemotherapy. Normal number of T-lymphocyte subpopulations recovered after 6 weeks of the first DLI if the remission was achieved. Absolute number of T-lymphocytes didn't recover in cases of DLI treatment failure.

ERYTHROPOIETIN LEVEL IN SICKLE CELL DISEASE PATIENTS NOT IN CRISIS

D Pulte[1*], D Axelrod[1]
[1]Thomas Jefferson University, Philadelphia, United States

Background: Patients with sickle cell disease (SCD) have lower than expected values of erythropoietin for the extent of their anemia. SCD may be complicated by hypoxia, renal insufficiency, and inflammation, all of which may change erythropoietin levels. We previously examined the relationship between erythropoietin level and hemoglobin and renal function as measured by glomerular filtration rate (GFR) in patients with SCD not in crisis and found that the expected correlation between erythropoietin level versus hemoglobin and renal function was not clearly maintained in SCD.
Aims: Here, we examine the relationship between erythropoietin and inflammation and hypoxia.
Methods: Charts of patients treated in the outpatient hematology clinic were reviewed. Patients who had sickle cell anemia (SCA), SC disease, or sickle-thalassemia and in whom erythropoietin had been measured on an outpatient basis while they were not in crisis and who did not receive exogenous erythropoietin were eligible for inclusion. Erythropoietin level, hemoglobin (hgb), platelet count, white blood count (WBC), mean corpuscular volume (MCV), oxygen saturation, reticulocyte count, serum creatinine, and patient characteristics including age, gender, and disease type were recorded. GFR was calculated using the CDK-EPI equation. Because direct measurements of inflammation such as erythrocyte sedimentation rate and c-reactive protein are not measured as part of standard of care, WBC and platelet count were used as proxy markers for this preliminary study.
Results: Data from a total of 54 patients was obtained, including 39 with SCA, 9 with SC disease, 5 with sickle-thalassemia, and one with S-O(Arab). Median hemoglobin was 8.3 and median erythropoietin level was 62 for all patients. Oxygen saturation ranged from 90% to 100% on room air. All patients had at least adequate iron stores. Because hemoglobin levels were higher and therefore corresponding erythropoietin levels lower in patients with SC disease, patients with SCA and sickle-thalassemia null were examined separately. Among patients with SCA and sickle-thal^0, lower hemoglobin levels (<7 versus 7+) were only marginally associated with higher erythropoietin levels (96 versus 64, P=0.07). When patients with oxygen saturation of less than 96% were compared to patients with an oxygen saturation of greater than 96%, no statistically significant difference in erythropoietin level was observed. However, patients with higher oxygen saturation had slightly higher hemoglobin levels (8.7 gm/dl versus 6.9 gm/dl, P=0.02). Smoking status (nonsmoker/former smoker versus current smoker) had no effect on erythropoietin level. Similarly, no difference in erythropoietin level was observed for patients with normal versus elevated WBC and platelet count. However, in contrast to hypoxia, high WBC was not associated with differences in hemoglobin. Interestingly, patients receiving hydroxyurea had a higher erythropoietin level, despite showing no difference in hemoglobin level, GFR, oxygen saturation, or WBC. Median MCV was higher in patients taking hydroxyurea, suggesting that compliance was acceptable.
Summary / Conclusion: Patients with sickle cell disease have low levels of erythropoietin, even when no kidney disease is evident. Hypoxia did not correlate well with erythropoietin levels. This may reflect the worsening clinical state of patients with hypoxia and sickle cell disease, but hypoxic patients did not show lower GFR than patients without hypoxia. Inflammation, as measured by the proxy measures of WBC and platelet counts, did not appear to affect erythropoietin levels. Hydroxyurea appears to preserve erythropoietin levels in patients with SCA and sickle-thal^0, but the mechanism by which it is protective is unclear.

B1784

EFFECTS OF IRON POLYMALTOSE COMPLEX, FERROUS FUMARATE AND FERROUS SULFATE THERAPIES IN ANEMIC PREGNANT RATS, THEIR FETUSES AND PLACENTAS

J Toblli[1*], G Cao[1], L Oliveri[1], M Angerosa[1]
[1]Laboratory of Experimental Medicine, Hospital Aleman, Buenos Aires, Argentina

Background: Iron deficiency anemia (IDA) during pregnancy is associated with adverse consequences in the mother, fetus, and placenta, such as preterm delivery and placenta insufficiency. Ferrous salts are commonly used to prevent and to treat mild to moderate IDA during pregnancy. The rapid release of iron from ferrous compounds and its uncontrolled plasma uptake can result in non-transferrin bound iron (NTBI) [1,2]. NTBI is taken up in an uncontrolled way, leading to oxidative stress [3]. Iron(III)-hydroxide polymaltose complex (IPC) is a well-tolerated, orally administered non-ionic oral Fe(III) preparation that effectively prevents and corrects IDA during pregnancy [4]. The iron from IPC is essentially taken up via active and controlled mechanism resulting in negligible levels of NTBI [1].
Aims: This study compared the effects of oral IPC, ferrous fumarate (FF) and ferrous sulfate (FS) treatments in anemic pregnant rats, their placentas and fetuses.
Methods: There were five experimental groups (n=8): untreated non-anemic control group, untreated anemic group and three anemic groups receiving 2 mg iron/kg body weight/day as IPC [Maltofer-Fol®, Vifor (International) Ltd., St. Gallen, Switzerland], FF (Anemidox Ferrum®, Merck Sharp & Dohme, Inc, Buenos Aires, Argentina), or FS (Fer-In-Sol, Mead Johnson, Buenos Aires, Argentina) from the start of pregnancy (day 0). On day 21, the animals underwent Caesarian section and were sacrificed. Pregnancy outcome was measured by number of fetuses, and by neonate and placenta weight. Maternal hepatic damage was assessed by analyzing aspartate aminotransferase (AST). Lipid peroxidation (MDA) and the ratio of reduced to oxidized glutathione (GSH:GSSG) were analyzed from homogenised fractions of the livers of mothers and fetuses and whole placentas. Interleukin 6 (IL6) and hypoxia inducible factor-1α (HIF-1α) were analyzed from homogenized fractions of the whole placentas.
Results: All therapies were comparably effective in correcting anemia. FS and FF resulted in higher lipid peroxidation in dams, fetuses and placentas vs. IPC. The FS group presented lower GSH:GSSG values in dams, fetuses and placentas than IPC and FF groups. IPC, but not FF or FS, restored normal IL6 expression levels in placentas whereas FS-treated animals presented the highest IL6 levels, suggesting a local inflammatory reaction. Anemia-induced high levels of HIF-1α were partially lowered by IPC and FF but further elevated by FS. Especially FS treatment was found to elicit hepatic damage in the dams and oxidative stress in the dams, fetuses and placenta as well as inflammation and high levels of HIF-1α in the placenta. Pregnancy outcome was worse in the FF and FS groups than in the IPC group.
Summary / Conclusion: Anemia-associated oxidative stress and inflammation, and also in part hypoxia, were resolved by IPC therapy. Treatment with ferrous salts, in particular with FS, was found to elicit maternal hepatic damage, oxidative stress in dams, fetuses and placentas, as well as high levels of IL6 and HIF-1α in the placenta.

ROLE OF REGULATORY T CELLS IN BETA THALASSEMIA

M Politou[1*], V KAPSIMALI[2], v komninaka[3], S VALSAMI[4], E VOSKARIDOU[3]
[1]Blood Bank-Hematology Laboratory ARETAIEION Hospital, [2]Microbiology, University of Athens Medical School, [3]THALLASEMIA UNIT, LAIKON HOSPITAL, [4]University of Athens Medical School, Athens, Greece

Background: Many immune defects in different compartments of immune response have been documented in patients with beta thalassemia. Ineffective erythopoiesis with chronic hemolysis, splenectomy, iron overload, infection with hepatitis B/C or HIV and the constant stimuli of transfusion have all been implicated in the pathogenesis of the immunologic abnormalities found in thalassemia patients
Regulatory T cells (Treg) characterized by expression of the transcription factor Foxp3 are responsible for maintaining peripheral immune tolerance and homeostasis. Data in the literature regarding the role of Tregs in thalassemia is very limited.
Aims: The aim of the study was to investigate the regulatory T cells compartment in beta thalassemia patients and to find factors which could influence their expression.
Methods: We studied 21 chronically transfused patients with beta thalassemia major (TM) (13 males and 8 females with a mean age of 48.8 years) , 9 thalassemia intermedia (TI) patients, who have never received transfusion (4 males and 5 females, with a mean age of 44.1 years) and 10 normal controls.
Iron overload was assessed with T2* of liver and heart. Peripheral blood samples were analyzed with five colour flow cytometry (CyFlow SPACE, PARTEC) using the following monoclonal antibodies. CD3- FITC, FOXP3- PE,CD127-PeCy5, CD4- PeCy7, CD25-APC. The regulatory T cells were characterized as CD3+, CD4+, CD25+ high, CD127 low/- ,FoxP3 +. Statistical analysis was performed by using the paired t-test.
Results: Twelve out of 21 TM patients and 2/9 TI patients had undergone splenectomy. Hepatitis C infection was recorded in 3 TM patients. The majority of TM patients (12/21) showed only mild to moderate hemosiderosis (7-13.9 mg/g of iron in liver T2*) , while 5 TM patients showed successful chelation therapy with < 2.9 mg/g of liver iron and only one showing increased liver hemosiderosis (>14 mg/g). There was no statistically significant difference of percentages of CD+, CD25+, Foxp3+ cells between controls (mean 0.226, SD 0.108) and TM patients (mean 0.39 ,SD 0.32) (P=0.13) neither between TM and TI patients (mean 0.2, SD 0.128) (P=0.59).

No difference of percentage of CD+, CD25+, Foxp3+ cells was found between the group of patients that had undergone splenectomy and the unsplenectomized ones. Hepatitis C infection did not seem to have significant effect on T regs percentag

Summary / Conclusion: It was previously suggested (by only one study) that increased percentage of the regulatory T cells found in TM could be explained by the chronic stimuli of transfusion but in our study we did not observe a difference of Tregs between the regularly transfused TM and the TI group that has never received transfusion. Controlled body iron stores, by eliminating the chronic inflammation background, could blunt the diversion of immunoregulatory balance. Further studies of the cytokines' pathways through which Tregs exert their effect can clarify the role of the nature of the disease (thalassemia) itself in immunomodulation

ENDOTHELIAL DYSFUNCTION IN YOUNG TRANSFUSION DEPENDENT B-THALASSEMIA PATIENTS

A Adly[1*], N Elsherif[1], E Ismail[2], Y Ibrahim[3], A Farouk[2]
[1]Pediatrics, [2]Clinical pathology, [3]Radiology, Ain Shams, cairo, Egypt

Background: In patients with beta thalassemia an increased level of circulating endothelial cells reflecting endothelial damage and denudation. Repair of the denuded endothelial might be crucial for the restoration of endothelial function

Aims: The aim of this work is to study the endothelial dysfunction among patients with beta thalassemia, the ability to repair the denuded endothelium and the effect of iron load on these cells number correlating with the efficacy of iron chelation

Methods: twenty five patients aging more than 12 years with transfusion dependent β-thalassemia were recruited from the haematology/oncology clinic, Children hospital Ain Shams University and compared with 15 healthy age and sex matched controls. The quantity of circulating Endothelial microparicles (CD144+ /VE-cadherin+endothelial MPs) and Von willebrand factor Ag (vWF Ag) as markers of endothelial dysfunction, and the quantity of circulating CD34+VEGFR2+ cells were determined in relation to erythropoietin(EPO) level, echocardiographic cardiac parameters and carotid intimal thickness.

Results: The quantity of circulating CD34+VEGFR2+ cells was significantly higher among beta thalassemia patients than the controls (P=0.001) , however no significant difference existed between the patients and the control as regard quantity of Endothelial microparicles and vWF Ag level (P=0.66,P=0.33) . We found no significant correlation between Endothelial microparicles, vWF Ag level and circulating CD34+VEGFR2+ cells nor between EMPS , vWF Ag level, circulating CD34+VEGFR2+ cells and EPO level, mean ferritin in last 2 years , type of chelation, and compliance. Patients with increased left ventricular dimensions had a significantly higher circulating CD34+VEGFR2+ cells(P=0.005) and a lower vWF Ag level(P=0.02). Although 72% of the patients had increased carotid intimal thickness, yet it did not correlate with Endothelial microparicles , circulating CD34+VEGFR2+ cells quantities and vWF Ag level.

Summary / Conclusion: In this study the levels of procoagulant MPs of endothelial origins was not significantly elevated in patients with beta thalassemia, indicating probably the greater involvement of platelet or RBCs MPS in the process of endothelial damage among these patients. Patients with the greatest iron overload did not show a significant increase in the quantity of circulating CD34+VEGFR2+ cells suggesting a more significant qualitative effect of iron overload on these cells

PEROXIREDOXINS PLAY AN IMPORTANT ROLE IN THE SURVIVAL OF ERYTHROID CELLS IN BETA THALASSEMIA AND SICKLE CELL DISEASE PATIENTS.

K Romanello[1], K Lopes[1], S Nagamatsu[1], M Bezerra[2], Betânia L Hatzlhofer[2], I Domingos[2], A Araujo[3], M Oliveira[4], L Netto[5], F Costa[6], I Malavazi[1], A Cunha[1*]
[1]Universidade Federal de São carlos, São Carlos, [2]Universidade Federal do Pernambuco, [3]HEMOPE, Recife, [4]Universidade Estadual Paulista Julio Mesquita Filho - Campus Experimental do Litoral Paulista, São Vicente, [5]Universidade de São Paulo, São Paulo, [6]Universidade Estadual de Campinas, Campinas, Brazil

Background: The oxidative stress, occurs mainly by Reactive Oxygen Species (ROS) and is responsible for aggravating the symptoms of several diseases, including hemolytic anemias such as sickle cell disease (SCD) and beta thalassemia (BT). Peroxiredoxins (PRDXs), are a group of enzymes involved in the detoxification of ROS. In erythroid cells, their abundance and high reactivity can be highlighted. For example, in erythrocytes, PRDX2, is the third most abundant protein, indicating its possible role in the cell development and homeostasis. However, there are few studies connecting these proteins to hemolytic anemias, which remarkable feature is an increased production of ROS.

Aims: This study evaluated the expression and production of PRDXs in reticulocytes of SCD and BT patients compared to healthy blood donors.

Methods: To evaluate the difference in gene expression of *PRDX*s, Real Time PCR was used and Western blot analysis was used to evaluate the protein production.

Results: Our results showed that the levels of transcript and PRDX1 protein were increased in BT patients and decreased in SCD. The *PRDX2* transcript showed no differences in both diseases. However western blot analysis showed a decrease in PRDX2 protein in SCD reticulocytes, indicating a possible pos transcription regulation process for this gene in SCD. High levels of *PRDX5* transcript were found in BT patients and no difference was observed for SCD, however the protein was not found in western blot analysis. The PRDX5 protein is located at mitochondria, an organelle absent in reticulocytes and only residues of mRNA could be observed in these cells. A reduction in mRNA and protein levels for PRDX6 was observed in BT and SCD patients. Besides acting in the ROS detoxification, PRDX6 also has a phospholipase A2 activity, thus regulating the phospholipid turnover at the cell membrane. The decrease of this enzyme found in both patients could indicate that the erythroid cells membrane are not being properly renovated leading to hemolysis.

Summary / Conclusion: This is the first study correlating gene expression of peroxiredoxins in these hemolytic anemias. The results could contribute for a better understanding of the role of these proteins and for the identification of new targets that could help in the management of diseases and improve the survival of these patients.

B1788

COMPARISON OF THE PHYSICO-CHEMICAL CHARACTERISTICS OF ORIGINATOR IRON POLYMALTOSE COMPLEX AND FOUR IRON POLYMALTOSE COMPLEX SIMILARS

S Burckhardt[1*], P Geisser[1], T Koskenkorva-Frank[1]
[1]Chemical and Preclinical Research and Development, Vifor (International) Inc., St Gallen, Switzerland

Background: The originator iron(III)-hydroxide polymaltose complex (IPC_{ORIG}, Maltofer®) is a macromolecular iron-carbohydrate complex for oral treatment of iron deficiency (anemia) [ID(A)]. It has well-defined physico-chemical properties that enable a controlled release of iron within the gastrointestinal (GI) tract, resulting in good GI tolerability, low toxicity, and reliable correction of ID(A) [1]. The physico-chemical properties and pharmacological activity of iron-carbohydrate complexes, such as IPC, are highly dependent on the manufacturing process [2,3]. IPC copies, so-called IPC similars (IPCSs), have been shown to display different physico-chemical characteristics than those of IPC_{ORIG} [4], likely to affect their bioavailability, tolerability, and efficacy in correcting ID(A) [4]. Indeed, in a comparative study of IPC_{ORIG} versus an IPCS in infants with iron deficiency anemia, IPC_{ORIG} showed a favorable efficacy profile with a significantly higher increase in hemoglobin and serum ferritin levels vs. IPCS [5].

Aims: This study assessed the physico-chemical properties of IPCS preparations marketed in Israel and China, and compared them with those of IPC_{ORIG}.

Methods: The physico-chemical analyses of Ferri care ($IPCS_{FERRI}$), Iron Baby ($IPCS_{IBABY}$), Iron-3 Drops ($IPCS_{IRON3}$), and Niferex® ($IPCS_{NFRX}$) were carried out in the Quality Control and Analytical Development Laboratory of Vifor (International) Inc. The molecular weight distribution parameters were measured by gel filtration chromatography. Turbidity point and *in vitro* degradation kinetics were determined according to methods described previously [6]. The results were compared with published [6] and recently measured data of IPC_{ORIG}.

Results: IPCSs from Israel had 7.5-9 times higher weight average molecular weight (Mw) and significantly higher number average molecular weight (Mn) than those of IPC_{ORIG}. Significant differences in Mw and Mn were also found between the lots of a given product. Mw of $IPCS_{NFRX}$ was almost double and Mn significantly higher than that of IPC_{ORIG}. All IPCSs had significantly higher polydispersity (P) than that of IPC_{ORIG}. The differential rate parameters (k), determined when 10, 50, or 80% of the complex was degraded (q = 0.1/0.5/0.8), were significantly smaller for all the IPCSs vs. IPC_{ORIG}, indicating a slower degradation rate for IPCSs vs. IPC_{ORIG}, a result that was in line with the larger size of the IPCSs. $IPCS_{NFRX}$ presented with a turbidity point at pH 2.8, indicating that it might not be stable under GI conditions.

Summary / Conclusion: The analyzed IPCS preparations showed physico-chemical characteristics significantly different from those of the IPC_{ORIG}. In addition, the variable physico-chemical characteristics between different lots of a given IPCS preparation suggest that they were not produced under standardized conditions. The large size and the high stability of the analyzed IPCSs indicate that iron from these IPCs may not be utilized efficiently, which may lead to poor correction of Hb in patients with ID(A). We suggest that incorporation of isotope-labeled iron into erythrocytes and/or 3-month efficacy studies should be performed to demonstrate the efficacy of IPCS preparations.

BCL11A POLYMORPHIC VARIATIONS INFLUENCES FETAL HEMOGLOBIN LEVELS IN PORTUGUESE SUBJECTS WITH COMMON HEREDITARY PERSISTENCE OF FETAL HEMOGLOBIN

C Pereira[1], L Relvas[2], C Bento[2], A Abade[1], M Ribeiro[2], L Manco[1*]
[1]CIAS-Department of Life Sciences, University of Coimbra, [2]Department of Haematology, Centro Hospitalar e Universitário de Coimbra , Coimbra, Portugal

Background: Common forms of hereditary persistence of fetal haemoglobin (HPFH) (HbF levels 2-30%) occur in some adult individuals with normal haematological parameters. This form of HPFH typically results from polymorphic variations in the fetal globin genes (*HBG1* and *HBG2*) or along the β-globin cluster. Recent genetic association studies found other loci involved in HbF expression, including polymorphisms in *BCL11A* gene (chr. 2p) and *HBS1L-MYB* (HMIP) intergenic region (chr. 6p), in patients with β-globin disorders (sickle cell disease and β-thalassaemia) originated from different populations.
Aims: To evaluate whether genetic variability in *loci BCL11A*, *HMIP* and *HBG2* (XmnI) are involved in common forms of HPFH.
Methods: Sixty subjects of Portuguese origin, with normal haematological parameters and HbF levels ranging from 0.2% to 7.4%, aged 2-61 years, were recruited. Informed consent was provided by all the participants. HbF levels were determined by HPLC (Variant[2] Bio-Rad Laboratories, Hercules, CA, USA) and log transformed. SNPs rs11886868, rs766432, rs9399137, rs6934903 and rs7482144 were genotyped by PCR-RFLP or TaqMan assays. Statistical analysis was performed by using the PLINK software (http://pngu.mgh.harvard.edu/purcell/plink/).
Results: Allele frequencies, Hardy-Weinberg p-values and association results between SNPs and HbF were assessed for all the polymorphisms. Linear regression used to test the association between SNPs and HbF levels showed statistical significance for *BCL11A* SNPs rs11886868 ($P=7.3x10^{-5}$) and rs766432 (P=0.002), even after age and gender adjustment ($P=2.9x10^{-5}$ and P=0.005, respectively). No significant interactions were observed between HbF levels and the *HMIP* or *HBG2* (XmnI) SNPs (P>0.05). In concordance with linear regression models, a case (HbF>2%; n=15) *vs.* control (HbF<1.7%; n=45) study, showed significant associations for *BCL11A* rs11886868 (OR =4; 95% CI, 1.6-9.6; P=0.001) and *BCL11A* rs766432 (OR=3.7; 95% CI, 1.5-8.9; P=0.002) but not for *HMIP* rs9399137 (OR=1.6; 95% CI, 0.6-4.0; P=0.318), *HMIP* rs6934903 (OR=1.8; 95% CI, 0.6-5.3; P=0.290) or *HBG2* (XmnI) rs7482144 (OR=1; 95% CI, 0.4-1.4; P=1).
Summary / Conclusion: Our results suggest that the increase of HbF levels in Portuguese individuals with common forms of HPFH is associated with *BCL11A* polymorphisms, but not with *HMIP* or *HBG2* (XmnI) *loci*.

B1790

NGAL (NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN): A NEW BIOMARKER FOR THE DIFFERENTIAL DIAGNOSIS OF ANEMIA?

O Akay[1*], M Karagulle[1], G Temiz[2], S Tokmak[3], F Mutlu[4], A Yalcin[2]
[1]Hematology, [2]Nephrology, [3]Eskişehir Osmangazi University Medical School, Eskişehir, Turkey, [4]Biostatistics, Eskişehir Osmangazi University Medical School, Eskişehir, Turkey

Background: NGAL (neutrophil gelatinase-associated lipocalin), a small 25-kD peptide identified as a component of neutrophil granules, inhibits bacterial growth by depleting their intracellular iron stores. NGAL is also a promising marker of kidney injury that predicts acute renal impairment. Its overexpression is associated with a poor prognosis in a variety of cancers including breast carcinomas. In addition, NGAL was shown to induce apoptosis of primary bone marrow cells including erythroid progenitor cells and inhibit erythroid cell production leading to anemia. Finally, it has been proposed as a new tool in the assessment of iron deficiency and in the management of iron therapy for hemodialysis patients.
Aims: The aim of the present study was to evaluate its utility as a biomarker for the differential diagnosis of iron deficiency anemia and chronic disease anemia, and to compare it with other conventional anemia parameters.
Methods: 35 patients with IDA (iron deficiency anemia) of whom serum hemoglobin <12 gr/dl, transferrin saturation (TSAT) <20% and serum ferritin <20ng/ml and 35 patients with chronic disease anemia (CDA) of whom serum hemoglobin >12 gr/dl, TSAT >%20 and serum ferritin >50 ng/ml were enrolled.
Results: Median serum NGAL values were 0.44 ng/ml(0.32-0.66) in IDA group and 2.16 ng/ml (1.39-3.22) in CDA group and a statistically significant difference was observed between two groups in respect to NGAL (P<0.001). NGAL showed a significant positive correlation with hematocrit, MCV, MCH, MCHC, serum iron, TSAT and ferritin (P<0.001) and a significant negative correlation with transferrin and total iron binding capacity (P<0.001). A 'cut-off' value of NGAL was determined as 1.02ng/ml (97.1% sensitivity, 83.9 % specifity) by ROC analysis (NCCS 2007, PASS 2005 ve GESS 2006).
Summary / Conclusion: Various biochemical parameters are being used for the diagnosis of iron deficiency anemia. However, there might be some difficulties in the assessment of these conventional parameters. For example, ferritin behaves as an acute phase reactant which limits its diagnostic accuracy greatly. The serum ferritin level is frequently increased independent of iron status by factors such as acute/chronic inflammation, infection, malignancy, liver disease and alcohol use. Serum iron levels also decrease with infection, inflammation, and malignancy and increase with liver disease.Transferrin saturation is a calculated parameter, and therefore reflects confounding effects on individual components. Therefore, besides the current conventional parameters that we use in routine practice to diagnose IDA, there is still need for more sensitive and powerful parameters. Our results show that NGAL is a useful parameter that can be confidentially used in the diagnosis of IDA and NGAL cut-off value of 1.02ng/ml predicts iron deficiency anemia.

B1791

HEMOGLOBIN BART'S LEVELS IN CORD BLOOD OF BAHRAINI NEONATES AND ITS CORRELATIONS WITH GENOTYPES OF ALPHA THALASSEMIA

A Shabib[1], D Shome[2*], A Alawi[1], J Bapat[1], J Barsheed[3]
[1]Pathology, Salmaniya Medical Complex, [2]Pathology, Arabian Gulf University, College of Medicine and Medical Sciences, Manama, [3]Pathology, BDF Hospital, Riffa, Bahrain

Background: Alpha-thalassemia (α-thal) is common in the Arabian Peninsula. The majority of previous studies have used electrophoretic methods and demonstrated correlations between Hb Bart's levels in neonates and deletional α-thalassemia genotypes. However, there is a notable lack of information related to (a) the quantitation of neonatal Hb Bart's levels with more sensitive techniques such as HPLC and (b) correlations of Hb Bart's levels with the non-deletional genotypes prevalent in this region. This has practical significance because many countries in this region have embarked upon neonatal screening programmes.
Aims: This prospective study was done with the specific objectives of determining (1) the extent to which neonatal Hb Barts levels correlate with α-thalassemia genotypes (2) the feasibility of establishing a cut-off value of Hb Barts that would be useful for diagnosis and (3) alterations in the erythrocyte indices in relation to α-thalassemia genotypes.
Methods: We screened umbilical cord blood samples of 435 Bahraini neonates with the aim of selecting cases with normal and elevated Hb Barts for molecular genotyping. Hb fractions were quantified by HPLC (Primus CLC 385). Hb Bart's levels showed a tri-modal distribution curve with a major peak occurring between 0.2% and 1.9% followed by a smaller peak between 2% and 9% and a minor one comprising cases with values greater than 9%. Representative samples from these three regions were selected for genotyping. Therefore, 78 of the screened cases were tested by an established polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) strategy to identify the four common alpha-thalassemia abnormalities prevalent in this region: (1) $-\alpha^{3.7}$ (2) $-\alpha^{4.2}$ (3) $\alpha^{Hph}\alpha$ and (4) $\alpha^{T\text{-}Saudi}\alpha$. Erythrocyte indices were estimated by an automated cell counter. This report describes the observations in these genotyped cases.
Results: Hb Bart's levels ranged from 0.2-18.2%. The distribution of various genotypes were as follows: αα/αα (normal, 29 cases); $-\alpha^{3.7}/\alpha\alpha$ (10); $-\alpha^{4.2}/\alpha\alpha$ (5); $\alpha^{Hph}\alpha/\alpha\alpha$ (1); $\alpha^{TS}\alpha/\alpha\alpha$ (2); $-\alpha^{3.7}/-\alpha^{3.7}$ (16); $-\alpha^{4.2}/-\alpha^{4.2}$ (2); $\alpha^{Hph}\alpha/\alpha^{Hph}\alpha$ (2); $-\alpha^{3.7}/-\alpha^{4.2}$ (1); $-\alpha^{3.7}/\alpha^{Hph}\alpha$ (2); $-\alpha^{3.7}/\alpha^{TS}$ (4); $\alpha^{TS}\alpha/\alpha^{TS}\alpha$ (4). These cases were classified into four genotypic groups based on the number and type of defects as follows: (I) normal genotype (αα/αα), 29 cases (II) 1-gene defect (-α/αα or αTα/αα), 18 cases (III) 2-gene defects excluding cases with the $\alpha^{T\text{-}Saudi}$ mutation (TS-), 23 cases and (IV) 2-gene defects with homozygous or double-heterozygous $\alpha^{T\text{-}Saudi}\alpha$ (TS+); 8 cases. Sickle cell trait was an associated feature in 13 cases (group II, 1; group III, 8; group IV, 4). Hb Bart's clearly discriminated between cases with 2-gene abnormalities and the normal group (Mann-Whitney test, P<0.001). Although there was a minor overlap of Hb Bart's values between the normal group and the group with 1-gene defects the difference between the mean values was also highly significant (P<0.001). A cut-off value of Hb Bart's 1.6% showed 83% sensitivity, 100% specificity, 100% positive-predictive value and 78.9% negative-predictive value in the diagnosis of α-thalassemia. Markedly elevated Hb Barts levels clearly separated the most severely affected group with 2-gene defects (TS+) from the other α-thalassemia genotype-groups. There was no difference between cases with and without sickle cell trait within the same genotypic group. Among red cell indices, MCH was the best discriminator in differentiating α-thalassemia from the normal group with 72.9% sensitivity and 96.7% specificity.
Summary / Conclusion: Quantitation of Hb Bart's in cord blood by HPLC has the ability to identify α-thalassemia in neonates with high discriminatory power provided a valid threshold value is established by prior molecular studies. Genotype-phenotype correlations are highly significant and Hb Bart's levels can accurately identify the most severely affected cases belonging to the group with homozygous or double-heterozygous $\alpha^{T\text{-}Saudi}$ mutation. This observation has added significance in view of the fact that this mutation is commonly associated with HbH disease in this geographic region.

B1792

THE HIGH FREQUENCY OF HB GROENE HART IN SPAIN: FIRST CASE OF ASSOCIATION OF THIS VARIANT WITH HB J-PARIS-I

F De La Fuente Gonzalo[1*], J Nieto[1], L Galán[1], P Gradilla[1], F Fernández[1], A Villegas[1,2], S Salazar[1], E Calderón[1], H Saccomani[1], J Paganini[1], G Gómez[1], J Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]on behalf of Spanish Erithropathology Group, Madrid, Spain

Background: Thalassemias are the most frequent monogenic disorder around the world. α-Thassemias should to a deficiency of synthesis in the α globin chain of the hemoglobin (Hb), andcharacterized by a hypochromic microcytic anemia. Around 5-10% of α-thassemias are due to punctual mutations. When they affect to posttranslational processing, originate hyper unstables Hbs, which cannot be detected by most electrophoretic or chromatographic methods.
Hb Groene Hart, also called Hb Bernalda, is a variant hyper unstable which precipitates in an early stage of erythroid precursors and is characterized by CCT>TCT mutation at codon 119 of the α1 gene, resulting in the change of proline (Pro) by serine (Ser) at position H2 of the peptide chain. This variant was described for the first time in 2 patients from Morrocco. These patients showed a phenotype of mild α-thalassemia minor with microcytosis and hypochromia.
Aims: In this abstract we show the study of 21 cases belonging to fifteen families affected by Hb Groene Hart, one of them associated with Hb J-Paris-I.
Methods: 21 patients from 15 unrelated families (6 of them from North African) were included in this study because they showed microcytosis without iron deficiency. Hematological data were obtained on a hematologic counter. Quantification of A2 and F hemoglobin were conducted by ion exchange HPLC. Hemoglobins were studied by capillary electrophoresis and ion exchange HPLC and the globin chains by reversed-phase HPLC. Most frequent mutations in α globin genes were ruled out by *a-globin StripAssay*. Molecular characterization was performed by specific sequencing.

	9	M	II1	13,7	81,1	26,3	3,4	0,4	0,31	$\alpha\alpha^{Gr}/\alpha\alpha$

Results: α_1 gene selective sequencing showed CCT>TCT mutation (Pro>Ser) at codon 119 (Hb Groene Hart). Moreover, we also observed a patient with GAC>GCC mutation (Ala>Asp) at codon 12 of the α_2 gene (Hb J-Paris-I). All mutations were heterozygous. Hematimetric parameters, Hb A2, Hb F and alpha genotype are listed in Table 1.
Summary / Conclusion: Hyper unstables Hbs carriers present a thalassemic syndrome which is due to anomalous chains posttranslational precipitation. This type of Hb variants accounts for 9.5% of structural hemoglobinopathies and it is very difficult to distinguish by electrophoretic techniques and ion exchange HPLC. In the Hb Groene Hart [CD119 (H2) Pro>Ser α_1], the residue 119 of α globin chain is affected, which has a key role to preserve the stability of α globin chain when it interacts with α hemoglobin–stabilizing protein (AHSP). AHSP is a chaperone which binds alpha globin chains to protect their precipitation. In the case of Hb Groene Hart, hyper unstability is due to its decrease in affinity for AHSP. Many others Hbs in which is affected residues in G or H helix H show a similar unstability. Finally, it is remarkable the presence of this variant in both immigrant and native population. Native population is a carrier of the mutation because during seven centuries of the Middle Ages the Iberian Peninsula was occupied by Muslims. Both contributions (immigrant and native population) maintain a great frequency of Hb Groene Hart in our area, still relatively high compared with other less common variants and therefore the molecular identification of Hb Groene Hart mutation carriers should be considered in the study of α-thalassemia cases in the context of microcytosis screening programs, as is done in Northern Africa.

B1793

ASSOCIATION IN THE SAME GENE OF TWO MUTATIONS INTERFERING WITH BETA GLOBIN RNA SPLICING IN A BETA MAJOR THALASSEMIC PATIENT.

E Levrat[1*], P Vuichard[1], T Araud[2], F Guerry[2], G Georgiou[3], P Menoud[2], P Beris[3]
[1]Department of Medicine, Hôpital fribourgeois, Fribourg, [2]Molecular Biology, Unilabs - Switzerland, Lausanne, [3]Hematology, Unilabs - Switzerland, Coppet, Switzerland

Background: Beta thalassemia is characterised by the decrease or absence of beta chain production. Mutations interfering with either the donor or the receiving splicing site of both IVS of beta globin gene have been described. The IVS-1-nt5(G>C) leads to β^+ thalassemia while mutation of the IVS-1-nt130(G>C) leads to β^0 thalassemia. Both mutations have never been described in the same chromosome, while their association (double heterozygous state), is the cause of beta major transfusion depended thalassemia. These mutations are frequent in the Indian subcontinent region.
Aims: We investigated the molecular pathology of a severe beta thalassemia major found in a patient of Bangladesh origin living in Fribourg Switzerland.
Methods: This 39 years old male patient is regularly transfused for beta thalassemia major since his very young age. Furthermore he is receiving chelation therapy by Deferasirox. DNA was extracted from his peripheral blood leucocytes just before the next programmed transfusion. Amplification of the whole beta globin gene and alpha2 and alpha1 globin genes followed by bi-directional sequencing was done.
Results: The following mutations were found in the two beta globin genes: 1. IVS-1-nt5(G>C) in homozygous state and 2. IVS-1-nt130(G>C) in heterozygous state. Sequencing of both alpha2 and alpha1 genes showed no mutations. The molecular analysis of the beta globin gene was confirmed twice.
Summary / Conclusion: The above mentioned mutations at IVS-1 of beta globin gene have been described by Kazazian et al, EMBO J. 1984 Mar;3(3):593-6 and Yamamoto et al, Hemoglobin 1992;16(4):295-302. However both mutations were described in a beta globin gene not presenting any other nucleotide substitution or deletion. The association of both mutations in the same beta globin gene to our knowledge has never been described before. Because both of them are relatively frequent in that region of the globe, we can admit an abnormal crossing over of two chromosomes carrying the two mutations, as the genesis mechanism of the new beta thalassemic mutation. As the patient is adopted by a Swiss family, studies of his parents' beta globin genes at a molecular level are not possible to realize. It will be interesting to investigate the result of the above mentioned mutation at the mRNA level.

B1794

ACERULOPLASMINEMIA IN A TURKISH ADOLESCENT WITH A NOVEL MUTATION OF CP GENE: THE FIRST DIAGNOSED CASE FROM TURKEY

A Gunes[1*], B Baytan[1], M Evim[1]
[1]Dpt. Ped. Hematology, Uludag University, Bursa, Turkey

Background:
Ceruloplasmine (CP) is required for proper iron transport in the plasma**.** CP gene mutations cause the lack of *in vivo* ferroxidase activity of which enables theoxidation of ferrous iron (Fe^{+2}) into ferric iron (Fe^{+3}). Hence, iron in the plasma can not bind to the transferrin in aceruloplasminemia (aCp). Elevated free iron leads to the generation of free radicals causing oxidative stress. This process ultimately results pathological iron overload, especially in basal ganglia, pancreas, liver and retina. The most early symptoms of disease is hypocromic anemia and retinal degenerations.
Aims: Here, we discuss a case of aCP in a teenage with a novel mutation prior to the onset of neurologic symptoms
Methods: A 16 year old girl was admitted to our clinic with refractory anemia. Her medical history revealed that she had complains of pallor and fatigue and received intermittent oral iron supplementation within the last four years. Her full blood count and peripheral blood smear showed hypochromic microcytic anemia with a low serum iron level (14 µg/dl; 25-156µg/dl) and normal serum iron binding capacity (305 µg/dl; 100-370µg/dl) and transferrin level (263mg/dl; 200-360mg/dl). However, repeated measurements of serum ferritin levels were found high, ranging between 326 and 433 ng/dl in the absence of inflammatory state.
Results: Clinical and laboratory signs related to lead accumulation (1 µg/dl; 0-20 µg/dl) and zinc (12.8 µmol/L; 10.7-19.5 µmol/L) deficiency were not found. She had no clinical signs of copper deficiency, but, her serum copper and ceruloplasmin levels were extremely low (serum copper:<25µg/dl (80-155 µg/dl), ceruloplasmin:<2 mg/dl (20-60mg/dl) whereas 24 hours urinary copper excretion was normal (4.2 µg/d; 3-35µg/d). Kayser-Fleischer ring in the cornea was not observed. The diagnosis of aCP was suspected on the basis of the biochemical data. Ceruloplasmin gene was amplified in Tokyo University, Japan. Direct sequence analysis was performed by using the ABI 3700 instrument. A homozygous nonsense mutation at exon 7 of the CP gene was determined at 1306th base of CP mRNA. This mutation produces an early stop codon (X: TGA) at 436th amino acid which is originally arginine (R:CGA) (Figure I). We could not find a similar mutation in the aCP database**,** hence accepted as a nov-

el mutation. The fasting blood glucose level was determined within normal limits (84mg/dl; 70-126 mg/dl). Magnetic resonance imaging (MRI) of both liver and heart was performed for detecting iron overload. Mild iron overload in liver was determined and quantified as 3.8ms (Normal:>6.3ms). No iron accumulation was observed in the heart (28.2ms; Normal:>20ms). Cerebral MRI findings and examination of the eye including retina and fundus were found normal. Family history revealed that it was a fifth degree consanguineous marriage.
Summary / Conclusion: the diagnosis of aCp in early stages before the onset of typical symptoms is quite difficult. Although it is a rare disease, one should keep in mind the differential diagnosis of aCp with persistent hypochromic microcytic anemia with high serum ferritin level.

B1795
THE EFFECT OF IRON OVERLOAD ON THE RAT BONE MARROW ERYTHROBLAST DIFFERENTIATION AND THE EXPRESSION OF IRON REGULATORY GENES
E Gülen[1], A Toylu[2], M Ulubahşi[3], O Salim[1*], A Timurağaoğlu[1]
[1]Internal Medicine-Hematology, [2]Medical Genetics, [3]Division of Flow Cytometry, Akdeniz University, Antalya, Turkey

Background: Erythroblastic differentiation is closely related with the iron metabolism both in bone marrow and liver. Investigation of the cellular transport and storage of iron were showed the importance of signaling pathways which are sensing iron availability and regulating the iron metabolism by the needs of erythropoiesis. It has also been found that the effect of iron overload on bone marrow and liver tissues has had a therapeutic importance on iron overload diseases.
Aims: The effect of iron overload on distribution of erythroblasts in bone marrow was assayed and the expression of iron regulatory genes were investigated at the bone marrow and liver tissues of iron overloaded rats.
Methods: Rats were treated with 100 mg/kg iron dextran for 2 weeks and than bone marrow and liver samples were collected. Bone marrow cells were analyzed with flow cytometry for the CD71 transferrin receptor expression. The mRNA expression levels of iron regulatory genes were measured by Q-PCR method in bone marrow and liver tissues. Plasma levels of hepcidin and bone morphogenic protein 6 (BMP6) were measured with ELISA method.
Results: Distribution of CD71 (+) erythroblasts among total bone marrow cells were not changed but the size distribution of CD71 (+) erythroblasts has showed a tendency towards to higher FSC levels with iron overload. mRNA expression levels of CD71 in bone marrow cells were decreased by iron overload but erythropoietin receptor (EpoR) and type II transferrin receptor (TfRII) expressions were significantly increased. Contrary to these results, expressions of CD71, TfRII and HFE genes were decreased in liver tissue. Hepcidin and hepcidin-regulatory gene BMP6 were remained unchanged between control and iron overloaded rat livers. Additionally, plasma levels of hepcidin were slightly decreased although BMP6 levels were not changed.
Summary / Conclusion: Flow cytometry analysis of bone marrow cells has implied that late erythroblast differentiation was blocked with iron overload. Decreased expression of CD71 was considered as a cellular response of bone marrow cells to iron excess and as a cellular effort to limit the intracellular levels of iron. Liver cell response to iron overload was indicated that both iron uptake and the signaling receptor components of transferrin were down-regulated. Its possible to conclude that this down regulation of iron uptake related genes may responsible for the suppression of hepcidin expression.

B1796
HB CIBELES [ALPHA2 CD25(B6)(GLY>ASP)]: A NOVEL ALFA CHAIN VARIANT CAUSING ALPHA- THALASSEMIA
F De La Fuente Gonzalo[1*], J Nieto[1], L Galán[1], P Gradilla[1], J Sevilla[2], F Fernández[1], A Villegas[1,3], S Salazar[1], E Calderón[1], M Alvariño[1], A Guarch[1], E Ramírez[1], J Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]Pediatric Hematology , Hospital Niño Jesús, [3]on behalf of Spanish Erithropathology Group, Madrid, Spain

Background: Thalassemias are the most common monogenic disorders worldwide, representing a serious health problem in areas where the incidence is higher. The α-thalassemias are caused by a deficiency or absence of hemoglobin (Hb) α-chain synthesis, and are characterized by a hypochromic microcytic anemia. Its main molecular mechanisms are large deletions. However, around 5-10% of the α-thalassemias are caused by point mutations (non deletional α-thalassemia) caused by a defect in the transcription, translation or post-translational processing. This latter mechanism originates Hb hyper unstables, which cannot be detected by most electrophoretic or chromatographic methods.
Aims: In this study we show a case with a new alpha chain structural variant in heterozygous state.
Methods: A four years old patient from Ethiopia was studied by presenting microcytosis and hypochromia with Hb A_2 and Hb F normal and without iron deficiency. Hematological data were obtained on a hematologic counter. Quantification of A_2 and F hemoglobin were performed by ion exchange HPLC. Hemoglobins were studied by capillary electrophoresis and ion exchange HPLC and the globin chains by reversed-phase HPLC. The most common forms of α thalassemia deletion and no deletion were ruled out by a-globin StripAssay and molecular characterization was performed by specific sequencing.
Results: α2 gene specific sequencing showed the mutation GGT>GAT (Gly>Asp) at codon 25 (B6). This finding leads to a new structural hyper unstable hemoglobinopathy named Hb Cibeles. Mutation was found in heterozygous state. Hematimetric parameters: Hb 12.6 g / dL, MCV 70.1 fL, MCH 22.6 pg, RDW 14.4%, 2.6% Hb A_2 and 0.5% Hb F. The abnormal Hb was not detected by capillary electrophoresis or by ion exchange HPLC. No abnormal α chains are separated by reverse phase HPLC.
Summary / Conclusion: Hyper unstables Hbs carriers present a thalassemic syndrome due to anomalous chains precipitation postraducional. This kind of alterations represent almost 10% of the structural hemoglobinopathies. They are very difficult to distinguish by electrophoretic techniques and ion exchange HPLC. This is the first description of a structural change that affects the residue 25 of the alpha globin chain, however others mutations were described in adjacent residues. Some of them, like Hb Luxembourg [alpha 24 (B5) Tyr>His] or Hb Shenyang [alpha 26 (B7) Ala>Glu], are also unstable because they affect to inner residues changing their charge and therefore their conformation. In the Hb Cibeles a larger, polar and negative aminoacid (Asp) is placed instead of Gly (smaller and apolar), turning the molecule hyper unstable.

B1797
HAPLOTYPE ANALYSIS OF COMMON HFE MUTATIONS IN THE PORTUGUESE POPULATION AND ASSOCIATION WITH IRON OVERLOAD
S Toste[1], L Relvas[2], C Bento[2], A Abade[1], M Ribeiro[2], L Manco[1*]
[1]CIAS-Department of Life Sciences, University of Coimbra, [2]Department of Haematology, Centro Hospitalar e Universitário de Coimbra , Coimbra, Portugal

Background: Hereditary Haemochromatosis (MIM:235200), an autosomal recessive disorder caused by increased iron absorption, is one of the most common genetic diseases among individuals of European origin. In Portuguese population, the haemochromatosis HFE gene mutations C282Y and H63D were found at frequencies (average) of 3.3% and 17%, respectively, however associated haplotypes using intragenic polymorphisms remains to be established.
Aims: To investigate i) the HFE intragenic haplotype background associated with C282Y, H63D and S65C mutations in the Portuguese population; ii) weather particular SNPs or haplotypes are associated with iron overload.
Methods: Three internal HFE SNPs IVS2(+4)T/C, IVS4(-44)T/C and IVS5(-47)G/A were analysed in a total of 150 subjects after informed consent was obtained: homozygous C282Y (n=12), H63D (n=19); heterozygous C282Y (n=18), H63D (n=34), S65C (n=6); compound heterozygous C282Y/H63D (n=17), S65C/H63D (n=3); subjects without HFE mutations (n=41). SNPs were genotyped by PCR-RFLP using RsaI, HaeIII and NlaIV, respectively. Sixty four adult subjects with high ferritin levels (>300 ng/mL) (excluding carriers for the C282Y mutation), with no other identified causes of iron overload, were compared with a control group of 20 adult subjects with normal/low ferritin levels (<100 ng/mL) (seven heterozygous H63D). Statistical analyses were performed with PLINK software (http://pngu.mgh.harvard.edu/purcell/plink/).
Results: Mutations C282Y (n=59), H63D (n=92) and S65C (n=9) were associated exclusively with haplotypes TTG, CTA and CCA, respectively. In non-mutant chromosomes five of the eight possible haplotypes were found: TTG (53.3%), TTA (23.5%), CTA (9.8%), CCA (7.1%) and CTG (6.3%). In the case/control study, mutation H63D (OR=3.4; 95% CI, 1.4-8.3; P=0.0045), and alleles IVS2(+4)C (OR=3.64; 95% CI, 1.69-7.81; P=0.00061) and IVS5(-47)A (OR=2.89; 95% CI, 1.39-6.00; P=0.0035) were found positively associated with iron overload. Moreover, the TTG haplotype in non-mutated chromosomes (0.55 in controls vs. 0.25 in iron overload subjects) suggested to have a protective effect (P=0.00039).
Summary / Conclusion: The mutation associated haplotypes C282Y:TTG, H63D:CTA and S65C:CCA, are the same that have been reported in other European populations, suggesting a single origin for each HFE mutation. Regarding normal chromosomes the most common haplotypes reported for other European populations were found. The case/control study suggests that alleles IVS2(+4)C and IVS5(-47)A could be associated with risk of iron overload.

B1798
INVESTIGATION OF HEMORHEOLOGICAL PARAMETERS AT THE DIAGNOSIS AND FOLLOW UP OF CHILDREN WITH IRON DEFICIENCY ANEMIA AND MIX ANEMIA
Y IŞIK-BALCI[1*], H TANCER-ELÇİ[2], M BOR-KÜÇÜKATAY[3], E KILIÇ-TOPRAK[3], Ö KILIÇ-ERKEK[3], H ŞENOL[4], S ROTA[5]
[1]Department of Pediatric Hematology, [2]Department of Pediatrics, [3]Department of Physiology, [4]Department of Biostatistics, [5]Department of Biochemistry, Pamukkale University, Faculty of Medicine, Denizli, Turkey

Background: Iron deficiency anemia (IDA) is characterized with decreased mean corpuscular volume (MCV), and in the peripheral blood smear microcytosis and hypochromia in the eryhrocytes, while in mix anemia (IDA+vitamin B12 deficiency anemia) MCV could be normal or decreased, and in the peripheral blood smear erythroctes could be morphologically normal. In the literature it has

been reported that, especially in hematological disorders which affect the morphology of the erytrocytes, hemorheological parameters are altered variously. The effects of IDA and vitamin B12 deficiency on hemorheological parameters have been investigated previously in different studies. These conditions are known to cause alterations in hemorheological parameters, but there is no data about how the hemorheological parameters are affected, when these two conditions coexist.
Aims: The aim of this study was to investigate the effects of iron deficiency anemia (IDA) and vitamin B12 deficiency anemia coexisting with IDA which is called as mix anemia (MA) in our study, on hemorheological parameters, to compare them with each other and healhty controls, and to assess the changes in hemorheological parameters after adequate treatment of these anemias.
Methods: The study enrolled 32 IDA patients (16 female, 16 male) aged 8 months-15.6 years (mean age: 6.3±5.3 years), 30 MA patients (15 female, 15 male) aged 7 months-16 years (mean age: 7.2±5.4 years), and 31 age and sex matched healthy controls (16 female, 15 male, mean age:7.1±5.2 years). Informed consent form was obtained from the parents. Elongation index (EI) which is the indicator of erythrocyte deformability was measured at 9 different shear stresses between 0.3 and 30 Pa by an ectacytometer. Erythrocyte aggregation amplitude (AMP) was also determined by an ectacytometer. Plasma and whole blood viscosities were determined by a cone-plate rotational viscometer. The differences between IDA and MA, and healthy controls were compared. Hemorheological parameters were repeated in both of the patient groups after treatment and compared with the initial results.
Results: In both of the patient groups (IDA and MA), erythrocyte deformability was found to be significantly decreased compared with the controls, and after adequate treatment it increased significantly. There was no statistically significant difference between the EI's of IDA and MA groups before treatment. No statistically significant alterations was found in erythrocyte aggregation measurements of both patient groups. Whole blood viscosities measured at either autologous or standardized hematocrit (40 %), and plasma viscosities were found to be significantly decreased in both of the patient groups before treatment compared with the controls, and after treatment these parameters showed a significant increase. There were no significant differences in these parameters between the IDA and MA group before treatment.
Summary / Conclusion: In conclusion, the results of this study indicate for the first time that hemorheological parameters except erythrocyte aggregation, are affected similarly in children with IDA and MA. The shortened lifespan of erythrocytes in these anemia types might be related with these hemorheological alterations. When vitamin B12 deficiency anemia coexists with IDA, no further hemorheological alteration occurs. The adequate treatment of these anemias helps to normalize the hemorheological parameters. We think that, further investigations are needed to identify the mechanisms of the alterations in hemorheological parameters, especially in children with mix anemia.

B1799
FLOW CYTOMETRIC TEST USING EOSINE-5 MALEIMIDE AS A FIRST-LINE SCREENING TEST FOR DIAGNOSTICS OF HEREDITARY SPHEROCYTOSIS.
J Prokhorova[1*], E Zueva[2], N Sokolova[3]
[1]St Petersburg State University, St Petersburg, Russia, [2]Pavlov State Medical University, [3]Children City Hospital #1, St Petersburg, Russian Federation

Background: Eosine 5-maleimide (EMA) test based on measuring the fluorescence intensity of red blood cells as EMA predominantly binding to band-3 and RH-proteins. In this study we evaluated the use of EMA for a rapid screening test of patients with Hereditary Spherocytosis (HS). The mean fluorescence intensity (MFI) for EMA-labelled RBCs from three groups of patients with HS were compared with 2 groups of random blood donors as a normal control group.
Aims: to find an optimal conditions for using EMA-test in diagnostic laboratories.
Methods: Flow cytometry to analyze EMA-labelled RBCs. Clinical features evaluating to identify RBCs membrane disorders. SDS-polyacrylamide gel electrophoresis and an Osmotic fragility test were used to verify diagnose of HS. ROCs analysis was done using MedCalc pro v.11.6.0.0. for Windows. In this study were included 5 groups of patients with informed consent:
- the adult control group consisted of random individuals without haematological pathology in routine blood test - 270 individuals (ages ranging 18-72 years);
- the children's control group – 18 randomly selected normal blood samples from routine donations (ages ranging 1 month – 15 years);
-children with verified HS diagnose (age ranging 1 month-18 years) -35 individuals;
-children with verified HS diagnose treated with blood transfusion one week prior to their RBCs analyses – 3 individual;
-adult splenectomised HS patients – 8 individuals (age ranging 20 - 48 years).
Results: Fresh RBCs were stained with EMA and analyzed for mean channel fluorescence (MCF) using one-colour flow cytometry. As EMA is non-sustainable dye and the results of different diagnostic laboratories are often non-comparable we offered to use index S to unify the records of EMA-tests: S=EMA MCF of examed blood sample/(total of EMA MCF for 6 normal control samples/6). RBCs from non-splenectomised patients with HS expressed a greater degree of reduction in MCF compared to those from the normal control group and splenectomised adult patient's group. Children with verified HS EMA MCF=21,2±2 units; S=0,7±0,1. Adult splenectomised patients RBCs EMA MCF was 25 u.; S=0,8±0,1.EMA MCF of adult individuals without haematological pathology and healthy children had no significant difference, EMA MCF=31±4 u., (P=0,45). We found significant difference in EMA MCF of children with HS and control groups (P<0,05). Evaluation of MCF for RBCs of patients treated with a blood transfusion showed few fluorescence peaks in the analysis and wider ranges of MCF. EMA method`s sensitivity =97 % and specificity=100%.
Summary / Conclusion: Comparing MCF of RBCs from adult and children control groups we found out that MCF is a non-age-connected characteristic and blood samples of normal individuals can be used as a normal control in this test with no connection with the age of individuals. We used the unifying index S to compare results of EMA-test. The method of EMA binding screening is speedy and a reliable diagnostic test and could be used as a first line screening test for diagnosis of hereditary RBCs membrane disorders.

B1800
A NEW FRAMESHIFT MUTATION IN THE B-GLOBIN GENE CAUSING B0-THALASSEMIA: CD 47 (-G)
P Ropero[1*], F González[1], F de la Fuente-Gonzalo[1], J Martínez-Nieto[1], S Medina[1], E Bolaños[1], A Villegas[1], J Díaz-Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: β-thalassemia is one of most common autosomal recessive disorders worldwide and one of the public health problems more important in some regions of the world. It has been estimated that about 1.5% of the global population (80 to 90 million people) are carriers of β-thalassemia, with about 60000 symptomatic individuals born annually. The total annual incidence of symptomatic individuals is estimated at 1 in 100000 throughout the world and 1 in 10000 people in the European Union.The beta globin gene mutations cause a reduced or absent production of β globin chains, the large majority is in functionally important regions of the β globin gene. More than 200 mutations have been so far reported. Rarely deletions are responsible of the β-thalassemia and the common of mutations is single nucleotide substitutions or deletions or insertions of oligonucleotides leading to frameshift. A complete updated list of β-thalassemia mutations is available though the Globin Gene Server Web Site.
Aims: In this report, we described a new β-globin gene frameshift mutation
Methods: β-Thalassemia minor was diagnosed using hemoglobin high performance liquid chromatography (HPLC) analysis (VARIANT II, Bio-Rad Laboratories, Hercules, CA, USA).Genomic DNA was extracted from peripheral blood leukocytes using an automated method [Bio-Robot® EZ1 (Quiagen GmbH, Hilden, Germany)]. The β-globin gene was amplified using these primers: β1D: 5'-CCT AAG CCA GTG CCA GAA G-3' (from nt –160 to –142) and CD2: 5'-GAC CTC CCA CAT TCC CTT TT-3' (from nt +1659 to +1643) (all nt positions are provided relative to the Cap site = nt1 from NCBI GenBank®). Polymerase chain reaction (PCR) products were treated with the ABI PRISM™ BigDye® Terminator V1.1 Cycle Sequencing Ready Reaction Kit (PE Applied BioSystems, Foster City, CA, USA) with b1D and CD2 primers for sequencing, following the manufacturer's instructions, and the sequence was analyzed on an ABI PRISM™ 310 Genetic Analyzer (PE Applied BioSystems) demonstrated that the patient was heterozygous for a deletion of one nucleotide (-G) at amino acid codon 47 in exon 2 [HBB:c.142delG]. α-Thalassemia was ruled out using α-globin StripAssay.
Results: The propositus was an 82-year-old Spanish man who was referred because he showed mild microcytosis and hypocromia [hemoglobin (Hb) 10.8 g/dL; MCV 67.1 fL; MCH 21 pg]. He was an increased Hb A_2 (4.9%) and normal Hb F (1.1%) and normal Hb pattern.
Summary / Conclusion: The codon 47 (-G) mutation introduces a premature termination codon TGA at position 60 instead of codon 147 in exon3, affecting the beta globin expression resulting in abnormal mRNA translation. Phenotypically is a β^0-thalassemia, characterized by the complete absence of beta chain production. This mutation has not been reported for the β-globin gene. This kind of mutation is called frameshift, there are currently over 100 described.

B1801
A PRELIMINARY STUDY ON RISK OF A COUPLE HAVING A CHILD WITH SEVERE THALASSEMIA SYNDROME, PREVALENCE IN KHON KAEN PROVINCE, THAILAND
P Wechagama[1*], S Pratipanawat[2], M Jantharaniyom[3]
[1]Thalassemia center, [2]Obstetrics and Gynecology, [3]Pediatrics, Khon kaen hospital, Khon Kean, Thailand

Background: Thalassemia is the leading genetic disease in Thai population, and certainly it was ranked in Thai national policy for prevention and control. Prevalence of couple at risk for having a child born with thalassemia major and incidence of thalassemia disease child differ from different region.
Aims: To known of the thalassemia epidemiologic data for help supporting the thalassemic prevention and control plan in each definite area.
Methods: The study was conducted on pregnant women and spouses who

attended the antenatal clinic at 10 community hospital and Khon kaen hospital in Khon kaen province form March 2011 – May 2011. All subjects had blood taken for diagnosis of thalassemia trait or diseases, based on quantitative electrophoresis, and PCR (polymerase chain reaction) technique. After identification of couples at risk for having a child born with thalassemia major, prenatal diagnosis (amniocentesis) was proceeded in those risked couples.
Results: 410 couples were recruited. Prevalence of heterozygous α thalassemia 1 was 2.2%, heterozygous β thalassemia 4.8%, heterozygous Hb E 28.3%, homozygous Hb E 10.8% and other abnormal Hb 0.08%. There were 14 risked couples (2.9%), 10 risked for compound heterozygous β thalassemia/ Hb E and 4 risked for Hb Bart's hydrops fetalis. Amniocentesis was performed in all couples and found thalassemia major child were 5 cases, 3 were compound heterozygous β thalassemia/ Hb E and 2 were Hb Bart's hydrops fetalis.
Summary / Conclusion: Prevalence of couples at risk in Khon kaen province in preliminary study was 2.9%. And the prevalence of thalassemia carriers among pregnant women were high, just about three months of the screening thalassemia program in this center was successful for practical to prevention and control of this disease.

B1802
GENETIC OF GLOBIN DISORDERS IN RUSSIA
I. O. Sadelov[1], V Bobrynina[1*], M Krasilnikova[1], N Smetanina[1]
[1]Federal scientific clinical center of pediatric hematology, oncology and immunology named after Dmitriy Rogachev, Moscow, Russian Federation

Background: Hemoglobinopathies are heterogeneous group of diseases caused by qualitative (abnormal Hb) or quantitative (thalassemia) failure in hemoglobin synthesis. They are the most common monogenic disorder in the world, creating major public health problem in many countries. However in Russia they are relatively rare.
Aims: Analysis of the spectrum of mutations in the α-globin locus and β-globin gene in children from Russian Federation with suspected hemoglobinopathies.
Methods: The presence of 7 most frequent deletions (α3.7, α4.2, α20.5, MED, FIL, SEA, THAI) and 3 control sequences of the α-globin locus were tested by conventional PCR followed by electrophoresis in 1% agarose gel. Direct sequencing of β-globin gene was performed in order to determine mutations. From May 2009 to January 2013 334 patients were screened for deletions in the α-globin locus and 383 patients were examined for mutations in β-globin gene. In most cases both studies have been carried out. Family members of some patients were examined as well. Totally 537 samples have been analysed.
Results: Three known α-globin locus deletions have been found in 33 families (9.8 % of investigated), namely α3.7 (17 cases, 52%), α4.2 (4 cases, 12%) and α20.5 (6 cases, 18%). Other 4 deletions have not been detected. Compound heterozygotes for α3.7 and α20.5 were found in 6 families (18%). In 5 families the deletions in α-globin locus were combined with mutations of β-globin gene. Thirty four various β-globin gene mutations have been found in 166 families (43.3 % of investigated). Mutation CD8 –AA was detected on 69 chromosomes (33% of all mutated chromoseomes, 11 homozygotes), IVS2-1 G®A on 24 chromosomes (12%, 6 homozygotes). Frequencies of prevailing mutations were: IVS1-110 G→A 6%, CD36/37 –T 5%, CD8/9 +G 5%. Totally 34 mutations were identified on 206 mutated chromosomes. In 14 families two different mutations of β-globin gene were present simultaneously.
Summary / Conclusion: Low level of mutations found in α-globin locus indicates that further study of the region is necessary. Implementation of methods that permits more dense analysis of the locus is required. Our data revealed an even distribution of mutations in β-globin gene. Therefore direct sequencing of the whole gene is the most logic diagnostic approach.

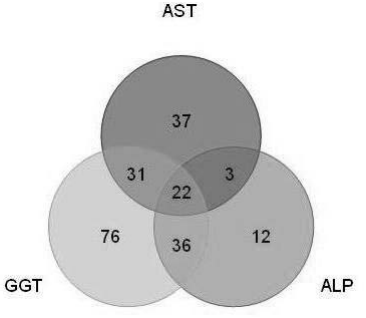
SAFETY AND TOLERABILITY OF AUTOMATED RED CELL EXCHANGE TRANSFUSIONS IN PATIENTS WITH SICKLE CELL DISEASE
S Patel[1*], B Sirigireddy[1], I Khan[1], R Nzouakou[1], D Tsitsikas[1], R Amos[1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Red cell exchange transfusion is an effective therapy in sickle cell disease (SCD) in the setting of both acute complications such as acute ischaemic stroke and acute chest syndrome, and chronic complications such as leg ulcers and recurrent vasoocclusive crises. Automated red cell exchange transfusion (ARCET) can achieve very low HbS levels rapidly and efficiently with minimal haemodynamic imbalance.
Aims: To assess the tolerability and complication rate of ARCET in patients with SCD.
Methods: This is a retrospective analysis of events occurring from May 2011 to December 2012 involving patients with SCD receiving ARCET at Homerton University Hospital.
Results: 40 patients have been transfused since May 2011. 26 of these patients are still on the programme. Three patients only had transfusion prior to elective surgery and one post surgery. Three patients discontinued due to ineffectiveness, 2 due to poor compliance, and 5 due to tolerability and complications that will be discussed later. Notes for 8 of the patients were unavailable so symptomatic history could not be discerned in these patients. The total number of transfusions in the remaining patients was 203. Of these, the documentation for 37 (18%) could not be found. Nine patients (28%) had no symptoms. Out of 166 transfusions with documented history, there were 10 episodes of paraesthesiae due to citrate toxicity (6%). 3 patients have each had 2 episodes of paraesthesiae. Only 4 were related to documented hypocalcaemia. 14 transfusions were associated with vasovagal symptoms (8%), but only 3 of these had a documented blood pressure drop. One patient had 2 episodes of vasovagal symptoms, one had 3. There have been only 2 episodes of rash requiring chlorphenamine (1%). One patient has had 6 symptomatic transfusions, accounting for 3 episodes of paraesthesiae, 2 of vasovagal symptoms and one with rash. However, he still continues the programme. Only one patient has their transfusion through peripheral access. All of the other patients have femoral lines on the day unit apart from 2 patients requiring a femoral line in theatre due to sedation purposes. This patient on another occasion also developed E-coli sepsis. One line tip result for another patient was positive for mixed skin flora and another for coagulase negative staphylococcus. All of the rest have been negative. There have been 6 episodes of mild bleeding (4%) from the femoral line site, of which 2 have been in one patient. Four patients have had major bleeding leading to a Hb drop requiring transfusion or readmission (2%). Only one patient (2.5%) has developed alloantibodies (Anti KpA). Out of the 5 patients that discontinued the programme due to complications, one developed hyperhaemolysis, one developed a line-related thrombosis and was also later found to have low protein C activity, one didn't like having a femoral line inserted and peripheral access was difficult, one discontinued due to repeated vasovagal episodes and one simply didn't like the procedure.
Summary / Conclusion: In general, ARCETs are well tolerated; approximately one quarter (26%) of procedures were associated with complications but the majority were mild. Only 5 (6%) patients have discontinued the programme due to problems tolerating the procedure or other complications, and more than a quarter of patients have had no symptoms.

B1804
LIVER DYSFUNCTION IN AN ADULT SICKLE COHORT
K Gardner[1*], E Drasar[1,2], A Hearn[3], M Allman[1], M Awogbade[1], A Suddle[4], A Bomford[4], S Thein[1,2]
[1]Haematological Medicine, King's College Hospital, [2]Molecular Haematology, King's College London, [3]General Medicine, West Middlesex Hospital, [4]Institute of Liver Studies, King's College Hospital, London, United Kingdom

Background: In developed countries, sickle cell disease (SCD) has evolved into a debilitating chronic disorder with significant morbidity due to end-organ damage. The liver is one of the organs affected, resulting in "sickle hepatopathy". This study focuses on liver dysfunction in SCD patients at King's College Hospital ("King's").
Aims: To examine the incidence and spectrum of liver dysfunction in an adult sickle cohort.
Methods: The King's sickle database (comprising demographic, genotypic, clinical and laboratory data) was analysed. The case notes of patients with significant liver dysfunction were subjected to in-depth analysis.
Results: The sickle database comprised 581 adults regularly attending clinic with genotypes: 61% HbSS, 33% HbSC, 5% HbSβ$^+$ thalassaemia, <1% HbSβ° thalassaemia and <1% HbS HPFH. A retrospective analysis of the liver enzymes in these patients over the previous three years was conducted to find

predisposing factors to liver impairment. Mean *steady-state* values of all three liver enzymes were calculated: aspartate transaminase (AST), gamma glutamyl transpeptidase (GGT), and alkaline phosphatise (ALP). 63% of patients had no abnormal liver enzymes; 21% had one abnormal liver enzyme; 12% had two abnormal liver enzymes; and 4% (22 patients) had all three liver enzymes at elevated levels (see *Figure 1: number and distribution of SCD patients with each abnormal liver enzyme(s)*). Our focus was these 22 individuals with abnormal liver function to better understand the spectrum of liver disease in SCD. 21 of these 22 patients had genotype HbSS, and one patient, HbSC. The mean age was 39 years, range 22-78 years. Six of these patients have died: two with no other identifiable cause, hence of "sickle hepatopathy" alone, one of sickle hepatopathy and iron overload; of the remaining three, two had pulmonary hypertension and one had Hepatitis C. In the remaining 16 patients, possible causes of liver dysfunction (some with multiple aetiologies) included:evidence of *cleared* Hepatitis B in three patients; significant iron overload in three (with liver iron concentration over 7mg/g dW); right heart failure in one; intra-abdominal lymphoma in one; end-stage renal failure in two; possible hepato-toxic anti-tuberculosis medication in one; chronic cholecystitis in one. Eight patients had only SCD directly as the possible cause of hepatic dysfunction, one of whom developed end-stage liver failure, and was liver transplanted. None had significant issues with alcohol misuse. None of the patients were obese.



Summary / Conclusion: Our population reflected a modern, urban cohort in a well-resourced setting with notably lower rates of both viral hepatitis and alcoholic hepatitis than previously reported. Iron overload appears to be a major contributor to liver dysfunction, perhaps reflecting the increased use of blood transfusion, and likely to escalate with the increasing lifespan in SCD. Notably, the King's dataset reflects this: older age correlates with more liver enzyme abnormalities for both HbSS and HbSC.
Further work is needed to characterise the natural history of "sickle hepatopathy" to enable us to identify patients at risk and the contributory factors, so that monitoring and intervention can be directed appropriately, including red cell exchange transfusion and liver transplantation.

B1806

MYOCARDIAL AND HEPATIC IRON OVERLOAD IN SICKLE/THALASSEMIA PATIENTS OF ITALIAN ORIGIN

A Meloni[1], G Ruffo[2], L Gulino[1], V Caruso[3], L Frizziero[4], C Tassi[5], P Keilberg[1], S Renne[6], C Tudisca[7], V Positano[1], M Lombardi[1], A Pepe[1*]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, [2]U.O.C. Ematologia con Talassemia, Ospedale civico, Palermo, [3]ARNAS Garibaldi P.O. Garibaldi-Centro, Catania, [4] Clin. di Emato-Oncologia Pediatrica, Università di Padova / Azienda Ospedaliera, Padova, [5]Servizio di Immunoematologia e Centro Trasfusionale, Policlinico S. Orsola "L. e A. Seragnoli", Bologna, [6]Struttura Complessa di Cardioradiologia, UTIC P.O. "Giovanni Paolo II", Lamezia Terme, [7] Istituto di Radiologia , Policlinico Paolo Giaccone, Palermo, Italy

Background: Sickle-thalassemia is an inherited hemoglobin disorder resulting from the combined heterozygosity for sickle-cell and β-thalassemia genes. Myocardial and hepatic iron overload in patients with sickle-thalassemia has been poorly studied. A small study including 10 multitransfused Arab patients has shown no evidence of cardiac iron and an higher prevalence of hepatic iron overload (6/10).
Aims: The current study aims to further evaluate cardiac iron overload assessed by a multislice approach and hepatic iron overload in a larger group of Italian patients and explore their correlation with transfusions, age and sex.
Methods: Fifty-nine sickle-thalassemia patients (29 males, mean age 35.6±14.1 years), enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network underwent MRI (1.5T GE Signa/Excite HD, Milwaukee, WI, USA). For the measurement of iron overload, fast-gradient-echo multiecho T2* sequences were used. The left ventricle was segmented into a 16-segment standardized model and the T2* value on each segment was calculated as well as the global value. In the liver, the T2* value was assessed in a single region of interest (ROI) defined in a homogeneous area of the parenchyma. Liver iron concentration (LIC) was derived from T2* values using the formula described by Wood et al.
Results: We found 55 (93%) patients with all 16 segmental T2* values normal (>20 ms). Of the 4 patients with abnormal segmental T2* values, all showed an heterogeneous MIO (some segments with T2* values >20 ms and other segments with T2* values <20 ms) and none showed an homogeneous MIO (all segment with T2* values <20 ms). Out of the 4 patients with heterogeneous MIO, only one had a global T2* global <20 ms.
The mean global heart T2* value was 34.4±6.2 ms.
The mean MRI LIC value was 5.9±6.5 mg/g/dw and 30 patients (50.8%) had a pathological value (≥ 3 mg/g dw). Table 1 shows the comparison of iron levels among different transfusional regimens. There was not a significantly difference in terms of cardiac iron overload while patients regularly transfused had significantly higher hepatic iron than sporadically transfused patient (P=0.0001). On linear regression analysis, there was a statistically significant positive correlation between global heart T2* and age but with poor linearity (R=0.368; P=0.004) and there was not a significant correlation between age and MRI LIC (R=-0.170; P=0.197). Males and females had comparable global heart T2* values (35.6±4.9 ms vs 35.2±7.2 ms; P=0.118) as well MRI LIC values (5.1±4.6 mg/g/dw *vs* 6.7±7.9 mg/d/dw; P=0.762).

	Transfusions			P
	No (N=7)	Sporadic (N=32)	Regular (N=20)	
Global heart T2* (ms)	33.4 ± 7.3	32.4 ± 6.3	35.5 ± 5.4	0.425
Pts with global heart T2*<20 ms, N (%)	0 (0)	0 (0)	1 (5.0)	0.458
MRI LIC (mg/g dw)	3.6 ± 3.3	3.6 ± 2.9	10.5 ± 8.9	0.001
Pts with MRI LIC ≥ 3 mg/g/dw , N (%)	3 (42.9)	11 (34.4)	16 (80.0)	0.004

Summary / Conclusion: In respect of myocardial iron deposition, the sickle/thalassemia patients are similar to patients with homozygous SCD for which iron overloading is relatively rare. Hepatic iron overload may develop also in no regularly-transfused patients, maybe due to increased absorption of iron from the digestive tract, characteristic of both SCD and thalassemia intermedia patients. This finding underline the importance to monitor by MRI also no regularly transfused sickle/thalassemia patients.

B1807

UTILITY OF THE MULTIVARIATE APPROACH IN PREDICTING THE BETA-THALASSEMIA INTERMEDIA OR MAJOR TYPES IN IRANIAN PATIENTS

M Banan[1*], H Bayat[1], P Namdar[1], A Azarkeivan[2]
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, [2]Transfusion Research Center, Tehran, Iran, Islamic Republic Of

Background: Recently, 5 genetic modifiers (β-globin mutations, co-inheritance of α-thalassemia, *XmnI* polymorphism, and single nucleotide polymorphisms (SNP) in the *BCL11A* and *HBS1L-MYB* loci) were used to predict the β-thalassemia (β-thal) major (β-TM) or intermedia (β-TI) types in 106 French patients. The dichotomous grouping was based on administration of 8 transfusions before (β-TM) or after (β-TI) the age of 4 years. Subsequently, multivariate regression analyses and a simple scoring system were used to predict the β-TM/β-TI with 83.2% accuracy.
Aims: Here, a similar study was conducted in a cohort of 306 Iranian β-thal patients having distinct β-globin mutations and minor allele frequencies (MAF) of key SNPs in these loci. The aim was to test the utility of this approach in predicting the β-thal types in Iranian patients.
Methods: The α1, α2, and β-globin mutations were determined by DNA sequencing. Deletions in the α- and β-globin genes were diagnosed by multiplex ligation-dependent probe amplification (MLPA) (MRC Holland, Amsterdam, The Netherlands). Genotyping of the *XmnI* polymorphism was carried out by using the PCR-restriction fragment length polymorphism (RFLP) method. Genotyping of the *BCL11A* and *HBS1L-MYB* SNPs was carried out by using the amplification refractory mutation system (ARMS)-PCR (rs4671393 and rs9399137) or tetra-ARMS-PCR (rs766432).
Results: Multivariate regression analyses and a simple scoring system were used to predict the β-TM/β-TI types in Iranian patients under three scenarios: 1) when considering only the severe β-TM and the mild β-TI cases, 2) using clinical parameters for β-thal typing, and 3) using age at first transfusion as the basis for classification. Under these scenarios, the β-thal types could be predicted in 77.6%, 75.5%, and 68.0% of the cases, respectively. Correct prediction, however, was especially difficult in the β-TI cases. When using clinical parameters for the classification, for example, 92.5% of the β-TM cases and only 45.2% of the β-TI cases could be predicted correctly.
Summary / Conclusion: Our results suggest that the multivariate approach is useful in predicting the β-thal types in Iranian patients. Furthermore, limitations in prediction are only partially due to the imprecise definition of β-TM and β-TI. However, correct prediction of β-TI remains to be difficult.

B1808

BONE MARROW IRON ACCUMULATION IN SICKLE CELL DISEASE, PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND THALASSEMIA PATIENTS ASSESSED BY MRI

L Gutierrez[1], M House[1], N Vasavda[2], E Drasar[2,3], A Kulasekararaj[3], S Thein[2,3*], T St Pierre[1]

[1]School of Physics, University of Western Australia, Perth, Australia, [2]Molecular Haematology, King's College London, [3]Haematology, King's College Hospital, London, United Kingdom

Background: Bone marrow iron accumulation, and its relationship to other organs, has not been extensively studied in diseases associated with iron imbalance owing to the difficulties in accessing this organ for quantitative measurements. Sickle cell disease (SCD), paroxysmal nocturnal hemoglobinuria (PNH) and β−thalassemia are all associated with iron overload, secondary to blood transfusion and/or disrupted iron regulation. Spin density projection assisted R2−MRI (FerriScan®) [St Pierre, T.G., *et al*., Blood, 2005. 105(2): p. 855−61] has been validated as a non-invasive tool for assessing iron load, with the proton transverse relaxation rate (R2) correlating with tissue iron concentration.
Aims: In this study we have compared bone marrow R2 data from patients with sickle cell disease, paroxysmal nocturnal hemoglobinuria, β−thalassemia, and a healthy control group.

Methods: Analysis of magnetic resonance images was retrospectively performed in patients that had already had an assessment of hepatic iron loading as part of their clinical care programme. There were 40 SCD patients (25 females, 15 males, 26.9±8.8 years), 15 PNH patients (7 females, 8 males, 45.5±15.7 years), 13 thalassemia patients (7 females, 6 males, 38.3±14.8 years), and 17 healthy control participants (4 females, 13 males, 37±7.7 years). PNH and thalassemia patients were receiving iron chelation; SCD patients were all chelation naïve. Axial images of the abdomen covering part of the thoracic and lumbar vertebrae were obtained from clinical MRI scanners operating at 1.5 T. Spin density projection assisted R2−MRI (FerriScan®) [St Pierre, T.G., *et al*., Blood, 2005. 105(2): p. 855−61] were used to assess liver iron concentration (LIC) in the participants. R2 values for the bone marrow were derived from pixel−wise mono−exponential fits to image data acquired with a single spin−echo sequence (FerriScan®). Group means were compared using Student's t test, with P=0.05 as the threshold for significance.
Results: Mean bone marrow R2 values for SCD (43.2±21.1 s−1, p <0.0001), PNH (36.1±19.2 s−1, P=0.0059) and Thalassemia patients (44.3±20.0 s−1, P<0.0001) were significantly higher than control mean bone marrow R2 values (21.8±4.9 s−1). Median LIC and ranges for these groups were: controls = 1.1 mg/g, range 0.4 – 1.8 mg/g; SCD = 4.7 mg/g, range 0.6 – > 43 mg/g; PNH = 7.6 mg/g, range 1.8 – > 43 mg/g and thalassemia = 10.8 mg/g, range 0.6 – 43 mg/g. LIC showed a significant positive correlation with serum ferritin (P<0.01)
Summary / Conclusion: These results indicate that we may be able to utilise R2 measurements of bone marrow to quantitatively assess bone marrow iron deposition in diseases such as SCD, PNH and Thalassaemia. This technique opens up the opportunities to assess the effect of chelators on bone marrow iron overload.

B1809

LONG-TERM EFFICACY OF DEFERASIROX FOR CARDIAC SIDEROSIS IN THALASSEMIA MAJOR

M Casale [1], S Citarella[1], F Palmieri [2], M Lo Mastro[1], U Pugliese [1], G Amendola [3], E De Michele[4], A Ragozzino [2], I Tartaglione [1], F Della Rocca[1], B Nobili [1], S Perrotta [1*]

[1]Dipartimento della Donna, del Bambino e di Chirurgia Generale e Specialistica, Seconda Università di Napoli, Napoli, [2]Unità di Radiologia e Diagnostima per immagini, Ospedale S. Maria delle Grazie, Pozzuoli, [3]Dipartimento di Pediatria, Ospedale Umberto1, Nocera Inferiore, [4]Medicina Immunotrasfusionale, Ospedale San Giovanni di Dio e Ruggi d'Aragona, Salerno, Italy

Background: Iron accumulation is a consequence of long-term transfusion. The majority of transfusion-dependant TM patients will succumb to cardiac-related mortality, resulting from iron loading in the heart. Lifelong iron chelation therapy is therefore necessary to reduce iron accumulation; however, compliance issues associated with parenteral treatments remain a challenge. Deferasirox provides an attractive alternative due to its longer half-life, which permits once daily oral dosing regimens. With the development of advanced myocardial imaging modalities, there is the opportunity for early intervention to delay and indeed reverse iron loading in these patients, with the hope of preventing adverse cardiac outcomes.
Aims: The aim of this study was to examine the long-term efficacy of deferasirox in improving myocardial T2* in both adult and pediatric TM patients.
Methods: This was a multicentre retrospective cohort study of TM patients over 2 years of age receiving iron chelation treatment with once daily oral deferasirox monotherapy. Patients underwent MRI scans at baseline, with at least 1 further scan during follow-up, as determined by standard care and clinical need. This allowed quantification of myocardial and hepatic iron burden, through myocardial T2* and estimated liver iron concentrations (LIC), respectively. Data pertaining relevant clinical and routine laboratory parameters were collected at baseline and follow-up. Data are presented as mean with standard deviation unless otherwise stated. Statistical comparisons were made using paired t-tests.
Results: Data from 3 participating centers describes 52 patients with TM, with a mean age of 23±11 years. Overall, 75% of patients (n=39) were adults (age ≥16 years) and 69% (n=36) female. Mean duration of follow-up was 3.3±0.9 years. Dosing regimens were titrated according to standard practice. There was significant increase in mean myocardial T2* from baseline to latest follow-up, with an increase from 29.9±9.6 ms to 35.2±10.3 ms (mean increase: 5.3 ms, P=0.004). This remained significant following stratification by baseline myocardial T2* values <20 ms (n=7, mean increase 13.8 ms, P=0.04) and ≥20 ms (n=45, mean increase 3.9 ms, P=0.03). The improvement observed in myocardial T2* was also significant in both patients with LIC ≥7 mg Fe/g dw (n=18, mean increase 6.8 ms, P=0.04) and LIC <7 mg Fe/g dw (n=34, mean increase 4.5 ms, P=0.04). Of those with T2* <20 ms at baseline (n=7), 85.7% achieved values ≥20 ms at last follow up. Secondary analysis confirmed that the observed improvement in T2* was most pronounced in adults, males, and those achieving final deferasirox doses ≥30 mg/kg/day. There was a trend towards improved left ventricular ejection fraction in the cohort as a whole, but this did not reach statistical significance (65.3% to 67.6%, P=0.08).
Summary / Conclusion: Our findings suggest that in patients with TM, deferasirox shows long-term efficacy for preventing as well as managing cardiac siderosis. The benefits of deferasirox are not restricted to patients with low hepatic iron burdens but are also noted in patients with considerable iron overload.

B1810

AUTOIMMUNE HAEMOLYTIC ANAEMIA IN MALIGNANT DISEASES

E Simonovic[1*], L Macukanovic/Golubovic[2], M Mirjana[1], V Colic[1]

[1]Internal, General Hospital Leskovac, Leskovac, [2]Internal, Clinic of Haematology, Nis, Serbia

Background: Autoimmune haemolytic anaemias (AIHA) are diseases characterized by increased degradation of erythrocytes due to the presence of plasma proteins (globulin) that have character of antibodies' reacting with antigens of erythrocyte membranes of patients. According to the temperature at which the auto-antibodies bind to antigens in erythrocytes, AIHA are divided into: 1) AIHA caused by warm antibodies. 2) AIHA caused by cold antibodies. 3) Mixed (mixing) type. Depending on the presence or absence of the underlying disease, AIHA are divided into primary and secondary.
Aims: The aim of this paper was monitoring the appearance of secondary AIHA in malignant diseases.
Methods: During the three-year period, 154 patients of both sexes were observed, aged between 22 and 84 years with a diagnosis of a malignant disease. About 30% were patients with lymphoproliferative disorders, 9% of patients with multiple myeloma and 61% of patients with other malignancies (breast carcinoma, lung carcinoma, gastrointestinal malignant tumours, prostate cancer and carcinoma of genitourinary tract).
Results: During the monitoring, 18% of patients were reported with autoimmune haemolytic anaemia occurrence. Anaemia is characterized by reticulocytosis, increased levels of lactate dehydrogenase, indirect hyperbilirubinemia, reduced levels of haptoglobin and positive direct Coombs antiglobulin test (DAT). In 80% of patients AIHA was caused by warm antibodies and in 20% of patients with cold antibodies. We have found that AIHA may occur before, along with the appearance of carcinoma, during or after completion of chemotherapy, or as the first sign of recurrence of the disease. Most frequently AIHA was ascertained in patients with lymphoproliferative disorders (about 60%). In patients with solid tumours AIHA was slightly more common in renal carcinoma and gastrointestinal tract. Secondary AIHA is well known paraneoplastic phenomenon in lymphoproliferative disorders, but this form of anaemia may also occur in solid tumours.
Summary / Conclusion: AIHA may precede the occurrence of malignant disease, which initially has a great diagnostic significance. AIHA also may be the first, early signs of recurrence of the disease. Promptly determination of the cause of AIHA is of great importance for the diagnosis, monitoring and therapy of primary malignant disease.

B1811

COMBINATION OF DEFERASIROX AND DEFEROXAMINE IN CLINICAL PRACTICE: ALTERNATIVE SCHEMES OF CHELATION IN THALASSEMIA MAJOR (TM) PATIENTS

E Cassinerio[1*], L Zanaboni[1], A Roghi[2], E Poggiali[1], I Gandolfi[1], M Mazzoleni[1], L Duca[1], N Orofino[1], M Cappellini[1]

[1]Internal Medicine, Hereditary Anemia Center, Ca' Granda Foundation IRCCS, University of Milan, Italy, [2]Cardiology, CMR Unit, Niguarda Ca'Granda Hospital, Milan, Italy , Milan, Italy

Background: The availability of three iron chelators improved the scenario of chelation therapy, allowing to tailor the drugs according to the goals expected for each patient. New drug combination (Deferasirox/Deferoxamine-DFX/DFO- or DFX/Deferiprone-DFX/DFP) have been reported as applicable in clinical

practice.
Aims: To evaluate the efficacy, tolerability and safety of DFX/DFO in TM patients.
Methods: Combinated DFO/DFX. Nine patients (pts) affected by TM have started DFO/DFX for different reasons: **1)**lack of efficacy in removing liver/cardiac iron with monotherapy; **2)**restriction to use standard combination therapy (DFO/DFP) for agranulocitosis on DFP; **3)**adverse events in DFX or DFO. The study design included: at baseline, cardiac and hepatic T2*MRI, transient elastography evaluation (Fibroscan), biochemical evaluation (liver and renal function, ferritin, NTBI, creatinine, creatinine clearance and proteinuria), audiometric and ocular examination. Biochemical tests were repeated at1,3, 6 and 12 months from baseline; Fibroscan, T2*MRI, audiometric and ocular examinations at 6 and 12 months. The starting doses were: DFO 30 mg/kg/day for 3-4 days a week and DFX 20 mg/kg/day. Based on ferritin level and patient tolerability, doses were gradually increased. *Alternated DFO/DFX***.** Three pts started in 2011 alternative use of DFO or DFX for personal reasons or slight elevation of creatinine during DFX. They used DFO at the mean dose of 40 mg/kg/day for 5 days/week for 139±28 days/year and DFX at the mean dose of 22±2,9 mg/kg/day for 226±28 days/year. They repeated T2*MRI every year and biochemical evaluation monthly.
Results: *Combined DFO/DFX.* All pts (3 males, 6 women, mean age of 33±6 years) started combination therapy in 2012. The actual mean treatment period is 8±3 months. At baseline the mean pre-trasfusional Hb levels was 9.4±0.4 g/dl, the mean iron intake 0.40±0.10 mg/kg/die, the median ferritin 5258 ng/ml (range 644-17681 ng/ml), the median NTBI1,82 mM (range 0,38-3,57 mM). The median Fibroscan value was 6.2 kPa (range4,4-75). The cardiac T2* values were 19,73±10,61 ms (<10 ms in 2 pts, between 10 and 20 ms in 2 pts). The mean LIC was 15,05±12,97 mg/g dw, abnormal in 8 pts. Data available at six months showed no alteration of renal/hepatic function and no adverse events. A marked reduction in LIC level was achieved in 5 pts during a 6-months-period (4,94±3,28 mg/g dw vs 9,30±4,46 at baseline), with a concomitant reduction of NTBI (2,14±1,25 vs1,33±0,65 mM) and median ferritin (1624 vs 875 ng/ml). No changes in cardiac T2* values were detected. No patient has been submitted at 12 months controls. *Alternated DFO/DFX.* All pts (3 males, mean age of 42±11 years) showed at baseline a mean pre-trasfusional Hb levels of 9.6±1 g/dl, a mean iron intake of 0.32±0.05 mg/kg/die, a median ferritin of 876 ng/ml (range 837-1160 ng/ml). Cardiac T2* value at baseline was 39.96±7.81 ms and mean LIC value was4,41±0,5 mg/g dw, showing absence of cardiac iron overload and slight liver iron load. After 2 years, no significant changes in cardiac T2* values were detected (38.33±7.07 ms) but a normal LIC was achieved (2.90±0.54 mg/gdw) with stable median ferritin (876 vs 989 ng/ml).
Summary / Conclusion: Combined or alternated DFO/DFX can be considered when monotherapy is not able to remove the iron overload or in presence of adverse events. Cardiac changes seem to need prolonged time versus a more rapid reduction in LIC. In our experience, the use of these schemes of chelation seems to be efficacious and safe, but a prolonged observation is mandatory.

B1812
HEPATIC IRON CONCENTRATION QUANTIFICATION BY MRI: DIAGNOSIS AND MANAGEMENT IN HEREDITARY HEMOCHROMATOSIS´S PATIENTS
L Del Pilar Costilla Barriga[1*], B De Rueda Ciller[1], S Agreda[1], V Flores[1], A Molias[1], P Beltran[1], J Ullrich[1], L Sarria[2], J Artigas[2], D Félix[1]
[1]Hematology and Hemotherapy, [2]Department of radiology, Miguel Servet University Hospital, Zaragoza, Spain

Background: The magnetic resonance imaging (MRI) is the most sensitive and specific imaging modality in the iron overload diagnosis and management of hereditary hemochromatosis (HH). The effect caused by the accumulation of iron leads to signal loss in the affected tissues, particularly with T2* weighted sequences, which makes the diagnosis of iron overload, as well as determining severity and monitoring therapy in a noninvasive procedure.
Aims: 1. To evaluate the utility of hepatic MRI for the iron overload diagnosis and follow-up in HH patients. 2. To determine correlation between serum ferritin levels (SF) and transferrin saturation index (TSI) with the hepatic iron concentration (HIC) estimated by MRI.
Methods: Descriptive and retrospective study, realized in an overall period of 5 years (2008-2013). Hundred three patients, with SF >=300 µg/L and/or TSI >= 45%, and hepatic MRI study in axial planes with sequences promoted in T1, DP, T2, T2* y T2**, and calculate of the HIC according to protocol of Rennes University (N.V: 36±30 µmolFe/g). The patients were divided into 2 groups: Group A (n=20): C282Y homozygotes and compound heterozygotes C282Y/H63D or C282Y/S65C; Group B (n=34): other homozygotes (H63D, S65C), simple heterozygotes (C282Y, H63D, S65C). Twenty six patients were excluded because of no mutations in HFE gene. The levels of iron concentration were classified while HIC estimated by MRI as follows: Group I: <20 µmolFe/g no iron overload and/or 20-39 µmolFe/g light iron overload, Group II: 40-79 µmolFe/g moderate iron overload and Group III: >79 µmolFe/g high iron overload. The data were then compared with SF and TSI levels for each group. Statistical analysis with SPSS 18.0 version.
Results: Seventy seven patients met the inclusion criteria. Mean age was 53 years (range, 27 to 75). Male 84.4% (n=65) and female 15.6% (n=12). The SF levels mean were 553.96 (38.60-1781) and the TSI mean were 41.83 (16.6-85.64). Group A: 36.4% (n=28); homozygotes C282Y (n=12), compound heterozygotes C282Y/H63D (n=15) and heterozygotes C282Y/S65C (n=1). Group B: 63.6% (n=49); homozygotes H63D (n=11) and S65C (n=1), heterozygotes C282Y (n=12), H63D (n=24) and S65C (n=1). Group I: 10.4% (n=8) all of as with HIC < 20 µmolFe/g, Group II: Group III: 40.3% (n=31), Group IV: 49.4 (n=38). The most frequent genotype in the group III (high iron overload) were C282Y homozygotes (n=12) and compound heterozygotes C282Y/H63D (n=10). The HIC in group A (high genetic risk) were 137.22±85.9 and in group B (low genetic risk) were 75.3±51.4. The relation between SF levels and TSI in each iron overload group is shown in table 1.

Descriptive study by risk group				
		Group A (n=28)	Group B (n=49)	
Age [a]		50 (27-66)	55 (29-75)	
Male [b]		66,7%(n=18)	94% (n=47)	
Female [b]		33,3% (n=9)	6% (n=3)	
SF [c]		468.37 (38.6-1185.8)	602.87 (137.8-1781)	
TSI [c]		52.03 (27.85-85.64)	36.00 (16.6-67.3)	
HIC [c]		137.22 +/- 85.9	75.3 +/- 51.4	
Correlation SF – TSI vs. HIC				
HIC µmolFe/g		I (<36)	II (37-79)	III (>79)
		Mean +/- ST	Mean +/- ST	Mean +/- ST
A	TSI	NV	42.13 +/- 17.81	54,21 +/- 17.71
	SF		445.23 +/- 135.10	533.54 +/- 228.20
B	TSI	34.10 +/- 11.12	34,63 +/- 9,4	38,76 +/- 13,14
	SF	370.7 +/- 155.25	590.78 +/- 226.23	690.36 +/- 338.19

Summary / Conclusion: Elevated values of TSI were more observed in high genetic risk group (A) than in low genetic risk group (B), according to awaited. In contrast, the elevated values of SF showed no correlation with genetic risk. Similar results were obtained in HIC correlation. The transferrin saturation index was a stronger parameter related with hepatic iron concentration than serum ferritin levels. This differences, probably in relation with others inflammatory disorders that influenced in SF levels; and no translated in hepatic iron overload, estimated by MRI. The assessment of HIC estimated by MRI with the Rennes university protocol has been a useful tool to follow up patients with hereditary hemochromatosis and with iron overload.

B1813
TRANSIENT ELASTOGRAPHY TO ASSESS LIVER FIBROSIS IN PATIENTS WITH SICKLE CELL DISEASE
G Graziadei[1*], A Marcon[1], I Gandolfi[1], R D'Ambrosio[2], M Fraquelli[3], P Ridolfi[1], M Cappellini[1]
[1]Internal Medicine, [2]Centro A.M. e A. Migliavacca, First Division of Gastroenterology, [3]First Division of Gastroenterology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Liver failure is a rare but potentially very severe complication of Sickle Cell Disease (SCD) in adult life.Liver involvementin SCD is multifactorial, often asymptomatic for long time but eventually can lead to liver failure and death. Assessment of liver fibrosis by liver biopsy (LB) is not a common practice in such patients being an invasive procedure and non-invasive tests such as Transient Elastography (TE) have not yet been validated in these conditions.
Aims: To early identify patients with SCD who could be at risk of hepatic fibrosis and cirrhosis development by using TE.
Methods: Seventy-eight patients affected by SCD, including Sickle Cell Anaemia (SCA), HbS/β-thalassaemia, (T-SCD) and HbS/HbC disease, regularly followed at the Haereditary Anaemia Center in Milan underwent concomitant blood tests and TE, a non-invasive test for liver stiffness measurement (LSM). According to those validated in the setting of chronic viral hepatitis, (Fraquelli *et al*, Gut 2007**)** the following cut-off were used: as follows: < 5.0 KPa no fibrosis (F0), 5.1-7.9 KPa mild fibrosis (F1), >7.9 kPa moderate fibrosis (F2), >10.3 advanced fibrosis (F3), >11.9 kPa cirrhosis (F4).
Results: Seventy-eight patients were evaluated; TE was not available in 19 (24%) and failed in 4 (5%); and therefore we analyzed data from 55 patients (20% HbS/HbC, 22% SCA, 58% T-SCD). Patients were: females (71%), Italians (60%), with a median age of 37 (19-57) years. Sixteen (29%) patients had a BMI >25. Median Hb values were 9.8 (7.2-13.3) g/dL and ferritin median was

411 (31-7238) ng/ml. Alanine amino-transferases (ALT) were increased in 8 patients (14.5%) and gamma-glutamil transferases (gGT) were increased in 16 (29.1%) respectively. Overall median TE value was 5.6 (2.8-21.3) kPa, with 4 (7%) patients showing a TE >11.9 kPa (F4); T-SCD patients had the highest LSM values (HbS/HbC vs SCA vs T-SCD, *P=0.03*). LSM was elevated in 8 of the 47 (17%) patients with normal ALT (4 F2, 1 F3, 3 F4) and in 2 out of 8 (25%) patients with elevated ALT (1 F2 and 1 F4) (*P=0.6*). Moreover, TE values were increased (2 F2, 3 F4) in 42% of the patients with increased gGT values and in 10% (3 F2, 1 F4) of those with normal gGT values (*P=0.018*). Diagnosis of cirrhosis was confirmed by liver histology in all the patients with TE >11.9KPa; HCV RNA was positive in 2 out of 4 cirrhotic patients. Overall regression analysis showed a statistically significant correlation between TE values and AST levels (*P<0,001*), whereas only in T-SCD patients a correlation between TE values and LDH was observed (*P=0,003*). In all patients who underwent TE, Liver Iron Concentration (LIC) derived by T2* MRI was measured and no correlation was observed with LSM.

Summary / Conclusion: Patients with SCD could benefit from regular non invasive assessment of liver fibrosis, independently of ALT and gGt values; increased GGT combined to TE, may identify patients who can be at risk of developing fibrosis and eventually cirrhosis. Further study to validate TE in SCD are worrented.

B1814

QUALITY OF LIFE IN THALASSEMIA PATIENTS: ALMADINAH EXPERIENCE

A Tarawah[1*], S ALI[1], Z ALHAWSAWI[1], M ZOLALI[1], W TURKUSTANI[1]
[1]PEDIATRICS HEMATOLOGY, MATERNITY ANDCHILDREN HOSPITAL, MADINAH, Saudi Arabia

Background: Thalassemia major is a genetic disorder affecting beta globin chain synthesis with various clinical manifestation, requiring lifelong regular blood transfusion. common complications related to high iron load are heart failure, liver fibrosis, diabetes mellitus, growth retardation and delayed puberty. Quality of life (QOL) is consider as an important health outcome and index of effective treatment. Few studies conducted on QOL worldwide on thalassemia. To the best of our knowledge this had not been studied in Saudi Arabia or Middle East .

Aims: The present study aimed to find out levels of QOL among thalassemia patients in Saudi Arabia at hereditary blood disorders center in AlMadinah

Methods: A cross-sectional study was performed on 43 transfusion-dependent thalassemia patients compared with 43 normal subjects, as a control, using World Health Organization Quality Of Life (WHOQOL)-Bref questionnaire; Arabic version. Data were analyzed by Microsoft Excel 2010 and SPSS version 19.0. Chi^2 test was used for qualitative variables and t-test was applied for quantitative variables. Binary Conditional Logistic regression was used to determine the differences between cases and controls and QOL domains. P<0.05 was considered significant.

Results: 43 thalassemia patients has been examined, 23 males and 20 females age 15-31 years. Compared to 43 peered control group 24 males and 19 females. The level of education was high in 8 patients, secondary school in 14 and 21 had basic education. 26 had serum ferretin < 2500 and 17 were > 2500. 28 were using desferroxamine as iron chelator. 13 were employees, 17 were students. Parent level of education were 23 basic education, 9 secondary and 11 had higher education. There was no statistical difference between patients and control group at Psychological domain (53.4 vs 56.9, P=0.059) and Environmental domain (56.6 vs 57.0, P=0.884). Control group had better Physical QOL than patients (55.4 vs 61.9, P=0.047) while patients had better social QOL (39.3 VS 31.7, P=0.003). Further analysis has shown, basically educated control group had better Physical QOL (P=0.01) while basically educated patients had better social QOL(P=0.00), There was no statistical difference between patients and control group at other domains or higher level of education. Control males had better QOL at Physical (P=0.03) and Psychological domain(P=0.03) with no statistical difference in other domains. Female patients had better QOL at social domains(P=0.04) with no statistical difference in other domains. There was no statistical difference between Saudi patients and Saudi control group. Non-Saudi controls had better QOL at Physical domain(P=0.02) and patients had better QOL at social domains(P=0.00). Older patients had better QOL at social domains(P=0.00), with no statistical difference between patients and control group in other domains or younger age.
Among patients group, There was no statistical difference in QOL domains at variables of sex, nationality, level of education, use of Desferroxamine, health status, family history, socioeconomic, Parents level of education and employment. There was a statistical correlation between school, employment and physical health with a better QOL (P=0.01,0.01,0.01 respectively)

Summary / Conclusion: QOL in thalassemia patients is similar to control group particularly social life, though physical health is less. Improvement of patients care from all aspects will improve their QOL. More studies in this field is needed with a bigger sample size.

B1815

CORTISOL RESPONSE TO LOW DOSE VERSUS STANDARD DOSE (BACK-TO-BACK) ADRENOCORTICOTROPHIC STIMULATION TESTS IN CHILDREN AND YOUNG ADULTS WITH THALASSEMIA MAJOR.

A Soliman[1*], M Yassin[2], A Sabt[1], N Abdelmajeed[1], MAbdelrahman[3], V de Sanctis[4]
[1]Pediatrics, [2]hematology , [3]Clinical chemistry, Hamad Medical Center, doha, Qatar, [4]Pediatrics, Quisisana Hospital , ferrara, Italy

Background: Patients with thalassemia major with repeated blood transfusion have high prevalence of endocrinopathies due to iron overload. Both adrenal and pituitary iron overload can affect cortisol secretion and risk patient life during stress conditions

Aims: To study cortisol response to low dose and standard dose ACTH test in thalassemic children and adolescents.

Methods: We examined the adrenocortical function in 23 thalassemic patients (10 children and 13 young adults) aged 8 to 26 years. Serum cortisol and dehydroepiandrosterone sulfate (DHEA-S) concentrations were determined in each subject before blood transfusion both in basal condition and after low dose (LD) (1 microgram) followed by standard dose (SD) (250 micrograms) respectively) with synthetic corticotrophin beta 1-24 ACTH (Synacthen Ciba). Normal controls were a group of 13 age and sex matched normal subjects.

Results: Using a peak total cortisol cutoff level of 550 nmol/L and increments of 200 ug above basal cortisol, adrenal insufficiency was demonstrated in 8 patients (34.7%) after the LD ACTH and in 2 patients (8.7%) after SD ACTH test and in none of the controls. Using a peak total cortisol cutoff level of 420 nmol/L and increments of 200 ug above basal cortisol, adrenal insufficiency was demonstrated in 5 patients (21.7%) after the LD ACTH and in 2 patients after SD ACTH test (8.7%) but none of controls. All patients with biochemical adrenal insufficiency were asymptomatic with normal serum sodium and potassium concentrations and no history suggestive of adrenal pathology. The peak cortisol concentrations in thalassemic patients with impaired adrenal function both after 1ug and 250 ug cosyntropin, (294±51 nmol/L and 307±58.6) were significantly lower than those with patients with normal (454±79.7 nmol/L and 546.1±92.2 nmol/L respectively) and controls (460.2±133.4 nmol/L and 554.3±165.8 nmol/L respectively). Adolescents and young adults but not children with thalassaemia had significantly lower peak cortisol concentration after SD cosyntropin test versus controls. Peak cortisol response to LD cosyntropin test was correlated significantly with peak cortisol response to SD in all patients (r = 0.83, P<0.0001). In adolescents and young adults with thalassemia DHEA-S levels before and after LD ACTH stimulation were significantly lower and the cortisol/DHEA-S ratios significantly higher than controls

Summary / Conclusion: The use of LD ACTH test diagnoses more adrenal abnormalities versus SD ACTH in thalassemic patients. The relatively high prevalence of AI in thalassemic adolescents and young adults necessitates that these patients have to be investigated for AI before major surgery and those with impaired cortisol secretion should receive stress doses of corticosteroids during the stressful event

B1816

EVALUATION OF THE EFFECTIVENESS OF HEMOGLOBIN MEASURED BY A NON-INVASIVE SPECTROPHOTOMETRIC PORTABLE DEVICE AS A SCREENING METHOD FOR ANEMIA DURING PREOPERATIVE ASSESSMENT

A Khalafallah[1,2*], C Chilvers[3], M Thomas [4], S Renu [3], M Sexton[1], M Mohamed [1], A Al-Barzan [2], C Chilvers [5], I Robertson [2], M Vialle [3], T Brain [6]
[1]Haematology, LAUNCESTON GENERAL HOSPITAL , [2]School of Human Life Sciences, University of Tasmania, [3]Anaesthesia, [4]Medicine, LAUNCESTON GENERAL HOSPITAL , Launceston, [5]School of Medicine, Monash University, Melbourne, [6]Pathology, LAUNCESTON GENERAL HOSPITAL , Launceston, Australia

Background: To date, there are no data available concerning non-invasive measurement of spectrophotometricHb in the preoperative setting. Standard laboratory testing may take considerable time to identify patients with preoperative anemia and hence may delay the appropriate management and accordingly the operative procedure.

Aims: To evaluate Hb as measured by portable spectrophotometric device compared to standard laboratory as a screening tool for the preoperative population.

Methods: This is a parallel prospective assessment of instant Hb versus standard Hb which was conducted between March 2012 and January 2013 at the Launceston General Hospital, Launceston, Tasmania.
We screened 322 patients in the pre-operative clinicwith spectrophotometricHb (Pronto-7, version 2.1.9, Masimo Corporation, Irvine, USA) in correlation to the Hb as measured on the same day using Cysmex XE5000 automated analyzer ((Sysmex Corporation, Kobe, Hyogo, Japan). A control group of 87 patients with a known low Hb (≤ 100 g/L) was also assessed simultaneously by both methods in order to assess the effect of low Hb on the spectrophotometric Hb (SpHb) reading. The study was approved by the Tasmanian Human Research Ethics Committee and registered in the Australian New Zealand Clinical Trials Registry (http://www.ANZCTR.org.au/ACTRN12611001256965.

Results: Median age of recruited patients was 66 years (range, 26-92) with a male to female ratio of 155:143, while the median age of the control group was 57 years (range, 21-89) with a male to female ratio of 29:26.
The median and mean Hb as measured by SpHbwas 132 and 131 g/L versus 140 and 138 g/L respectively by the standard laboratory. In the control group, the median and mean Hb as measured by SpHbwas 102 g/L versus 96.5 and 98.5 g/L respectively by the standard laboratory. Our data showed that the correlation between spectrophotometricHb and standard Hb measurement was highest among males compared to females (P=0.001).
Summary / Conclusion: Our data suggest that SpHb correlates well with the standard Hb particularly in males and especially in detecting true low Hb values. Therefore, instant Hb measurement can be integrated into the routine preoperative work-up for screening patients with low Hb and hence offers a prompt management for patients with anemia. Addressing adequately the important issue with preoperative anemia will result in a major health saving and improvement of outcome of surgery. Further studies to confirm these findings are warranted.

B1817

EVALUATION OF QUALITY OF LIFE AND ANALYSIS OF EFFICACY AND SAFETY OF TWO IRON CHELATORS IN PATIENTS WITH IRON OVERLOAD

B Medrano-Engay[1*], P Irún[2], L Sarría[3], M Andrade[4], I Murillo[4], A Montes[4], M Pocoví[5], P Giraldo [6]
[1]Unidad de Investigación Traslacional, Instituto Aragonés de Ciencias de la Salud, [2]Departamento de Bioquímica y Biología Molecular y Celular, Universidad de Zaragoza, [3]Departamento de Radiología, [4]Departamento de Hematología, Hospital Universitario Miguel Servet, [5]Departamento de Bioquímica y Biología Molecular y Celular, Centro de Investigación Biomédica en Red, [6]Departamento de Hematología, Instituto Aragonés de Ciencias de la Salud, Zaragoza, Spain

Background: Iron excess in blood and tissues causes irreversible tissue damage.It has been demonstrated that removal of excess iron has a positive influence in the response to treatment and survival in patients with overload.
Aims: To evaluate the efficacy and the safety of two iron chelators (intensity and time to response), presence and frequencies of adverse events and quality of life (QOL).Quantify biomarkers of macrophage activation: Chitotriosidase (CT) and CCL18/PARC and to evaluate if they can be used as markers of response of chelation therapy
Methods: A comparative, randomized, open, non-inferiorityexperimental study into two arms (EUDRACT: 2009-017799-26). A total of27 patients with maintained iron overload (ferritin>600 mg/L), MDS/AML (13) iron overload after transfusion, alo-BMT(8) and type 1 Gaucher Disease (6), were compared with a healthy control group of 27 subjects with normal serum iron profile stratified by age and sex to analyze comparatively the biomarkers. The study was approval by the Ethical Commitee of Aragon and supported by a grant (TRA-158). All participants signed informed consent. The analysis included physical exam, blood counts, iron profile, protein profile, natriuretic peptide (proBNP) concentration, CT activity and CCL18/PARC, study of *HFE* genes, quantitation of iron liver deposits by MRI, calculating Liver Iron Concentration (LIC) by the ratio of strength signal between liver parenchyma *vs* the paravertebral muscles, and QOL using SF36 questionnaire.Treatment period: 4 months. Patients were weekly monitorizared in the first 4 weeks and every month after. Two randomized groups: A: Deferasirox 20 mg/Kg/day p.o. and B: Desferoxamine: 30 mg/Kg/day sc for 8 hours, three times a week.Statistical analysis: Descriptive statistics and frequency distribution. Comparison of means in independent groups using t-Student considering significance level <0.05
Results: Mean age: 56.9 y (29-77), 52% female. From 26 patients analyzed, 31% were heterozygous for *H63D,* 4% were homozygous,11% were double heterozygous *C282Y/7H63D* and 54% were no mutation. Mean at baseline; Hb: 12.4 g/dL (7.2-15.2), Hematocrit: 36.3% (20-45.2), Ferritin: 1042.8 ng/mL (635-1461), ProBNP: 381.1 pg/mL (18.8-2804), LIC: 83.2 mmol/g (0-240), Chitotriosidase: 65.2 nmol/mL/h (0.81-186) and CCL18/PARC: 150.3 ng (56-393). Fifteen patients were included in A group and twelve in B.Nine patients required transfusion of packed red cells during the study period (mean 14 units).After 4 months on therapy, 80% of patients showed a significant reduction in ferritin levels in both groups A: 490.7 ng/mL (155-1090) (P<0.001), B: 662.7 ng/mL (312-1395) (P<0.05), the differences in reduction grade were similar in the two series. proBNP 368 pg/mL (30-2705), LIC: 50.6 mmol/g (0-190). According the diagnosis, the patients with GD have a significant baseline ferritin leves lower than the other groups (P<0.04) but the grade of reduction after therapy was similar. Related to QOL, A patients group showed significant better scores in SF (P=0.04), RE (P=0.05), MH (P=0.025) MCS (P=0,031) than B group.Adverse events: In A group three patients experimented a reversible mild increase in creatinine level, one of them was grade 3 and mild digestive intolerance in other 3 cases
Summary / Conclusion: There were no differences in the severity iron overload regarding to the *HFE*genotype.Efficacy: Significant decrease of ferritin and iron liver deposits after four months on chelation therapy but more significant in arm A.No relationship were observed between ferritin decrease and plasma biomarkers of activated macrophage: CT and CCL18/PARC.Respect to LIC, were observed decrease of iron deposits, but non statistical differences in reduction of iron between both types of chelator. We have not observed differences in ProBNP concentration.Consequently, and according to the results of this study, ferritin concentration remains the best indicator, in clinical practice, of iron overload Quality of life: Patients under oral therapy, arm A, best scores that arm B, and statistical differences in: SF, RE, MH and MCS_SP.Safety: 11 patients had, at least, one adverse effect, patients in oral therapy had gastrointestinal disturbances and slight and reversible increase of creatinine levels (<2 mg/dL) in the first weeks.

B1818

PYRUVATE KINASE DEFICIENCY: CLINICAL AND MOLECULAR CHARACTERIZATION OF 11 PEDIATRIC CASES FROM ARGENTINA

E Fermo[1], V Gomez[2], C Cervio[2], S Eberle[2], A Zanella[1], W Barcellini[1], A Torres[2], P Bianchi[1*]
[1]U.O. Ematologia e CTMO, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Italy, [2]Servicio de Hematología, Hospital de Pediatría "Dr. J.P.Garrahan",, Buenos Aires, Argentina

Background: Pyruvate kinase (PK) deficiency is the most common enzyme defect of erythrocyte glycolytic pathway causing hereditary nonspherocytic chronic haemolytic anaemia. The severity of thedisorder is highly variable, ranging from mild to severe anaemia, which can be life-threatening and requiring continuous transfusion therapy. PK deficiency is transmitted as an autosomal recessive trait and more than 200 mutations associated with the disorder have been so far reported in the gene encoding the red cell pyruvate kinase (*PK-LR*). Pyruvate kinase deficiency has a worldwide distribution with the higher prevalence of 1 in 20,000 in the Caucasian population. No reports were so far available on PK deficiency in Argentina.
Aims: We report the clinical, haematological and molecular characteristics of 11 PK deficient Argentinean children.

IT : Italian, ES: Spanish, SF : Serum Ferritin, n.a : not available; new mutations are reported in bold.

Methods: Eleven patients (4 males, 7 females) from 9 families, with a median age of admission 0.2 yrs (range 0-2.4yrs) were studied. Seven patients were of Gypsy ethnic group and consanguinity of parents was declared. The remaining 4 patients had Italian or Spanish origin. Haematological parameters and red cell enzyme activity were determined according to standard methods. The entire coding region and promoter of the *PK-LR* gene were amplified by PCR and automatically sequenced.
Results: The most important clinical and haematologic parameters and the results of the molecular characterization are reported in Table 1. All the patients displayed a severe clinical picture at birth with hyperbilirubinemia and need of phototherapy, and 7 required exchange transfusion. Because of the high transfusion requirement (median 15/year, range 6-29) , 9 patients were splenectomised (median age at splenectomy 2.2, range 8 months- 4 yrs). Splenectomy did not lead to normalization of anaemia, but resulted in stabilisation of the haemoglobin to slightly higher levels in all patients but one (median Hb increase 1.8 g/dL, range 0.2-4.2) with a drastic reduction of transfusion requirement (median 2/year, range 1-4). All patients but one had increased serum ferritin levels (median SF 1013 ng/ml), and 6 underwent chelation therapy. As typically reported in PK deficiency, a conspicuous rise of reticulocytes after splenectomy was observed. Nine different mutations were found in *PK-LR* gene, four of them never described before: three missense mutations (Ala495Thr, Val506Ile Gly341Ser) and a 6 nt duplication (c.364_369 ins GGCTCC), resulting in the in-frame duplication of amino acids Gly122-Ser123. In all the patients of Gipsy origin we confirmed the presence at homozygous level of mutation c.1437-518_1618+440 del 1149 bp (already reported as "Gypsy mutation").
Summary / Conclusion: This is the first comprehensive report of molecular characterization in PK deficiency from Argentina. Four novel mutations were identified in the patients of Italian and Spanish origin. For the first time the clinical and haematological parameters of a large group of Gypsy subjects were described.

B1819

HB RIAD/LAUSANNE, A NEW B-VARIANT RESULTING FROM A DOUBLE MUTATION TGC >TCT, (ALA>LEU), AT CODON 71. IDENTIFICATION BY CLONING AND SEQUENCING

T Araud[1*], G Georgiou[2], F Guerry[1], J Mandier[2], P Menoud[1], P Beris[2]
[1]Molecular Biology, Unilabs - Switzerland, Lausanne, [2]Hematology, Unilabs - Switzerland, Coppet, Switzerland

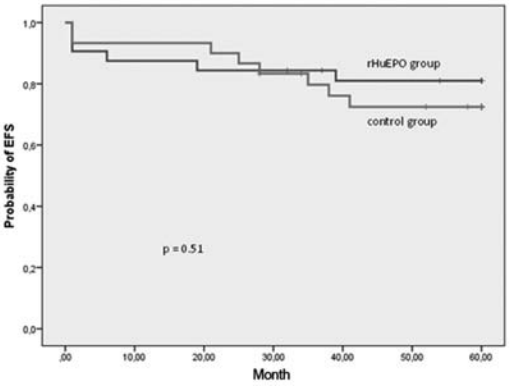
Background: Four different mutations have been previously described at the amino acid position 71 of human beta-globin gene (initiation codon included): Hb Abington (c.211G>C, p.Ala71Pro), Hb Seattle (c.212C>A, p.Ala71Asp), Hb Hershey (c.212C>G, p.Ala71Gly) and Hb Marineo (c.212C>T, pAla71Val).
Aims: The aim of this study was to identify a new variant resulting in an abnormal HPLC pattern, never described up to date and with a normal isoelectric focusing (IEF) of the hemolysate. Preliminary molecular analysis localised this variant to codon 71. This abnormal Hb was found in a Saudi Arabian patient from Riad
Methods: A 26 year old woman was investigated because of slight anemia: Hb 118 g/L; MCV 96.7 g/l; MCHC 311 g/L. WBC and platelets count was normal. An hemoglobinopathy was investigated by IEF and HPLC of the hemolysate as well as by gel agar electrophoresis at acidic pH. An α-globin variant was looked by sequencing both α2 and α1-globin genes. A β-globin variant was looked by sequencing of β-globin. Sequencing was performed by classical capillary Sanger sequencing.
Results: No abnormal Hb was found in IEF. In HPLC we found 43% of HbA and 43% of an abnormal Hb migrating adjacent to HbA. This fraction has never been described before and was not separated by pH acidic electrophoresis. Sequencing of α-globin genes was normal. Sequencing of β-globin made in evidence two mutations at positions c.211G>C and c.212C>T in an heterozygous state. As blood from the parents was not available and in order to rule out that each mutation is located on different chromosome, we performed cloning of the first PCR product using pCR™4-TOPO TA vectors (Invitrogen). 8 colonies were analysed by sequencing of the insert. We found that 5 were positive for both mutations while 3 were wild type for the β-globin exon 2 region.
Summary / Conclusion: Our molecular studies made in evidence a new β-globin variant resulting from a double mutation at codon 71 leading to a substitution of Alanine to Leucine in a heterozygous state. Taking into consideration the already described variants at codon 71 (see background) our patient combines in the same codon the two already described mutations c.211G>C and c.212C>T. This raises the question concerning the genesis of this new hemoglobine: Is this new variant the result of a crossing over of the previous Hb Abington and Hb Marineo between nucleotides 211 and 212? Studies of the parents and analysis of further β-globin genes of the Riad region are needed to check this hypothesis or to see if this new Hb is endemic. Because the percentage of this variant equals the percentage of HbA in HPLC analysis and because the Hb value is in the lower limit of the normal for a young lady, we postulate that this variant is asymptomatic. This new variant is called Riad/Lausanne from the origin of the patient and from the location of the identification.

B1820

EFFECT OF RHUEPO THERAPY ON LONG-TERM SURVIVAL OF ANEMIC CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA, UNDERGOING CHEMOTHERAPY

M Lunyakova[1*], A Rumyantsev[2], V Demikhov[1], A Beznoshchenko[1], A Pavlov[1], E Morshchakova[1]
[1]Ryazan Branch, Federal Clinical Research Center for Pediatric Hematology, Oncology and Immunology named D. Rogachev, Ryazan, [2]Federal Clinical Research Center for Pediatric Hematology, Oncology and Immunology named D. Rogachev, Moscow, Russian Federation

Background: Anemia is one of the most frequent problems during treatment of children with acute lymphoblastic leukemia (ALL). Up to now recommendations for use of erythropoiesis stimulating agents (ESA) in children with the malignant disease (MD) are absent. There are only several publications, which have reported about safety and efficiency of the option in correction of anemia in ALL children, undergoing chemotherapy. However serious contradictions in a question of impact of ESA treatment on survival of adult patients with MD are available. We analyzed long-term survival of ALL children with chemotherapy-induced anemia, who recieved ESA treatment during phase of intensive chemotherapy.
Aims: To estimate 5-year event-free survival (EFS), relapse-free survival (RFS) and overall survival (OS) in chemotherapy-induced anemia children with ALL, treated with rHuEPO.
Methods: Sixty two patients undergoing chemotherapy according to the program ALL BFM-90m were enrolled in the clinical trial. Thirty two children received rHuEPO (epoetin-alfa) throughout an intensive phase of chemotherapy (mean duration was7,6±0,17 month) in dosage of 200 IU/kg subcutaneously 3 times a week or 600 IU/kg intravenously weekly. Thirty children comparable on age and clinical manifestations were controls (without rHuEPO). Kaplan-Meier analyses were used to compare the EFS, RFS and OS.
Results: At the minimum term of supervision more than 5 years 27 (84,4%) patients in rHuEPO treated group and 22 (73,3%) patients in control group were in complete remission (P=0,347).The 5-year EFS for patients treated with rHuEPO was 81±4% compared to 73,3%±3% in control group (P=0,513). Increasing RFS in rHuEPO treated group in comparison with control was noted (93±3% and 79±4% respectively), however difference wasn`t significant (P=0,130). Probability of 5-year EFS of children with ALL in rHuEPO-group and control group shown on the figure.
Summary / Conclusion: Long-term survival analysis didn't reveal negative effect of rHuEPO treatment on survival of ALL children with chemotherapy-induced anemia, undergoing chemotherapy.



B1821

EPIDEMIOLOGICAL SURVEY OF ALPHA-THALASSAEMIA SYNDROMES IN NORTHERN GREECE

S Theodoridou[1*], S Hissan[1], E Vlachaki[1], A Teli[1], M Economou[1], F Boutou[2], A Balassopoulou[2], V Delaki[2], E Vetsiou[1], D Adamidou[1], E Lefkou[1], V Aletra[1], O Karakasidou[1], E Voskaridou[2], N Gombakis[3], F Papachristou[3]
[1]Haemoglobinopathy Unit, Hippokration Hospital of Thessaloniki, Thessaloniki, [2]Thalassaemia Unit, Laikon Hospital, Athens, [3]First Paediatric Clinic, AUTH, Thessaloniki, Greece

Background: Greece is a Mediterranean country with a high frequency of thalassaemia and haemoglobinopathies. The α-Thalassaemia syndromes are due to mutations of the linked pair of α globin genes on chromosome 16 and result in imbalance in the production of α- and β- globins. Clinically they range from a lethal condition (hydrops fetalis) to a silent carrier state of no hematologic significance. Hb H disease is the cinical significant form of α-thalassaemia syndromes with a phenotypic variation due to the different molecular basis.
Aims: The aim of the study was to investigate the incidence of α-Thalassaemia syndromes in Northern Greece
Methods: The carrier identification is carried out by a standard scheme which includs CBC and red cell indices, a Cation Exchange HPLC variant system to determine HbA, HbA2 and HbF levels. Hb H identification is made by electrophoretic techniques. Hb H inclusion bodies after incubation and serum ferritin levels are also investigated. The molecular basis of Hb H disease was investigated in some cases and in heterozygous carriers in cases of genetic counseling.
Results: A total of 88003 subjects were screened for heamoglobinopathy in our unit from 1986 to 2011 at the regions of Central and Western Macedonia in Northern Greece with a population of around 2.5 million. We found 1390 heterozygous carriers of α-thalassaemia, (1,5% of the population screened). From 1986 to 1999 hemoglobin biosynthesis was performed in cases of genetic counseling. Since 2000 molecular tests are mostly used for the identification of α mutations in order to consult couples at risk. 62 heterozygous carriers of α- thalassaemia had had molecular identification due to genetic counseling. 65% (40) carried the –α3,7/ αα, 12,9%(8) carried the mutation –med/αα, and 9,7%(6) had the mutation α2pPoly A. We found 9 heterozygous carries of both α and β thalassaemia, 2 heteroygous carriers of Sickle cell and α- thalassaemia, 1 heterozygote for both α and δ thalassaemia, 1 heterozygote for both α and E thalassaemia, all DNA tested. Moreover we found 28 patients with HbH disease (14 males and 14 females). The most prevalent genotype was the -α 3.7/—med, (5 cases), 2 cases of –α3,7/-α5,2, 1 case of –med/α Poly A, 1 case of –α3,7/Hb Adana. 10 patients (36%) were under the age of 14. 7 patients (25%) were transfused occasionally (3 due to pregnancy, 2 due to infection, 1 due to surgery and 1 due to severe haemolytic crisis at the age of 10). 17 patients (61%) presented splenomegaly and only one was splenectomized. Hepatomegaly was present in 5 (18%). 4 patients had chololithiasis and 2 of them underwent cholocystectomy. Half of the patients have an annual follow up, 25% a rare follow up, 18% have no follow up at all and 7% come to our unit 3 times a year. The phenotype suggests that HbH disease in Greece has in general a moderate presentation.
Summary / Conclusion: The molecular characterization of the patients with HbH disease is useful for the prediction of the clinical outcome and the genetic counselling of the couples at risk.

B1822

SCREENING PARADIGM FOR B-THALASSEMIA CARRIERS; FROM CLINICAL TO MOLECULAR

M Ayoub[1*], I Youssef[2], S Youssef[2], G Mokhtar[3], M Elmogy[2], H Mahmoud[2], S Pessar[2]
[1]Hematology, [2]clinical pathology, [3] Pediatrics Hematology, Ain shams university, Cairo, Egypt

Background: β thalassemia (β-thal) represents a major health problem worldwide and particularly in Egypt. Its prevention, when compared to treatment, is found to be cost-effective, possible and practical. This work aimed to evaluate the effectiveness of diagnostic techniques in detection of the β-thalassemia carrier state.
Aims: This work aims to evaluate the effectiveness of automated HPLC followed by PCR in screening for β-thal carriers before nationally adopting a premarital screening strategy for β-thal carriers.
Methods: The present work included 1627 child and adolescent of both sexes presenting as outpatients to clinics of Ain-Shams University Hospitals during period from 1/11/2009 to 30/6/2010. In the first phase microcytic hypochromic for age CBCs were selected. In the second phase, Iron profile and HPLC testing were performed. Molecular characterization by PCR reverse hybridization for detection of 22 common β-globin gene mutations was done as a final step.
Results: Clinical characteristics of the studied population The population selected for having microcytosis & hypochrom ia was 280/1627 cases (17.2%). It comprised representative groups from infancy to young adults (30.7% infant, 21,8% young child, 21.8% older child, 9.6% adolescent and 16.1% young adult) including both males (64.3%) & females 35.7%). First & second phases of screening for β-TT; Phenotypic diagnoses There were 14 possible causes or phenotypes for the microcytic hypochromic indices based on clinical and hematological parameters including CBC, iron profile and HPLC. 44.6% (125 cases) were suspected to be βTT by CBC, 35.4% (99 cases) were suspected to be βTT after iron profile & HPLC. Iron deficiency anemia was the commonest cause of microcytosis and hypochromia (38.6%) followed by βTT (35.4%) (21.8% had HbA_2 >4% & were considered classic β-TT and the rest were suspected β-TT but required confirmation by genotyping). Final Phase; Genotypic confirmation of the thalassemia carrier state - In our study, 74% (37/50) of the genotyped cases exhibited presence of β-thalassemia mutations. The commonest four mutations were; IVS 1.6 (27%, 10/37 cases) followed by IVS 1.110 mutation and IVS 1.1 mutation (21.6%, 8/37 cases for each) followed by IVS 2.745 mutation (13.5%, 5/37 cases). Four cases were homozygous for IVS 1.6 mutation, one case was homozygous for IVS 2.745 mutation and one case was compound heterozygous for IVS 1.110 mutation and IVS 1.6 mutation. The commonest four genotypes constituted about (83.8%, 31/37 cases), followed by other less frequent mutations as IVS 2.848 and codon 5 (5.4%, 2/37 cases for each) then IVS 2.1 mutation, -87 mutation and codon 39 mutation (2.7%, 1/37 case for each). Diagnostic performance of hematologic parameters in screening for βTT. By utilizing the Receiver Operating Characterestic (ROC) curve HbA >3.5% provided 100% sensitivity, 70% specificity, 75% PPV, 100% NPV and accuracy of 70% to identify βTT and at a cut off 4%: it provided 97.4% sensitivity, 72.7% specificity, 92.6% PPV, 88.8% NPV and a diagnostic accuracy of 92%. As regards MCV, a cut off 61fl revealed 72% sensitivity, 20% specificity, 25% PPV, 71% NPV and accuracy of 40%.
Summary / Conclusion: In conclusion, HPLC proved to be a reliable screening tool for βTT to be followed by molecular characterization for selected cases in which HbA_2 lied in the interval from 3.6% to 4%**.** It is our belief that such a strategy would capture most of the βTT cases with minimum costs making it applicable for a national βTT screening programs.

B1823

EFFICACY OF RITUXIMAB IN AUTOIMMUNE HEMOLYTIC ANEMIA

A Almomen[1*], A Aleem[2], R Hasanato[3], K AlSaleh[2], F Anjum[2]
[1]Medicine-Hematology, [2]Medicine-Hematology/Oncology, [3]Pathology-Clinical Biochemistry, King Saud University, Riyadh, Saudi Arabia

Background: Autoimmune hemolytic anemia (AIHA) affects males and females of all age groups, but more frequent in young adult females. Most patients respond initially to corticosteroids and intravenous immunoglobulin (IV IgG) as first line therapy. Splenectomy is recommended for those who do not respond well to first line treatment. For patients who do not respond to Splenectomy, several single immunosuppressant or immune modulator agents are tried. These include danazol, mycophenolate, colchicine, dapson, azathioprine, vincristine, cyclophosphamide, and Thrombopoitin receptor agonists such as Romiplostim and Eltrombopag.
Aims: The aim this non-randomized, prospective study is to explore the safety and efficacy of Rituximab as a new modality treatment for refractory AIHA.
Methods: Treatment with rituximab was explained to patients and an informed consent was obtained from a series of 15 patients (7 males and 8 females, aged 33 +I- 15 years), who agreed to take rituximab as an off label treatment. Their Hb level was 73 +I- 14 g/l (range 35-95). Each patient was given rituximab 375 mg/m2 intravenously weekly for four weeks, then monthly for four months, then maintenance every three months for two to three years.
Results: All patients showed a rapid and sustained response with significant rise in Hb level to 128±10.8 g/l within one to four months. Rituximab was tolerated very well without any major adverse effect during the follow up period, which was 27.6±21.8 months
Summary / Conclusion: Rituximab is probably highly effective in the treatment of patients with refractory AIHA with sustainable response. It could be considered for refractory patients prior to Splenectomy. However, larger studies are needed to verify the optimal utilization of rituximab in AIHA cases.

B1824

THE EFFECT ON WEIGHT, BODY MASS INDEX AND SUBCUTANEOUS ADIPOSE TISSUE FAT OF DIFFERENT CHELATING AGENT: A SURVEY FROM MIOT DATABASE

P Ricchi[1], A Meloni[2], V Positano[2], T Casini[3], M Batzella[4], L Pitrolo[5], G Valeri[6], L Gulino[2], M Lombardi[2], A Pepe[2*]
[1]Unità Microcitemia, A.O.R.N. Cardarelli, Napoli, [2]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, [3]Centro Talassemie ed Emoglobinopatie , Ospedale Meyer, Firenze, [4]Centro trasfusionale , Ospedale San Gavino, San Gavino Monreale, [5]Az. Osp. "Villa Sofia", U.O. Pediatria II, Palermo, [6]Dipartimento di Radiologia , Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi", Ancona, Italy

Background: Several studies showed that the use of Deferiprone (DFP) alone and in combination with desferioxamine (DFO) was associated with both an increase in food intake and body weight. However, very few data are available on the long term effect of different chelation therapies on some nutritional parameters.
Aims: This study aimed to evaluate the effect of DFP versus DFO and deferasirox (DFX) in monotherapy on Body Mass Index (BMI) and body composition assessed by magnetic resonance imaging (MRI) .
Methods: Among the first 1506 thalassemia major (TM) patients enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) project, 792 performed a MRI follow up study at 18±3 months, according to the protocol. Patients under 18 years were excluded. We evaluated prospectively the 159 adult TM who had been received each monotherapy between the two MRI scans and three groups of patients were identified: 66 treated with DFO, 37 treated with DFP and 57 treated with DFX. BMI and Body Surface Area (BSA) were calculated from anthropometric parameters available according to the protocol. Subcutaneous adipose tissue (SAT) measurement was obtained by MRI (HIPPO FAT*)performing a retrospective analysis of selected SPGR imagesof homologous axial abdominal slices at baseline and follow up and evaluation of the SAT/Body size ratio.
Results: Basal weight and BMI in the tree groups are indicated in Table 1. At baseline 53/57 DFP patients were taking the considered therapy from > 6 months. The percentage of patients overweight or obese (BMI ≥ 25 Kg/m2) was significantly higher in the DFP (40.5%) group than in both DFO (18.2%) and DFX (16.1%) groups (P=0.013 and P=0.028, respectively). Due to technical reasons the analysis of the ratio SAT/body size was carried out on 64 (40%) patients (29 patients in DFO, 14 in DFP and 20 in DFX) and showed that at baseline patients under DFP treatment had the highest ratio SAT/body size (20.1±8.1) with respect to that observed in DFO (19.1±6.9) and in DFX (19.1±6.7) groups but the difference among three groups was not statistically significant. Table 1 shows also weight and BMI in the tree groups at follow up examination. Apart from a significant increase in weight (P=0.011) in DFO users, not other statistically significant differences at intra-treatment and inter-treatment prospective comparisons were observed. Similarly, at follow up, the changes in the ratio SAT/body were not of relevance among the three groups of patients.
Summary / Conclusion: Although the differences in the previous chelation treatments limit the applicability of our conclusions, the data at baseline suggest that in clinical practice, DFP users had highest weight, BMI and ratio SAT/body probably as a result of a steady and stable effect of the drug on nutritional parameters. Differently from what observed in DFO users, the prolonged (18±3 months) treatment with DFP seemed not to be associated to a further progressive increase in body weight, BMI and ratio SAT/body. Further longitudinal studies are needed to better clarify these effects of DFP treatment on naïve patients from the start of the therapy.

	DFO (N=66)	DFP (N=37)	DFX (N=56)	P
Basal MRI				
Weight (kg)	59.67 ± 10.45	63.02 ± 9.77	58.73 ± 12.89	0.182
BMI (Kg/m²)	22.53 ± 2.61	24.14 ± 2.88	22.78 ± 3.55	0.031

B1825

LONGITUDINAL MRI AND SERUM FERRITIN MONITORING OF IRON OVERLOAD IN CHRONICALLY TRANSFUSED CHILDREN WITH HEMOGLOBINOPATHIES

V Brousse[1*], M Aubard[1], P Ou[2], C Elie[3], M de Montalembert[1]
[1]Pédiatrie Générale, [2]Radiologie Pediatrique, [3]Biostatistiques, Hôpital Universitaire Necker Enfants Malades, Paris, France

Background: Iron overload is an ineluctable complication in chronically transfused children with hemoglobinopathies. Accurate assessment of iron overload is therefore crucial to avoid iron related morbidity and mortality and to monitor chelation therapy. Pediatric studies are scarse and have provided contradictory results regarding correlation between serum ferritin levels and MRI imaging.
Aims: We investigated longitudinally the relationships between ferritin levels and hepatic and cardiac T2*MRI imaging in a cohort of chronically transfused children receiving chelation therapy.
Methods: Data regarding chronically transfused children, 30 affected with sickle cell anaemia (SCA) and 7 with thalassaemia major (TM), were collected between June 2005 and April 2010. Data included in particular annual numbers and cumulated volumes of transfusion and blood withdrawal, calculated iron intakes before first and before each annual MRI measurement, types and dosages of chelation therapy, and mean ferritin levels in the semester preceding MRI imaging. The same chelation protocol was applied in SCA and TM patients and used deferasirox.
Results: Sex ratio, age, and median duration of transfusion programs (5 years [2-14]) were comparable in both TM and SCA children. Median iron load received by each child was 0.54 mg/kg/day [0.27 -0.74]. It was not significantly different in SCA and TM patients (P=0.26). Median ferritin level in the whole population was 1550 mg/L [184-6204] and differed significantly between SCA (1917 mg/L [184-6204]) and TM patients (842 mg/L [266-5332]), P=0.002. A correlation (rho=0.27, P<0.001) was found between iron load and ferritin level.
Results of 73 hepatic T2*MRI were analysed. Severe hepatic iron overload was found in 38.3% cases (7 TM, 21 SCA) and was more frequent in TM patients when compared to SCA patients (P=0.037). A positive correlation was found between serum ferritin level and hepatic iron overload (rho = 0.57, P<0.001) in the whole population and in both SCA and TM groups. 55 cardiac T2* MRI measurements were analysed. No cardiac overload was found in the majority of cases. Iron overload was found moderate in 4 cases (5.4%) and severe in 1 case (1.8%), regarding exclusively TM patients. There was no correlation between serum ferritin levels and cardiac iron overload. Comparison of trends of ferritin levels and hepatic MRI results were analysed in 37 cases. In 19 cases trends were similar: the direction of changes of both ferritin and hepatic overload was congruent. Among them, 7 showed both improvement in ferritin levels and hepatic iron overload (3 TM, 4 SCA), 8 demonstrated aggravated results (3 TM, 5 SCA) and 4 showed (4 SCA) stable trends for both parameters. Conversely, opposite trends were observed in 3 cases, interestingly only in SCA patients: ferritin levels increased whilst hepatic overload decreased in one case, and the contrary in 2 cases. In all the other cases, analysis of trends did not allow conclusion. Comparison of trends of ferritin levels and cardiac MRI results were analysed in 19 cases. Similar trends were found in 5 (26%) cases: in 2 cases of TM patients both trends decreased, in 3 cases trends were stable (2 SCA, 1 TM). Opposite trends (concerning exclusively SCA patients) were observed in 5 cases (26%): In3, ferritin levels increased whilst MRI measurement improved; in 2 cases ferritin level decreased whilst MRI cardiac overload increased. In all the other cases, analysis of trends did not allow conclusion.
Summary / Conclusion: This study shows that iron overload is not controlled in all regularly transfused and chelated children with hemoglobinopathies. These findings emphasize the importance of MRI imaging for iron load assessment as ferritin trends may fault in both over or underestimating tissular iron load. Our results indicate in particular that data drawn from TM cohorts may not be extrapolated to SCA patients. This study argues for tailoring chelation therapy according to MRI results and not ferritin results.

B1826

RELATIONSHIP BETWEEN QT DISPERSION, PRO-BNP, T-WAVE ALTERNANS, HEART RATE VARIABILITY AND BODY IRON BURDEN DETECTED BY THE FERRITIN, HEART AND LIVER MRI IN ASYMPTOMATIC PATIENTS WITH THALASSEMIA MAJOR

Z Karakas[1*], S Celik[2], Y Kıvanc[3], B Kaya[3], R Omeroglu [4]
[1]Pediatric Hematology-Oncology, Istanbul University Istanbul Medicine Faculty, Istanbul, [2]Pediatric Allergy/Immunology, Uludag University Medical Faculty, Bursa, [3]Cardiology, [4]Pediatric Cardiology, Istanbul University Istanbul Medicine Faculty, Istanbul, Turkey

Background: The most important cause of mortality in patients is iron accumulation. Cardiac complications due to iron overload is the major cause of death in patients with thalassemia major. Increased QT dispersion and reduced heart rate variability has been reported to be associated with ventricular arrhythmias and sudden cardiac death.
Aims: Aim of the study is to evaulate the relationship between the non-invasive methods (heart rate variability, QT dispersion, T-wave alternansproBNP) that can be used to determine cardiac damage at early stagesand ferritin, heart and liver iron overload in patients with thalassemia major.
Methods: Thirty-one patients with thalassemia major, fifteen boys and sixteen girls (12-37 years old) were included in the study. By calculating the difference between the largest and the smallest corrected QT (QTc) on standard 12-lead ECG, QTc dispersion (QTcd) was found respectively. Limit value for QTcd was set as 50 ms. Automatically measured time-based heart rate variability parameters from 24-hour Holter recordings and serum ferritin values of the pateints were recorded. Heart and liver MRI was performed by 1.5 Tesla Philips device considered as T2 *in the Department of Radiology, Istanbul Faculty of Medicine. The iron overload indicators, ferritin levels, heart and liver MRI results, were compared with age, sex, heart rate variables (SDNN 24, SDANN1, SDNN1, RMSDD, pNN50) QTc dispersion (QTcd) and pro-BNP values. Statistical analysis was performed with SPSS program, Pearson's correlation test.
Results: The mean ferritin level of the patients was 2033±1970 ng / dL. There was not a correlation between cardiac and liver MRI. There was a significant relation between ferritin levels and liver iron overload. Ferritin was not related with cardiac iron detected by MRI with Pearson's correlation test. Cardiac iron overload was associated with age. In 3 patients with severe iron overload in the heart (cardiac T2 * values <10 ms), we found that the heart rate variables were associated with age, gender, proBNP and ferritin. Corrected QT dispersion was associated with age and ferritin (p <0.01). In 5 patients with moderate iron overload in the heart (cardiac T2 * values 10-20 ms), heart rate variables associated with age; corrected QT dispersion associated with ProBNP, and Liver MRI associated with ferritin and Aver HR (p <0.01). In 23 patients without iron overload in the heart (MRI T2 * values> 20 ms), Liver MRI was associated with ferritin. In 9 patients with hepatic iron < 5 mg, ferritin was associated with QTc, proBNP, TWA. Cardiac MRI was also associated with pNN50 and RMSDD (P<0.01). In 16 patients with liver MRI 5-20 mg; Cardiac MRI associated with age, LIC associated with ferritin (p <0.01). In 6 patients with severe liver iron overload (LIC> 20 mg), ProBNP was associated with Aver HR (p <0.05). LIC was assoociated with age. Cardiac iron overload was associated with sex (p <0.05).
Summary / Conclusion: Although ferritin shows the liver iron load, it is not enough to assess cardiac state. Cardiac iron overload may seen in patients with low ferritin levels. In patients without any cardiac symptoms, to predict the risks of lethal arrhythmias, sudden cardiac death and heart failure due to iron toxicity, should be performed liver MRI, pro-BNP, QTc dispersion and HRV at regular intervals without considering ferritin levels.

B1827

STUDY OF THE ALTERATIONS OF PLATELET FUNCTIONS IN CHILDREN AND ADOLESCENTS WITH IRON DEFICIENCY ANEMIA AND RESPONSE TO THERAPY

G Mokhatar[1], W Ibrahim[1*], N Kassim[2], E Ragab[1], A Saad[2], H Raheem[1]
[1]Pediatrics, [2]Clinical Pathology, Faculty of Medicine Ain Shams University, Cairo, Egypt

Background: Iron deficiency anemia (IDA) is the commonest type of malnutrition. Several changes in platelets in IDA have been reported, so, a relationship between iron metabolism and thrombopoiesis should be considered**.**
Aims: to study the alterations of platelet functions in patients with IDA by assessment of platelet aggregation with collagen, ADP and ristocetin and by measuring platelet function analyzer (PFA-100) closure time together with the effect of iron therapy on the same tests.
Methods: A case control study was conducted in Ain Shams University Children's hospital in the period from June 2011 to June 2012 including 20 patients with confirmed IDAand 20 healthy age and sex matched control. Their ages ranges between 2-18 years.Patientswith coexisting chronic disease,decompensated severe IDA, thrombocytopenia and inherited platelet function defect were excluded. All patients and control were subjected to history takingwith emphasis on socioeconomic standard according to Park classification, Dietetic history of iron intake with Food frequency questionnaire and Diet Analysis Program1995*;* Symptoms suggestive of anemia, history of blood transfusion, history of bleeding tendency and drug history.Laboratory analysis included complete blood count to assess the erythrocyte indices(Hb, MCV, MCH, MCHC, RDW) and platelet parameters including(count ,size anddistribution width), assessment of iron status by measuring serum iron, total iron binding capacity and ferritin, assessment of platelet functions by PFA-100 closure time and platelet aggregation with collagen, ADP and ristocetin. Patients with IDA were treated by oral iron therapy 6mg/kg/day of ferrous sulphate for 12 weeks. Post therapeutic assessment of patients clinical improvement including bleeding, and laboratory iron status,erythrocyte indices , platelet functions after 48 hours of discontinuation of oral iron therapy.
Results: Mean age of IDA patients was 5.7±4.2 years compared 7.6±4years in control group (P>0.05). Bleeding manifestations were more common in patients group. One patient was diagnosed as Glanzmannthrombasthenia and excluded from statistical analysis. Mean PFA-100 closure times (with epinephrine) were significantly longer in patients(179.1±86.4sec)compared to control group(115±28.5sec)(P <0.05). Platelet aggregation by ADP(38.1±22.2%), epinephrine(19.7±14.2%) and ristocetin(58.8±21.4%)were significantly reduced in patients compared to control (62.7±6.2, 63.3±6.9, 73.8±8.3 respectively)

(P<0.001). After treatment all hemoglobin parameters and iron profiles were improved, platelet aggregation tests induced by ADP(64.78±18.25%), and epinephrine(55.47±24%) were significantly increased in patients with IDAcompared to before treatment(39.44±21.85%, 20.33±14.58%)(P<0.001).PFA 100closure time as well showed significant decreased after treatment(118.4±27.242) compared to before treatment(186.2±90.35) (P<0.05). A negative correlation between platelet aggregation induced by ADP and mean values of serum ferritin before treatment (r=0.042, P<0.05) and)was detected.
Summary / Conclusion: A mutual effect is considered between iron deficiency and platelet functions. Sublte bleeding manifestations can occur in patients with IDA with delay in platelet aggregation and prolongation in PFA-100 closure timeswhich can be reversed by iron therapy.Iron containing enzymes of the platelets including cycloxygenase and lipoxygenase might play a role.

B1828
SUCCESSFUL CHELATION THERAPY WITH THE COMBINATION OF DEFERASIROX AND DEFERIPRONE (3 PATIENTS) AND DEFEROXAMINE AND DEFERASIROX (2 PATIENTS).
Si de la Iglesia[1], A Herrera[2], B Arrizabalaga[3*], G Nuñez[4], M Orero[5], I Amarika[3], A Villegas[6, 7]
[1]Hematologia, Hospital Dr. Negrin, Las Palmas de Gran Canarias, [2]Hematologia, Hospital Virgen del Rocio, Sevilla, [3]Hospital Universitario de Cruces, Baracaldo, [4]Hematologia, Hospital Virgen del Puerto, Plasencia, [5]Hematologia, Hospital General Universitario, Valencia, [6]Hematologia, Hospital Clinico San Carlos, [7]Spanish Group of Erthropathology, Madrid, Spain

Background: Iron overload occurs commonly in patients with congenital anemias mainly as a result of the frequent blood transfusions. Without adequate iron chelation therapy, almost all patients will accumulate iron levels that are toxic to the heart, liver and endocrine glands.
Deferoxamine (DFO) has been the standard of care for transfusional iron overload for more than 40 years, although subcutaneous infusion negatively affects patient compliance. The oral iron chelators, deferiprone (DFP) and deferasirox (DFX) are effective in reducing iron burden, while at the same time they improve compliance and patients´quality of life.
Extensive long-term experience has shown that combined chelation with DFP and DFO improves cardiac function and reduces cardiac mortality. However, there are very limited data in the literature for effective combinations of two oral chelators. Two chelators can be used either sequentially (on different days) or in combination (both given on the same day).
Aims: To evaluate combined therapy with more than one chelator in 5 patients with congenital anemias transfusion-dependent and refractory severe iron overload.
Methods: Demographic data, diagnosis, prior chelation therapy, combined chelation regimens and results are listed in Table I.
Refractory iron overload was defined if ferritin levels>2000 ng/mL and/or Liver Iron Concentration (LIC) > 10 mg/g and/or cardiac T2*<20 mseg.
Results: Efficacy: After a media time of 11 month treatment of combined therapy (4-16m), ferritine level had decreased in 4 patients, from a media value of 6196 ng/mL (2600-11948) to 2808 ng/mL (1872-5360) (see Table 1).
Security: All combination regimens were very well tolerated and no kidney function alterations, arthralgias, skin reactions, neutropenias, gastrointestinal adverse effects or other safety problems were documented in none of the 5 patients. The adverse effects disappearance is probably related to the lower necessary dose of each chelator drug when prescribing it combined with other chelator drug. Patients compliance was excellent.

	DIAGNOSE	PRIOR THERAPY	PRIOR ADVERSE EFFECTS	COMBINED CHELATION	MONTHS OF THERAPY	FERRITINE ng/ml	
						BASELINE	Feb 2013
Patient 1 female/51y	hb SS Refractory iron overload LIC 19mg/g	DFO DFP	audiologic, ophthalmologic	DFP 75mg/k/d + DFX 10mg/k/(2d/w)	16	11948	5360
Patient 2 female/23y	Pyruvate Kinase deficiency Refractory iron overload LIC18mg/g	DFO DFP	gastrointestinal	DFP 75mg/k/j + DFX 10-20mg/k/d	6	2600	1872
Patient 3 male/32y	Thalassemia major Myocardial siderosis T2 *16ms	DFO + DFP DFX	gastrointestinal	DFP 75mg/k (4d/w) + DFX 30mg/k (3d/w) alternating days	4	452	
Patient 4 female/36y	Thalassemia major Refractory iron overload LIC 18mg/g	DFO DFP		DFO 30mg/k (3d/w) + DFX 30mg/k/d	18	7450	2016
Patient 5 female/35y	Thalassemia major Refractory iron overload LIC 10mg/g	DFO DFP	gastrointestinal	DFO 40mg/k (4d/w) + DFX20mg/k (3d/w) alternating days	12	2786	1964

Summary / Conclusion: The use of combination therapies for overcoming toxicity and improving efficacy over the use of single agents has been estab lished in several patiens. The combination regimen was very well tolerated and no adverse events were documented. Our patients were treated with two drugs simultaneously or in a daily alternating regimen and the combination was always very efficacious and very safe for all the patients. Larger studies are needed to know if dual-chela tor therapy at different schedules, may improve compliance and enhance iron removal if an additive or synergistic effect occurs.

B1829
PREGNANCY AND SICKLE CELL DISEASE: A SINGLE GREEK CENTER EXPERIENCE
E Vlachaki[1*], S Hissan[2], S Theodoridou[2], E Vetsiou[3], A Mamopoulos[4], N Sousos[1], I Onoufriadis[1], N Neocleous[2], P Klonizakis[1], N Gombakis[2], P Boura[1]
[1]Second Department of Internal Medicine, [2]Haemoglobinopathy Unit, [3]Second Depattment of Internal Medicine, [4]Third Department of Obstetrics and Gynaecology, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece

Background: Pregnancy in women with sickle cell disease is considered to be a challenging condition. Pain crises become more frequent during pregnancy, particularly in the third trimester. A pregnant woman with sickle cell disease is more likely to have a miscarriage, preterm labor or a low-birth-weight baby.
Aims: In the present retrospective study we report on the pregnancy course and outcome in women with sickle cell disease being treated in our hospital.
Methods: A retrospective study of the medical records from 74 sickle cell women older than 18 years (57 Hb S-Beta and 17 Hb SS) revealed 25 pregnancies characterized by 12 Hb S-Beta and 3 Hb SS haemoglobinopathy. The course and outcome of pregnancy including pain episodes and transfusions, the types of labor and delivery as well as the clinical characteristics of the neonates were evaluated.
Results: All the women were in a month scheduled come to our unit for exams during pregnancy. None of them received hydroxyurea for six months before pregnancy. Overall, in twelve Hb S-Beta haemoglobinopathy women with a maternal age between 24-36 years old, we recorded sixteen successful pregnancies and five spontaneous abortions. Conception was spontaneous in all pregnancies. All but one woman (91%) suffered from more than one pain episodes during pregnancy, were hospitalized, received analgesics therapy and were transfused when their haemoglobin level dropped to 7-8 gr/dl. Five women (41,6%) gave birth by Caesarean section. The weight of the neonates was between 2600-3200 gr. Only one neonate was pre-term due to premature rupture of membranes. Among three Hb SS haemoglobinopathy women with a maternal age between 32-36 years old, we recorded four successful pregnancies. Only one woman experienced pain episodes, hospitalized and received transfusion during pregnancy. Conception was also spontaneous. The average weight of the neonates was normal.
Summary / Conclusion: Our study suggests that pregnancy is safe and usually has a favorable outcome under close monitoring. The interesting in our study is that the women with HbS-Beta haemoglobinopathy present more complications during pregnancy than the Hb SS women despite the fact that Hb SS type is the most severe disease. The small sample size in the current study precludes any definitive conclusions.

B1830
FACTORS AFFECTING ANEMIA IN NORTHEAST THAI VEGANS
P Sanchaisuriya[1*], K Sanchaisuriya[2], K Wongprachum[2], F Schelp[1]
[1]Department of Nutrition, Faculty of Public Health, Khon Kaen University, [2]Centre for Research and Development of Medical Diagnostic Laboratories, Faculty of Associated Medical Sciences, KhonKaen University, Khon Kaen, Thailand

Background: Practicing vegan lifestyle for a long time may increase the risk of anemia due to micronutrient deficiencies, especially vitamin B12 deficiency and iron deficiency (ID).
Aims: To investigate factors attributed to anemia among northeast-Thai vegans.
Methods: A cross-sectional study was conducted at a vegan community in northeast Thailand. A total of 260 vegans (121 males and 139 females within the age range from 5 to 85 years) participated. The duration of practicing a vegan lifestyle varied from 3 months for young children to more than 30 years for the elderly. All participants were healthy based on their physical appearance and self-report. Informed consent was obtained from all participants including the guardians of all children and adolescents aged below 18 years. Hemoglobin (Hb) concentration and red blood cell (RBC) parameters were measured using an automated blood cell counter. Serum ferritin (SF) and vitamin B12 levels were determined by chemiluminescent immunoassay. Thalassemia and hemoglobinopathies were identified using standard methods including DNA analysis for a-thalassemia.
Results: Based on the WHO criteria adjusted for age and sex, 140 out of 260 (53.9%) vegans were anemic, 62 (23.9%) had ID (SF < 15 ng/ml), and 117 (45%) had vitamin B12deficiency (B12 < 160 pg/ml). Thalassemia and hemoglobinopathies were detected in 51.2 % of participants. Calculating the proportions by age revealed that 36.7% of adolescents (age 13-19 years) and 36.2% of reproductive age participants (age 20-45 years) had ID. The proportions of vitamin B12 deficiency of 54.4% and 50% in adolescents (age 13-19 years) and reproductive age (age 20-45 years) were significantly higher than in the other age groups. The highest proportion of anemia of 73.7% was found in the elderly (age > 60 years), and 35.7% of them had anemia of unknown causes. Based on a multiple logistic regression analysis, factors affecting anemia among vegans included age, sex, ID and thalassemia. No significant association was obtained for vitamin B12 status and the duration of practicing a vegan lifestyle.
Summary / Conclusion: Adolescents and reproductive age vegans are most

vulnerable not only ID but also vitamin B12 deficiency. Though participants were apparently healthy at the time of investigation, iron and vitamin B12 supplementation as well as modification of food consumption patterns might be necessary to prevent the adverse clinical outcomes due to a long term negative balance of iron and vitamin B12 status.

B1831
RENAL DYSFUNCTION MONITORING IN ADULT BETA-THALASSEMIC PATIENTS
C Grazia[1], S Giudice[1], R Rosso[1], B Ximenes[1], R Meli[1], C Conticello[1*], F Di Raimondo[1]
[1]Division of Hematology,, University of Catania, Catania, catania, Italy

Background: Iron deposition and organ failure are the most important cause of mortality and morbidity in patients with beta-thalassemia. While cardiovascular and liver damage have been frequently described, little is known about renal involvement in patients with beta-thalassemia. The main underlying cause of renal damage are chronic anemia, iron overload and chelating therapies.
Aims: The aim of this study is to evaluate renal dysfunction in adult beta-thalassemic patients with different chelating treatment.
Methods: We described the glomerular and tubular function of 64 adult beta-thalassemia (βT) patients (13 βT major, βT-M, and 51 βT intermediate, βT-I) in comparison with age matched healthy control group (25). For each patients and healthy control urinary samples were collected and analyzed (three times monthly) for protein, urine osmolality, urobilinogen, hemoglobin and NAG activity, whilst blood samples were analyzed for complete blood count, blood urea nitrogen, serum creatinine, electrolytes uric acid, albumin, total cholesterol, calcium/phosphate ratio (C/P), beta2-microglobulin, and ferritin. Patients were divided into 5 groups depending on the chelating therapy they received: group I with deferoxamine (DFO) and deferiprone (P) chelation (n=7, 2 βT-M and 5 βT-I), group II with deferasirox (E) chelation (n=20, 8 βT-M and 12 βT-I), group III with DFO chelation (n=11, 1 βT-M and 10 βT-I), group IV with P chelation (n=5, 2 βT-M and 3 βT-I) and group V without any chelation therapy. The patients included in the study had either tubular dysfunction or glomerular dysfunction.
Results: Data demonstrated that glomerular renal dysfunction is a common complication (52%) of βT-M and βT-I, independently from the chelation therapy. Moreover, renal tubular dysfunction represents the majority of renal damage and NAG activity evaluation allows to detect early renal tubular damage since the alteration of its activity precedes other markers of renal damage. Noteworthy, tubular injure depends on chelating therapy: patients receiving DFO and deferiprone (43%) or deferoxamine alone (36%) are less damaged than patients receiving deferasirox (75%) or deferiprone (80%) alone.
Summary / Conclusion: Renal tubular dysfunction represents the majority of renal damage in thalassemic patients and the monitoring of this renal dysfunction my be made by NAG activity evaluation since the alteration of NAG activity precedes other markers of renal damage.

B1832
MEDICAL RADIATION EXPOSURE IN SICKLE CELL DISEASE PATIENTS WITH FREQUENT HOSPITAL ATTENDANCE FOR PAINFUL CRISES
J O'Nions[1], G Cho[1*]
[1]Haematology, Central Middlesex Hospital, North West London Hospitals NHS Trust, London, United Kingdom

Background: Patients with Sickle cell disease (SCD) experience frequent episodes of painful vaso-occlusive crises, often requiring emergency department (ED) attendance, involving radiographic imaging such as chest x-rays (CXR), skeletal x-rays and CT scans. Many SCD patients frequently attending our ED are young adults. Due to the increased risk of malignancy from medical radiation exposure, we analysed the numbers of radiographic studies performed and the resulting radiation exposure in this group. To our knowledge, this is the first such study in adults with SCD.
Aims: We evaluated the number of ED attendances and radiographic studies performed for young adult SCD patients, assessing radiation exposure and investigating strategies to minimise this.
Methods: We reviewed the electronic patient records for 11 adult SCD patients who frequently attend ED for painful crises. We determined the number of hospital admissions and number and type of radiographic studies performed per patient from 2007 to January 2013. We analysed the maximum numbers of studies performed in 1 or 12 months per patient and calculated the average rate of CXR exposure to allow comparison despite different follow-up durations. We also calculated the total radiation dose received.
Results: 11 patients were evaluated, aged 19-37 years (mean 25), with 840-2112 days follow-up (mean 1703 days). 62.5% patients were female and 37.5% male, 73% patients had HbSS SCD, 18% HbSC and 9% HbS/beta-thalasseamia. Hospital admissions during the study period ranged from 11-42 (mean 22), with a maximum of 18 in any 12 month period. A total of 377 radiographic studies were performed in the study period (range 13-64 per patient); most commonly CXRs, totalling 304 (mean 27.6 per patient, range of 8-58). Other studies included AXRs (6) and skeletal films (65), including spinal, hip, shoulder and extremity. The highest numbers of CXRs for one patient in a 1 and 12 month period were 6 (mean 3.1) and 31 (mean 11.5) respectively. This corresponded to an average CXR rate of 6.2 per year (range 1.6-13.1) and 0.5 per month (range 0.13-1.1), giving an exposure rate of 0.124 mSv per year (range 0.032 - 0.262). The maximum radiation dose received by one patient from plain x-ray studies was 0.62mSv in a year (0.12 mSv in a month). The average total exposure over the study period was 0.55mSv (range 0.16-1.16). We extrapolated the expected CXR and radiation exposure over 10 years as 62 CXRs and 6.2mSv per patient.
Summary / Conclusion: Patients with SCD who experience frequent painful crises are exposed to increased medical radiation , particularly from CXRs. Many of these patients are young adults and females, and iatrogenic risk of malignancy is increased in this population therefore it's essential to limit this exposure. If imaging continues at the current average rate, patients will be exposed to >6mSv in 10 years from CXRs alone (approximately 1 CT scan). Currently, there are no set criteria for appropriate imaging requesting. Principles such as reviewing recent imaging, only requesting CXRs in the presence of chest signs, symptoms or fever and carefully considering the indication for skeletal imaging (rarely of diagnostic benefit in early sickle bone complications) could help reduce radiation exposure but can be easily forgotten in a busy ED.

B1833
CHALLENGES AND IMPACT OF INTRODUCING AN INTEGRATED CLINICAL PATHWAY AT THALASSEMIA CENTRE – DUBAI
K Belhoul [1], S Darwazeh[1], M Bakir[1*], L Saldanha[1]
[1]Thalassemia centre , Dubai Health Authority , Dubai, United Arab Emirates

Background: Dubai thalassemia centre was established in 1995 to meet the increasing needs of patients with β-Thalassemia major in UAE. In May 2010 Thalassemia centre has developed the first integrated clinical pathway (ICP) to standardize care and to facilitate the use of guidelines. The authors believe that this is the first report of such an occurrence.
Aims: To describe the challenges and the impact of introducing an ICP to guide the care of the chronically transfused β-Thalassemia major patients.
Methods: We began in January 2010 with a team being created to investigate and adapt a methodology that meets the specific needs of the centre. Series of educational and orientation sessions involving nurses and physicians were held. Chronic blood transfusion program was selected being high volume, high risk and high cost process. The chosen process of care was reviewed against the guidelines. The various aspects in the process that were challenging and needed improvement or monitoring were included. Patients' education and medication compliance monitoring were thoroughly stressed throughout the pathway. Prior to pathway implementation, staff roles were clearly defined and both physicians and nurses took part in the process. The pathway was finally implemented in May 2010 and was evaluated through variance analysis, patients' satisfaction, patients' awareness and staff's satisfaction. Variance analysis was the tool used to monitor variation in chronic care management. The data from 2010 through 2012 was analyzed.
Results: The ICP introduction was met with physician resistance. The format had to be acceptable to physicians and nurses and good enough to be used as permanent medical record. Another major challenge was developing a variance reporting tool that identifies appropriate variances and that is easy to understand and complete by the staff. Upon implementation, we were challenged by the huge number of variances being reported without knowing what level of variance is meaningful to our practice. We couldn't find a leading practice to help defining thresholds or ranges so we tweaked these ranges as appropriate to support proper analysis and decision-making. A variance of 3% or less occurrence was considered minor, while an occurrence of 15% or more was considered significant. Monthly analysis of variances was time consuming and not useful, so we decided to perform annual analysis. Patients' visits guided by the ICP went from 3171 in 2010 to 5639 in 2012. Significant variances with occurrence rate of 15% or more declined from 76.9% in 2010 to 16.8% in 2012. Reduction in significant variances occurrence was considered as an indicator of a more uniform care provision. Patients' satisfaction data in 2012 showed significant improvement in patients' satisfaction with counseling sessions and with the time spent with health care provider when compared to 2010; from 68% to 92% and from 87 % to 98% respectively. Patients' awareness of the disease and its complications has improved from 85% in 2010 to 95 % 2012. Staffs' satisfaction survey conducted at the end of 2010 revealed 98% satisfaction with the ICP.
Summary / Conclusion: This report has provided evidence that introducing an ICP to guide the care of β-Thalassemia major patients undergoing chronic blood transfusion may improve the quality of care and patient's satisfaction. Analyzing the impact of the ICP on patients' clinical outcomes is yet to be studies as well as discovering the root causes for the repeatable elements that lead to positive variances.

B1834

PARTNER TESTING FOR PREGNANT WOMEN AT RISK AND PRE-NATAL DIAGNOSIS OF SICKLE CELL DISEASE. A SINGLE CENTRE 5 YEAR EXPERIENCE.

T Ahmed[1*], S Patel[1], I Khan[1], R Nzouakou[1], D Tsitsikas[1], R Amos[1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Pregnant women suffering of sickle cell disease (SCD) or are carriers of the HbS gene or other haemoglobin variants that combined with HbS can give rise to the sickle cell phenotype, are at risk of having a child affected by SCD if their partner is also affected in a similar way. It is therefore essential for partners of such women to be tested. Despite this, the number of partners testd remains unsatisfactory. Pre-natal diagnosis (PND) can help couples decide the future of the pregnancy but the decision to proceed with it depends on the ethical, cultural and social background of the family.
Aims: To assess the level of paternal testing in pregnancies where the mother is at risk of having a child with SCD and proportion of "at risk" pregnancies proceeding to PND in a London area with high prevalence of SCD..
Methods: Retrospective analysis of maternity data at Homerton University Hospital over a five year period (2007-2012).
Results: There was a mean of 5536 bookings / year (range 5036 – 5909) (table). The mean number of women at risk every year was 445 (8%). The number of partners tested improved over the years but remains less than 50%: Only 49 partners of the 400 women-carriers (12%) were tested in 2007-2008 but this figure picked in 2010-2011 at 229 partners of 492 women-carriers (46.5%) and the latest from 2011-2012 was 186 partners of 417 women-carriers (44.6%). The pregnancies "at risk" identified after partner testing ranged from 16% to 24.3%. No prenatal diagnosis (PND) was attempted in 2007-2008. Subsequently more "at risk" pregnancies as identified after partner testing underwent PND with a peak of 36% in 2008-2009. The number of terminations of pregnancy (TOP) after PND ranged from 0 to 25%. The number of affected children as identified by PND ranged from 17% to 50%.
Summary / Conclusion: We find a relatively stable number of bookings / year in our institution with a stable number of women who are at risk of having an offspring affected by SCD (7.1 – 9.1%, mean 8%). Even though the number of partners tested in recent years has increased, it remains below the UK average as less than half of partners are tested. Several social, cultural or religious factors may hinder the process but a more rigorous approach in identifying partners and pursuing their timely testing is essential. An increasing number of couples at risk seek PND.

B1835

STUDY OF THE RENAL FUNCTIONS IN BETA (B)-THALASSEMIA (B-THALASSEMIA MAJOR, B-THALASSEMIA INTERMEDIA AND B–THALASSEMIA MINOR) AND COMPARISON WITH THE TOTAL ANTIOXIDANT CAPACITY

E UZUN[1], Y IŞIK-BALCI[2*], S YÜKSEL[3], H AYBEK[4], B AKDAĞ[5]
[1]Department of Pediatrics, [2]Department of Pediatric Hematology, [3]Department of Pediatric Nephrology, [4]Department of Biochemistry, [5]Department of Biostatistics, Pamukkale University, Faculty of Medicine, Denizli, Turkey

Background: Beta-Thalassemia is a chronic disorder, characterized with defective hemoglobin synthesis and ineffective erythropoiesis, causing microcytic anemia. It is divided into three groups; thalassemia major (TM), thalassemia intermedia (TI) and thalassemia minor. The iron that accumulates in beta-thalassemia as a result of the increased iron absorption in the intestines, hemolysis and erythrocyte transfusions causes functional impairment in the liver, pancreas, and heart, as well as in the kidneys, particularly in the proximal tubules, and results in alterations in the concentrations of some substances in the urine and blood. Although the pathological effects on the organs including heart, endocrine glands and liver have been focused on till now, there are a limited number of studies concerning the kidneys, which are important organs of the body.
Aims: The aim of this study was to measure the renal functions and the antioxidant system established in the body against the oxidant substances in the β-thalassemia group and the healthy control group, and to compare the similarities and differences of the groups.
Methods: The study enrolled total 49 transfusion-dependent TM patients (23 boys, 26 girls), 18 TI patients (11 boys, 7 girls), and 51 thalassemia minor patients (28 boys, 23 girls), aged between 4-17 years. The control group consisted of age and sex matched 51 healthy individuals (29 boys, 22 girls). Informed consent form was obtained from the parents. Blood and urine samples were collected and hemogram parameters were studied, sodium, potassium, magnesium, phosphorus, uric acid, protein and creatinine were measured in serum and centrifuged urine samples; in addition, total antioxidant capacity (TAOC), cystatin-C were studied in serum samples, and retinol binding protein (RBP), α-1 microglobulin (α-1MG) and β-2 microglobulin (β-2MG) were studied in urine samples. The tubular reabsorption and excretion was calculated from the results obtained, and the glomerular filtration rate (GFR) was calculated using the Shwartz formula.
Results: FENa values in TM and TI groups were found higher compared with the thalassemia minor and the control groups. No differences were found between the groups in the urinary potassium excretion (FEK), urinary magnesium excretion (FEMg) and the tubular phosphorus re-absorption (TPR). The uric acid-GFR values were significantly higher in the TM group, compared to the thalassemia minor and control groups. RBP was significantly higher in the TM group compared to the control group, while the urinary β-2MG was significantly higher in the TM group compared to the thalassemia minor and the control groups. No differences was found between the groups in GFR, while the mean values of cystatin-C were similar in the thalassemia minor and control groups and in TM and TI groups respectively, and the values of TM and TI were higher compared to the other two groups. The urinary protein/creatinine ratio was found higher in the TI and TM groups. Additionally, a negative correlation between TAOC and FENa, and a positive correlation between ferritin and FENa was found. There was a negative correlation between α-1MG and TAOC, while there was a positive correlation between α-1MG and ferritin. Negative correlation was found between cystatin-C ,ferritin and TAOC.
Summary / Conclusion: In conclusion, both tubular and glomerular functional renal impairments can be found in varying levels in all three β-thalassemia groups. FENa can be considered as a marker of the tubular function in all the β-thalassemia types, uric acid-GFR value as an indicator of early tubulopathy in TM and TI, α-1MG and β-2MG as parameters strongly related with the oxidative damage with ferritin in TM and TI; and RBP can be considered as a parameter indicating the relation of the tubular functions with iron accumulation. However, TPR and GFR may not be good markers. Cystatin-C can be used as a perfect marker of the glomerular functions in all the β-thalassemia types. Urinary protein/creatinine ratio can be used to show the relation between the glomerular function and the iron accumulation in the TM and TI groups. Additionally, we have the opinion that studies in molecular levels could provide important data.

B1836

EVALUATION OF IMMUNE STATUS IN IRON DEFICIENCY ANEMIA

S Daghbashyan[1], V Khachatryan[2*], K Israelyan[3], A Pepanyan[3]
[1]Chef of Haematology Center, [2] Outpatient department, [3]Department of Science, Center of Haematology, Yerevan, Armenia

Background: Zinc and iron deficiency significantly disturbs the structural and functional state of erythrocytes as well as of immunocompetent cells. In the recent years, a special significance is attached to the role of microelements status as a regulator of immunologic homeostasis. Development of iron deficiency aggravated with zinc insufficiency (critical level in serum equal to 12mmol/l) brings to deep disorders of immune system, cellular and humoral links of immunity with development of secondary immunodeficiency. It is well known that the iron and zinc disbalance regulates the activity of T and B-lymphocytes. In the process of proliferation and differentiation of lymphocytes the zinc containing enzyme ecto-5'-nucleotidase (e5N, CD73) takes part.
Aims: The aim of the research was to study the changes of immunoregulatory protective system in iron deficiency anemia aggravated by zinc insufficiency.
Methods: The research group consisted of female patients aged from 20 to 55 years. The average age of the patients was 37, 0 ±1, 65 years. The analysis was conducted between the control and two groups of patients with iron deficiency anemia with various degrees of zinc insufficiency (in group 1 the content of zinc in blood serum was <12mmol/l, in group 2 - >12mmol/l).
Results: We have found out a significant decrease in the e5N activity in membrane lymphocytes in group 2 patients (Zn<12mmol/l). It should be also noted, that acute decrease of immune index CD4/CD8 is typical for these patients.
The obtained results demonstrate presence of a positive correlation between T-cellular immunosuppression and activity of e5N (CD73) in case of development of iron deficiency anemia and zinc insufficiency.
Summary / Conclusion: New possible ways of regulation of ineffective erythropoiesis in iron deficiency anemia are discussed.

B1837

HIDDEN VITAMIN B12 DEFICIENCY

R Hasanato[1*]
[1]Clinical Biochemistry, Department of Pathology, King Khalid University Hospital, King Saud University, RIYADH, Saudi Arabia

Background: Mild to moderate vitamin B12 (Cobalamin) deficiency is common due to inadequate intake of animal products, gastro-intestinal disorders (including inefficient digestion, parietal cell disorders), systemic comorbidities such as autoimmune diseases, and medications including proton-pump inhibitors and metformin. In most cases, hematological values are not affected due to the wide range of normal values and to the presence of other hematological disorders such as thalassemia trait and co-existence of iron deficiency which prevent increase in MCV values beyond normal range. In most cases, patients suffer from vague, non-specific neurological and/or psychiatric symptoms such as fatigue and mode disturbance. For all of these reasons, vitamin B12 deficiency is commonly overlooked and the diagnosis is missed or delayed
Aims: The aim of this retrospective study was to find the prevalence of hidden

Vitamin B12 deficiency among patients with normal hematological finding
Methods: We reviewed Vitamin B12 results that were tested from 1st of January to the 30th of December 2012. The total number cases was 2698 patient
Results: we found 3 cases with severe B12 deficiency and megaloblastic anemia (B12 < 22 pmol/l), 380 patients (14%) with moderate B12 deficiency (B12 =45-140 pmol /l), and 2315 with normal or elevated B12 (145-1400 pmol/l). We compared B12 level, Hb and MCV between the 380 patients with Vitamin B12 deficiency (B12 45-140 pmol/l) 124 males and 256 females, aged 36.01±18.1 years and 418 patients with normal Vitamin B12 level (200-400 pmol/l),157 males and 261 females, aged 39.7 ±22 years. There was no difference in Hb or MCV between the two groups. However, there was a significant difference in Vitamin B12 values, 111.32±19.72 pmol/l versus 273.39±54.05 pmol/l. Despite normal Hb and MCV values in both groups, the difference in B12 level was significant, indicating that vitamin B12 deficiency may exist despite normal hematological parameters.
Summary / Conclusion: Moderate B12 deficiency is common without hematological; manifestations. Diagnosis is commonly missed or delayed. Therefore due to lack of awareness and clear symptoms and signs., physician needs to be aware of hidden B12 deficiency

B1838
PREVALENCE OF 25-HYDROXYVITAMIN D DEFICIENCY IN KOREAN PATIENTS WITH ANEMIA
E Yoo[1], H Cho[1*]
[1]Department of Laboratory Medicine, Konyang University Hospital, Daejeon, Korea, Republic Of

Background: Vitamin D deficiency is a very common health problem in Korea. Vitamin D is suggested to play an important role in non-skeletal functions, including cellular proliferation and differentiation, muscle function, immunity, and erythropoiesis. Recent studies have reported that vitamin D deficiency is associated with anemias of iron deficiency (IDA), chronic disease (ACD), and inflammation.
Aims: This study investigated the prevalence of vitamin D deficiency in Korean anemia patients and analyzed the association between vitamin D status and specific anemia subtypes.
Methods: We included 200 anemic patients (median 66 years, range 19~91 years) and 300 nonanemic controls (median 65 years, range 23~91 years). Anemia was defined according to WHO criteria. Serum 25-hydroxyvitamin D [25(OH)D] was measured using electrochemiluminescence immunoassay. Deficiency of 25(OH)D was defined as <20 ng/mL and severe deficiency was defined as <10 ng/mL. We compared serum 25(OH)D levels based on the presence and subtypes of anemia.
Results: There was 90% (179/200) and 87% (262/300) 25(OH)D deficiency in the anemic (median Hb, 9.7 g/dL) and nonanemic groups (median Hb 13.8, g/dL), respectively. Severe 25(OH)D deficiency was significantly higher in the anemic group than in the nonanemic group [43% (85/200) vs. 13.7% (41/300), *P*<0.0001]. The odds ratio for severe 25(OH)D deficiency in anemic patients was 4.67 (95% confidence interval, CI 3.03–7.20, *P*<0.0001). The 25(OH)D deficiency prevalence was not different between IDA and ACD groups. However, severe 25(OH)D deficiency was significantly higher in the ACD group than in the IDA group [50.8% (61/120) vs. 34.3% (24/70), *P*=0.03].
Summary / Conclusion: This study demonstrated that severe vitamin D deficiency is associated with anemia in Korea. Although vitamin D deficiency is also very common in nonanemic Koreans, anemia is related to a poor vitamin D-deficient status. Multiple factors, including poor nutritional status and the potential roles of vitamin D in inflammation and erythropoiesis may be considered.

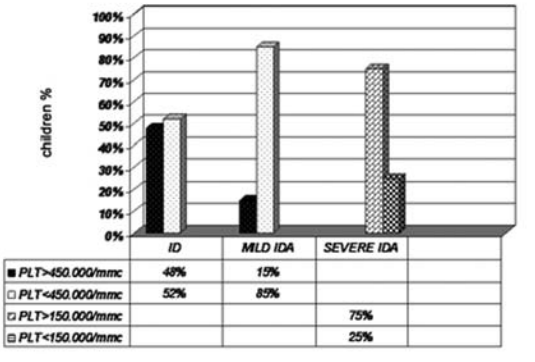
B1839
ORAL IRON CHELATION ENHANCES PYRIDOXINE EFFECT IN ONE PATIENT WITH INHERITED SIDEROBLASTIC ANEMIA
A Aly[1*], H AlZubaidi[2], E Al Zaabi[1]
[1]Pathology & Medical Laboratory Department, [2]Internal Medicine/Hematology Oncology, Mafraq Hospital / UAE, Abu Dhabi, United Arab Emirates

Background: Inherited Sideroblastic anaemia is a rare disease, characterized by decreased haem synthesis and mitochondrial iron overload, which are diagnosed by the presence of ringed sideroblasts in the bone marrow aspirate.
Aims: In our study we aim to evaluate the effect and safety of oral iron chelation in lowering the ferritin level and improving the response to pyridoxine treatment in a case of inherited sideroblastic anemia
Methods: Serum ferritin , Hb ,LFT,creatinine & urine protein were done as baseline and every month after initiation of oral iron chelation with deferasirox along with pyridoxine treatment for one year..The starting deferasirox dose was 10 or 20 mg/kg per day depending on baseline iron burden. Dose adjustments were permitted based on serum ferritin trends (rises of >=1000 µg/l on 2 visits or >2500 µg/l without decreasing trend) and reduced for elevated levels of creatinine, urinary protein and transaminases, ,in response to adverse events and drop of Hb level.
Results: An improvement to pyridoxine treatment noted and elevation of Hb level to 113g/L and drop of S ferritin to 1076ug/L compared to the baseline of Hb level of 80g/L and S ferritin level of 4000ug/L. In general, adverse events were mild and consistent with that documented throughout the registration studies of deferasirox. We noticed that the maximum enhancement of pyridoxine effect, in the form of higher Hb concentration ,seen with the lower dose of deferasirox 10mg/kg.
Summary / Conclusion: Inherited sideroblastic anaemia usually have hypochromic and microcytic red cells, reflecting a reduction of haem synthesis in the erythroid precursors. In those not requiring blood transfusions, transfusion-independent iron loading may occur, usually in adulthood, as in thalassemia intermedia because of ineffective erythropoiesis and of increased intestinal iron absorption. Iron depletion may be an effective treatment in inherited siderblastic anemia and can be undertaken after pyridoxine supplementation, when the haematological response is stable. Iron chelation with deferasirox proved to be a safe and effective means of substantially lowering ferritin levels in case of transfusion independent inherited sideroblastic anemia.

B1840
ROLE OF IRON DEFICIENCY IN CHILDREN WITH THROMBOTIC EVENTS.
M Ferrara[1*], f bertocco[1], l incarnato[1], d ferrara[1], l capozzi[1]
[1]pediatric, SUN, napoli, Italy

Background: Iron deficiency (ID) and iron deficiency anaemia (IDA)have been associated with increased risk of developing thrombotic events in both children and adults.
In children with ID reactive and often severe thrombocytosis was frequently observed even if the mechanisms causing thrombocytosis are not completely understood.
Aims: The aim of this study is to evaluate the effects of thrombocytosis due to ID or IDA on development of venous thromboembolism (VTE) in children and possible interaction with some genetic risk factors .
Methods: In the last 7 years we have studied 125 children, of both sexes aged between 5 and 15 years, affected by ID or IDA.
Diagnosis of ID and IDA was performed on the basis of WHO criteria for Hb, MCV, serum ferritin and transferrin saturation values. Secondary thrombocytosis was diagnosed at platelet counts ≥ 450.000/mmc, without infectious diseases, while thrombocytopenia at platelet counts ≤ 150.000/mmc.
Polymorphisms in MTHFR C-677-T, PT G20210A and G1691A FV Leiden have been also assayed.
Informed consent was obtained from parents. Principles outlined in the Declaration of Helsinki were followed. Procedures followed were in accordance with the ethical standards.
Results: In our cohort of patients 70 children had ID (Hb11.5±0.5g/dl), 35 mild IDA(Hb 9,5±0,2 g/dl) and 20 severe IDA(Hb 6.5±0.4g/dl). Furthermore our data showed that 48% of patients with ID had secondary thrombocytosis (PLT 650.000±110.000 /mmc) as well as 15% of children with mild IDA (PLT 520.000±55.000/mmc) while 25% of patients with severe IDA showed mild thrombocytopenia (PLT160.000±20.000/mmc) (Graph 1). Two female patients, aged 12 and 15 years respectively, with ID and thrombocytosis (PLT 620.000 and 580.000 /mmc), werereferred to us because they had developed VTE characterized by deep venous thrombosis (DVT) particularly saphaenous vein thrombosis, confirmed by Doppler ultrasonografy and magnetic resonance.
In both casesthe G1691A polymorphism in the Factor V Leiden gene (FV) in heterozygous form was detected.

graph 1 : Platelet count in children whit ID, mild IDA, severe IDA



Summary / Conclusion: Our data show that thrombocytosis is frequently associated with ID or mild IDA while severe IDA is associated with thrombocytopenia.. So normal iron levels are required to prevent thrombocytosis by inhibiting thrombopoiesis but a minimum amount of iron is required to maintain platelet production. Furthermore ID could cause increased oxidant stress with tendency to platelet aggregation. We observed 2 cases of VTE in adolescent females with secondary thrombocytosis associated with G1691A polymorphism of FV

Leiden in heterozygous form. Some genetic factors at homozygous and/or compound heterozygous state have been frequently associated with a higher risk of thromboembolic events. We suggest that the interaction between thrombocytosis secondary to ID and genetic risk factors, even at heterozygous state, may trigger hypercoagulability.

B1841

NEW INSIGHT ON IRON STUDY IN MYELODYSPLASIA

N Husseiny[1*], D Mehany[2]
[1]Heamatology Department, [2]chemical pathology Department, Kaser El Eini University, Cairo, Egypt

Background: Hepcidin plays a pivotal role in iron homeostasis. It is predominantly produced by hepatocytes and inhibits iron release from macrophages and iron uptake by intestinal epithelial cells. Competitive-ELISA is the current method of first choice for the quantification of serum hepcidin, because of its low limit of detection, low costs, and high throughput.
Aims: This study aims to discuss the role of hepcidin in iron overload pathogenesis in MDS cases recently diagnosed.
Methods: Methods: The study included 21 recently diagnosed MDS cases and 13 healthy control individuals.
We used ELISA technique for hepcidin assay in blood. In this work, we chose newly diagnosed MDS cases within 6 months of symptomatology to limit impact of over-transfusion on hepcidin level. And to abolish effect of acute transfusion of hepcidin expression, samples were drawn at least five days after last transfusion. All subjected to ferritin, hepcidin and soluble transferrin receptor assay using ELISA.
Results: This study included 21 MDS patients recently diagnosed in the Clinical Haematology unit of Cairo University (average 6 months since onset of symptoms) and 13 age and sex matched controls. Mean age was 56±10.2 years. Fifty seven percent were males and 43% were females. Mean HB level of MDS cases was (6.8 +/-4.8) gm/L. Mean blood transfusion was 6 units (3-9 units). The hepcidin mean in MDS was 55.8+/-21.5 ng/ml while in the control was 19.9+/- 2.6 ng/ml. Mean STF in MDS was 45.7+/-8.8 while the control was 31.1+/-5.6. Mean Ferritin in MDS was 539.14+/- 83.5 while in the control was 104.6+/- 42.9. Though the mean hepcidin, STF and ferritin were higher in MDS cases in comparison to the control, only ferritin was statistically significant among the two groups (P<0.005). Correlation analysis between hepcidin and other parameters was statistically significant with STF (r=0.45; P:0.039). No difference between males and females in hepcidin though it was less in males in comparison to females (47.9+/-27.6 vs 66.7+/-35.7) p value >0.05.
MDS patients were classified according to type of MDS; 8 cases with RCMD, 7 cases with hypoblastic MDS and 6 cases with RAEB. No differences among the three groups in hepcidin, STF or ferritin (p value>0.05). Mean hepcidin/ferritin ratio in MDS cases was higher than control (0.48+/ 1.2 vs 0.32+/-0.19) but statistically not significant (p value>0.6).
Summary / Conclusion: we can conclude that there is no correlation between hepcidin and serum ferritin in MDS cases and so hepcidin may not be a main player in iron overload in MDS.A possibility of peripheral unresponsiveness to hepcidin in MDS or failure of production may be the underlying cause but further studies are required.

B1842

PRESCRIPTION OF APPROPRIATE OPIATE ANALGESIA AND OTHER ESSENTIAL MEDICATION FOR PATIENTS WITH SICKLE CELL DISEASE PRESENTING WITH ACUTE VASOOCCLUSIVE CRISIS TO THE EMERGENCY DEPARTMENT.

I Khan[1*], S Patel[1], R Nzouakou[1], D Tsitsikas[1], R Amos[1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Acute vasoocclusive crisis is the most common hospital presentation of patients with sickle cell disease (SCD). Prompt and adequate analgesia, often with parenteral opiates, is essential. At Homerton University Hospital we have a day unit dedicated to the acute management of patients with SCD. However, the day unit operates only during week days and from 9am to 7pm. Outside those hours and at weekends, sickle cell patients present to the emergency department (ED). Each of the patients known to the hospital has an individualised analgesia protocol in place to help guide ED and acute medical admitting teams on the ideal analgesic regimen.
Aims: To assess whether: 1) prescription of opiate analgesics is safe and appropriate and 2) other essential drugs are being prescribed correctly for patients with SCD being admitted to hospital from the ED. We also wanted to assess whether any initial mistakes or omissions were identified and corrected at the post-take medical ward round and after the haematology ward round.
Methods: We retrospectively examined the drug charts from the last 28 SCD admissions for vasoocclusive crisis that originally presented to the ED. We had initially aimed for the last 30 admissions, but 2 of the required drug charts were missing. Data were collected on what opiates at what doses and what combinations were prescribed, prescription of anti-emetics, anti-histamines, laxatives, folic acid, penicillin, simple analgesics, as well as hydroxyurea and chelating agents when applicable and regular prescription medications.
Results: Opiate prescription by the admitting junior doctor was not in accordance with the individualised protocol in 9 (32%) patients, and was potentially unsafe in 3 (11%). All three "unsafe" opiate prescriptions involved simultaneous prescription of a short acting opiate by two different routes of administration One unsafe combination of prescribed opiates (33%) was identified and corrected at the post-take medical ward round. 100% of opiate prescriptions could be considered safe after the patients were seen by the haematology team. Regular anti emetics, anti - histamines and laxatives were not prescribed by the admitting team for 8 (29%), 8 (29%) and 10 (35%) patients respectively. These were corrected in2, 1 and 5 cases respectively after the post-take medical ward round, and after the patients were seen by the haematology team there was only 1 patient with no prescribed anti-histamines and 1 without laxatives. Folic acid, hydroxyurea and penicillin V were appropriately prescribed by the admitting team in 26 (93%) of cases. However, other regular prescription medications were left off the drug chart in 6 (21%) of cases on admission. Missed drugs were boarded in 50% of cases at the post-take ward round and 100% of cases by the haematology team. None of the assessed patients was on chelation therapy.
Summary / Conclusion: Patients with SCD are often admitted to hospital for management of a vasoocclusive crisis after presenting to the ED. Individualised patient protocols devised by the haematoligsts are essential and should be made readily accessible to all relevant staff. Even with such protocols in place, the initial management differs and can sometimes even be unsafe. Furthermore, other essential medications to minimise opiate side effects are underprescribed. This is likely to result in sub-optimal management of a crisis, longer hospital stay and higher probability of related to opiate side effects.

B1843

TOLERABILITY, SAFETY AND EFFICACY OF RECOMBINANT ERYTHROPOIETIN TREATMENT IN PATIENTS WITH SICKLE CELL DISEASE: A SINGLE CENTRE EXPERIENCE.

R Nzouakou[1*], S Patel[1], I Khan[1], D Tsitsikas[1], R Amos[1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Long-term erythropoietin (EPO) is being increasingly used in the management of patients with sickle cell disease (SCD). Its indications vary and can be used alone or in combination with a disease modifying therapy; hydroxyurea (HU) or transfusion. HU and EPO are more effective for treating patients with sickle cell disease who also have kidney disease or pulmonary hypertension.
Aims: To assess the tolerability, safety and efficacy of EPO in patients with SCD in our institution
Methods: This is a retrospective data analysis of patients with SCD treated with EPO at Homerton University Hospital
Results: Eight patients have received EPO to date (Table). The median age was 43.7 year-old (range 26-78) and the median level of endogenous EPO was 52.4 iu/L (9.8 – 75.1 iu/l). For 4 patients with secondary iron overload, the indication of EPO was to reduce the frequency of transfusion (one of them had chronic renal impairment); for 3 other patients, it was to gain the synergistic effect of combined therapy with HU and for the last patient, EPO was introduced because of his reluctance to start a formal transfusion programe or HU. The median dose of EPO was 30µg (30 – 40 µg). It was planned to administer 30µg EPO weekly at the initiation for all of them but for 4 patients, the dose was increased to 40µg and for 3 other patients, the frequency of administration was slowed down (2 to 3 weeks) due to high haemoglobin levels. Three patients stopped the treatment within 4 months (2 were having HU and one on transfusion programme) due to non-compliance of blood tests monitoring. There was no significant increase in the blood pressure or other side effects reported for any of the patients while on treatment with EPO. For 3 patients having transfusion, EPO allowed us to slow down the frequencies of transfusion from 4 weeks to 5 - 6 weeks. For the last patient with EPO alone, the advantage was marginal despite the fact that he was using it weekly. The median Hb level 90 days after the initiation of EPO was not significantly different (7.7 vs 8.2; P=0.5), which was expected because of a fix target of Hb levels in 4 patients on transfusion programme. Inversely, the median of HbF level was significantly higher after 90 days of EPO treatment (2.4 % vs 3.5 %; P<0.01), which tend to correlate with the fact that EPO is involved in HbF synthesis.
Table: EGFR = estimated glomerular filtration rate. * Normal range 3.7 – 31.5iu/l
Summary / Conclusion: In our experience, EPO appears to be safe in patients with SCD. We saw a modest improvement in some of the parameters measured but our sample is too small to draw any conclusions. Even though there were no side effects reported, some patients found it difficult to adhere to the administration schedule or its necessary monitoring, making poor compliance the main factor that would hinder its wider use.

B1844

THE 12 MONTHS FOLLOW-UP RESULTS FROM A COHORT OF PEDIATRIC PATIENTS WITH HEMOGLOBINOPATHY AND USING ORAL IRON CHELATOR FOR TRANSFUSIONAL HEMOSIDEROSIS IN TURKEY

B Antmen[1*], Z Karakas[2], G Oktay[3], E Kurtoglu[4], G Aydogan[5], M Akın[6], Z Salcioglu[5], S Unal[7], C Vergin[8], E Kazanci [9], U Caliskan [10], S Bayraktaroglu [11], M Berktas [12], K Organ [11], M Yesilipek [13]
[1]Acibadem Hospital, Adana, [2]Istanbul University, Istanbul, [3]Antakya State Hospital, Hatay, [4]Antalya T&R Hospital, Antalya, [5]Kanuni Sultan Suleyman T&R Hospital, istanbul, [6]Denizli State Hospital, Denizli, [7]Mersin University, Mersin, [8]Behcet Uz Pediatric Hospital, İzmir , [9]Dortcelik Pediatric Hospital, Bursa, [10]Selcuk University, Konya, [11]Novartis Pharmaceuticals, [12]Yeditepe University Pharmacoeconomy and Pharmacoepidemiology Research Center, istanbul, [13]Akdeniz University, Antalya, Turkey

Background: Management of the transfusional iron overload (TIO) is still a challenge in treatment of hemoglobinopathies. The outcomes of chelation therapy for TIO show remarkable variation across geographical regions and socialeconomic status. The differences between efficacy, safety, tolerability and adherence profiles of chelators contribute the variation.
Aims: A nation-wide prospective, multi-center, non-interventional study in Turkey is still ongoing to evaluate the burden of TIO and its treatment with oral iron chelators (OIC) in patients with beta-thalassemia major (bTM) or sickle cell anemia (SCA). This abstract aims to represent 12-months follow-up results of the study.

	Baseline (n=476)	6. month (n=459)	12. month (n=420)	P value
Hemoglobin (g/dL)				
DFX (n=436) - mean (SD)	9.0 (1.2)	8.9 (1.1)	8.9 (1.1)	0.161
DFP (n=40) - mean (SD)	9.0 (1.2)	9.3 (1.2)	9.2 (1.0)	0.347
Serum ferritin (ng/mL)				
DFX (n=436) - mean (SD)	2070.0 (1318.5)	1940.9 (1412.4)	1746.4 (1213.5)	<0.001
DFP (n=40) - mean (SD)	2534.4 (1377.2)	2317.1 (1213.4)	2205.3 (1115.2)	0.697
ALT (U/L)				
DFX (n=436) - mean (SD)	34.8 (32.0)	35.9 (36.1)	32.1 (34.1)	0.341
DFP (n=40) - mean (SD)	39.4 (46.9)	37.0 (30.9)	30.8 (24.2)	0.651
Creatinine (mg/dL)				
DFX (n=436) - mean (SD)	0.41 (0.14)	0.41 (0.13)	0.41 (0.12)	0.614
DFP (n=40) - mean (SD)	0.40 (0.09)	0.43 (0.11)	0.44 (0.10)	<0.001

DFP: deferiprone, DFX: deferasirox, SD: standard deviation

Methods: The bTM or SCA patients with 2–18 years of age suffering from TIO and under OIC treatment have been included and are still being followed (planned follow-up time 3 years). The data about clinical and demographic characteristics of the patients, comorbidities, OIC details, laboratory and imaging results related to TIO, and safety are collected. All patients and/or their parents gave informed consent. The baseline characteristics of smaller population from study have been presented before.
Results: Of the 476 patient included from 30 centers, 452 (95.0%) (50.7% female, mean [standard deviation-SD-] age: 9.5 (4.2)) has been diagnosed as bTM whereas 24 (5.0%) (33.3% female, mean[SD] age: 10.1 (4.2)) as SCA. Of these patients; 420 (88.2%) completed 12-month follow-up. The mean hemoglobin levels of patients under deferasirox (DFX) and deferiprone (DFP) were similar and this could be sign of similar iron load and iron uptake in these patients. Hemoglobin levels of 233 (55.5%) patients at 12. month were ≤ 9 g/dL. On the other hand, serum ferritin levels decreased with all treatment, the decrease in serum ferritin over 12 months was significant with DFX but not significant with DFP. The ratio of patient with serum ferritin levels <1000 ng/mL increased from 80 (16.8%) at baseline to 107 (25.5%) at the 12. month. Similarly mean DFX dose increased from 26.3 (6.1) mg/kg/day to 28.5 (8.7) mg/kg/day at 12. month. As a parameter of liver function; ALT decreased with both treatments and only 10 (2.8) patients experienced 3 times increase of upper limit of normal (ULN) ALT level. Most of these patients also had relatively higher ALT level at the baseline. Mean creatinine level decreased with DFX while it increased with DFP, but creatinine level of no patients was over ULN.
Summary / Conclusion: The study is the largest cohort including bTM or SCA patients suffering from TIO and under OIC treatment and follow-up period is still ongoing.More than half of the patients were still under hemoglobin limit of 9 g/dL which reveals that such patients still do not receive optimal transfusion regimens. On the other hand, serum ferritin level decreased with oral chelators and the usage of DFX and DFP did not cause any significant change in liver and kidney functions. These findings show that oral iron chelator treatment at increased dose can provide improvement but many patients still need more intense treatments including active dose adjustment.
In the future, the results of the 24 and 36-month follow-up result will also be presented.

B1845

NON- IRON DEFICIENCY ANEMIA IN PATIENTS WITH INFANTILE RICKETS

I Ragab[1*], M Hashim[2], N Abdel-Hamid[1], M El-Alfy[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Cairo, Egypt

Background: Rickets and anemia are still prevalent in Egyptian infants in the age group 6 and 24 months respectively. Vitamin D receptors have widespread distribution on different body systems; not only on the skeleton, specially in the bone marrow; it is believed that they have a role in hematopoeisis.
Aims: We aimedto detect the prevalence of non iron deficiency anemia (Hb < 11 gm/dl with normal iron profile) as well as the iron status in infantile rickets.
Methods: A cross-sectional study included 100 infants (6months-2years) with rickets systematically recruited from the outpatient clinic, Ain-Shams University, Children `s hospital. Rickets was diagnosed according to clinical, biochemical and radiological criteria. Infants with either known chronic illness, healed rickets or stoss therapy for vitaminD were excluded. Dietary recall with calculation of iron, calcium and vitamin D according to food reference tables was performed. Biochemical analysis included serum Calcium (sCa), phosphorus(sPh), alkaline phosphatase(ALP), , iron profile and 25 Hydroxy Vitamin D level by Enzyme-Immuno-Assay . Vitamin D deficiency and insufficiency were considered at levels <30 and 30-75 ng/mL respectively. A complete blood picture and hemoglobin electrophoresis were done for all participants.
Results: Mean age±SD was 13.5 (6.1) months; 69.4% of them were males; 85.7% of patients had active rickets and 14.3% had healing rickets; their mean daily dietary vitamin D intake was 21.8±13.8 IU/day , calcium intake 466.4±172.5 mg/day and iron intake 2.8±1.89 mg/day. Two patients were further excluded as their anemia proved to be of hemolytic etiology. Mean sCa was 8.1±1.5mg/dl , sPh 3.5±1.1mg/dl , and ALP 937.8±626.3IU/L , while mean vitamin D level was 41.69 ±21.44ng/ml, hemoglobin level 9.96±1.60gm/dl , MCV 69.4 ±8.2 fl , MCH 22.1±3.6 pg , and reticulocytic count 0.7±0.6%. Mean serum ferritin was 21.1±24.7ng/ml , serum iron was 19.5±19.6 µg/dl , TIBC 521.4±127.4 µg/dl and transferrin saturation 5.3±8.8%. Out of the infants with rickets, 75.5% had anemia. Vitamin D deficiency was more frequent in anemic patients compared to non anemic patients (51.4% vs. 12.5%, P=0.001)). Vitamin D level was significantly lowerin infants with anemia (37.15±20.65ng/ml), compared to non-anemic 55.7±17.7ng/ml, P<0.001. Anemia among studied infantile rickets was IDA in 65 (87.8%) , while 9 (12.2%) were non IDA. A significantly low vitaminD level in infants with non IDA (21.2±16.5ng/ml) compared patients with IDA (39.4±20.3ng/ml) P=0.001.
Summary / Conclusion: Anemia was prevalent among infants with rickets ; a considerable group of them had non IDA which could be related to vitamin D deficiency. The role of vitamin D therapy in correcting non-iron deficiency anemia associated with rickets should be prospectively studied.

B1846

A COHORT STUDY TO ASSESS THE CONTRIBUTION OF PATIENT COMPLIANCE PROGRAM ON PERSISTENCE TO DEFERASIROX IN PATIENTS WITH CHRONIC IRON OVERLOAD IN TURKEY (EX-PAT PROGRAM)

B Antmen[1*], K Organ[2], I Sasmaz[3], M Berktas[4], Y Kılınc[3]
[1]Acibadem Hospital, Adana, [2]Novartis Pharmaceuticals, istanbul, [3]Cukurova University, Adana, [4]Yeditepe University Pharmacoeconomy and Pharmacoepidemiology Research Center, istanbul, Turkey

Background: Deferasirox is more efficacious and related a higher persistence than other treatment options in the treatment of chronic iron overload due to more convenient oral use. Moreover, higher persistence to chelating treatment is associated with improved mortality and morbidity.
Aims: It is highly recommended to educate the patients under iron chelating treatment about possible complication and usage of chelating agent. Exjade Patient Compliance Program (EX-PAT) was established to increase patients' knowledge about deferasirox usage. This abstract aimed to represent the results of the pilot EX-PAT program.
Methods: Patients using deferasirox were assigned to either the home-visit or control group. During February-June 2009; the home-visit group was educated and visited at home every 30 day, phoned every 15 days and texted daily by nurses, whereas the control group was only phoned and not educated. All procedures were performed after a written consent form had been signed by the patients. If a patient did not use deferasirox for ten days or less, he/she was accepted as persistent. All patients and/or their parents gave informed consent
Results: A total of 45 patients were in the home-visit group (58% male, median (inter-quartile range-IQR-) age: 135.8 (124.9) months), and 41 patients were in the control group (63% male) were followed up median (IQR) 83.0 (12.5) and 82.0 (25.5) days, respectively. Median (IQR) deferasirox dose-per-kilogram of patients with data was 25.0 (7.4) mg/kg. Based on 211.2 patient-months follow-up data; patients in home-visit and control groups did not use deferasirox mean (95% confidence interval-CI-) 1.6 (0.9-2.3) days and 5.5 (3.1-7.9) days in mean 81.1 days and 77.3 days follow-up duration, respectively (P=0.016). Persistency rates were 95.7% and 80.5% in home-visit and control groups, respectively (P=0.025). An exploratory covariance analysis with gender, follow-up duration and deferasirox dose as covariates revealed that a patient in home-visit group would use deferasirox mean (95%CI) 19 (6-32) days more than one in control group in one year (P=0.004).

Summary / Conclusion: EX-PAT program, including education and tight follow-up, increased persistence to deferasirox and similar nation-wide programs for patients and physician would improve correct usage of deferasirox.

B1847

EFFECT OF PATIENT EDUCATION ON IMPROVING KNOWLEDGE AND PRACTICES OF THALASSEMIC ADOLESCENTS AT ZAGAZIG UNIVERSITY HOSPITAL

M Hesham[1], A El Dakhakhny[2], M Beshir[1*], S El Awady[2], E Aboelela[2]
[1]Pediatric, Zagazig University, [2]Pediatric Nursing, Zagazig University , Zagazig, Egypt

Background: Thalassemic adolescents need information about their disease in order to provide appropriate care, to decrease uncertainty, and to hold realistic expectations for themselves.
Aims: The present study was aimed to identify the effect of patient education on improving knowledge and practices of thalassemic adolescents at Zagazig university hospital.
Methods: A quasi experimental study was conducted on a sample of 50 thalassemic adolescents aged between 12- 18 years (30 male and 20 female) at the Pediatric Hematology Outpatient Clinic at Zagazig University Hospital in Sharkia Governorate, Egypt , in the period from February to October 2012.. Three tools were used in the present study. The first was a structured interview questionnaire to collect data about characteristics of the studied adolescents as well as their knowledge about β thalassemia major and chelation therapy. The second tool was a clinical checklist to evaluate adolescents during administration of deferoxamine subcutaneously with infusion pump. The third tool was health instructions to educate the studied adolescents about β thalassemia major and its management. Adolescents' knowledge about the disease and its care practices were assessed. Then, the health instructions were developed and implemented. Later, each adolescent was interviewed to reassess his knowledge and practices immediately after implementation of the health instructions and 2 months later.
Results: the present study revealed that the studied adolescents did not have satisfactory knowledge about their disease and its management before implementation of the health instructions. Our results showed that score of thalassemic adolescents' knowledge about the disease had changed from 4% to 100% and slightly decreased to 94% throughout the three phases of implementing health instructions, with highly statistically significant difference (P<0.01). No one of the studied adolescents had satisfactory knowledge score about disease's complications before the health instructions, but all (100%) had satisfactory score after the health instructions and 90% in follow up phase. Satisfactory total adolescents' knowledge score about their care had been changed from 42% to 100% and then to 96% respectively before, immediately after implementation of health instructions and after 2 months later (P<0.01).It was also found that 74% of the studied adolescents had satisfactory total practice score before the health instructions, compared to 100% of them after the health instructions. The percentage decreased to 86% in the follow up phase (P<0.01).
Summary / Conclusion: the health instructions had improved thalassemic adolescents' knowledge and practices. Based on the results of the present study continuous health instructions and educational programs should be conducted for thalassemic adolescents about the disease, its treatment regimen and care practices.

B1848

SUCCESSFUL LIVER TRANSPLANTATION IN SCD: CASE REPORT AND LITERATURE REVIEW

K Gardner[1*], S Atwal[2], E Drasar[1,3], M Allman[1], M Awogbade[1], A Bomford[4], A Suddle[4], S Thein[1,3]
[1]Haematological Medicine, King's College Hospital, London, [2]Haematology, Kingston Hospital, Kingston upon Thames, [3]Molecular Haematology, King's College London, [4]Institute of Liver Studies, King's College Hospital, London, United Kingdom

Background: Sickle cell disease (SCD) is an escalating public health issue, with the potential for multi-organ damage. Little is known of the natural history of sickle hepatopathy; there are no management guidelines, and the role of liver transplantation in SCD remains to be elucidated.
Aims: Define the collective experience of liver transplantation in SCD
Methods: Case report and literature review.
Results: An African-Caribbean man was diagnosed with SCD (HbSS) as a child. He developed abnormal steady-state liver function at age 23 years, and regular blood transfusions were initiated to treat sickle-cell intra-hepatic cholestasis (SCIC). However, his baseline liver function deteriorated. Laboratory tests and liver imaging revealed the only other contributor to liver impairment was transfusion-related iron overload. Top-up transfusions were switched to exchange transfusions and iron chelation initiated with deferasirox. In early 2011, he developed decompensated liver failure, and was listed for liver transplantation. The patient was age 33 years when he received a liver transplant, from an 18-year-old heart-beating graft. The explanted liver was nodular and weighed 3700g; histology demonstrated sickle cells in sinusoids, sclerosing cholangitis, moderate siderosis, and a biliary abscess. Post-transplant, his liver enzymes have normalised and he has been maintained symptom-free on a monthly exchange blood transfusion programme with a HbS target of <30%.
This case adds to the 22 cases of liver transplantation in patients with SCD reported in the literature. Only six of these 22 cases report the primary indication for transplant as SCIC. The remaining 17 cases had the following indications: Hepatitis C (6), Hepatitis B (1), autoimmune hepatitis (3), biliary cirrhosis (1), sclerosing cholangitis (1), hepatic sequestration (1), iron overload (2), cryptogenic (2). We have full case details on five of the six patients with SCIC; four of the five had genotype HbSS, the fifth had HbSβ° thalassaemia; all five were maintained on an exchange transfusion programme post-transplant. Two cases were reported as successful. A third patient died 22 months post-transplant from a pulmonary embolus, with an intact graft. The fourth case had three liver transplants with early rejection, and died 6 months later. The final case died one month post-transplant of sepsis and multi-organ failure. Overall mortality rate was 58% in the wider cohort and 60% in the SCIC cohort
Summary / Conclusion: The collective experience demonstrates that liver transplantation can be successful as a treatment option in sickle patients with end-stage liver failure, but poses additional challenges. Particular attention must be given to maintaining a low HbS% with exchange transfusion rather than top-up transfusion both pre- *and* post-transplantation; minimisation of sickling pre-transplant reduces sickle-related damage of other organs, and post-transplant, it limits risk of recurrence. Surgery itself can pose problems for SCD patients: intra-operative events themselves can induce sickling (ischaemia, hypothermia and acidosis). Peri-liver transplantation issues of vascular problems and acute rejection may be confused with sickle-related crises. Risk of immunosuppression-related infections are higher in this population who have an underlying immunodeficiency.
There is a need to identify SCD patients at risk of developing SCIC early so that timely exchange blood transfusion can be initiated to ensure a successful liver transplantation if needed

B1849

ASSESSMENT OF ERYTHROCYTE PHOSPHATIDYLSERINE EXPOSURE IN B-THALASSEMIA

N Abousamra[1*], H Ibrahim[2], M Fouda[3], R Yahya[2], R Elazim[2]
[1]Clinical Pathology Department, Faculty of Medicine, Mansoura University, [2]Department of Physiology, Faculty of Science , [3]Clinical Pathology Department, Clinical Pathology Department, Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background: phospholipid asymmetry is well maintained in erythrocyte (RBC) membranes with phosphatidylserine (PS) exclusively present in the inner leaflet. The appearance of PS on the surface of the cell can have major physiologic consequences, including increased cell-cell interactions. Eryptosis, the suicidal death of erythrocytes, is characterized by cell shrinkage, membrane blebbing and cell membrane phospholipids scrambling with PS exposure at the cell surface.Erythrocytes exposing PS are recognized, bound, engulfed, and degraded by macrophages. Eryptosis thus fosters clearance of affected erythrocytes from circulating blood which may aggravate anemia in pathological conditions. Thalassemia patients are more sensitive to the eryptotic depletion and osmotic shock which may affect RBC membrane phospholipid asymmetry.
Aims: we aimed in this work to determine the erythrocyte PSexposure in splenectomized and nonsplenectomized β-thalassemia (β-TM) patients and correlate it with the clinical presentation and laboratory data.
Methods: fresh whole blood was simultaneously stained for annexin V (AV) to detect phosphatidylserine (PS) exposure in 46 patients with β-TM (27 splenectomized and 19 nonsplenectomized) in addition to 17 healthy subjects as a control group..
Results: we reported significant increase in erythrocytePSexposure in β-TM patients compared to control group (P=0.000). Erythrocyte PSexposure was significantly higher in splenectomized β-TM patients as compared with nonsplenectomized β-TM patients (P=0.001). No correlation was found between erythrocyte PSexposure and clinical or hematological data of β-TM patients but there was positive correlation between erythrocyte PSexposureand ferritin level in β-TM patients.
Summary / Conclusion: these findings suggest that β-TM patients have higher level of erythrocyte PSexposure and splenectomy was shown to aggravate erythrocyte PSexposure without aggravation of anemia

B1850

IRON OVERLOAD IN AN ADULT SICKLE CELL ANEMIA POPULATION

C Dinu[1*], M Azerad[1], A Demulder[2], B Dohet[1], A Efira[1]
[1]internal Medicine, [2]laboratory Of Hematology, Chu Brugmann, Brussels, Belgium

Background: Iron overload is a significant source of complications in sickle cell anemia patients, especially in case of regular transfusions. Serum ferritin measurement shows a good correlation with the amount of liver iron as measured by MRI and can be used as screening test. Treatment aims to reduce the amount of body iron by the realization of exchange transfusions and the use

of chelating agents, three of which are commercially available (deferoxamine, deferiprone and deferasirox).
Aims: Data on iron overload in the adult sickle cell anemia population are more limited than for the children. We evaluated retrospectively this parameter in our cohort of patients regularly followed in a western public hospital without access restriction to care.
Methods: 51 adult sickle cell anemia patients were evaluated at the hematological consultation in 2011. The median age was 29 (17-48) and the M/F ratio 0.8. 48 patients exhibited a phenotype SS, 2 SC and 1 CC. Serum ferritin was measured in all but three of them.
Results: Serum ferritin median value was 244 ng/ml (27-3645). 8 patients (17%) had a serum ferritin value ≥ 1000 ng/ml; their mean age was 32,5 vs 28,7 years for the other patients. Mean hemoglobin concentration, white blood cells and platelets levels were identical in the two groups. Mean serum creatinin was more elevated in the heavily iron loaded patients: 4.35 vs 2.01 mg/dl (P=0.05). Liver enzymes (LDH, SGOT, SGPT, alkaline phosphatases) were comparable in two groups except for the alkaline phosphatases that were also more elevated in the patients with a serum ferritin ≥ 1000 ng/ml: 396 vs 255 IU (P=0.01). Measurements of cardiac tricuspid Vmax (2.4 vs 2.17 m/sec) and LVEF (58.8 vs 63.4%) were not statistically different. Major bone disease (e.g. hip or schoulder osteonecrosis) was also equally found in the two populations. Similarly, central neurological (MRI findings) and ophtalmologic complications were also evenly distributed in the two groups.
Summary / Conclusion: Patients with iron overload had a more compromised renal and liver function. but no increased need to be hospitalized for acute complications (vaso-occlusive crisis and/or acute chest syndrome). Interestingly, only three of these eight patients took initially part of a regular transfusion program, that was later changed for exchange transfusions. 6 of these patients received a chelating agent (5 deferoxamine and 1 deferasirox); the two others refused it. 3 patients with a serum ferritin < 1000 ng/ml were currently under erythrocyte exchanges, two of them without need for a chelating treatment.

B1851
LONGITUDINAL STUDY ON THYROID FUNCTION IN PREPUBERTAL AND PUBERTAL PATIENTS WITH THALASSEMIA MAJOR: HIGH INCIDENCE OF CENTRAL HYPOTHYROIDISM BY 18 YEARS
A Soliman[1*], M Yassin[2], V Desanctis[3]
[1]Pediatrics, [2]Hematology, Hamad Medical Center, doha, Qatar, [3]Pediatrics, Quisisana Hospital, ferrara, Italy

Background: Primary hypothyroidism is one of the most frequent complications observed in patients suffering from thalassemia. We investigated and reviewed the thyroid function in all thalassemic patients attending the Pediatric Endocrine Clinic of Hamad Medical Center, Doha, Qatar during the last 10 years of follow up.
Aims: To investigate and reviewe the thyroid function in all thalassemic patients attending the Pediatric Endocrine Clinic of Hamad Medical Center, Doha, Qatar during the last 10 years of follow up.
Methods: 48 patients with ß-thalassemia major between 5 and 18 years of age. Thyroid dysfunction was defined as follows: overt hypothyroidism (low FT4 and increased TSH levels >5 µIU/ml); subclinical hypothyroidism (normal FT4, TSH between 5-10 µIU/ml) and central (secondary) hypothyroidism (low FT4 and normal or decreased TSH).
Results: 48 patients completed a 12 year-period of follow-up. During this period hypothyroidism was diagnosed in 17/48 (35%) of patients, 16 of them after the age of 10 years (94%). The prevalence of overt hypothyroidism had risen from 0 % at the age of 7 years to 35% at the age of 18 years. None of the patients had high anti-thyroperoxidase (TPO) antibody titers. Thirteen out of the 17 patients with hypothyroidism, had normal or low TSH level (not appropriately elevated) indicative of defective hypothalamic pituitary response to low FT4 (central hypothyroidism). Three patients (6.3%) had subclinical hypothyroidism (TSH between 5 and 10 uIU/ml and normal FT4). The general trend of free thyroxine level showed progressive decrease over the 12 years, whereas TSH levels did not show a corresponding increase. These data suggested defective hypothalamic pituitary thyroid axis involving both TSH and FT4 secretion in patients with TM over time. There was a significant negative correlation between serum ferritin and FT4 (r = - 0.39, P=0.007) but no correlation was found between ferritin and TSH.
Summary / Conclusion: Worsening of thyroid function was observed in 35 % of the studied thalassemic patients by the age of 18 years. The lack of proper increase of TSH in response to low circulating levels of FT4 in 13/17 (76%) of these patients indicates a relatively high incidence of defective pituitary thyrotrophic function in these patients.

B1852
AUTOIMMUNE THYROID DYSFUNCTION IN YOUNG EGYPTIAN TRANSFUSION-DEPENDENT B-THALASSEMIA PATIENTS
A Tantawy[1*], N El-Sherif[1], Iman A Ismail[2]
[1]Pediatric Department, [2]Clinical Pathology Department, Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: Although autoimmunity was not proved to be involved in tissue damage of B-Thalassemia, yet nonspecific triggering of autoimmunity by iron overload has been suggested. The prevalence of hepatitis C among Egyptian beta thalassemia patients is ranging from 60-80%. Hepatitis C virus infection associated autoimmune diseases are well reported, especially autoimmune thyroiditis .
Aims: This study aims to assess the prevalence of autoimmune thyroid disease among children and young adults with transfusion dependent beta thalassemia major ,especially in relation to iron overload and hepatitis C virus status.
Methods: The study is a cross sectional study done in the Pediatric Hematology Unit , Children's Hospital,Ain Shams University,Cairo,Egypt including 84 transfusion-dependent β-thalassemia patients compared with 40 age- and sex-matched healthy controls.Data were collected including: transfusion history, splenectomy, chelation/hydroxyurea therapy.Investigations included hematological profile ,serum ferritin,liver function tests ,ELISA testing for hepatitis C virus antibodies. Thyroid functions were tested by estimating free T4 and basal thyroid stimulating hormone (TSH), and antithyroperoxidase (anti-TPO) by enzyme linked immunosorbent assay (ELISA) was done as marker of autoimmunity.
Results: The patients age ranged from 10-25years (mean 14.96 ±4.40), with 1.2:1 male to female ratio. Thyroid dysfunction was found in 11 thalassemia patients (13.1%).Subclinical hypothyroidismwas found in 3 patients (3.6%) while overthypothyroidism in 1 patient (1.2%) . Five patients (5.9%) had subclinical hyperthyroidism and 2 patients (2.3%) had clinical hyperthyroidism. The male to female ratio was 1:3 in hypothyroid patients , and 1: 6 in hyperthyroid patients , with predominance of females ; but no age difference.Thalassemia patients with thyroid dysfunction (hypo- and hyperthyroidism) had insignificantly higher ferritin level, transfusion index than euthyroid patients (P=0.2 and P=0.25,respectively).The prevalence of hepatitis C antibodies was 82% in the whole studied patients and 90.9% in patients with thyroid dysfunction . Anti-TPO was significantly elevated in beta thalassemia patients compared with controls (P<0.001) ,values were relatively higher in patients with thyroid dysfunction in comparison to euthyroid patients (P=0.17). β-thalassemia patients with hypothyroidism had relatively higher anti-TPO levels than those with hyperthyroidism while the lowest anti-TPO levels were found in euthyroid patients. Patients with positive hepatitis C antibodies had higher yet insignificant AntiTPO level than those with negative antibodies (P=0.37). Anti-TPO positively correlated with ferritin level (P<0.001), but insignificantly with transfusion index(P=0.84).
Summary / Conclusion: The present results reveal that thyroid dysfunction in transfusion dependent thalassemia is related to iron overload,however thyroid autoimmunity in our cohort of Egyptian patients could be an associated contributing factor. The higher level of AntiTPO among our beta thalassemia patients compared to literature could reflect the combined effect of high prevalence of hepatitis C virus infection with higher degree of iron overload . Patients with hyperthyroidism might represent an early hyperthyroid phase of autoimmune thyroiditis before eventually becoming hypothyroid.

B1853
BIOLOGICAL DIAGNOSIS OF THROMBOTIC THROMBOCYTOPENIC PURPURA: NOTHING BUT EYES?
J Mondet[1*], A Deroux[2], F Sarrot-Reynauld[2], L Bouillet[2], M Lugosi[3], P Mossuz[1]
[1]Institut de Biologie Pathologie, Laboratoire d'Hématologie cellulaire, [2]Internal medicine, [3]Reanimation, University Hospital, Grenoble, France

Background: Thrombotic thrombocytopenic purpura (TTP) diagnosis is based on the association of mechanical haemolytic regenerative anemia with schistocytes, consumptive thrombocytopenia and typically includes neurological symptoms and end-organ damage. An optimal treatment with plasma exchange has decreased mortality rate from 90% to less than 20%. Fragmented red cell (%FRC) measurement has been described as a revolutionary automated laboratory method for shistocytes assay in the diagnosis of thrombotic microangiopathies, and thereby in therapeutic decision making. The measurement of %FRC is based on a double gating selection on the reticulocyte channel scattergram according to forward scatter and intensity of fluorescence. It combines rapidity, capacity to analyse numerous cells and huge reduction of inter-individual variability compared to reference method using microscopic examination. A %FRC below a threshold at 1% had an excellent negative predictive value especially in normocytic red blood cells and allowed biologists to exclude the presence of shistocytes without microscopic evaluation on blood smears.
Aims: However, we urge caution for the use of automated schistocytes measurement %FRC after patient's death of a typical TTP with several %FRC below the significant threshold.
Results: A 72-year old woman was brought to the hospital for sudden neurological disorders with right arm paresis and transient aphasia. In her clinical history, she was known to have untreated chronic hepatitis C with extrahepatic manifestations such as fatigue, cryoglobulinemia and distal sensory neuropathy. An angio-MRI realized in emergency to exclude stroke was normal. Admission laboratory investigation results revealed hemoglobin of 10.2g/dL, mean corpuscular volume 90.3 fL, reticulocyte count of 178 ×10^9cells/l, platelet count of 14×10^9cells/l, lactate dehydrogenase of 508 (normal range,84-246 U /L) and haptoglobin <0.1 g/l. The combination of haemolytic anemia, thrombocytopenia and neurological disorders evoked a TTP. From the first day to fifth day of

the hospitalization, six %FRC were done. During the first four days, %FRC results were between 0 and 0.16. At the fifth day, % FRC reached 0.7% but never rose 1%. The lack of significant automated schistocytosis delayed the patient's transfert in an intentive care unit and the setting up of plasma exchange. Unfortunately, the patient died of hypoxic cardiac arrest on the fifth day of evolution. Retrospective blood smears examination reveals schistocytosis ranging from 2 to 3.5%. Moreover, diagnosis of TTP was confirmed by the absence of ADAMTS13 activity (<3%) and the presence of anti-ADAMTS-13 antibodies to 40.5 U/ml (standard <15 U/ml). Our patient's case gives rise to several issues on the diagnostic value of automated %FRC. The cutoff value of %FRC for TTP of1% must be interpreted with caution especially in case of cryoglobulinemia. Known for erroneous white blood cells and/or platelet counts, cryoglobulinemia could hypothetically interfer with %FRC measurements. Furthermore, no quality control and standards are nowadays available for %FRC.
Summary / Conclusion: We argue for caution on management of patient with suspicion of TTP based on automated %FRC determination. Microscopic examination of blood smears, even though requires high skillness, should remain the reference method to eliminate shistocytosis. Finally, absence of schistocytosis should not overpass clinical expertise.

B1854
LIPOSOMIAL IRON HAS AN ANTI-INFLAMMATORY EFFECT AND IS BETTER THAN IRON SULFATE IN CORRECTION OF ANEMIA OF CHRONIC INFLAMMATORY DISEASE OF YOUNG WOMEN.
G Giordano[1*], s vittorio[2], f d'amico[3], d antonietta[1], m de maria[1], p nicola[4], g sticca[1]
[1]oncology, Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [2]catholic university, rome, [3]Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [4]chieti university, chieti, Italy

Background: Liposome has a described anti-inflammatory effect and transports its content directly in blood, beyond gastric and enteric wall.
Aims: Aim of this study is to verify if liposomial iron is most effective than iron sulfate in correction of anemia of chronic inflammatory disease of young women.
Methods: In group A 9 patients (4 with systemic erythematous lupus, 3 with mixed connectivitis, 2 with rheumatic fibromyalgia), median age 32 years (R27-42), Hb 8.5 g/dl (R8-10), saturation of iron binding capacity < 20%, with a median ferritin level of 100 ng/ml (R90-250), ESR 35 mm/1st hour (R22-95), CRP 18 mg/l (R12-24), normal B12 and folate, received liposomal iron 60 mg/day orally for 3 months. In group B 12 patients (6 with systemic erythematous lupus, 3 with mixed connectivitis, 3 with rheumatic fibromyalgia), median age 38 years (R29-45), Hb 9 g/dl (R8-9.5), saturation of iron binding capacity < 20%, with a median ferritin level of 120 ng/ml (R80-190), ESR 33 mm/1st hour (R20-87), CRP 15 mg/l (R13-27), normal B12 and folate, received iron sulfate 210 mg/day orally for 3 months.
Results: After treatment, group A showed a median hemoglobin level of 11.5 g/dl (R10.5-12), a median ferritin level of 260 ng/ml (R 190-280), a ESR decrease to a median value of 8 mm/1st hour (R 3-10) and a median CRP 3 mg/l (R2-4). After treatment, group B showed a median hemoglobin level of 9.5 g/dl (R8-9.5), a median ferritin level of 100 ng/ml (R 90-180), and ESR and CRP don't showed any improvement. 4 patients showed hepygastralgia, 2 stipsis, 5 diarrohea.
Summary / Conclusion: Liposomial iron is most safe, effective, well tolerated, effective than iron sulfate in increase hemoglobin level and reduce inflammatory markers in correction of anemia of chronic inflammatory disease of young women.

B1855
ELEVATED SERUM FERRITIN LEVELS >3,000 MG/DL ARE HIGHLY ASSOCIATED WITH ENDOCRINOPATHIES IN PATIENTS WITH THALASSEMIA
A Tantiworawit[1*], S Hantrakool[1], L Norasetthada[1], E Rattarittamrong[1], C Chaiadisaksopha[1], M Phornphutkul[2], S Srichairattanakool[3], W Nawarawong[1]
[1]Internal medicine, division of Hematology, [2]Internal medicine, division of Endocrinopathy, [3]Biochemistry, Chiang Mai university, Maung, Thailand

Background: Endocrinopathies are well recognized major complications in thalassemic patients with iron overload. Elevated serum ferritin levels reflect severity of iron overload and areassociated with adverse clinical outcomes. Increasedserum ferritin >2,500 µg/dl is associated with impaired cardiac function, but the predicting serum ferritin level for endocrinopathies has not been determined.
Aims: To evaluate the correlation between serum ferritin levels, non–transferrin binding iron (NTBI) and labile plasma iron (LPI) with endocrinopathies (diabetes, hypothyroidism and hypogonadism) in thalassemia patients.
Methods: All patients with thalassemia, age >18 years old were enrolled between August 2011 and December 2012. Fasting blood sugar, thyroid and gonadal functions were evaluated. Serum ferritin, NTBI and LPI were measured at the same time. The medical records were reviewed for age, sex, splenomegaly, history of splenectomy, transfusion requirement, serum ferritin levels, and iron chelation history.
Results: There were 118 patients with thalassemia [60% females] with a median age of 28 years (18-71). The majority of patients were β-thalassemia/hemoglobin E (49.2%), then homozygous β-thalassemia (28.8%) and hemoglobin H with variant (20.3%). Most patients (58.5%) underwent splenectomy while only one third (37.3%) were non-transfusion dependent thalassemia (NTDT). The mean values and maximum ferritin levels were2,379 µg/dl (279-9,817) and4,914 µg/dl (279-37,656), respectively.
The prevalence of diabetes mellitus, hypothyroidism, subclinical hypothyroidism and hypogonadism were 11.9%, 7% , 23.5% and 34.8%, respectively. Mean NTBI and LPI of these patients were 7.2 µM (0.05-30.3) and 4.3 µM (0.01-15.8). NTBI were correlated well with LPI, serum iron and transferring saturation. The maximum ferritin level of >3,000 µg/dl was independently associated with diabetes [OR 9.94 (95%CI 1.34-79.27), P=0.004], hypothyroidism [OR 3.73 (95%CI 1.51-9.20), P=0.003] and hypogonadism [OR 3.54 (95%CI 1.63-7.69), P=0.001].
Summary / Conclusion: High prevalence of endocrinopathies were found among patients with thalassemia. The maximum ferritin level of >3,000 µg/dl was a major risk factor of the development of diabetes, hypothyroidism and hypogonadism. These findings warrant the value of iron chelating therapy to maintain serum ferritin level below3,000 µg/dl for avoiding the development of endocrinopathies in patients with thalassemia.

B1856
MISDIAGNOSIS OF HEMOGLOBIN D-PUNJAB/BETA THALASSEMIA IS A POTENTIAL PITFALL IN HEMOGLOBINOPATHY SCREENING PROGRAMS: A CASE REPORT
K Belhoul [1], M Bakir[1*], M Abdulrahman[2]
[1]Thalassemia centre , [2]Dubai Health Authority , Dubai, United Arab Emirates

Background: Hemoglobinopathies are the most common single gene disorder in the United Arab Emirates (UAE); in particular, beta-thalassemia is a major public health problem in this country. A premarital screening program to prevent beta-thalassemia major has been in effect in the UAE since 2006. This is a compulsory procedure that utilizes complete blood count (CBC) and hemoglobin high-performance liquid chromatography (HPLC) as screening tools.
Aims: To emphasize that Compound heterozygous hemoglobin (Hb)D-Punjab/beta-thalassemia must be carefully differentiated from homozygous HbD-Punjab in premarital screening, especially when the partner has the beta-thalassemia trait.
Methods: A case of three months old baby with beta-thalassemia major, who was the product of a marriage between a mother with beta-thalassemia trait and a father with compound heterozygous Hb D-Punjab/beta-thalassemia, is presented. The father had been misdiagnosed with homozygous HbD-Punjab during premarital screening, even though the screening program utilized complete blood counts and high-performance liquid chromatography. On arrival at Dubai Thalassemia Centre the case was revaluated and reinvestigated. Consequently, both parents underwent CBC, iron study, HPLC, and alpha- and beta-globin gene DNA analyses.
Results: The baby's CBC showed hypochromic microcytic anemia and beta-globin molecular test showed homozygous beta-thalassemia IVS-1-5(G>C)/IVS-1-5(G>C), which was not consistent with the premarital HPLC results of her parents. While Reviewing parents' re-investigation, the father had again shown low Hb A_2 on HPLC but the molecular tests revealed that he was a compound heterozygous Hb D-Punjab/beta-thalassemia IVS I-5(G>C), not the homozygous HbD-Punjab disease that had been diagnosed by the premarital screening. Both the proband and her parents had a normal alpha globin gene.

TABLE 1 Laboratory Data of the Proband and Her Parents on Arrival at the Dubai Thalassemia Centre (normal ranges are in parentheses)

Parameters	Proband	Father	Mother
Ferritin (ng/mL)	–	141.3 (18.7-323.0)	32.2 (9.3-59.0)
Iron (mg/dL)	–	107.0 (59.0-158.0)	99.0 (37.0-145.0)
TIBC (mg/dL)	–	354.3 (250.0-450.0)	298.4 (250.0-450.0)
Hb (g/dL)	6.1 (11.1-14.1)	13.4 (13.0-18.0)	10.8 (11.0-15.0)
RBC (10^{12}/L)	3.13 (4.1-5.3)	7.11 (4.5-6.0)	5.68 (3.7-5.4)
MCV (fL)	77.6 (68.0-84.0)	60.8 (77.0-92.0)	61.5 (77.0-92.0)
MCH (pg)	19.6 (24.0-30.0)	18.9 (26.0-34.0)	19.1 (26.0-34.0)
MCHC (g/dL)	25.3 (30.0-36.0)	31.1 (32.0-36.0)	31.0 (32.0-36.0)
Hb A (%)	–	1.26 (90.0-95.0)	88.0 (90.0-95.0)
Hb A_2 (%)	–	1.19 (1.5-3.4)	5.09 (1.5-3.4)
Hb F (%)	–	0.03 (0.0-3.0)	1.2 (0.0-3.0)
Hb D-Punjab (%)	–	89.17	–
β Genotype	IVS-I-5(G>C)/ IVS-I-5(G>C)	IVS-I-5(G>C)/ codon 121(GAA>CAA)	IVS-I-5(G>C)/β^A
α Genotype	αα/αα	αα/αα	αα/αα

NB: The parent's premarital screening results (CBC and HPLC) were similar to those obtained on arrival at Dubai Thalassemia Centre

Summary / Conclusion: It is recommended that in cases of HbD-Punjab syndromes, the hemoglobin analysis results should be evaluated carefully in conjunction with a close examination of the mean corpuscular volume values. Moreover, molecular genetic studies should be performed in HbD syndromes if the partner is a beta-thalassemia carrier.

B1857

CHANGES IN HAEMATOLOGICAL AND BIOCHEMICAL PARAMETERS IN PATIENTS WITH SICKLE CELL DISEASE UNDERGOING AUTOMATED RED CELL EXCHANGE TRANSFUSIONS

D Warcel[1*], B Sirigireddy[1], S Patel[1], I Khan[1], R Nzouakou[1], D Tsitsikas[1], R Amos[1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Exchange transfusions are often used as a disease-modifying strategy in patients with sickle cell disease (SCD). Automated red cell exchange transfusions (ARCET) can rapidly and efficiently achieve low HbS levels whilst at the same reduce the risk of iron overload compared to top-up or manual exchange transfusions.
Aims: To assess the incidence and severity of biochemical and haematological imbalances occurring in patients with SCD during ARCET
Methods: At Homerton University Hospital we have a large number of patients with SCD on a regular exchange transfusion programme the vast majority of which are ARCETs. Pre- and post- transfusion samples are collected for all procedures and the results are recorded in a database. This is a retrospective analysis of the results in our database for a 12 month period (Jan2012 – Dec2012).
Results: There were 105 procedures involving 33 patients for the period 01/01/12 – 31/12/12. The mean reduction in HbS level was 80%, (median -82%). The mean rise in HbA was 114% (median +80%). The modest elevation in HbA reflects the fact that most of those patients were on a regular transfusion programme and their pre-transfusion HbA was already high. Both Hb and haematocrit rose by a mean 15% per procedure (range -14% to +81% and -17% to +83% respectively). There was a 28% mean reduction in the white cell count (median -35% and range -61% to +49%). We have previously reported a significant but transient reduction in the platelet count (BSH annual meeting 2013). Indeed we found a 67% mean reduction of platelets per procedure. Fibrinogen was also reduced ranging from -66% to 32% per procedure (mean -30%, median -31%). Many biochemical parameters were also found to be reduced post ARCET. Serum ferritin levels were reduced by a mean of 22% (range -73% to +123%). The reduction in albumin ranged from -38% to -3% (mean -25%, median -23%). LDH was reduced by a mean of 33% (range -70% to +80%). There was a 22% mean reduction in Alkaline Phosphatase (range -40% to +11%) and a 25% mean reduction in ALT per procedure (range -57% to +20%). Bilirubin was reduced by a mean 13% (range -54% to +93%) and serum Creatinine was only slightly reduced by a mean of 5% (range -33% to +40%). Hypocalcaemia is a known side effect of ARCET due to citrate toxicity. We found a reduction of calcium ranging from -24% to -4% (mean -13%, median -13%).
Summary / Conclusion: Automated red cell exchange transfusion is a quick, safe and efficient way of lowering HbS levels in SCD. Our results reveal a modest reduction in most biochemical parameters measured post ARCET which most likely occurs as a result of loss of plasma during the procedure.

B1858

HEMATOLOGICAL PROFILE BETWEEN PATIENTS WHO SUFFER FROM ISCHEMIC HEART DISEASE AND PATIENTS WITH DILATED CARDIOMYOPATHY

G Liapas[1*], S Patiakas[2], S Chatzizisi[3], B Kelesiadou[2], B Stavrou[4], A Nikolaidou[5]
[1]Cardiological Clinic of Universal General Hospital of Ioannina, Ioannina, [2]Hematological Laboratory and Blood Donation Department of General Hospital of Kastoria, Kastoria, [3]Pathological Clinic of General Hospital of Thessaloniki "Saint Dimitrios", [4]Hematological Laboratory of General Hospital of Thessaloniki "Theageneion", [5]Hematological Laboratory of Universal General Hospital of Thessaloniki "ACHEPA", Thessaloniki, Greece

Background: As we Know the relevant bibliography mentions that anaemia, definitely affects the evolution and the course of patients with congestive heart failure, yet the ESR is usually low in cases like these.
Aims: To investigate the variations of the hematocrit (Ht), the white blood cells (WBC), the 1st hour erythrocyte sedimentation rate (ESR), the C-reactive protein (CRP) and also of the fibrinogen (Fib) and the immunoglobulins found in blood, between patients who suffer from ischemic heart disease (IM) and patients with dilated cardiomyopathy (DCM) and to study the potential prognostic value in each case.
Methods: 106 patients, who have constituted the material for our study (81 males and 25 females), suffered from heart failure and presented left ventricular dilation and dysfunction, and ejection fraction (EF) <35%. 59 of them (44 males and 15 females) suffered from DCM and 47 (37 males and 10 females) from IM. For the patients who were under frequent observation at regular intervals for more than a year, specifications of Ht, WBC, ESR, CRP, fibrinogen and immunoglobulins were carried out, while previously, the coexistence of other pathologic situations such as malignity, hematological diseases, injuries, gynecological diseases, severe febrileinfections etc, which would affect the results of these tests was eliminated.
Results: Although the Ht, the White Blood Cells and the immunoglobulins were measured in higher values in DCM, in correlation with the IM, they did not present statistically significant difference between them. Also, even though the CRP and the fibrinogen presented higher values in IM, in correlation with the DCM, their difference wasn't statistically significant. On the contrary, regarding the ESR, it appeared substantially increased (P<0.001) in the case of IM (25,6+/-13,9), comparatively to DCM (10,6+/-9,6).
Summary / Conclusion: It is established then, that between IM and DCM, statistically, there is no significant difference in the laboratory parameters that were previously mentioned (which vary within normal ranges), with the exceptions of the ESR, who was presented with decreased values (<10) in DCM (but not with poor prognosis), and the Ht, in which its decreased value in IM, points undeniably an unfavorable prognostic factor, which must not escape from our attention.

B1859

FLOW CYTOMETRY QUANTITATIVE ANALYSIS OF HOWELL-JOLLY BODIES IN CHILDREN WITH CHRONIC HEMOLYTIC ANEMIA

A Tantawy[1*], J. Labib[1], A. Adly[1], M Shams[2]
[1]Pediatric Department, [2]Clinical Pathology Department, Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: In sickle cell disease functional asplenia is reported to develop early in life and has important clinical consequences, with quantitative measurement of splenic function reported using a flow cytometric method for quantitating of Howell-Jolly bodies (HJB) that isolates HJB-containing $CD71^+$ and $CD71^L$ erythrocytes.Analysis of these cell populations allows quantitative measurement of splenic filtrative function and possible chromosomal damage[1]. Splenic dysfunction has been described in Beta thalassemia major ,however quantitative measurement of splenic filtrative function by flow cytometry was not reported.
Aims: To evaluate the filtrative splenic functions using flow cytometry in patients with β thalassemia major (BTM)and thalassemia intermedia (TI) compared to patients with sickle cell anemia (SCA), sickle thalassemia (SCT),splenectomized BTM, and healthy controls.
Methods: The study is a cross sectional study done in the Pediatric Hematology Unit , Children's Hospital,Ain Shams University,Cairo,Egypt.It included 15 patients with sickle cell anemia (mean age 7.8±3.9 years),20 patients with sickle thalassemia, (mean age 12.5±4.9 years),30 non splenectomized β thalassemia major patients(mean age 9.8±4.8 years), 20 splenectomized patients with β thalassemia major, (mean age 14.0±2.7 years), and 32 patients with non spenectomized β thalassemia intermedia (mean age 12.5±3.7 years), compared to 30 age- and sex-matched healthy controls.Data were collected including: transfusion history, splenectomy, sickling crisis, thrombotic events, chelation/hydroxyurea therapy,as well the frequency of hospitalization with serious infections. Investigations included hematological profile ,hemoglobin electrophoresis and serum ferritin .Howell-Jolly Bodies (HJBs) were quantitated by flow cytometric method , identifying HJB-containing CD71- erythrocytes in peripheral blood (used to identify older erythrocytes containing micronuclei, indirectly measuring splenic function), and HJB-containing CD71+ reticulocytes, indicating young erythrocytes containing micronuclei (used as an index of cytogenetic damage and/ or ineffective erythropoiesis)
Results: Compared to healthy controls ,patients with SCA and SCT had higher HJB frequencies within CD71+ reticulocytes (P<0.05 and P< 0.01,respectively), and higher HJB frequencies within CD71- erythrocytes (P< 0.01 , for both). Patients with BTM (splenectomized) ,BTM (non-splenectomized) and TI had significantly higher HJB frequencies within CD71+ reticulocytes (P< 0.01,for the three groups) and CD71- erythrocytes (P< 0.01, P< 0.001, P< 0.01) compared to healthy controls . Comparing SCA patients with SCT, BTM (splenectomized) , BTM (non-splenectomized) and TI : there was no significant difference regarding the HJB frequencies in both CD71+ reticulocytes and CD71- erythrocytes (P>0.05). However, splenectomized BTM patients had higher frequencies of HJB in CD71+ reticulocytes in relation to non-splenectomized patients and TI (P=0.01 and P< 0.01). The mean level CD71+ reticulocytes containing HJB was higher in SCA and SCT patients on regular hydroxyurea therapy compared to non treated patients but not statistically significant (P>0.05).
Summary / Conclusion: Splenic hypofunction can be present in non splenectomized patients with β thalassemia major and thalassemia intermedia , and may contribute to the immune dysfuncion observed in this group of patients. However, splenic dysfunction in those patients can be to a lesser degree than splenectomized thalassemics and sickle cell disease patients. The use of hydroxyurea in SCD was associated with higher levels of CD71+ reticulocytes containing HJB, which represent an index of cytogenetic damage.

RETROSPECTIVE STUDY OF IRON DEFICIENCY ANEMIA IN HEMATOLOGY CLINIC
I MIHAI[1*], I IOANA[1], C DESPINA[1], C LIVIU[1], C MARIA[1], I CLAUDIU[1], I MARIA[1], D MONICA[1], I HORTENSIA[1]
[1]Hematology, UNIVERSITY OF MEDICINE AND PHARMACY „VICTOR BABEŞ", TIMIŞOARA, Timisoara, Romania

Background: Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide and occurs in 3,5-5,5% of adult men and postmenopausal women. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.
Aims: *Aim* of the study is to evaluate retrospectively adult men with IDA.
Methods: One hundred and fifty-six pateients with IDA participated at this study from January 2005 to december 2012. Anemia was defined as Hg<13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Mot patients underwent esophagogastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive.The abdominal CT scan were performed according to clinician's recomandation.
Results: The median age was 56 (range 26 to 84) years old. 131 of 156 (83,9%) men with IDA had symptoms such as fatigue, dizzines, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 25 (16%), 33 (21,1%), patients, respectively. FOBT was positive in only 39 (25%) subjects. 140 (89,7%) patients underwent EGD. The most common findings from EGD were gastritis (36 patients) and peptic ulcer (27 patients). Forty-nine (31,4%) patients were found to have upper gastrointestinal disorders (9 patients with erosive gastritis, 13 gastric ulcer, 10 duodenal ulcer, 17 gastric cancer. Seventy-eight (50.7%) patients underwent colonoscopy. Evaluation with colonoscopy showed 37 clinically important lesions that probably caused IDA; colon cancer in 13 (8.3%) patients, colon polyp in 11 (7.05%) patients and hemorrhoid in 13 (8.3%) patients. Concerning malignant lesions which are responsible for IDA, 21 malignant lesions were found in patients older than 50 years accounting for 21.4% (21/98 patients) and patients younger than 50 years were 17.2 % (10/58 patients).
Summary / Conclusion: This study demonstrated that gastrointestinal blood loss is the main cause of IDA in adult men, and that there is a high rate of malignancy in men older than 50 years, emphasizing a complete and rigorous gastrointestinal examination in this group of patients.

B1861
DIAMOND-BLACKFAN ANEMIA: A CENTER EXPERIENCE
I Cuadrado[1*], A Godoy[1], B De Rueda[1], M del Valle Recasens[1], J Lao[2], R Pazo[2], D Rubio[1]
[1]Hematology, [2]Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: Diamond-Blackfan anemia (DBA) or congenital erythroblastopenia is a rare ribosomal disorder characterized by red cell aplasia, congenital anomalies and predisposition to develop malignancies. Several therapies have been tested, nevertheless only steroid have proven to be efficacious
Aims: Evaluate the clinical characteristics and treatment response of DBA in our medical center.
Methods: This is a retrospective observational study of patients diagnosed in our center DBA (n = 7). Patients medical records were reviewed by assessing the following parameters: age and Hb level at diagnosis, current Hb level, presence of other cytopenias, DBA associated genetic alterations, associated congenital anomalies, ferritin and current IST, type of treatment received, maximun dose, current dose and occurrence of side effects, current need of transfusions and secondary neoplasias.
Results: male: female ratio 4:3. Age at diagnosis was within the first 18 months of life in all cases with a median of 3 months (2-13 months). Medium current age: 15 years (6 months-36 years). Median hemoglobin (Hb) at diagnosis was 5.6 g / dL (2.1 to 6.6) with a current value of 9.9 (9.1 to 13.4). No patient had another cytopenia. The molecular study was conducted in five of them: two have shown mutations in the RPS19 gene regions analyzed; five patients are awaiting to complete the sequencing of the other 8 genes associated with DBA. The prevalence of congenital malformations in our series is 71%, mostly of the cardiovascular type. Prednisone was the main treatment in this series and 86% of patients achieved response. Highest median prednisone dose was 2 mg / kg / day (1.5 to 3); current median dose is 0.2 mg / kg / day (0.08 to 1.7). 71% of patients had therapy-related side effects, mild to moderate in all cases. Other adjuvant therapies: danazol in one case, with no objective response; hemotherapy support: 1 transfusion-dependent patient, iron overload in 3 patients and 2 patients are awaiting chelation. No patient developed secondary malignancies.
Summary / Conclusion: To date, there are few therapeutic options for the DBA; bone marrow transplantation remains as the only potentially curative therapy. As in most studies, in our series of patients corticosteroid therapy is the first line therapy. New therapeutic targets need to be identified urgently to improve the outcome of this ominous disease.

B1862
MACROCYTIC ANEMIA AND ITS CAUSES: A PROSPECTIVE COHORT STUDY
K Stouten[1*], J Riedl[1], M Levin[1]
[1]Albert Schweitzer hospital, Dordrecht, Netherlands

Background: PAGAS, a prospective study concerning anemia and its causes, was started in February 2007 by the Albert Schweitzer hospital in Dordrecht, the Netherlands, in co-operation with 63 general practitioners. Between February 2007 and February 2013, 5833 patients who were diagnosed with anemia and did not exhibit anemia in the preceding two years, were included. Of these patients, 426 (7,3%) were found to have a raised MCV (reference values: 80-100 fl) and were diagnosed with macrocytic anemia.
Aims: An evaluation of the causes of macrocytic anemia found in these 426 patients.
Results: Additional testing demonstrated B12 deficiency in 48 (11,2%) of these 426 patients (reference values: 130-700 pmol/L), and folic acid deficiency in 24 (5,6%, reference values: >5). In addition, 122 patients (28,6%) were shown to have a raised LDH level (reference values: <450 E/L), of whom 52 patients (12,2%) showed raised reticulocytes (reference values: <2,5%), differential diagnosing haemolysis or myelodysplastic syndrome. Raised LDH levels, raised reticulocyte percentage and a raised bilirubine level (reference values: <17 µmol/L) was demonstrated in 9 (2,1%) patients, indicative for haemolytic anemia.
Summary / Conclusion: 179 patients (42%) did not demonstrate a raised reticulocyte count, bilirubin or LDH pointing to bone marrow diseases, e.g. myelodysplastic syndrome, of whom additional testing will be described.

B1863
TRANSCRANIAL DOPPLER IMAGING IN THE MANAGEMENT OF PEDIATRIC SICKLE CELL DISEASE PATIENTS: IMPACT OF HYDROXYUREA
A Elbeshlawy[1*], m el tagui[1], e raouf[1], m hamdy[1], f said[2], i gamal[1], a elashmawy[3], j maakaron[4], a taher[4]
[1]pediatric hematology, [2]clinical pathology, [3]internal medicine, cairo university, cairo, Egypt, [4]internal medicine, american university, beirut, Lebanon

Background: Background: Abnormal interaction of sickle red cells with the vascular endothelium has been implicated in the changes affecting the large vessels of the central nervous system of sickle cell disease patients (SCD).
Aims: Aim: The purpose of this study was to evaluate these changes by transcranial Doppler imaging (TCD) and to assess the effect of hydroxyurea in ameliorating these abnormalities.
Methods: Methods: Fifty five SCD patients in the steady state of the disease (mean age of 10.48±4.44 years) were included in this study. Eleven β thalassemia patients (mean age 10.27±2.69 years) and 11 healthy candidates (mean age 10.38± 3.1 years) were selected as control groups. All patients and control groups were subjected to TCD of the middle cerebral (MCA) and the anterior cerebral arteries (ACA) at baseline, 6 months and one year.
Results: Results: Twenty four of the 55 SCD patients were on hydroxyurea therapy for one year. The mean values of MCA and ACA velocities were statistically higher in SCD patients compared to controls and β thalassemia patients (P<0.001) at baseline. At baseline, the time average peak systolic velocity (TAP) of the MCA was >200 cm/s (high risk) in two SCD patients. One patient was in the intermediate risk group (TAP =170-199 cm/s) and the rest of the patients (52 patients) were low risk (TAP<170 cm/s). After one year of follow up, the patients on hydroxyurea showed reduction of the peak systolic velocity (PSV) and TAP of the MCA when compared to those on conservative treatment. This drop only approached statistical significance (P=0.066& 0.060, respectively). There was a negative correlation between the PSV and TAP of MCA and the age of SCD patients (R = - 0.397 & - 0.348; P=0.003&0.009, respectively). A significant reduction in the number of transfused units of blood and vaso-occlusive crises was observed after hydroxyurea therapy (P=0.005& 0.017, respectively). The percentage of fetal hemoglobin significantly increased while the percentage of Hb S significantly decreased after treatment (P=0.003& 0.003, respectively).
Summary / Conclusion: Conclusion: TCD is a safe method for detection of CNS vasculopathy in SCD. Hydroxyurea can successfully decrease transfusion requirements and vaso-occlusive crises and lead to the reversal of the changes seen on TCD.

B1864

IRON AND VITAMIN D STATUS IN EXCLUSIVELY BREAST-FED INFANTS UNDER 24 MONTHS AND LACTATING MOTHERS

M Kim[1*], J Kim[1], E Ahn[2], E Yoo[1]
[1]Pediatrics, [2]Obstetrics and Gynecology, CHA University, School of Medicine, Bundang Medical Center, Seongnam, Korea, Republic Of

Background: Breast milk is the best nutritional resource for infants. But breast milk cannot satisfy the requirements after 6 months. Since iron deficiency(ID) can adversely affect of neurodevelopment, lactating mothers must maintain sufficient Fe status. Vitamin D stores in the fetus depend on maternal vitamin D status and the breast-fed infants continue to dependent upon their mother afterwards. Vitamin D deficiency(VDD) in exclusively breast milk-fed (EBMF) infants and lactating mothers is prevalent in many parts of the world, especially in Asia. Concurrent deficit of micronutrients might result in wide spectrum of adverse effects in rapid growing infants.
Aims: To assess the Fe and 25-hydroxyvitamin D [25(OH)D] status in lactating mothers and their infants.
To find specific factors affecting both infant and mother to have iron deficiency anemia (IDA) and/or VDD.
To analyze the seasonality of Fe and 25(OH)D
Methods: The infants aged 4-24 months who were exclusively breast-fed were included from Mar 2012 to Feb 2013, who visited CHA Bundang Medical Center (Latitude 37.4°N). The data were collected by questionnaire and laboratory tests such as CBC, reticulocyte, ferritin, Fe, TIBC, CRP, Ca, P, ALP, 25(OH)D. The lactating mother was evaluated for the same laboratory tests a week later. Through the questionnaire, information about the maternal history, birth-related history, breast feeding and weaning pattern, etc.
The infants were divided into IDA, ID and Normal group according to Hb (<11 g/dL) and ferritin (<12 ng/mL). Vitamin D deficiency was defined as 25(OH)D < 20 ng/mL, vitamin D insufficiency as 20-30 ng/mL. The mother's Fe status was defined as ID if ferritin < 50 ng/mL. The subjects were divided into 2 group, winter/spring (November to April) and summer/autumn (May to October), according to the date of laboratory test. Winter/spring group (WS) was compared with summer/autumn group (SA).
Statistical analysis was done by SPSS (version 17.0) with P value < 0.05.
Results: There were 64 infants and lactating mothers who agreed to participate. Nine were excluded because they had previous Fe and/or vitamin D supplements. The average age of the infants was 10.2 months and the average age of the mothers at delivery was 32.2 years. IDA was found in 32 infants and VDD in 45. Maternal Hb was < 12 g/dL in 6 and VDD was found 51 mothers. Weaning food was started in 50 infants and 23 of their mother reported having feeding problem due to refusal. Thirteen of 56 mothers had previous history of IDA before pregnancy, 26 of them needed additional Fe supplementation during pregnancy and only 6 were taking multivitamin at present. The averages of 25(OH)D were subnormal in both infants and mothers (12.7, 12.9 ng/mL respectively). Maternal ferritin did not affect the Fe status of infants but mothers with 25(OH)D < 20 ng/mL had infants with lower 25(OH)D level (P<0.05).
If the mother had a history of IDA before pregnancy, there was a tendency to have maternal ferritin < 50 ng/mL at present (P<0.05), and maternal 25(OH)D < 12 ng/mL (P<0.05). If the mother started menstruation during lactation, they had a lower ferritin (t test, P<0.05). First born infants were 27. If the infant was 2nd child or after, there was a preference to have a lower maternal 25(OH)D and higher TIBC in infants but statistically not significant (P=0.61, 0.63 repectively).
The infants in WS group had significantly lower 25(OH)D (P<0.005), but no difference in Hb, MCV, reticulocyte and ferritin (Table 2). The mothers in WS group also had significantly lower 25(OH)D, but SA group had lower reticulocyte and ferritin (P<0.05) with no differences in Hb and WBC.

Table 2. Comparison between WS group and SA group*

	Infants			Mothers		
	WS	SA	p**	WS	SA	p**
Hb	10.4	10.1	ns	13.1	13.0	ns
MCV	72.1	69.5	ns	87.8	87.6	ns
RDW	14.8	14.9	ns	12.8	12.8	ns
Reti	1.51	0.82	ns	1.04	0.89	0.04
Ca	9.6	9.4	ns	9.0	8.9	ns
P	4.7	4.8	ns	3.7	3.8	ns
ALP	561	656	ns	226	237	ns
25(OH)D	9.6	15.7	0.003	11.5	14.2	0.02
Ferritin	41.4	31.6	ns	59.4	37.1	0.02

* All the data are in average,
WS: winter/spring, SA: summer/autumn
** Student's T test, ns: not significant

Summary / Conclusion: IDA was prevalent in EBMF infants but ID was not in lactating mothers because of amenorrhea. The average of vitamin D was subnormal both in infants and mothers. If the mother has a history of IDA before pregnancy, EBMF might result in concurrent deficiency of both Fe and vitamin D. Consecutive pregnancies might result in more profound deficits but research in needed. Seasonal variation of 25(OH)D emphasizes the concern about VDD, and ID might be prevalent among lactating mothers in summer and autumn in Korea. Supplementation of micronutrients such as Fe and vitamin D should be routinely practiced in EBMF infants and their mothers especially who starts menstruation during lactation.

B1865

MAY BE PREDICTED THE PATIENTS WITH IRON DEFICIENCY WITHOUT ANEMIA FROM PARAMETERS OF COMPLETE BLOOD COUNT?

C Beyan[1*], E Beyan[2]
[1]Department of Hematology, Gulhane Military Medical Academy, [2]Department of Internal Medicine, Kecioren Training and Research Hospital, Ankara, Turkey

Background: Iron deficiency without anemia (IDNA) was three times more common from iron deficiency anemia (IDA) which is the most common nutritional deficiency in the world. Data from the Third National Health and Nutrition Examination Survey (NHANES III; 1988 to 1994) indicated that iron deficiency anemia was present in 1 to 2 percent of adults and IDNA was occurred up to 11 percent of women and 4 percent of men.
Aims: The aim of the study is to investigate whether or not differentiation of the cases with IDNA from healthy subjects using with parameters of complete blood count or related formulas.
Methods: This study was carried out on 37 IDA patients (35 female) ages ranging from 18 to 77 (mean±standard deviation: 39.46±13.29 years), 23 IDNA patients (22 female) ages ranging from 24 to 73 (37.74±11.20 years) and 40 healthy subjects (20 female) as control group ages ranging from 19 to 79 (42.27±13.35 years). Mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), red cell distribution width (RDW), platelet count (PLT), mean platelet volume (MPV), plateletcrit (PCT), microcytic anemia factor (MAF) (=[hemoglobin x MCV]/100), volume hemoglobin/distribution factor (VHDWf) (=[MCV×hemoglobin]/[RDW×10]) and RDW x PCT were used for comparisons.
Results: There was statistically significance for indices of MAF and VHDWf between IDNA group and healthy subjects. The percents of sensitivity, specificity, accuracy and Youden's index belonging to cut-off values of these indices were shown in Table 1. The cut-off value of MAF <12.5 has high ratio from accuracy and Youden's index.
Summary / Conclusion: The cut-off value of MAF <12.5 may be warranted to differentiate the patients with IDNA from healthy subjects.

	Sensitivity	Specificity	Accuracy	Youden's indeks
MAF <11.21	60.9%	85.0%	76.2%	45.9%
MAF <11.50	65.2%	82.5%	76.2%	47.7%
MAF <12.00	65.2%	70.0%	68.3%	35.2%
MAF <12.50	91.3%	65.0%	74.6%	56.3%
MAF <12.81	95.6%	50.0%	66.7%	45.6%
VHDWf <7.86	56.5%	87.5%	76.2%	44.0%
VHDWf <8.00	56.5%	85.0%	74.6%	41.5%
VHDWf <8.50	65.2%	77.5%	73.0%	42.7%
VHDWf <9.00	82.6%	60.0%	68.3%	42.6%
VHDWf <9.37	87.0%	50.0%	63.5%	37.0%

MANAGEMENT OF INVASIVE FUNGAL INFECTIONS IN PEDIATRIC ACUTE LEUKEMIA AND THE APPROPRIATE TIME FOR RESTARTING CHEMOTHERAPY

Ö Tüfekçi[1], Ş Yılmaz[1], F Yenigürbüz[1], E Şimşek[1], T Karapınar[1], G İrken[1], H Ören[1*]
[1]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, İzmir, Turkey

Background: Invasive fungal infection (IFI) is a life threatening problem in patients with leukemia. Rapid and effective treatment is important for survival. The optimal time for restarting chemotherapy in these patients is not clear.
Aims: We aimed to describe variations regarding clinical features, treatment modalities, time of restarting chemotherapy (CT) and outcome in children with IFI and acute leukemia (AL).
Methods: The charts of all pediatric AL patients in our clinic between the years 2001 and 2013 were retrospectively reviewed and data of patients with IFI were analysed.
Results: IFI was defined in 25 (14%) of 174 AL patients. Of those, 17(68%) had ALL and 8(32%)had AML. The median age was 12 years (range 0.7-17.5 years). Nine (36%) of the patients were in induction, 14 (56%) of the patients were in the consolidation phase and 2 (8%) of the patients were in the maintenance phase of CT and overall 18 (72%) patients were in remission at the time of diagnosis of IFI. The median time between the leukemia diagnosis and the definition of IFI was 122 days (range 15-305 days). ANC was <500/mm3 in 86 % of patients. The median time for duration of neutropenia was 13 days (range 0-47 days). All of the patients were febrile at the time of diagnosis. Of the 25 AL patients with IFI, 23 patients had isolated pulmonary IFI, one patient had isolated orbitocerebral aspergillosis infection and one patient had both orbitocerebral and pulmonary mucor and aspergillosis infection. Those two patients with orbitocerebral IFI needed surgery . The most frequent finding on computed tomography was typical parenchymal nodules. Galactomannan was screened in 21 patients and of those, 9 (42%) had positive galactomannan antigenemia. The episodes were defined as proven in 2 (8%) patients, probable in 9 (36%) patients and possible in 14 (56%) patients. The median time for discontinuation of chemotherapy was 27 days (range 0-57 days). Chemotherapy was not restarted in three patients due to refractory/progressive primary disease. Out of 22 patient in whom chemotherapy was restarted, the duration for cessation of chemotherapy was 0-14 days in 5 (23%) patients and 15-28 days in 6 (27%) patients. Overall chemotherapy was restarted in 50% of the patients safely before 4 weeks, and none of those patients experienced relapse of IFI. IFI was treated succesfully in all patients with voriconazole, amphotericin B, caspofungin, posaconazole alone or in combination. All of them were given secondary prophylaxis with oral voriconazole, itraconazole, or posaconazole. The median time for secondary prophylaxis was 90 days (range 39-429 days). None of the patients died due to IFI.
Summary / Conclusion: Our data shows that rapid and effective antifungal therapy with rational treatment modalities may decrease the incidence of death in children with AL and IFI. Depending on the clinical status of the patient, restarting chemotherapy in several weeks may be safe and relapses of IFI may be prevented with secondary prophylaxis.

B1868

RISK FACTORS FOR ACQUIRED BLOODSTREAM INFECTION AMONG NEUTROPENIC PATIENTS.

D Theocharidoy[1], E Papadakis[2], E Siskou[1], V Papageorgiou[2*], K Loukidis[3], K Tsepanis[1], K Skarmoutsou-Tsimirika[2], E Georgiou[2], A Karagianni[2], V Koulouri-da[1], A Kioumi[2]
[1]Microbiology Department, [2]Hemostasis Unit-Hematology Department, Papageorgiou Hospital, Thessaloniki, Greece, [3]Hematology Clinic, Offenbach General Hospital, Offenbach, Germany

Background: Febrile Neutropenia is a major cause of mortality among hematological patients. It is estimated that about 10- 15% of patients with severe neutropenia will develop bloodstream infection during their hospitalization. Especially Gram negative -Gram(-)- bacteremia is associated with high mortality rates (25%) during the first 24- 48 hours of febrile episode onset
Aims: To estimate risk factors and incidence of bloodstream infection among neutropenic patients of our Hematology Department (10/2007- 9/2011) and to develop a risk score for Gram(-) bacteremia.
Methods: We evaluated 50 patients (25 male, 25 female), with a median age of 58.50 years, who underwent 106 episodes of febrile neutropenia. Bloodstream infection was diagnosed when a positive blood culture was in total compliance with clinical signs. Risk factors that were investigated were: Age, gender, malignancy type, diabetes, renal failure, insertion of central vein catheter (CVC), positive urine/ sputum culture, length of stay in the hospital, WBC/Neutrophil count, Serum Total Protein/ Albumin and prophylactic antibiotic administration. Multivariate logistic regression analysis (MLRA) was performed in order to determine independent risk factors of acquisition of blood stream infection. Covariates were included in the model if univariate analysis revealed that were significantly associated with bacteremia at a P<0.1. Independent risk factors in MLRA were used to build a predictive score for Gram(-) bloodstream infection
Results: Among 106 febrile episodes, 46 (43.4%) were attributed to bacteremia. In a univariate analysis, statistically significant risk factors for bloodstream infection were: insertion of CVC (P<0.0005), positive urine culture (P=0.03), Acute Myeloid Leukemia (AML) (P=0.009), Neutrophil Count (P<0.0005). A Multivariate Logistic Regression Analysis revealed neutrophil count (decrease of 10 degrees at the neutrophil count is associated to 4.9% higher probability of acquiring bloodstream infection) and presence of CVC (5 times higher risk) as independent risk factors. Gram(-) bacteremia in a univariate statistical analysis was significantly associated with neutrophil count (P=0.049), CVC line (P=0.01), AML (P=0.013) and positive urine culture (P=0.007). Multivariate Logistic Regression Analysis revealed positive urine culture (risk 8 times higher), presence of CVC (risk 5 times higher) and neutrophil count <250/μL (risk 5 times higher), as independent risk factors. A risk score for Gram(-) bloodstream infection was developed by weighting independent risk factors and the presence of AML (CVC+2, positive urine cuture+1.5, neutrophil count <250μL+1, AML+0.5). Diagnostic ability of our scoring system as reflected by the area under the curve of the receiver operating characteristic was 0.792 (95% CI: 0.705- 0.879). Performance of our scoring system and post test probabilities according to different prevalence rates of Gram(-) bacteremia (0.05, 0.1, 0.2) led us to propose a Gram(-) risk score >=2.5 as indicating high probability of Gram(-) infection. A detailed description of independent risk factors for acquiring bloodstream infection, and precisely Gram(-) bloodstream infection, and the performance of our Gram(-) score is shown on table attached.
Summary / Conclusion: Our scoring system identifies patients with high probability of Gram(-) bloodstream infection. If confirmed in a validation set, this score could be considered in the choice of first line antibiotics in febrile neutropenia.

B1869

POSACONAZOLE PROPHYLAXIS DURING INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA (AML): RESULTS OF A PROSPECTIVE AUDIT OF 102 PATIENT EPISODES

C Roughley[1*], F Muhlschlegel[2], P Elton[3], K Lang[4], M Mohamed[1], J Lindsay[1], K Saied[1], V Ratnayake[5], C Pocock[1]
[1]Department of Haematology, [2]Department of Microbiology, [3]Department of Radiology, East Kent Hospitals, [4]Department of Haematology, East Kent Hospital Trust, Canterbury, [5]Department of Haematology, East Kent Hospitals, Ashford, United Kingdom

Background: Aspergillus species are ubiquitous, but invasive pulmonary aspergillosis (IPA) only occurs in immunocompromised hosts. Posaconazole is a broad spectrum triazole, active against aspergillus species, which has been shown to be more effective than fluconazole or itraconazole at preventing IPA in patients receiving therapy for AML or high risk myelodysplastic syndrome (HR-MDS; N Engl J Med. 2007;356[4]:348).
Aims: This study was designed to look at the effectiveness of posaconazole prophylaxis in preventing IPA in patients receiving intensive chemotherapy for AML and HR-MDS.
Methods: Posaconazole 200mg tds was started when neutrophils were $0.8x10^9$/l and falling; and was stopped when neutrophils were $0.5x10^9$/l and rising. Data collected included length of stay, numbers of days of posaconazole and other antifungals, and whether posaconazole was started and stopped as per local protocol. Data collected included number of high resolution CT (HRCT) scans and their results including any follow up scans. We did not monitor galactomannans or perform bronchoscopy, and change in antifungal therapy was determined by radiological changes only. If an HRCT scan was positive for IPA, then caspofungin was commenced. This abstract looks at the outcomes of 102 patient episodes (57 patients) treated with prophylactic posaconazole.
Results: The mean patient age was 57.3y (range of 20-82) with median age of 61. Length of Stay mean was 21.9d (median 24, range 0-53) with 7 episodes where patients were not admitted. Mean length of posaconazole use was 22d (median 21, range 0-54). One patient did not become neutropenic and therefore did not receive prophylaxis. There was 1 dose of empirical caspofungin (given over a bank holiday weekend) and only 1 day of empirical liposomal amphotericin. Fifty five HRCT scans were performed in total (predominantly of chest, 2 of sinuses). There were 13 patient episodes where there was new radiological evidence of IPA. All but one of these was in patients during induction chemotherapy with proceeding neutropenia. One episode was in a patient during first consolidation phase that had entered a morphological but not cytogenetic remission. One patient died of haemoptysis due to IPA (*Hormographiella aspergillata* isolated at post mortem) following induction therapy but having obtained remission. Fifteen episodes received caspofungin for mean 8 days (range 1-14, median 7 days). Four episodes received liposomal amphotericin (mean 7.3d, range 1-16 days). Voriconazole was received in 5 episodes for mean of 10.2 days (range 7-16, Median 7 days).
Summary / Conclusion: No patient to date in complete cytogenetic and mor-

phological remission at the start of the chemotherapy cycle went onto develop clinical evidence of IPA. Of the 102 patient episodes in the study, there were 13 episodes where there was new radiological evidence of IPA. There was only one death from IPA in a patient who was in remission. Posaconazole prophylaxis appears effective in this situation.

B1870

PERIPHERALLY INSERTED CENTRAL CATHETERS IN PATIENTS WITH HEMATOLOGICAL DISEASES: A RETROSPECTIVE STUDY

V Papageorgiou[1], A Samaras[2], E Georgiou[1], K Kokoviadou[1]*, A Karagianni[1], A Adamidis[1], V Papadopoulos[1], A Mpanti[1], E Siskou[3], E Papadakis[1], K Karamoschos[2], A Kioumi[1]

[1]hematology Department Papageorgiou General Hospital, [2]2nd Surgical Clinic Papageorgiou General Hospital, [3]microbiology Department Papageorgiou General Hospital, Thessaloniki, Greece

Background: Peripherally inserted central catheter (PICC) is an intravenous device inserted through a peripheral vein, under ultrasound guidance, and then advanced until its tip reaches the superior vein cava. There is a widespread use of PICCs in medical practice and especially in patients with hematological diseases, who usually face coagulation disorders or are at high risk for infection,and most of the times need long term central access. PICCs have eliminated the need for prolonged hospitalization, which was once necessitated for antibiotic and fluid administration, blood sampling or chemotherapy. This device is widely used due to its easy insertion, long term use and reduced risk of complications.
Aims: The present study aims to analyze the data available regarding the use of PICCs in hematological patients, using data collected from medical records of our hospital.
Methods: It is a retrospective study of 81 hematological patients, in whom a PICC was inserted in a 42-month-period, since January 2009 until June 2012. Complete data was available from the records for 72 patients. Definite catheter-related bloodstream infection was defined as the isolation of a pathological microorganism from the catheter segment and the blood drawn from the peripheral vein and/or the positive catheter tip's culture after its removal.
Results: A total of 72 patients were recruited, including 38 (52, 8%) males and 34 (47, 2%) females. In all patients PICC was inserted via a peripheral vein of the upper extremity. All insertions were successful and there were no major complications like hemorrhage or pneumothorax. The total duration with PICC use was 5504 patient days. The growth curve in the use of PICC was from 0, 75 per month in 2009 to3, 5 per month in 2012. Concerning the underlying condition of the patients data showed that: 30 patients (41, 7%) suffered from acute leukemia, 20 (27, 8%) from Hodgkin lymphoma, 14 (19, 4%) from non Hodgkin lymphoma, 3 (4, 2%) from chronic lymphocytic leukemia, 4 (5, 5%) from multiple myeloma and 1 (1, 4%) from severe iron deficiency anemia. The duration of PICC's use varied from a minimum of 1 day to a maximum of 306 days. The catheters that were routinely removed without any related complications were 39 (54, 2%), whereas those removed earlier than expected were 33 (45, 8%). Causes for earlier removal: catheter's migration in 2 cases (6, 1%), thrombosis in 2 cases (6, 1%), obstruction in 7 cases (21, 2%), localized inflammation in 3 cases (9, 1%), accidental removal in 5 cases (15, 2%), fever without definite catheter-related bloodstream infection in 8 cases (24, 2%) and definite catheter-related bloodstream infection in 6 cases (18,2%). Microorganisms isolated were: acinetobacter in 2 patients (33, 3%), serratia in 1 patient (16,7%), klebsiella in 1 patient (16, 7%), e.coli in 1 patient (16, 7%) and staphylococcus hominis in 1 case (16, 7%). In none of the patients who died, a catheter-related complication was the cause of the fatal outcome. According to our data, 9 patients died due to natural progression of their disease. The removal of the catheter in all cases was without the need of any special measures. All patients that carried the catheter on an outpatient basis received regular care by trained healthcare personnel.
Summary / Conclusion: Peripherally inserted central catheters have been used in clinical practice and seem to offer a reliable way of providing therapy and support. Their insertion and extraction is safe and simple. These catheters may be used in hematological patients, suffering from benign or malignant diseases that need long term therapy. Infectious complications, seem to be the same or even slightly better when a PICC is used versus a traditional central venous catheter. Larger comparative studies are needed in order to compare PICC and other central venous catheters concerning infectious and other complications.

B1871

ROLE OF SEDO-ANALGESIA IN EXECUTION OF BONE MARROW BIOPSIES

M Postorino[1]*, R Rossi[2], A Zizzari[3], F Marchesi[4], I Provenzano[1], L Franceschini[1], L Pupo[1], M Rizzo[1], L Gianni'[1], S Gumenyuk[1], G De Santis[1], D Renzi[4], G Guiducci[1], E Fiorelli[3], C Filadelfo[2], R Puliti[2], A Berrini[2], M Dauri[2]

[1]Haematology, [2]Anesthesiology, [3]SIMT, Policlinico Tor Vergata, [4]Haematology, Campus Biomedico, Rome, Italy

Background: Both, morphological and architectural analysis of bone marrow (BM) represent one of the key aspects in the diagnosis and staging of hematological diseases. The former is obtained from the bone marrow aspiration, the latter from bone marrow biopsy (BMB). The BMB is one of the most painful procedures for hematological patients. It consists of an extraction of a boned-sized cylinder of 20x0.8 mm and it is executed on the posterior iliac crest. During the patient's medical history this procedure is often repeated several times. It generallyinvolves patients in a pediatric or old age with associated comorbidities. The BMB procedure is frequently performed in outpatients. For this reason, it has to be quick with an extremely reduced level of risk of complication. Being the procedure itself invasive, anesthesia has been introduced not to have negative phsychological effects on seriously ill patients. However, this procedure might encounter some difficulties because of the shortage of specialized personnel (anesthesiologist), lack of facilities for respiratory assistance, long standing and patient observation. It might increase clinical risk in patients with an severe comorbidity or mediastinal syndrome. In our Department, an observatory study has been carried out for the execution of BMB by using short sedation analgesia through pharmacological low posology.
Aims: The objectives of this study are: to verify the feasibility of a sedo-analgesia , to evaluate its clinical and operational advantages, to standardize the procedure, so that trained health personnel can perform it with the availability of the anesthesiologist.
Methods: From 10/11/2011 to 7/01/2012, 169 patients affected by oncohematology disease aged 12-78 years old (averaged 60 years old), 48% male and 52% female, were subjected to sedation to perform the BMB practice. Of these 169, 3 were classified in a pedriatric age, 42 were affected by cardiovascular diseases and 12 refearred neuropsychiatric diseases. Patient's medium weight was 56 kg (range 42-102 kg). In our court of patients, 85% was affected by lymphoproliferative disorders, 6% by myeloproliferative disorders, 9% by other affections. This procedure was performed morethan once in 33% of the patients. They were all monitored by ECG and by a digital oximeter. The induction was executed with 100 ug of Fentanyl push, whose quantity was reduced in pediatric and patients with acute heart disease. After 5 minutes it was followed by an administration of 7cc of Propofol at the 1% in 1-2 minutes. Reached the total sedation with spontaneous breathing with ventimask . When the BMB had started it was followed by a continuous infusion of 0,3 ml/min of Propofol as maintenance till the end of the procedure.
Results: The average duration of the sedation was 860 sec.(360-1800 sec), with a median administration of Profofol like 12cc (range 4-30cc); in 22% of the cases itwas necessary to re-induce it with 2cc of Popofol for an initial sedation at the time of the subluxation and the exportation of the bone cylinder, 3/134 (2%) had hiccups and in 1% the use of atropine was necessary. The wake up took about 110 seconds (35-390 sec.); just one patient required assisted ventilation for an acute desaturation caused by a regurgitation in a patient not completely compliant in the preparation. Any major cardiovascular side effect was verified. Discharge of patients took place about an hour after the end of sedation, no patients required hospitalization for late complications following the sedation. This one hour time comprised both, the quick wake up and the post-observation of the patient.
Summary / Conclusion: The above results have demonstrated that our protocol of sedation is effective, safe and simple to apply since it requires only the monitoring of anesthesia and the availability of the anesthesiologist.

B1872

EPIDEMIOLOGY OF BLOODSTREAM INFECTION IN FEBRILE ADULTS WITH HEMATOLOGICAL CANCER

G Mendez[1]*, H Bernard[2], C Niveyro[3], J Fernandez[3], C Devecchi[4], M Beligoy[4], A D´Elia[4]

[1]INFECTIOUS DISEASES DEPARTMENT, [2]HEMATOLOGY DEPARTMENT, [3]INFECTIOUS DISEASES, [4]HEMATOLOGY, HOSPITAL ESCUELA DE AGUDOS DR RAMON MADARIAGA, POSADAS, Argentina

Background: The majority of patients with haematological malignancy are at high risk of infection during the period of neutropenia. Microbiologically documented infections, especially those with bacteriemia, remains a major concern in the treatment of hematological patients undergoing intensive cytotoxic chemotherapy. The study of the most frequent pathogens and their susceptibility must be continuosly used to guide the initial and empiric antimicrobial therapy and to develop strategies to minimize the emergence of resistant pathogens.
Aims: To describe the epidemiology of bacteriemia in adults patients with hematological cancer and febrile neutropenia (FN) in a terciary hospital.
Methods: A retrospective observational study of all positive blood cultures from June1, 2010 to January 31, 2013 from all consecutive oncohematologic patients >15 years old. The microorganism isolation was performed using BACTEC 9240 with classical identification and antibiogram disk by diffusion.
Results: A total of 193 episodes of FN corresponding to 94 patients, with 67 (34%) episodes of BSI. Male: 47 (70.14%), mean age 35.85 years (15-79); females: 20 (29.85%), mean age 32 years (16-79). Most common primary diseases associated with neutropenia were: acute lymphoblastic leukemia 29 (43%) episodes, acute myeloid leukemia 22 (32%) and non.Hodgkin´s lymphoma 8 (11%). Patients with disease relapse 18 (26%). An indwelling central catheter was present in 30 (44%) of them. We observed 36 (53%) Gram-neg-

ative bacteria infections, among *Escherichia coli* and *Klebsiella pneumoniae*, 5% and 16% respectively produced extended-spectrum β lactamases. Twenty-seven percent of *E. coli* and 25% of *K. Pneumoniae* were sensitive to cefepime, our first line empirical therapy. Twenty-nine (43%) Gram-positive infections were diagnosed (9 coagulase-negative *Staphylococcus* and 7 *Staphylococcus aureus*). Oxacilin resistance was present in 77% of CNS and in 14% of *Staphylococcus aureus*. Fungal represented 3% (2) of the isolates. Overall mortality was 14.92%, mortality caused by infection 10.44%.
Summary / Conclusion: The epidemiological profile of BSI and FN in our center and the necessity to continue the surveillance was described. Gram-negative bacteria are prevalent as cause of infection in our patients, followed by Gram-positive bacteria and fungal were uncommon.

B1873
HAND HYGIENE AUDIT AT THALASSEMIA CENTRE-DUBAI
K Belhoul [1], M Bakir[1*], S Libda[1], S Hassan[1]
[1]Thalassemia centre , Dubai Health Authority , Dubai, United Arab Emirates

Background: The hands of staff are the most common vehicle by which microorganisms are transmitted between patients and staff. Hand hygiene is the single most important measure in preventing the transmission of infection and can be considered the entrance door to better infection control and safer patient care. Despite advances in infection control this simple message is not consistently translated into clinical practice. Clinical audit is identified by the World Health Organization (WHO) as one of the effective approaches to ensure compliance with hand hygiene in health care settings.

		Mean of compliance for all HCW	Mean of compliance for Nurses	Mean of compliance for Doctors
International Audit	NHS 1st Audit Feb 2007	68%	75%	50%
	NHS 2nd Audit Sep 2007	79%	84%	62%
	NHS 3rd Audit May 2008	88%	92%	75%
	NHS 4th Audit Aug 2008	90%	94%	80%
	NHS 5th Audit Nov 2008	93%	95%	84%
	NHS 1st Bimonthly Audit Mar 2009	92%	92%	86%
	NHS 4th Bimonthly Audit Sep 2009	92%	94%	88%
	NHS 8th Bimonthly Audit May 2010	95%	95%	90%
	NHS 12th Bimonthly Audit Feb 2011	95%	95%	92%
	NHS 13th Bimonthly Audit Apr 2011	95%	95%	90%
	NHS 18th Bimonthly Audit Feb 2012	95%	96%	89%
	NHS 22nd Bimonthly Audit Oct 2012	95%	96%	89%
Thalassemia Centre-Dubai	1st Audit May 2007		39%	
	2nd Audit Oct 2007		84%	
	3rd Audit July 2008	63%	85.5%	66.5%
	4th Audit May 2009	79%	83%	87.5%

	11th Audit Nov 2012	92%	95%	88%

Table 1 Hand Hygiene Audit- mean compliance

Aims: To monitor compliance of health care providers (HCP) at thalassemia centre to hand hygiene guidelines and identify areas for improvement.
Methods: A prospective audit was conducted in 2007 at thalassemia centre through direct observationof nurses for compliance to hand hygiene guidelines before and after touching the patients. The audit was extended to involve all HCP in 2008. Thereafter, re-audits were performed twice annually (2009-2012). The grading of compliance was scored per RAG status as featured by Infection Control Nurses Association (ICNA) audit tool, used in NHS services audits; compliant(C)>85%, partially compliant (PC) 75-84% and minimally compliant (MC) <75%.
Results: The first audit conducted in May 2007 revealed 39% compliance (MC) which was improved to 84% (C) in Oct 2007 by identifying areas for improvement. This has included installment and thorough distribution of a new alcohol based hand rub that contained a moisturizer and vitamin E, in addition to continuous HCP education about the importance of their adherence to hand hygiene guidelines. In 2008, over all HCP compliance was 63% (PC) with nurses' compliance dropping to 65.5% (PC). Thereafter, compliance of all HCP could be maintained between PC to C (2009- 2010) by continuous regular education and by encouraging discussions among staff on how to improve hand hygiene. In 2011 and 2012, over all HCP compliance has improved to reach above90% (C) as shown in (Table 1). Compliance to hand hygiene after touching the patient was always better than before touching the patient. Our results are comparable to international results like NHS services and Niagara Health System.
Summary / Conclusion: Continuous re-auditing and targeted educational programs are effective approaches to improve compliance of HCP to Hand Hygiene guidelines as one of the infection control objectives.

B1874
A NOVEL FRAGILITY MARKER OF RECIPIENTS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION : PERITRANSPLANT CMV VIREMIA
Y Ono[1*], H Hashimoto[2], o Kazuma[1], Y Nagahata[1], J Takeda[1], N Yamauchi[1], Y Funayama[1], A Kato[1], K Aoki[1], S Tabata[1], N Yonetani[1], A Matsushita[1], T Ishikawa[1]
[1]Department of Hematology, Kobe City Medical Center Genaral Hospital, [2]Department of Cell Thearapy, Institute of Biomedical Research Innovation hospital, Kobe City, Japan

Background: Cytomegalovirus (CMV) infection remains to be one of the major obstacles for allogeneic hematopoietic stem cell transplantation (allo-HSCT). CMV can cause infectious diseases in various organ, such as pneumonia, hepatitis, gastroenteritis, retinitis and encephalitis. In addition, the mechanism of CMV infection is complex with interaction with the immune system through several effects on NK cell function, HLA expression and cytokines production, which resulted in increased risk of transplant-related mortality. Multiple studies reported that because CMV replication is delicately balanced with host immune system, in such a situation of admitting an intensive care unit(ICU), CMV reactivation without overt disease occurred and had an association with adverse clinical outcomes.
Aims: By using realtime polymerase chain reaction (RQ-PCR), we have monitored weekly CMV viremia in allo-HSCT recipients and explored risk factors of peritransplant reactivation of CMV in allo-HSCT recipients and effect of peritransplant CMV reactivation on clinical outcomes of allo-HSCT.

Characteristics		Peritransplant CMV reactivation(+)	Peritransplant CMV reactivation(-)	p
Sex (F/M)		5 / 3	27 / 26	0.71
Age	Mean (Range)	51.5 (37-64)	48.0 (17-66)	*0.0385*
Underlying disease	Non-lymphoid AML/RAEB/RA/CMML/AA	1/0/0/1/0	24/3/1/2/1	*0.1351* (non-lymphoid vs lymphoid)
	Lymphoid NHL/ALL/Ph+ ALL/ATL/ Aggressive NK leukemia	2/2/1/1/ 0	9/6/4/2/ 1	
Donor source	BM / CB / PB	5/3/0	42/9/2	0.5031
Conditioning intensity	MAC/RIC	4/4	29/24	1
HLA matching	Match	3	23	0.4868
	Rj way: 1MM/2MM/3MM	1/2/0	16/5/3	
	GV way: 1MM/2MM/3MM	1/2/0	15/6/3	

Methods: We analyzed data for 61 patients who underwent allo-HSCT in our institution and whose CMV DNA levels were weekly monitored using blood samples by RQ-PCR method. We did not use measures for prophylaxis for CMV reactivation as routine, but used low-dose acyclovir (200mg 3-4times daily) as prophylaxis for VZV. Peritransplant CMV reactivation is defined as an event where plasma CMV DNA exceeds1,000 copies/mL during peritransplant period before engraftment. Engraftment is defined as emergence of more than 500 /μL of donor-derived neutrophils in peripheral blood.
Characteristics of patients with or without peritransplant CMV reactivation were compared using the Fisher's exact test. Predictors of peritransplant CMV reactivation was estimated in a multivariate logistic regression model. Multivariate analysis of potential prognostic factors for overall survival from stem cell transplantation was estimated in Cox proportional hazard model with time-dependent covariates of CMV reactivation.
Results: Consecutive sixty-one patients were included in the analysis. Median age was 49 (range, 17-66). All patients except 5 were CMV seropositive. Other patients characteristics is shown in Table. The blood CMV DNA exceeded1,000 copies/mL before engraftment in 8 patients (peritransplant CMV reactivation+). In multivariate logistic regression, predictors of peritransplant CMV reactivation was: previous CMV reactivation(OR: 3.87; 95% CI: 5.48- $1.18x10^3$; P=0.00258), lymphoid malignancy in non-remission state(OR: 3.14; 95% CI: 0.881- $1.15x10^3$; P=0.0656) and age of more than 50-years old(OR: 2.649; 95% CI: 1.45-$3.70x10^2$; P=0.0459). Previous chemotherapy regimen and use of immunosuppressant other than corticosteroid were not significant. The OS rate at 1 years in groups with and without peritransplant CMV reactivation were 41.7 % and 71.2%, respectively [HR: 3.23 (95% CI: 1.18-8.83), P=0.0224]. The causes of death in the peritransplant CMV reactivation group included infectious diseases not associated with CMV in 2(50%), multiorgan failure in 1(25%) and underlying disease in 1(25%).
Summary / Conclusion: Peritransplant CMV reactivation may adversely impact on clinical outcome after allo-HSCT despite of preemptive therapy for CMV same as in an ICU setting. The cause of death was not overtly associated with CMV infectious disease. For patients with risk factors of peritransplant CMV reactivation, more aggressive intervention might be warranted.

B1875

FEBRILE NEUTROPENIA EPISODES AND EVALUATION OF AVAILABLE BIOMARKERS AMONG CHILDREN WITH HEMATOLOGICAL MALIGNANCIES

M Kourti[1*], I Iosifidis[2], A Slavakis[3], V Sidi[1], A Geladari[2], S Goumberi[1,4], D Koliouskas[1], E Roilides[5]
[1]Pediatric Oncology Department , [2]Pediatric Infectious Diseases Unit, [3]Department of Biochemistry, [4]Hippokration General Hospital, [5]Pediatric Infectious Diseases Unit, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Febrile neutropenia in children with hematological malignancies is related to substantial morbidity and mortality.
Aims: We prospectively monitored episodes of febrile neutropenia, complications and evaluated available biomarkers.
Methods: Prospective data collection on all episodes of febrile neutropenia (absolute neutrophil count<1000 cells/mm3) in children with hematological malignancies who were hospitalized in an 18-bed pediatric oncology department over one year period. Endpoints of this study were documentation of bacterial, viral or fungal infection and estimation of mortality. C-reactive protein (CRP) and procalcitonin were evaluated as predicting biomarkers.
Results: There were 423 admissions and 3189 bed-days during the studyperiod. A total of 78 episodes of febrile neutropenia (88% during induction chemotherapy) were identified in 37 children with median age 5 yeras old (range 1-14) and 67% girls. The majority of patients w (72%) were diagnosed with acute lymphoblastic leukemia. Documented bacterial infections were found in 22/78 episodes (19 bloodstream infections, 1 urinary tract infection and 2 other). The leading pathogen was Coagulase-Negative-Staphylococci (49%), followed by Escherichia coli (18%), Klebsiella spp (8%) and Pseudomona aeruginosa (8%). It is noteworthy that 4%% among Klebsiella spp and 39% among E.coli isolates were extended beta-lactamase producers (ESBL). There aws one documented CMV infection and 1 hepatosplenic candidiasis. A total of 3 deaths occured but only one was infection related. The median CRP in children with documented bacterial infection was 80.7, while in children without documented bacterial/viral or fungal infection was 29.3, respectively (P=0.019). Positive procalcitonin (>0.0 mcg/l) was significantly associated to proven bacterial infections (P=0.039)
Summary / Conclusion: Bloodstream infections remain the main complication of febrile neutropenia. Gram-positive bacteria have become more commonly isolated etiologic pathogens. Nevertheless, the significant increase of gram-negative episodes need special attention due to the growing incidence of antimicrobial resistance as a consequence of the widespread use of antibiotics. CRP and procalcitonin may provide useful and important assistance for guiding prompt treatment of episodes of febrile neutropenia in children with hematological malignancies.

B1876

PROCALCITONIN AND C-REACTIVE PROTEIN AS PREDICTIVE PARAMETERS FOR DEVELOPING SEVERE SEPSIS IN FEBRILE NEUTROPENIA.

I Olazabal[1*], A Balerdi[1], R Del Orbe[1], M Olivares[1], M Zamora[1], E Amutio[1], M Dueñas[1], L Elicegui[1], A Iglesias[1], M Puente[1], J García-Ruiz[1]
[1]Hematology, Cruces Universitary Hospital, Barakaldo, Spain

Background: The classical attitude towards treating febrile neutropenia (FN) is the intravenous administration of antibiotics, which in most cases, requires Hospital admission. In recent years a development of models that discriminate a subpopulation of patients with low-risk neutropenia may benefit from outpatient oral and / or a shorter duration of antibiotic treatment. This measure represents a significant impact on hospital resources and optimizes the quality of life of patients.
Inflammatory markers such as procalcitonin (PCT) and C-reactive protein (CRP) can help refine predictive models of low-risk febrile neutropenia validated in the literature (e.g. MASCC index).
Aims: Analyze the role of PCT and CRP as analytical predictors of clinical outcome in febrile neutropenia and its correlation with development of severe sepsis in patients with FN.
Methods: 84 consecutive episodes were collected in outpatients presenting with FN either to the Emergency Department or the Hematology Day Hospital. Values of PCT and CRP were measured on arrival, subsequently evaluating which of them developed sepsis during their clinical evolution.
Results: 41 patients (49%) had some hematologic malignant disease such as acute leukemia or myelodysplastic syndrome, 29 patients (35%) lymphoproliferative syndrome, 8 patients (10%) multiple myeloma and 6 patients (%) agranulocytosis.
24 patients (29%) developed sepsis, of whom 12 (14%) had a fatal outcome.
After having several cutoff values tested for PCT and CRP at the time of hospital care, and analyzing its correlation with development of sepsis, the optimal cut-off points based on negative predictive value (NPV) were the following:
· PCT 1 ng/ml:
  - · Sensitivity: 62.5% (42.7 to 78.8%)
  - · Specificity: 90% (from 79.9 to 95.3%)
  - · NPV: 85.7% (75 to 92.3%)
· CRP 10 mg/dL:
  - · Sensitivity: 70.8% (50.8 to 85.1%)
  - · Specificity: 70% (57.5 to 80.1%)
  - · NPV: 85.7% (73.3 to 92.9%)

Summary / Conclusion: The analytical determination of PCT and CRP is a valid tool for predicting clinical outcome in patients with FN, and can provide additional information to the predictive models of risk that already exist and therefore improve the management of these patients.
Cutoffs of 1 ng/ml for PCT and 10 mg/dL for CPR correspond to NPV around 85%.

B1877

BONE MARROW ALTERATIONS IN PATIENTS WITH HUMAN IMMUNODEFICIENCY VIRUS (HIV) INFECTION IN THE HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) ERA, IN A HIGH COMPLEXITY UNIVERSITY HOSPITAL IN BOGOTA, COLOM

F Vela-Lozada[1*], G Figueroa[1], G Puentes[1], M Bustos[1], J Solano[2]
[1]Internal Medicine, [2]Hematology, Pontificia Universidad Javeriana, Bogota, Colombia

Background: One of the most common complications of HIV is the presence of haematological alterations, that depend on different factors such as the levels of viral replication that rely upon the state of the disease, the opportunistic infections and antiretroviral therapy. Nevertheless, the physiopathological mechanisms that explain the hematological abnormalities remain uncertain. It is accurate to say that the detection of the cause of those haematological alterations would guide to an appropriate treatment.
Aims: To describe bone marrow findings in adult patients with HIV infection in the HAART era, which presented quantitative alterations in the different hematological cell lines during a four-week period.
Methods: A descriptive retrospective study of bone marrow findings in adult patients with HIV infection between 2009-2011
Results: Bone marrow findings of 52 patients were revised, the average age of the patients was 37 years±12.2, 43 patients were male (82,7%), average age in women was 38,8 years and in men 37,5 years; the time in months since the diagnosis of the retroviral infection and the bone marrow biopsy was 30.6±38.3 months; 100% of the patients was in stage C3; the average of CD4 count was 200 cells, the percentage of CD4 cells was 14% and the viral load was of 67.797 copies; 38 patients (73%) presented some sort of opportunistic infection; 27 patients were under other antibiotic treatment to control those opportunistic infections (51.9%), 41 patients received HAART (78.8%). The mean of the number of blasts in the myelogram was 1.2, promyelocytes 3.4, myelocytes 8.4, metamyelocytes 9.2, bands 10.8, neutrophils 23.8, eosinophils 3.8, lymphocytes 9.8, plasmocytes 4.8, histiocytes 1.7, monocytes 1.8 and erythroid series 23.5. In 26 patients (equivalent to 50%) hematopoiesis of the three cell lines without malignant evidence was found, myeloid hyperplasia was evidenced in 10 patients, megakaryocytic hyperplasia in 5 patients, lymphoma in 3 patients, hemophagocytosis in 3 patients, and in 5 patients epithelioid granuloma with augmentation of iron and reticular trama with unknown significance.The mean of the granulocytic line in the flow cytometry was 54,9, promyelocytes CD 13+/CD 11+4,4, myelocytes CD 13+/CD 11+ 23.4, immature neutrophils CD13+/CD11+37.5, monocytes 4.8, eosinophils 3.11, erithroid series 15.3, T lymphocytes 7.7, CD4 + 0.8, CD8 + 15,4, CD4-CD8- 0.09, CD4+CD8+ 0.05, B lymphocytes 1.84, Kappa 4.4, lambda 3.19, natural killers 0.92, plasmatic cells 1.1, myeloid CD34 1.05, lymphoid CD 34 0.3, B CD 34 precursors 0.2. There was no identified germen in the bone marrow culture in 31 patients, in 7 patients cryptococcosis was found, salmonellosis in 7 patients, tuberculosis in 5 patients and histoplasmosis in 2 patients.
Summary / Conclusion: Although 31 patients did not get any microbiological isolation is striking the high frequency of salmonellosis much higher than reported in the world literature, likewise by the conditions of our environment was often cryptococcal infection, mycobacterium tuberculosis and histoplasmosis. Additionally lymphoma was found in 3 patients, in 3 patients hemophagocytosis, and in 5 patients Granuloma with epithelioid augmentation of iron and reticular pattern with unknown significance.

B1878

EFFICACY OF POSACONAZOLE PROPYLAXIS IN AML INDUCTION THERAPY, SINGLE CENTER EXPERIENCE

A Katgı[1], Ö Sevindik[1*], Ş Solmaz[1], İ Alacacıoğlu[1], Ö Pişkin[1], M Özcan[1], G Özsan[1], B Ündar[1], F Demirkan[1]
[1]Department of Hematology, Dokuz Eylul University, İzmir, Turkey

Background: Primary antifungal propylaxis with posaconazole in AML induction therapy was found to be effective in reducing infection related mortality in previous studies.
Aims: We aimed to validate the efficacy of primary posaconazole prophylaxis in our AML patients.
Methods: 45 patients with AML diagnosis who received 101 induction cycles (induction and relapse re-induction) in our center between 2009-2013 were investigated retrospectively. Patients who have received or not received primary posaconazole prophylaxis were compared with regard to further therapeutic

antifungal need and mortality.
Results: Median age was 51 (22-74), with 24 male (53.3 %) and 21 female (46.7%). Of 101 induction cycles, while 45 cycles consisted of antifungal propylaxis (36 primary and 9 secondary) 62 cycles did not. Therapeutic antifungal treatment was applied in 65 of 101 cycles. Of those, treatment was initiated as ampiric in 27, pre-emptive in 34 and evidence based in 4 cycles. In patients receiving posaconazole prophylaxis, antifungal treatment need decreased (56.6 vs 69.2 %) but was not statistically significant (P=0.169). Overall median antifungal administration period (including prophylaxis) was 28 days (15-54) in prophylaxis group and 16 days (3-42) in non-prophylaxis group and it was statiscially significant (P< 0.001). When infection related mortality was taken into account, while no mortality was observed in primary prophylaxis group, the non-prophylaxis group consisted of 13.8 % mortality with statistical significance (P=0.025).
Summary / Conclusion: Primary prophylaxis with posaconazole reduced infection related mortality in AML patients without a significant decrease in total antifungal need and administration duration.

B1879

THE RELATIONSHIP BETWEEN LEVELS OF SERUM MANNOSE-BINDING PROTEIN AND BACTERIEMIA/SEPSIS IN FEBRILE NEUTROPENIC CHILDREN WITH CANCERS

A Akcay[1*], L Agaoglu[2], E Saribeyoglu[3], H Ekmekci[4], O Ekmekci[4], D Atay[5], D Tugcu[1], O Devecioglu[2], S Anak[2], Z Karakas[2], A Unuvar[2], G Ozturk[2]
[1]Pediatric Hematology and Oncology, Istanbul Kanuni Sultan Suleyman Education and Research Hospital, [2]Pediatric Hematology and Oncology, Istanbul University, Istanbul School of Medicine, [3]Pediatrics, Acibadem Univercity, [4]Biochemistry, Istanbul Univercity, Cerrahpasa School of Medicine, [5]Pediatric Hematology and Oncology, Istanbul Okmeydani Education and Research Hospital, Istanbul, Turkey

Background: Cancer patients with febrile neutropenia after chemotherapy have a variable risk of bacteriemia/sepsis. Especially Gram-negative bacteremia is associated with high mortality and/or morbidity. Early diagnosis of patients with bacteriemia/sepsis at the onset of febrile neutropenia is potentially useful in tailoring therapy.
Aims: The main aim in this study was to determine the diagnostic relevance of mannose-binding protein (MBP) levels for predicting bacteriemia/sepsis in children with febrile neutropenia.
Methods: In a prospective study, 54 febrile neutropenic epizodes from 30 pediatric cancer patients whose age ranged from 15 to 191 months old (median age 62,5 months, 14 female and 16 male patients) were analysed. Samples were obtained in two different clinical periods: afebrile neutropenic period after chemotherapy and febrile neutropenic period (on the first day of fever). MBP levels were determined. Patients were divided into three groups: those with clinically or microbiologically documented infection, bacteriemia/sepsis, and fever of unknown origin.
Results: Twenty seven (50%) episodes were clinically or microbiologically documented infection, 17 (31,5%) episodes were fewer unknown origin, 10 (18,5%) episodes were bacteriemia/sepsis. The measured levels of MBP in febrile neutropenic period were not useful for identifying the types of febrile neutropenia. In all patients, significant differences were documented between MBP values of the afebrile neutropenic patients and the peak values of the febrile patients (P<0,001). In the bacteriemia/sepsis and fever of unknown groups, significant differences were also documented between MBP values of the afebrile neutropenic patients and the values of the febrile patients (P=0.001 and P=0,03). In clinically or microbiologically documented infection group, there was no significant difference between MBP values of the afebrile neutropenic patients and the values of the febrile patients.
Summary / Conclusion: An initial MBP level may not predict bacteremia/sepsis in cancer patients with febrile neutropenia.

B1880

COMPARISON OF THE SIDE EFFECTS OF ANTIBIOTICS IN PATIENTS WITH THE DIAGNOSIS OF FEBRILE NEUTROPENIA

H Kurt[1*], Ü Ergene[2]
[1]Department of Internal Medicine, [2]Department of Hematology, Celal Bayar University Medical Faculty, Manisa, Turkey

Background: Febrile neutropenia is a life-threatening complication that is common in patients with hematological malignancies.
Aims: Side effects of antibiotics used in febrile neutropenic patients were retrospectively reviewed, and in febrile neutropenic patients and to determine whether the effect of an increase in mortality and morbidity.
Methods: Patients with febrile neutropenia who were hospitalized and treated in the hematology clinic of our hospital between January 2005 and December 2011 were retrospectively evaluated.
Results: A total of 127 neutropenic fever episodes noted in 71 patients were evaluated. Of the fever episodes, 75 were noted in men and 52 were noted in women. The primary disease was acute leukemia in 94 (74%) episodes, Hodgkin's lymphoma in3, non-Hodgkin's lymphoma in8, agranulocytosis in3, hairy cell leukemia in3, chronic lymphocytic leukemia in3, blastic phase chronic myeloid leukemia in6, myelodysplastic syndrome in5, primary myelofibrosis in 1 and multiple myeloma in 1 episode. In this study, while the rate of change in drug combination for any reason was 27.3% in the imipenem + ciprofloxacin / amikacin (ICA) group, it was 60% in the P/T + ciprofloxacin/amikacin (PTCA) group; the difference between the groups was significant (P=0.006). The rate of drug change due to side effects was significantly higher in the PTCA group than the ICA group (P=0.03). The rate of reducing fever within 72 hours was significantly higher for imipenem combinations than P/T combinations (P=0.05).The rate of side effects was 19.3% for imipenem combinations while it was 30% for P/T combinations (P=0.29). The rate of grade 3–4 mucocytis was 9.2% in the ICA group and it was 5.3% in the PTCA group. However, the difference did not reach statistical significance. The mean duration of antibiotic use was 24.75 days in the ICA group and it was 27.82 days in the PTCA group. The difference did not reach statistical significance (P=0.5). The frequency of side effects was 28.8% in amikacin combination and it was 10.6% in ciprofloxacin combination (P=0.02). Gram-positive bacteria were the most common isolates. Consistent with the literature, coagulase-negative staphylococci were the most common pathogen isolated (36.5%), followed by E. coli (13%), Klebsiella spp. (9.7%), and Enterococcus faecalis (8.9%). E. coli were isolated in 16 episodes. The ratio of resistance to the number of antibiograms was 0/6, 6/8, 7/13, 0/15 for amikacin, P/T, ciprofloxacin and imipenem, respectively. Klebsiella spp. were isolated in 12 episodes. The ratio of resistance to the number of antibiograms was 1/12, 5/12, 6/12, 4/12 for amikacin, P/T, ciprofloxacin, and imipenem, respectively. Acinetobacter spp. were isolated in 11 episodes. The ratio of resistance to the number of antibiograms was 5/11, 6/11, 9/11, 7/11 for amikacin, P/T, ciprofloxacin, and imipenem, respectively. P/T resistance was more common, and the ICA group being more successful than the PTCA group was attributed to this finding.
Summary / Conclusion: In conclusion, in the treatment of neutropenic fever, every hospital should determine an empiric antimicrobial therapy regimen that is convenient with its microbial flora in accordance with the guidelines. We found that imipenem combinations were more effective as an empiric antimicrobial therapy in our hospital. In accordance with the literature, we found no significant difference between combination therapy and monotherapy in terms of efficacy. Side effects were more common in patients receiving amikacin.

B1881

FEBRILE NEUTROPENIA: INCIDENCE, FOCI OF INFECTION, AND UNDERLYING MICROBIOLOGICAL PATHOGENS

M Schütz[1*], K Klein[1], R Schlenk[1], M Bommer[1], G Härter[1]
[1]Department of Internal Medicine III, University Hospital Medical Center, University Hospital Ulm, Ulm, Germany

Background: Patients with neutropenia have an increased risk for infections, especially bacterial and fungal infections. Febrile neutropenia is a potentially life-threatening complication.
Aims: The aim of our study was to identify the overall incidence of febrile neutropenia, specific foci of infection and the microbiological agents causing the infection.
Methods: Inpatients on hematological and infectiological wards with neutropenia were investigated on a regular basis. For practical reasons, neutropenia was supposed if leukocyte counts were below 1000/µl. Periods of neutropenia and febrile neutropenia were registered within a computer database.
Results: Investigation period was July 2012 until February 2013. 283 periods of neutropenia were included. Underlying diseases were: 1. Acute myeloid leukemia (N=115: 41%), 2. Non-Hodgkin-Lymphoma (N=52: 18%) and Hodgkins's disease (N=11: 4%), 3. Multiple myeloma (N=43: 15%), 4. MPS/MPN/Aplastic anemia/others (N=30: 11%), 5. Solid tumours (N=16: 6%), 6. Acute lymphoblastic leukemia(N=15: 5%). Others: 1 (Sarcoidosis). Febrile neutropenia occurred in 159 out of 283 periods (56%), 124 periods (44%) remained without fever during hospitalization. In the 159 febrile neutropenia episodes clinically documented infections could be detected in 116 cases (73%). Further evaluation revealed the following foci: Bacteremia (N=68: 34%), pulmonal infection (N=36: 18%), infection of central venous catheter (CVC) (N=35: 17%), abdominal infection (N=24: 12%), fungal infection (N=22: 11%), urological infection (N=15: 8%). Outcome of infections in cases with febrile neutropenia were cure (N= 136: 86%), improvement (N= 15: 9%), death (N=5: 3%), stable state (N=2: 1%), progress (N=1: 1%) during the febrile episode. Microbiologically documented infections could be detected in different materials: Blood culture (N=125: 52%), tip of CVC (N=31: 13%), urine (N=24: 10%), stool sample (N=20: 8%), wounds (smear) (N=13: 5%), anal-/rectal smear (N=10: 4%), sputum (N=8: 3%), bronchoalveolar lavage (N=4: 2%), serum (N=4: 2%), throat smear (N=3: 1%). The following pathogens were detected: Coagulase-negative staphylococci (N=89: 35%), E.coli (N=23: 9%), E. faecium (N=21: 8%), Enterobacteriaceae (N= 13: 5%), P. aeruginosa (N= 12: 5%), E. coli (ESBL): (N=12: 5%), Aspergillus spp.: (N=9: 4%), E. faecalis: (N=9: 4%), C. difficile: (N=8: 3%), Candida non-albicans: (N=7: 3%), Enterococcus spp.: (N=7: 3%), Streptococcus spp.: (N=7: 3%), S. aureus: (N=6: 2%), Candida albicans: (N=5: 2%), Others: (N=23: 9%).
Summary / Conclusion: Most patients in our cohort had underlying haematological malignancies. The incidence of febrile neutropenia in our cohort was

56%, and therefore lower than reported in the literature, which may be due to antimicrobial prophylaxis with a fluoroquinolone in neutropenia. Interestingly, clinically documented infections in those patients with febrile neutropenia could be observed in 73%, which is much higher than previously reported in the literature. The microbiologically documented infections showed coagulase-negative staphylococcus as the most common pathogen. Gramnegative organisms were detected in 24% of the microbiologically documented infections with a substantial amount of ESBL E. coli (5%). These observations strengthen the need for careful documentation and microbiological assessment of patients in neutropenia to evaluate the incidence, risk factors and trends for microbiological agents.

B1883

VISCERAL LEISHMANIASIS ASSOCIATED HAEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A CAREFUL BALANCING ACT

H Hussein[1*], I Kaddam[1], N Phillips[1], M Riste[2], A Cadwgan[2]
[1]Haematology, [2]Infectious Diseases, University Hospital North Staffordshire, Stoke on Trent, United Kingdom

Background: The clinical course of visceral leishmaniasis (VL) and the haemophagocytic lymphohistiocytosis (HLH) have a significant degree of overlap, causing diagnostic confusion. This case illustrates that patients taking immunosuppression can be particularly vulnerable when travelling to endemic areas, and the potential favourable outcome if detected and treated promptly.
Aims: A 45 year old lady presented to the general medical take with a one month history of fever, night sweats and weight loss. She had a background history of orofacial granulomatosis, diagnosed 6 years previously, and was receiving maintenance azathioprine and low dose prednisolone. Ten months prior to this, she had been on holiday to southern Spain.
Methods: On admission, her full blood count showed pancytopenia with severe neutropenia, and raised inflammatory markers. She was treated with broad spectrum intravenous antibiotics and her immunosuppression was stopped. An initial bone marrow aspirate showed evidence of HLH, with no excess lymphoid cells. At this stage, her ferritin was elevated at 8700ng/mL, triglycerides were 3.6mmol/L and EBV DNA PCR was raised at 6162 copies per mL. She was treated with intravenous immunoglobulin, dexamethasone and ciclosporin as per the local HLH protocol, with the omission of etoposide. Her symptoms and blood counts improved significantly, and she was discharged with a steroid taper, maintenance ciclosporin and regular follow up. Unfortunately, she was readmitted after one week with a severe steroid induced proximal myopathy. Shortly after this, her pancytopenia worsened, and a repeat bone marrow was arranged. This showed ongoing HLH, but with widespread evidence of leishmania amastigotes. Her immunosuppressive therapy was rapidly reduced, and treatment was started with liposomal amphotericin.
Results: Following this, her symptoms and blood counts had a sustained improvement for several weeks. Despite the anti-leishmaniasis treatment, the patient became pancytopenic again. A further repeat bone marrow showed a marked decrease in leishmania amastigotes, but with significantly increased haemophagocytosis. Her case has subsequently been managed with a careful balance of immunosuppression, followed by further liposomal amphotericin. In addition to this, prophylactic monthly pentamadine infusions were commenced. To date, her symptoms have greatly improved, and her full blood count has normalised.
Summary / Conclusion: HLH associated VL is very rare, with only 8 cases reported in adults in a recent systematic review*. This is due to both the overlap of the clinical features and difficulty identifying amastigotes early in the course of the disease. The use of immunosuppression in HLH, though initially beneficial in dampening the inflammatory response, can lead to overwhelming VL. Therefore, a thorough travel history, and repeated bone marrow examination where there are concerns with diagnosis are essential for diagnosis. Treatment with liposomal amphotericin is effective, with possible benefits with intravenous immunoglobulin and low dose steroid as an adjunct.

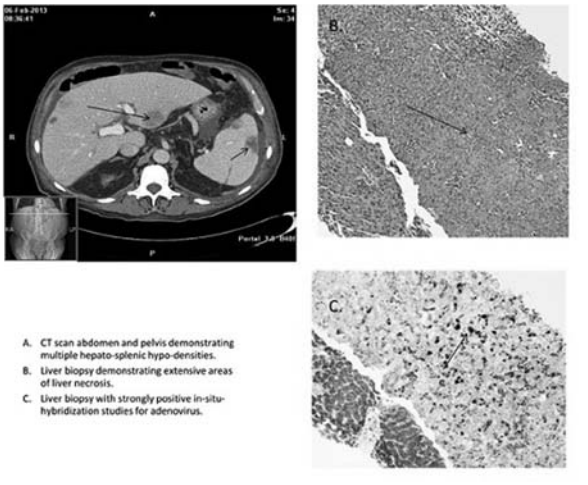
B1884

HEPATO-SPLENIC NECROTIC NODULES WITH NORMAL HEPATIC ENZYMES AND HEPATIC SYNTHETIC FUNCTION - AN UNUSUAL PRESENTATION OF ADENOVIRAL INFECTION AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

K Gundabolu[1], T Smyrk[2], W Hogan[1], M Litzow[1], S Hashmi[1], D Gastineau[1], M Patnaik[1*]
[1]Hematology, [2]Pathology, Mayo Clinic, Rochester, Rochester, United States

Background: Adenoviruses are non-enveloped double stranded DNA viruses belonging to the family Adenoviridae. Among the 52 identified serotypes, only a few are common clinically and include serotypes,1,2,3,5,7, 21, and 41. Majority of Adenoviral infections occur in the first decade of life, with both humoral and cell mediated immunity being critical in preventing and limiting infections. Adenoviral infections are also seen in patients that have undergone allogeneic stem cell transplants (SCT), with an estimated incidence of between 5-20%. Common presenting features include fevers, respiratory illness, pharyngo-conjunctival fever, hemorrhagic cystitis, gastroenteritis, with rare cases of disseminated adeno-viremia resulting in multi organ dysfunction, including acute hepatitis and hepatic necrosis.
Aims: To describe an unusual presentation of adenovirus infection with multiple hepato-splenic necrotic nodules in a patient who underwent allogeneic SCT.
Methods: The patient is 67 year old male, who underwent a reduced intensity conditioning (Fludarabine, BCNU and melphalan) 9/10 HLA mismatched unrelated donor allo SCT for transfusion dependant *JAK2*V617F mutated primary myelofibrosis. He received graft versus host disease (GVHD) prophylaxis with tacrolimus and methotrexate. Due to the development of seizures the tacrolimus was discontinued and he was started on sirolimus. At D+60 he developed grade II acute GI GVHD and was started on enteric coated budesonide and mycophenolate mofetil, with good response. He presented at D+125 with a self-limited prodrome consisting of; fevers, pharyngitis, nausea, vomiting, diarrhea and vague abdominal pain. A CT scan abdomen/pelvis demonstrated multiple hepato-splenic nodules (figure one A).



Results: His liver enzymes and hepatic synthetic function at presentation and through his clinical course remained normal. On admission, blood cultures and viral studies were drawn. An adenovirus PCR was positive, with a viral load of 500,000 copies/ml. He underwent an ultrasound guided biopsy of a liver nodule. This demonstrated extensive hepatic necrosis with strong in-situ-hybridization studies for adenovirus (figure one B & C). A transesophageal echocardiogram was negative for a cardioembolic source. His immunosuppression was tapered over the next 4 weeks and he received 2 doses of IV Cidofovir with an excellent response. At the time of writing this report his viral load was down to 20,000 copies/ml. He has had no recurrence in his GI GVHD and he is due to receive an additional two doses of cidofovir.
Summary / Conclusion: Adenovirus is not an uncommon opportunistic pathogen in immunocompromised hosts. While most cases present with limited respiratory or gastrointestinal manifestations, in a few patients hemorrhagic cystitis, keratoconjuctivitis, acute hepatic necrosis and multiorgan failure can occur. We describe a unique case of severe adenovirus associated hepatosplenic necrosis without alteration of liver enzymes or synthetic function. Withdrawal of immunosuppression and cidofovir are effective treatment strategies.

B1885

MICAFUNGIN FOR ANTIFUNGAL PROPHYLAXIS IN PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

P Sierra[1*], F Torres[1], M Quesada[1], J López[1], J Huerta[1], S Nieto[1], A Muñoz[1]
[1]Hematology, University Hospital of Jaen, Jaen, Spain

Background: Micafungin is an echinocandin antifungal approved for prophylaxis in patients undergoing hematopoietic stem cell transplantation. It has a broad spectrum against yeasts and filamentous fungi.
In our institution, we employ Fluconazole as first line option for prophylaxis in patients under autologous stem cell transplantation (ASCT), since the absolut neutrophils count (ANC) is less than 1000/mm^3, until two consecutive days above 1000/mm^3. For patients who are intolerant or resistant to azoles or have shown a previous Invasive Fungal Infection (IFI), we use Micafungin at doses of 50 mg daily as prophylaxis.
Aims: Analyzing the efficacy and safety of the use of Micafungin for antifungal phophylaxis in patients undergoing ASCT.
Methods: We have used the incidence of fungal infection and the proportion of patients requiring empirical treatment as measurement of the efficacy.
We have measured baseline levels of creatinine and total bilirubin to determine safety and we have measured the maximum value of these parameters under treatment with micafungin.
Between November 2011 and January 2013, 34 patients have received Micafungin at doses 50 mg daily. 23 of them were male. The mean age at transplantation was xx. Diagnoses were fifteen Non-Hodgkin Lymphoma (12 B and 3 T), six Hodgkin Disease, two Acute Myeloid Leukemia, nine Multiple Myeloma and 1 Case of Ewing Sarcoma. The median of days of granulocytes under 1000/mm^3 was 12 days (10-16). The mean baseline creatinine was 0.88 mg / dL (0.4-1.9) and the baseline level of total bilirrubin was 0.71 mg/dL (0.36-1.44). No patient had developed previous IFI.
Results: The median duration of treatment with micafungin was 15 days (11-23). Only two empirical treatments were initiated (6.06%) (with Voriconazole and Anidulafungin) and none of the cases developed IFI (0%). One case presented colonization by Candida Albicans and other one had persistent fever, isolated with Staphylococcus Aureus in blood culture later.
With regards to tolerance, there were no reports about any infusional reaction. The mean maximum creatinine was 1.23 with an average change of 0.34 mg / dL from baseline. Regarding hepatotoxicity, the maximum average number of total bilirubin was 1.34 with a variation of 0.59 mg / dL.
Summary / Conclusion: 1. Micafungin at doses of 50 mg/24 hours, is an effective and safe option for antifungal prophylaxis in patients undergoing ASCT. 2. In our series, there was no development of IFI and in most patients it was not necessary to use empirical treatment. 3. The safety of the treatment was excellent, without tolerance problems. The kidney and liver function was not altered by treatment with micafungin. 4.We will need to be stricter in the future in implementing the protocols in place, as the median of micafunina use (15 days) exceeds in three days the median of ANC phase below to 1000/mm^3 (12 days). 5. Retrospective studies are needed comparing these results with historical cohorts with itraconazole and fluconazole in our instituion, and cost-effectiveness studies to confirm these benefits.

B1886

REAL LIFE EXPERIENCE OF ANTI-FUNGAL PROPHYLAXIS WITH POSACONAZOLE IN PATIENTS WITH ACUTE LEUKEMIA AT A SINGLE CENTER LACKING HEPA-FILTER

T Tuglular[1*], F Tanrıkulu[1], A Vergili[2], A Ozel[2], A Eser[1], C Adiguzel[1], I Atagunduz[1], Z Odabasi[2], V Korten[2]
[1]Hematology, [2]Infectious Disease, Marmara University Hospital, Istanbul, Turkey

Background: Invasive fungal disease (IFD) is an important problem complicating the therapy of
patients with acute leukemia receiving induction chemotherapy. Both yeasts and molds cause serious infections. Candida is the most important yeast pathogen and rates of invasive Candida infection in patients with hematologic malignancies not receiving antifungal prophylaxis range between 8 to 24 percent. On the other hand, aspergillus is the most common mold pathogen and in patients with acute myelogenous leukemia , the incidence of invasive aspergillosis ranges between 5 to 10 percent. Recently, patients receiving induction chemotherapy for acute myeloid leukemia were shown to have fewer IFD and mortality attributable to IFD with posaconazole prophylaxis.
Aims: To document the real life experience with posaconazole on the incidence of IFD during the course of remission induction chemotherapy in patients with acute leukemia who were hospitalised in a single center without hepa-filter .
Methods: We conducted a retrospective review of patients with de novo or relapsed acute myelogenous leukemia (AML) and acute lymphoblastic leukemia (ALL) who were hospitalised for remission induction chemotherapy from December 2010 to December 2012. Our policy of anti-fungal prophylaxis was changed in June 2012 and we started to give posaconazole prohylaxis in AML patients. We compared our fungal disease incidence in AML patients before (group A) and during posaconazole period (group B).
Results: Fourty-seven treatment episodes for remission induction in 37 patients were included. Among these episodes, 22 were in ALL and 25 were in AML patients. A total of 28 (%59) episodes were noted to end up with the need for anti-fungal treatment , despite prophylaxis in 15 (%53) of them. Considering ALL, prophylaxis with fluconazole and posaconazole were given in 17 and 2 treatment periods respectively, and no prophylaxis was given in 3 episodes. A total of 8 (%36) episodes were ended up with anti-fungal treatment in ALL patients:1, 2 and 5 episodes for empiric, probable and possible IFD respectively. Regarding AML, there were 13 episodes in which remission induction was given without anti-fungal prophylaxis (group A) and among these 11 (%84) were ended up with need for anti-fungal treatment: the number of episodes for empiric therapy, probable and possible IFD were4, 1 and 6 respectively . There were 12 episodes after the initiation of policy for posaconazole prophylaxis (group B). In this group, despite posaconazole prophylaxis 9 (%75) patients needed anti-fungal treatment during neutropenia:3, 4 and 2 episodes for empiric, probable and possible IFD respectively. Analysis of the reasons to initiate anti-fungal treatment revealed 3 Candidial infections which were all in group A. There was no Candidial breakthrough in group B. Considering breakthrough with Aspergillus there was no difference between the two groups.
Summary / Conclusion: We found that in patients undergoing remission induction chemotherapy for AML posaconazole prophylaxis prevented Candidial infections, but it did not have any effect on Aspergilus infection. This may be due to the small number and retrospective nature of our study, since we were not able to evaluate the patients' drug competence during the prophylaxis period and posaconazole is known to be affected by meals and other drugs like proton pump inhibitors. It is necessary to evaluate the value of anti-fungal prophylaxis with posaconazole in the real life scenarios with prospective observational studies.

B1887

INCIDENCE, MORTALITY AND CAUSATIVE PATHOGENS OF SEPTIC SHOCK IN NEUTROPENIC PATIENTS AFTER INTENSIVE CHEMOTHERAPY

J Lukas[1*], S Kubalova[1], M Mistrik[1], D Horvathova[1], L Sopko[1]
[1]Department of Hematology and Transfusion Medicine, University Hospital in Bratislava, Bratislava, Slovakia

Background: Chemotherapy used during induction and consolidation for acute leukemia causes severe agranulocytosis (ANC <500/mm3) lasting more than 10 days and patients are in a high risk of developing severe sepsis or septic shock.
Aims: Evaluation of septic shock in neutropenic patients.
Methods: 64 patients with diagnosis of acute leukemia (48 pt. AML and 16 pt. ALL) were treated with intensive chemotherapy at the University Hospital in Bratislava between September 2010 and December 2012. Together we have administered 149 cycles of chemotherapy (induction 64, second induction 21 and consolidation 64 times).
Results: Incidence of septic shock after intensive chemotherapy was 13,5% (20/149) and proven bloodstream infections (BSI) with positive blood culture was in 55% (11/20). Isolated patogens were gram-negative (7x) and gram-positive (4x) bacteria. Among gram-negative bacteria were isolated 2 carbapenem-resistant K.pneumoniae and 1 carbapenem-resistant P.aeruginosa, resulting in irreversible shock. Mortality rate from septic shock in neutropenic patients after chemoterapy was 30% (6/20).
Summary / Conclusion: Sepsis remains a leading cause of mortality in neutropenic patients. Despite of a great improvement in managment of septic shock, we stand in front of the problem, what to do with increasing number of carbapenem-resistant bacteria.

B1888

THE DEFEAT OF THE COLON BY HEMOBLASTOSES: CLINICAL, ENDOSCOPIC, IMMUNOHISTOCHEMICAL FEATURES AND OPTIMIZATION OF TREATMENT

I Davydkin[1*], T Gritsenko[1], A Osadchuk[1]
[1]The department of hospital therapy with course of hematology, The Samara State Medical University, Samara, Russian Federation

Background: Conducting polychemotherapy (PCT) in patients with hematological malignancies in 20-40% of cases accompanied by a lesion of the colonic mucosa (CM).Mechanisms of epithelial lesions of the colonic mucosa in patients receiving chemotherapy, not sufficiently studied, and the successful treatment of colorectal disease largely determines the success of treatment of the underlying disease.Thus, improving supportive care lesions of the colon in patients with hematological malignancies is actual scientific task.
Aims: To assess the effectiveness of dibikorum in the treatment and prevention of colorectal pathology in patients with hematological malignancies, based on studies of apoptosis index and cellular regulation molecules (Ki-67 and TLP).
Methods: Total 135 patients were examined: 120 patients with hematological malignancies receiving polychemotherapy (PCT) and 15 healthy people. All

the patients were divided into 2 equal groups, depending on the severity of lesions of colorectal colon: Division 60 patients with first degree mucositis and 60 patients with the second degree mucositis. Patients in each group are 2 equal subgroups: in the first subgroups conducted therapy from linex end enterol; in the second conducted therapy from enteral, linex and dibikorum. Patients were surveyed in dynamics to treat colorectal disorders and 4 weeks later. All patients were sigmoskopy, General morphological study, determined by the index of apopotosis (Iapt) colon cells, immunohistochemical studies conducted using monoclonal murine antibodies to marker of proliferating cells-Ki-67 (1: 100, Novocastra, USA) and transterritin-like protein (TLP) (1: 100, Novocastra, USA).
Results: Application of dibikorum in the treatment of colorectal pathology in patients with hematological malignancies receiving PCT, to achieve the best clinical outcomes compared to patients without dibikorum. In patients receiving dibikorum, is significantly more severe clinical symptoms early colorectal disorders (bloating, diarrhoea), accompanied by the restoration of the mucous membrane of the large intestine and the improvement of parameters of cellular homeostasis (decreased Iapt, increased expression of Ki-67 and TLP).
Summary / Conclusion: Application of dibikorum in the treatment of patients with hematological malignancies receiving PCT, improves the process of cellular homeostasis colon cells in terms of reducing the Iapt, increase of the expression of Ki-67 and TLP, accompanied by early termination clinical symtoms intestinal disorders, normalization of macroscopic and microscopic structure of mucous membranes of the colon.

B1889

THE EFFICACY OF PALONOSETRON IN MANAGING SYMPTOMS INDUCED BY HIGH AND MODERATE EMETOGENIC CHEMOTHERAPY-THE EXPERIENCE OF FUNDENI CLINIC OF HEMATOLOGY

I Ursuleac[1*], m mustata[1], a colita[1], d coriu[1]
[1]Hematology, Fundeni Clinical Institute, Bucharest, Romania

Background: Antiemetic agents represent an useful tool for supportive care in patients with hematological malignancies treated with high and moderate emetogenic chemotherapy.Their role is directed through controlling nausea and emesis induced by chemotherapy both in acute (0-24 hours from the first dose of chemotherapy) and late phases(24-120 hours). The antagonists of $5HT_3$ receptors represent the basis of antiemetic therapy. Palonosetron is a major antagonist of $5HT_3$ receptors with an unique profile of action due to high receptor's affinity, long lasting action and high efficacy in both acute and delayed phases of emesis; it is preferred to be administered in high emetogenic chemotherapy and in multi day schedules.
Aims: assessment of complete response (no emesis, no nausea) in acute and late phases after moderate or high emetogenic chemotherapy and safety profile of Palonosetron
Methods: an unicentric, retrospective, clinic-epidemiological, observational study(march-september 2012) including 57 patients treated in Fundeni Clinic of Hematology using moderate and high emetogenic chemotherapy and multiday schedules of treatment . Palonosetron was administered as first intention or second line antiemetic therapy. We included patients with a large broad of hematological malignancies (31 patients with chronic lymphoproliferative syndroms, 10 patients with Hodgkin's lymphoma, 1 patient with chronic myelogenous leukemia treated with Imatinib 600 mg/day, 10 patients with acute myeloblastic leukemias and 5 patients with acute lymphoblastic leukemias). There was a female preponderence (40 female patients - 68,9%) . 22 patients were treated with Palonosetron as first line antiemetic therapy, all of them associated to high emetogenic chemotherapy (ABVD,DHAP, multiday regimens in acute leukemias). 5 patients from those who were previously treated with first generation $5HT_3$ R inhibitors experienced anticipatory emesis
Results: in acute phase (first day of chemotherapy) 47patients (81%) had complete response (no emesis, no nausea) and 56 patients (96,5%)with complete response during late phase (24-120 hours). We identified as risk factors for anticipatory emesis the female sex and younger ages. The repeated administration of Palonosetron in day 3 and 5 of a multiday regimen was associated with complete response both in acute and late phases of emesis. The most frequent adverse reactions were constipation and headache.
Summary / Conclusion: Palonosetron is efficient not only in controlling symptoms induced by moderate and high emetogenic chemotherapy regimens but also for anticipatory emesis. Adverse reactions were easily manageable.

B1890

COMPARISON OF ANTIFUNGAL AGENTS EFFECTS AND SIDE EFFECTS IN NEUTROPENIC FEVER ATTACKS

Z Akcalı[1*], Ü Ergene[2]
[1]Internal Medicine, [2]Hematology, Celal Bayar University, Manisa, Turkey

Background: Febrile neutropenia (FEN) is a life-threatening complication that is common in patients with hematological malignancies. Invasive fungal infections (IFI) are serious cases of mortality in neutropenic patients. In order to treat these infections early and right time are preferred instead of targeted antifungal therapy.
Aims: The aim of this retrospective study was to evaluate efficiency of antifungal treatment and side effect of antifungal agents in patients with high-risk febrile neutropenia (the expected duration of neutropenia was more than 7 days and PNL count <100/mm^3)
Methods: Between January 2005 and March 2012, 78 febrile neutropenic patients was retrospectively analyzed in Manisa Celal Bayar University, Department of Hematology.
Results: 78 patients **(**43 (55%) male and 35 (45%) female and 46.7±15.06 years) were included in the study. The distribution of disease was AML, ALL, chronic leukemia, lymphoma and other hematologic malignancies and ratios were 50%, 12%, 7%, 15%, 6% respectively. In 78 patients, 135 FEN attacks were evaluated. 90 FEN attacks were received antifungal agents. Empirical antifungal therapy was given early and changed by clinical, microbiological and serologic results for the high efficacy. 45 FEN attack were not needed any antifungal treatment. The efficacy of first-line antifungal therapy was 72% (65/90 FEN). The efficacy of second-line antifungal therapy (i.e. refractory to (25/32) or intolerant of prior antifungal therapy) was 97% (30/32 FEN). The side effect of first line antifungal therapy was 48% (43/90 antifungal used FEN). The side effect of second-line antifungal therapy was 42% (13/32). First and second-line antifungal therapy were included conventional amphotericin B, liposomal amphotericin B (LAmB), caspofungin, vorikonazol and flukonazol. The side effects of first and second-line antifungal therapy were infusion related, metabolic and visual toxicity, hepatotoxicity, rash, diarrhea and their numbers and ratios were 3(5%), 49(86%), 2(3,6%), 1(1,8%), 1(1,8%), 1(1,8%) respectively. Conventional amphotericin B was used in three FEN attack and infusion-related side effects were seen. Within these severe anaphylaxis reaction was observed in one of them. Metabolic side effects such as hypokalemia, hypomagnesemia were observed in LAmB used patients. These side effects were less in patients who used voriconasol. Voriconazole-induced transient visual disturbance were observed in FEN attack. And also hepatotoxicity was observed in LAmB used patients. The another side effects such as rash and diarrhea were observed in fluconazol used patients. In this study 27 fungal pathogens (27/90) were isolated microbiologically and/or histopathologically in 27 FEN. C.albicans, C.tropicalis, C.glabrata, C.crusei, Aspergillus, yeast species were found in 12(44%), 3(11%), 2(8%), 1(4%), 3(11%), 6(22%) respectively. The most isolated fungal pathogen was C.albicas (P=0.001). After the isolation of fungal pathogens antifungal treatment were given in accordance with the guidelines of antifungal treatment to these patients (7 patients; liposomal amphoterisin, 12 patients; caspofungin, 2 patients; vorikonazol, 5 patients flukonazol and 1 patient; posakonazol)
Summary / Conclusion: Most common observed side effect was metabolic side effect in our study but treated without mortality. Future studies with larger number of patients are needed to confirm these results.

Transfusion medicine

B1891

EFFECT OF BLOOD DONATIONS ON IRON STORES OF BLOOD DONORS

Y Yaman[1*], S Öztürk[2], Y Oymak[3], Y Ayhan[2], G Özek[1], Ö Carti[1], A Türedi[4], B Güneş[1], E Albudak[1], B Demirağ[1], C Vergin[1]
[1]Pediatric hematology, [2]Dr.Behçet Uz Children Hospital, izmir, [3]Pediatric hematology, Harran University Medical Faculty, Urfa, [4]Pediatric hematology, Diyarbakır Children Hospital, Diyarbakır, Turkey

Background: A blood donor looses approximately about 200 to 250 mg of iron per donation which corresponds to a loss of four to ten percent of total iron. Loss of iron replaces quickly by mobilizing iron stores, followed by filling the iron stores if diet is adequate. The situation, however, is different for donors with high frequency of blood donations. For men who donating six or more times in the last two years; serum ferritin level has began to decrease within time. In the absence of iron replacement this can lead to emptying of iron stores. We undertook this study to evaluate the effect of frequent blood donations on iron stores of regular male blood donors in Turkey.
Aims: To evaluate the effect of frequent blood donations on iron stores of blood donors in Turkey.
Methods: This study was planned prospectively with randomization of blood donors into two groups. The first group was 'frequent donation group' that comprised of donors who had donated more than three times in the last year and more than 6 times in the last two years. The second group was 'infrequent donation group' that comprised of donors who was donated one or two times in the last year. Serum hemogram, serum iron, total iron binding capacity, ferritin, peripheral blood smear and monthly income of all cases were evaluated.
Results: 169 cases were recruited to study. 52/169 (30%) of cases were classified in 'frequent donation group'. Any of the cases in this group was not deferred from blood donation because of low haemoglobin level. The other 117 were classified in 'infrequent donation group'. There was no statistically significant differences in hemoglobin, serum iron, total iron binding capacity, mean corpuscular volume, peripheral blood smear findings and monthly income between two groups. Mean serum ferritin level was 45 ng/ml in frequent donation group and 55 ng/ml in infrequent donation group and these results were statistically significant (P<0,05).
Summary / Conclusion: Being a frequent blood donor is a condition that could lead to the development of iron deficiency in blood donors. Monitoring ferritin levels yearly for frequent blood donors and education of the donors about iron supplementation and diets are highly recommended.

B1892

CERTIFICATION AND EDUCATION PROGRAM. HOW TO IMPROVE QUALITY MARKERS OF TRANSFUSION THERAPY IN HOSPITAL

J Fernandez[1*], F Berenguel[1], S Hinojosa[1]
[1]Hematology, Hospital de Baza, Baza, Spain

Background: The regular assessement of blood bank activity allows us to know changes over time and influence clinical practice at point "weak" system. Actions taken in order to modify and standarize transfusions procols and transfusion indications in hospital practice are difficult and complex due to staff resistance to change.
Aims: We analyse de dates in order to know if certain mesures are be able to change clinical practice and improve quality markers of transfusion therapy specially those related to the percentage of fresh frozen plasma transfusion
Methods: We examine whether the actions carried out: 1.-active committee of transfusion with publishs update monthly statistics, 2.-transfusion guide, 3.-joint meetings with all hospital sections and 4.-a program of clinical medical education (CME) and 5.-Process of certification by an external agent (CAT)achieved in april 2010; have had a real impact on the comsumption of blood products. We analyse the blood products transfused and quality markers specially those related with FFP transfusión.
Results: During the past 17 years we have transfused a total of 33.106 blood products (1947 per year). ther is no clear trend in terms of global transfusion and erythrocyte transfusion, but there is a significant decrease in the case of fresh frozen plasma and platelets concentrates, specially in the case of FFP in year 2000 and in the periode from year 2009 to 2012, a sistematically CME program was developed in both cases previously. The improvement of packed erythrocytes/fresh frozen plasma ratio reached was 11,1 in year 2000 and 38,6 in year 2012. This is very important because we can product other products: inmunoglobulins, albumin, factor VIII concentrates with this raw material.
Summary / Conclusion: 1.-Ther is a stability in transfused blood products over time. Global average ratio: blood products/hospital admissions: 0,31.
2.-Ther is a statistically significant decrease transfusion of FFP from 2009 to 2012 that produces an improvement in packed erythrocytes/fresh frozen plasma ratio= 38,6 higher to that found after the development of a law about plasma safety in year 2000. Our problem today is plasma expiry date, so we have only a short stock of blood group plasma AB and A.
3.-The CME "campaigns" on transfusion therapy are effecive but lose its effect, so it is very important to maintain a "continue" CME program in transfusion therapy.

B1893

EVALUATION OF APOPTOSIS MARKER AT THE MEMBRANE SURFACE OF RESIDUAL LYMPHOCYTES IN GAMMA-IRRADIATED PLATELET CONCENTRATES

M Ogorodnikova[1*], T Zabotina[2], A Borunova[2], D Onufrievich[1], E Ogorodnikova[2], O Rukavitzin[1]
[1]N.N. Burdenko Main Military Clinical Hospital, [2]N.N. Blochin Cancer Research Center, Moscow, Russian Federation

Background: Gamma irradiation (GI) of blood components, including platelet concentrates (PC), is used for inactivation of allogenic T-lymphocytes to prevent transfusion-associated graft-versus-host disease. The accepted dose of GI in Russia is 25 Gy. Damaging of T-lymphocytes DNA leads to their death by apoptosis way.
Aims: The aim of this study was to evaluate apoptosis marker exposure at the allogenic lymphocytes membrane surface after gamma-irradiation of PC during the storage.
Methods: To perform investigation of residual lymphocytes, we used an experimental model of PC (not for clinical using) in the form of pooled random-donor PC.16 PC were obtained by the buffy coat method (five buffy coats were pooled) with centrifugation. We studied four groups of samples obtained from each PC: 16 samples after GI on Day 1 and 16 - on Day 5 of storage, 16 untreated samples on Day 1 and 16 - on Day 5 of storage. PC were irradiated with a gamma-source cesium-137 in dose of 25 Gray during the first twenty-four hours after collection. All samples were investigated by flow cytometry. Lymphocytes were identified by the binding of the PE Cy-7-conjugated anti-CD45 antibodies and lymphocytes apoptosis was measured by phosphatidylserine (PS) exposure with FITC-labeled Annexin V. During the investigation we analyzed more than 2000 events in the lymphocytes region, however the total number of all events ranged from 200000 to 600000. Further the number of lymphocytes was expressed as percentage of all analyzed events.
Results: The percentage of lymphocytes in untreated samples on Day 1 was1,44±0,92%. Gamma-irradiation of PC was not lead to statistically significant changes (P=0,77) in the number of CD45+ cells on Day 1: the percentage of CD45+ cells was1,5±0,95%. The same number of CD45+ cells (P=0,26) was detected in untreated samples on Day 5:1,27±0,99%.The investigation of gamma-irradiated samples stored for 5 days has shown significantly (p=0,04) reduction of lymphocytes: the percentage of CD45+ was1,18±1,0%. PS exposure at the lymphocytes membrane surface of untreated samples on Day 1 didn't exceed 10,32±3,79%. The degree of Annexin V binding didn't change significantly (p=0,94) after GI on Day 1 (10,34±3,95%). The percentage of apoptoticlike changed lymphocytes in untreated samples of PC remained unchanged (p=0,51) after 5 days of storage and PS exposure was detected on 10,84±2,81% of CD45+ cells. PS externalization at the membrane surface of lymphocytesin gamma-irradiated PC was detected on 13,22±3,16% of CD45+ cells on Day 5. This level of PS expression was statistically significant increased in compared with Day 1 after GI of PC samples (p=0,007) and in compared with untreated PC on Day 5 (p=0,02) and on Day 1 (p=0,011) of storage.
Summary / Conclusion: There was no found destruction of residual lymphocytes in untreated PC within 5 days of PC storage. While GI of PC with 25 Gy leads to reduction of lymphocytes by apoptosis on Day 5 of PC storage.

B1894

ACUTE EFFECTS OF BLOOD TRANSFUSION ON LEFT CARDIAC FUNCTIONS AND CARDIAC MARKERS IN WELL-TREATED THALASSEMIA MAJOR PATIENTS

A Ayhan[1*], Y Ayhan[1], C Timur[1], M Erguven[1]
[1]Pediatric Hematology, Medeniyet University Goztepe Education and Research Hospital, Istanbul, Turkey

Background: Cardiac complications are still the leading causes of mortality and morbidity in thalassemia major patients.
Aims: This study was planned to investigate acute effects of erythrocyte transfusion on left cardiac functions and to assess changes in serum levels of cardiac troponin I, creatine kinase, creatine kinase-MB due to transfusion in a group of patients with thalassemia major.
Methods: Twenty-five thalassemia major patients (14 male, 11female) aged between 3 and 24 years (mean age 12 ±5,49 years) were included in the study. Patients with impaired left ventricul functions, any congenital or acquired heart disease were not included in the study. We recorded pre-transfusional hemoglobin levels, serum CK, CK-MB, troponin levels which were studied from the blood obtained before tranfusion. These measurements were repeated after 5 days as post-transfusional evaluation. Pre and post transfusional echocardiographic indices for left ventricular functions were compared.
Written informed consent was obtained from adult patients or parents of children.
Results: Mean serum ferritin level at the time of the study was 1359,20±477,76 ng/ml (ranged between 560 and 2190 ng/ml). Mean pre-transfusional hemo-

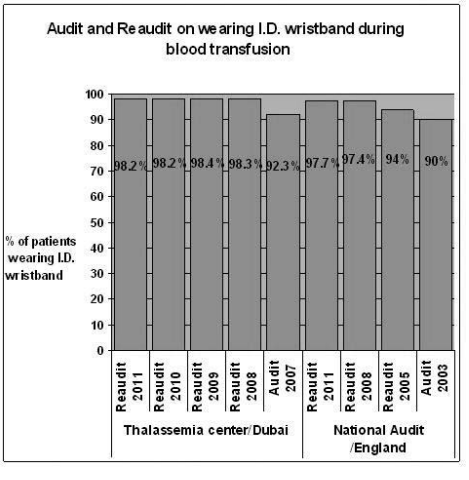
globin concentration was7,85±0,98 gr/dl while mean post-transfusional hemoglobin concentration was 10,24±1,28 gr/dl. Pre-transfusional CK,CK-MB, troponin I levels were not statistically different than post-transfusional values. Pre-transfusional EF, FS, LVIDd, LVIDs, aort diameter, left atrium diameter did not differ than the post-transfusional measurements, the differences were not statistically significant for these parameters, P>0,05 for all.
Pre-transfusional aort valve peak gradient, aort valve mean gradient, pulmonary valve peak gradient, pulmonary valve mean gradient measurements were not statistically different than values obtained after transfusion (P>0,05)
Pre and postransfusional EF, FS values of patients with ferritin levels <1000 ng/ml and those with serum ferritin levels ≥1000 ng/ml did not differ statistically (p›0,05).
There was not any correlation between CK, CK-MB, cardiac troponin I and LVIDd, LVIDs, EF, FS (P>0,05). Pre and post transfusional hemoglobin concentrations did not show any correlation with LVIDd, LVIDs, EF, FS (P>0,05). Hemoglobin concentration did not show any correlation with troponin, CK and CK-MB levels either.
Summary / Conclusion: The present study demonstrates thatcardiac troponin I, creatine kinase and creatine kinase-MB are not effected from hematological profile of thalassemia major patients. Echocardiographic measurements are not effected from acute changes in hemoglobin concentration in well-treated patients. Erythrocyte transfusion does not lead to any acute change in cardiac parameters

B1895

AUDIT AND REAUDIT OF WEARING IDENTIFICATION WRISTBAND DURING BLOOD TRANSFUSION AT DUBAI THALASSEMIA CENTER

K Belhoul [1], M Bakir[1*]
[1]Thalassemia centre , Dubai Health Authority , Dubai, United Arab Emirates

Background: Mistransfusion is the term used to describe an episode where "the wrong patient receives the wrong blood" and is considered by most authorities to be the leading cause of transfusion-related morbidity and mortality. Positive patient identification is essential at all stages of blood transfusion process to prevent such a serious adverse event. Dubai thalassemia centre daycare unit serves patients with hemoglobinopathy requiring chronic blood transfusion. Nearly7,000 patient visits are received every year.
Aims: The purpose of this audit was three folded. Firstly, assess compliance to wearing the correct identification (I.D) wristband all the time during blood transfusion cycle. Secondly, identify the reasons for not wearing I.D wristband. Thirdly, evaluate the impact of process standardization and staff and patients' education through re-auditing.
Methods: Five prospective audits were performed from 2007 to 2011 using the same methodology. Each audit was conducted prospectively on all patients admitted to thalassemia centre day care unit for blood transfusion over one month period. Patients were inspected twice daily for wearing I.D wristband that has the correct five core identifiers. The reasons for not wearing were recorded.
Results: In June 2007, 495 patients were subjected to auditing, 457(92.32%) patients were wearing the correct I.D. wristband during blood transfusion. 1.7% refused to wear their I. D. wristband because they are known to all staffs, 1.4% clipped their band to the IV dressing, 1.0% was removed by the child patient himself accidentally, 0.2% had ID band allergy and the remaining 3.4% were others. Following staff and patients' intensive education, 490 patients were subjected to re-auditing in Jan 2008 which revealed compliance improvement to 98%. 1.8% continued to refuse to wear I.D wristband because they are known to all staffs and 0.2% were allergic to the band. The same level of compliance to I.D wristband was maintained in the subsequent reaudits (2009, 2010 and 2011) and the reasons for not wearing the I.D wristband remained the same.Our results were comparable to other international audits' results (Graph1).



Summary / Conclusion: Auditing and continuing staff and patients' education about the importance of wearing the correct identification band all the time during blood transfusion are useful tools to improve compliance to identification guidelines.

B1896

POSTTRANSFUSION PLATELET RESPONSE IN HEMATOLOGICAL INPATIENTS

J Schuh[1*], J Carreira[2], C Gaspar[1], A Gil[1], A Tome[1], J Veiga[1]
[1]Serviço de hematologia, Hospital dos Capuchos, [2]Serviço de Imuno-hemoterapia, Hospital de São José, Lisboa, Portugal

Background: Thrombocytopenia is a common feature in hemato-oncological diseases, mainly in acute leukemia patients. Platelet transfusion (PT) may be used to prevent or treat associated hemorrhagic events and diminishes morbidity and mortality. Unfortunately, PT is not always effective on increasing the platelet counts, and the specific cause is identified in only a minority of cases.
Aims: To evaluate posttransfusion platelet response and its contributing factors.
Methods: From 13/04 to 13/06/2012, a prospective observational study of 354 consecutive transfusions in 50 inpatients (26 men; median age 58 years; acute myeloid leukemia as predominant pathology) was performed. Posttransfusional platelet response was evaluated using the 1 hour and 24 hour corrected count increment (CCI). Good responses were defined as 1h-CCI ≥ 7.500/µL or 24h-CCI ≥ 4.500/µL. Platelet quality, clinical status, laboratory results (renal and hepatic function, coagulation, complete blood count, LDH, PCR) and prescribed medications in the 24 hour interval before and after transfusion were evaluated.
Results: The median 1h and 24h-CCI were 6.500/µL (interquartile range, IQR, 2.632 - 11.985) and 2.146/µL (IQR -715 - 8.123), respectively; 44% of the PT had a good response after 1 hour, while only 39% after 24 hours. There was no significant correlation between 1h and 24h-CCI (rho 0.39). The platelets had acceptable quality concerning pH and lactate. The pretransfusion platelet count, (median 9.000/µL, IQR 6.000 – 15.000), did not influence the 1h-CCI. Male and older patients had significantly poorer responses. Also, the presence of fever and splenomegaly negatively affected the CCI. None of the laboratory results correlate with the CCI. Patients who were given piperacillin-tazobactam, potassium chloride, cyclophosphamide or omeprazol had significantly better responses, while etoposide, acetaminophen and bromazepam negatively influenced the posttransfusional response.
Summary / Conclusion: We found a low posttransfusional response among our hematological patients, which is in agreement with other similar institutions. The identification of manageable contributing factors for a deficient response may help optimizing the way we transfuse these patients, and it would probably improve efficacy and reduce costs. These factors should be further investigated in clinical trials.

B1897

CLINICAL EXPERIENCE OF GRANULOCYTE TRANSFUSION IN THE MANAGEMENT OF PEDIATRIC PATIENTS WITH FEBRILE NEUTOPENIA: A RETROSPECTIVE STUDY FROM A REFERENCE CENTER IN TURKEY

T Patıroğlu[1*], M Karakukcu[1], E Unal[1], F Mutlu[1], B Isık[1], E Yılmaz [1], M Ozdemir[1]
[1]Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Despite intensive chemotherapy with improved supportive care for neutropenia contribute to the recent advances in treatment outcome in children with cancer.Febrile neutropenia is a still major risk factor for severe infections and mortality in malignancies. Granulocyte transfusion (GT) therapy is recommended to treat infections.
Aims: We retrospectively analyzed the clinical characteristics of patients with malignancies receiving GT therapy.
Methods: A total of 50 patients (30 boys, 20 girls) with a median age of 9 years (range: 2 months-21 years) were included in the study. Out of these 50 patients, 15 suffered from relapsed acute lymphoblastic leukemia, 11 acute myeloblastic leukemia, 10 aplastic anemia, 3 familial hemophagocytic lymphohistiocytosis, 6 lymphoma, 4 neuroblastoma and 1 germ cell tumor. All patients had persistent fever and prolonged neutropenia (>7 days). GT therapy was given because of fungal (13), viral (CMV 27, herpes virus 1) and bacterial (gram-negative11, gram-positive 20) infections.
Results: All patients received a median of 5 tranfusions (1-15) and appropriate antibacterial therapy combined with or without antifungal agents. G-CSF and addition to GT therapy was given to all patients except 8 with AML. The controlling of persistent fever and clinical signs of infection were achieved in all patients, but 12 patients (24 %) died due to subsequently developed uncontrolled infections.
Summary / Conclusion: A substantial proportion of severely ill pediatric patients with complicated febrile neutropenia benefited from GT therapy.

B1898

PLATELET EXPENDITURE IN HEMATOLOGY PATIENTS

F Raka[1*], S Useini[2], R Grubovic[2], I Nikoloska[3], M Blagoevska[1]
[1]Blood collection and processing, [2]Apheresis department, [3]Immunohematology department, National Institute for Transfusion Medicine(NITM)- Skopje, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Thrombocytopenia is a major cause of morbidity and mortality in patients receiving chemotherapy for malignancy as well as for other specific hematologic disorders that also require frequent platelet (PLT) transfusions
Aims: To report on the expenditure of platelets (PLTs) aimed for the patients at the University Clinic of Hematology in relation to the total annual number of released PLTs for clinical use
Methods: A retrospective three - year survey (from January 2010 through December 2012) has been done, using data from the blood component production and apheresis department at the National Institute for Transfusion Medicine (NITM) – Skopje.
Results: The total annual number of whole blood units aimed for component preparation varied from 21 488 to 28 443 blood units. In 2010, 81.9% (12 666) of the produced PLTs by mainly the platelet- rich plasma (PRP) – method, were released for clinical use. 80.7% of these PLTs were intended for hematologic patients. These percentage has slightly decreased in 2011 showing 77, 5 % PLT release for these patients. Further reduction of usage of PRP- derived PLTs was noticed the next year (64.4%). Regarding this issue, the apheresis department has increased its performance by increasing the production of PLTS (from 46 in 2010; 65 in 2011 and 80 apheresis procedures in 2012). Most of these single-donor apheresis PLTs were aimed for hematologic patients (78.3% in 2010; 75.4% in 2011 and 55% of the collected PLTs were released in 2012).
Summary / Conclusion: The number of PLT transfusions for the purpose of treating hematologic patients has slightly decreased. This may be due to a more stringent PLT transfusion policy. However, these patients still remain most transfused ones when considering PLT transfusions. Replacing prophylactic transfusions by a therapeutic transfusion strategy following the latest guidelines as well as introducing new therapeutic modules, the number of PLT transfusions may further be reduced.

B1899

USE OF RECOMBINANT FACTOR VIIA (RFVIIA) IN ACUTE LIFE THREATENING PRIMARY POSTPARTUM HAEMORRHAGE: A CASE REPORT

J Quigley [1*], J Byrne[1], M Diaz[1], M Culliton[1], K Murphy[1], I Regan[2], G Flannelly[3]
[1]Department of Pathology & Laboratory Medicine, The National Maternity Hospital, Dublin2, [2]Department of Pathology & Laboratory Medicine, Our Lady's Children's Hospital Crumlin, Dublin 12, [3]Department of Obstetrics & Gynaecology, The National Maternity Hospital, Dublin2, Ireland

Background: Primary Postpartum Haemorrhage (PPH), although falling in recent years, is one of the leading causes of maternal mortality and morbidity in the western world with a maternal mortality rate of 8.4% of all direct maternal deaths in the United Kingdom (CEMACH 2011). Massive PPH is defined as a cumulative blood loss >1,500mls of blood or ongoing severe bleeding. The treatment for massive PPH is a combination of blood and blood product transfusion, uteronics, surgical and pharmacological agents such as Tranexamic Acid and recombinant FVIIa (rFVIIa). RFVIIa is a prohaemostatic drug that activates Factor X on activated platelets and on tissue factor to promote thrombin generation at the site of injury with the formation of a stable fibrin clot. RFVIIa is used in the treatment of haemophilia and FVII deficiency. Outside this, use of rFVIIa is very controversial, in particular in the field of Obstetrics where it is not licenced for the treatment of obstetric haemorrhage due to severe risk of thrombosis in an already prothrombotic patient.
Aims: To review the efficacy of rFVIIa post major post-partum haemorrhage and to review the clinical outcome of the patient post obstetric haemorrhage.
Methods: This was a retrospective individual case report. 39 year old, Para3, (LSCS x3, cord prolapse, breech presentation and elective section). Antenatal care was uneventful; however ultrasound at 33 weeks noted placenta acretia. Planned caesarean section and tubal ligation planned for 38 weeks gestation.
Results: Delivery: Laparotomy, high transverse caesarean section, ligation internal iliac artery, sub total hysterectomy and left salpingo-oopherectomy. Liveborn female infant, 3710g, Apgars $7^{1}9^{5}$. Maternal estimated blood loss (EBL) = 19570 mls. Hb decreased from 12.0 to 4.0 g/dl, received 31 RCC, 4 Pools of platelets, 21 Plasma units, and 11g of fibrinogen. The patient continued to bleed. The patient then received recombinant Factor VIIa under Consultant Haematologist instruction (Fibrinogen = 1.63g/l and PT = 13.4 seconds). The bleeding arrested with no further requirement for red cell transfusion. A top-up platelet transfusion was required post event.
Summary / Conclusion: This case demonstrates that rFVIIa was effective in arresting an acute life threatening primary post partum haemorrhage with no thrombotic adverse effects seen it the aftermath. In the absence of randomized controlled trials on the use of rFVIIa in obstetrics, the use of independent case reports and review articles published lend support to the weak evidence that is currently available on the use of rFVIIa for obstetric haemorrhage.While some studies support the use of rFVIIa as a safe and efficacious treatment for massive obstetric haemorrhage, other studies do not support its routine use. Until randomised controlled trials take place in obstetrics with established protocols for its use, rFVIIa should only be prescribed by a Consultant Haematologist.

B1900

PHENOTYPE FREQUENCIES OF BLOOD GROUP SYSTEMS AND ALLOANTIBODIES TO RED BLOOD CELLS IN BLOOD RECIPIENTS IN CENTRAL ANATOLIA OF TURKEY

Y Torun[1*], L Kaynar[2], C Karakukcu[3], M Yay[4], F Kurnaz[2], S Sivgin[2], M Cetin[2], B Eser[2]
[1]Pediatric Hematology, Kayseri Education and Research Hospital, [2]Hematology, Erciyes University, [3]Biochemistry, Kayseri Education and Research Hospital, [4]Blood Transfussion Center, Erciyes University, Kayseri, Turkey

Background: In routine practice, appropriate blood group for ABO and Rh blood group system should be given for a safe and effective erythrocyte transfusion. A total of 308 RBC antigens are now recognized by the International Society of Blood Transfusion (ISBT), 270 of which are clustered in 30 blood group systems, 9 of which (ABO, Rh, Kell, Kidd, Duffy, MNS, P, Lewis and Lutheran) are considered to be major blood group systems. Alloimmunization caused by the immunogenic reactions is a serious problem especially in patients receiving multiple transfusions.
Alloantibody data bank can be obtained by determining the antibody profile of the community by the screening of red cell antigen phenotype. Thus, potential development of alloimmune transfusion reactions can be prevented in patients. In literature, except for the frequency of ABO and Rh antigens, there is no study available about the frequency of red cell antigens in Turkey.
Aims: Routine erythrocyte antibody screening to prevent alloimmunization reactions in erythrocyte suspension recipients has been going on in Erciyes University in Kayseri, which is a city in the central Anatolia in Turkey, since January 2008. The present study is the first report detecting the frequencies of the RBC antigen and phenotypes of different blood groups in Kayseri, a city in middle Anatolia in Turkey.
Methods: A total of 48750 blood recipients typed for ABO, Rh system and other blood groups were retrieved from January 2009 to July 2011. The patients in whom antibodies were detected were also screened for the presence of autoantibodies. ABO group types and Rh specifities of the blood samples are screened and identified by DiaMed–ID Micro Typing System (Diamed AG, Switzerland) by gel centrifugation technique. The screened blood group antigens in recipients were Kidd (Jk^a, Jk^b), Kell (K, kp^a, kp^6), (Duffy Fy^a, Fy^b), MNS (M, N, S, s), Lewis (Le^a, Le^b), P (P), Lutheran (Lu^a, Lu^b) and Xg (Xg^a). ID card antigen profile-I (P_1, Le^a, Le^b, Lu^a, Lu^b), ID card antigen profile–II (K, k, kp^a, Kp^b, Jk^a, Jk^b) and ID K typing cards were used with a red cell suspension (5 %) for phenotyping. ID card antigen profile–III (M, N, S, s, Fy^a, Fy^b) was used with a red cell suspension prepared in 0.8 % LISS.
Results: The retrospective analysis of transfusion history and medical records of 48750 patients who have received at least one transfusion found that 196 (0.4 %) patients had developed antibodies. Of the patients whose antibody test results were positive, 28 (14 %) were found to have autoantibodies. In the Kell blood group system, 22 % (43/196) recipients were typed as K antigen positive. This rate was found to be 0.08 % (43/48750), in the screened population. A rare Kp^a phenotype was found with a frequency of 2.04 % (4/196) in recipients. For the Kidd and Duffy blood group system, Jka rate was 2.5 % (5/196), Jkb was 1.02% (2/196); and Fy (a+) was 2.5 % (5/196). Neither Luteran nor Xg^a phenotypes were observed in this study population. M + and S + were the most common phenotypes observed in the MNS blood group system (3.6 % and 1.02%, respectively). According to the Lewis blood group system, Le^a and Le^b antigens were observed with a frequency of 1.5 % and 0.5 % respectively, whereas frequency of P_1 antigen was 0.5 %.
Summary / Conclusion: Multiple antigen detection is an important problem in blood banking. In patients undergoing chronic transfusion, if hemoglobin levels drop suddenly and need for transfusion frequency increases without any other cause, the probability of multiple antibodies should be considered. Also transfusions applied in different centers increases the antibody rate.
In conclusion, we think that logical alloantibody screening can prevent transfusion reactions in patients undergoing multiple transfusions, if a data bank can be created. Antibody screening tests particularly in recipients would avoid both time and the financial loss.

B1901

CORRELATION BETWEEN ABO BLOOD TYPE AND THE SITE OF CANCER

A Argyrou[1*], A Charalambous[1], K Kamitaki[1], K Manta[1], M Georgopoulou[1], A Podaras[1], A Gafou[1]
[1]Blood Bank, General and Oncology Hospital "Agioi Anargyroi", Athens, Greece

Background: The relation between ABO blood type and various malignancies has been an issue of research since the 1950's, but only in the late 2000's a certain association between A blood group and pancreatic cancer was established. The existence of pancreatic cancer loci in the ABO gene and the ele-

vated plasma markers of inflammation in these patients suggested a link between chronic inflammation, A blood type and pancreatic cancer, according to which, blood group antigens may alter the systemic inflammatory response that leads to this specific type of neoplasia.

Table 1: ABO distribution (cancer patients- general greek population)

CANCER SITE	N(%)	A (%)	B (%)	AB (%)	O (%)	P-value
BREAST	312(23,5)	127(40,7)	48(15,4)	16(5,1)	121(38,8)	0,989
COLORECTAL	199(14,2)	79(41,8)	24(12,7)	13(6,9)	73(38,6)	0,546

OTHER	370(27,8)	145(39,2)	53(14,3)	18(4,8)	154(41,6)	
TOTAL	1329(100)	561(42,2)	174(13,1)	64(4,8)	530(39,9)	0,172
GENERAL GR. POPULATION	1105(100)	441(39,9)	178(16,1)	58(5,2)	428(38,7)	

Table 2: ABO distribution in respiratory and pancreatic cancer (recent results)

RESPIRATORY CANCER		PANCREATIC CANCER	
PATIENTS (N=198)	GENERAL GREEK POPULATION (N=1105)	PATIENTS (N=75)	GENERAL GREEK POPULATION (N=1105)
Blood Type B: N=15 (7,7%)	Blood Type B: N=178 (16,1%)	Blood Type A: N=41 (54,7%)	Blood Type A: N=441 (39,9%)
Blood Type non-B: N=183 (93,2%)	Blood Type non-B: N=927 (83,9%)	Blood Type non-A: N=34 (45,3%)	Blood Type non-A: N=664 (60,1%)
P-value: 0.002		P-value: 0.012	

Aims: To check the distribution of the ABO blood type among the Greek cancer patients and detect the existence of any correlation between ABO and the site of cancer.
Methods: From the archives of the Blood Bank Department in our Oncology Hospital we had recorded 1329 cases of cancer patients, their ABO blood type and the site of cancer. The ABO distribution was studied in the whole cancer-population and also among various sites of cancer-categories, and it was compared to the distribution in the general Greek population. The results had revealed the already known association between pancreatic cancer and A blood type, and also a newly mentioned association between respiratory cancer and non-B blood-type. Now, having expanded further the database (1518 cases), we are particularly focusing in the prevalence of A and non-B blood type among the pancreatic and the respiratory cancer patients respectively, by comparing the A and non-A and the B and non-B distribution in the general Greek population to the distributions in the pancreatic cancer group and the respiratory cancer group respectively (x^2test).
Results: The ABO distribution in the general Greek population, in the whole cancer population and in each cancer site-oriented group studied, as well as the levels of statistic significance testing the O versus non-O prevalence in each site of cancer, are shown in table 1. The results regarding the A/non-A distribution among the pancreatic cancer patients and the B/non-B distribution among the respiratory cancer patients are shown in table 2 (the calculations in these two categories were done on the updated data).
Summary / Conclusion: 1. The ABO distribution among cancer patients is not different when compared to that in the general Greek population and this is in accordance to the national bibliography. 2. Blood group A is associated with pancreatic cancer, according to the national bibliography. 3. Non-B blood group is associated with respiratory cancer.
Gathering further data, especially on patients with respiratory cancer, would enforce the level of statistic significance of these results

B1902
CLINICAL OUTCOMES OF ABO INCOMPATIBLE RBC TRANSFUSIONS
S Mahjoub[1*], B Hela[1], B Neila[1]
[1]hopital LA RABTA, TUNIS, Tunisia

Background: ABO mismatch blood transfusion is one of seriousness events related to blood components administration.
Aims: we performed a retrospective review of ABO-incompatible RBC transfusions from our institution during four years (2007-2011).
Results: Within the period of observation, 20 ABO mismatches were detected (effective transfusions and near miss events). 12 ABO mismatches were detected when blood samples are studied for pre-transfusions tests (mistake in sample collection or identification and one case of usurpation of identity). Of 8 patients who received more than 50 ml of incompatible blood, 4 (50%) manifested signs or symptoms related to the incompatible transfusion but none died. Hypotension, hemoglobinuria, postoperative bleeding was detected in survivors. In the half of our cases (4 patients), there were no associated signs or symptoms due to the incompatible transfusions.
Summary / Conclusion: ABO incompatible RBC transfusion does not inevitably mean death or even occurrence of symptoms. Awareness of staff at the bedside and laboratory of the potential for errors is one of the most effective tools for detecting and preventing transfusion errors.

B1903
COMBINATION OF DEFERASIROX AND DEFEROXAMINE IN MANAGEMENT OF IRON OVERLOAD IN MYELODYSPLASTIC SYNDROMES (MDS): AN UPDATE IN A HEPATOPATIC PATIENT
C Cerchione[1*], G Cerciello[1], R Della Pepa[1], N Pugliese[1], L Marano[1], O Vitagliano[1], M Matarazzo[2], F Pane[1], F Alfinito[1]
[1]Hematology, [2]Internal Medicine, AOU "Federico II", Napoli, Italy

Background: Although other treatments are now available, the standard treatment for many MDS patients remains supportive care. Most MDS patients eventually become red blood cell (RBC) transfusion dependent, risking iron overload, which may lead to cardiac, hepatic, and endocrine dysfunction.
Aims: Iron-chelation is recommended in guidelines in MDS when there is at least an evidence of iron overload: elevated serum ferritin, iron related organ dysfunction, or chronic RBC transfusions. Deferasirox is a well tolerated oral iron chelator drug that produces relevant benefits but, because of its potential hepatotoxicity, it is usually not recommended for patient with known hepatic diseases.
Methods: A 62-year-old man, with Refractory Anaemia, affected by HCV positive cirrhosis, started recombinant Erythropoietin therapy without results, and then he went in RBC transfusion program, with 2 blood package/month. At a ferritin serum concentration 700 ng/mL iron chelation therapy with deferoxamine was started in consideration of pre-existing hepatic disease. The patient was absolutely not compliant to this therapy, and transfusion need increased until to 2 blood package/week while serum ferritin concentration was, after 12 months, more than 6000 ng/mL. Since high levels of ferritin correlate with a dangerous condition for hepatic cells, deferasirox was started at low dosage, 10 mg/kg/die. Before treatment was started, an accurate study of hepatic, renal and cardiac functions was performed. After three months, serum ferritin was not modified as well as other biochemical parameters, and so deferasirox dosage could be gradually increased, reaching 30 mg/kg/die after two months without any liver damage. After five months of therapy with deferasirox at full dosage, serum ferritin concentration was more than 5098 ng/mL.
Results: Then, considering all risks related to secondary hemochromatosis, a combined iron chelation therapy with deferasirox (30 mg/kg/die) and deferoxamine (2 g/day for 5 days/week) was established : after 3 months serum ferritin concentration decreased to 3000 ng/mL. In that period, Haemoglobin concentration decreased significantly, so that the patient had to receive 2 RBC package/week and, after two years of combined therapy, serum ferritin concentration was at a stable level under 3000 ng/mL. During treatment, a regular monitoring of hepatic, renal and cardiac functions was performed and there was no alteration. Then, the patient, after a 4-years period of transfusion and related iron-chelation therapy, died from septic shock.
Summary / Conclusion: In conclusion, management of iron overload with deferasirox and deferoxamine as combined therapy can be considered as a safe and useful therapeutic choice in critical transfusion-dependent iron overload in MDS patients with pre-existing hepatic disease, even if these preliminary observations need to be validated by controlled studies enrolling larger number of patients.

B1904
COMPARATIVE STUDY OF DEFERRED BLOOD DONORS CHARACTERISTICS- HOW THEY CORRELATE WITH WHERE THE BLOOD DONATION TOOK PLACE (HOSPITAL OR MOBILE UNITS)
S Patiakas[1*], B Kelesiadou[1], K Basilakos[1], P Tsiatsiou[1], A Nikolaidou[2], U Tsiatsiou[1]
[1]Blood Donation departmant of General Hospital of Kastoria, Kastoria, [2]Hematological Laboratory of University Gneral Hospital of Thessaloniki "ACHEPA", Thessaloniki, Greece

Background: A study of the questionnaires that the possible blood donors fill in was performed.
Aims: To record and study the characteristics of the possible blood donors who were deferred and to comparatively study this data according to the place of blood collection.
Methods: During the last six years, 16580 possible blood donors presented. 13974 of them gave blood, while 2606 (15.7%) were deferred. In the hospital presented 14241 possible donors and 11922 of them gave blood, while 2319 possible donors where deferred (16.3%). In case of collecting blood with a mobile unit, 2339 possible donors presented, 2052 of them gave blood and 287 (12.3%) were deferred.
Results: You can see the result at the Table below:

	MEN	WOMEN	VOLUNTARY	FAMILY	OLD	NEW REPLACEMENT
IN HOSPITAL	56,2%	43,8%	17,7%	82,3%	63,6%	37,4%
MOBILE UNITS	38,6%	61,4%	78,2%	21,8%	51,7%	48,3%

Summary / Conclusion: he result's are readily explained by the fact that in case of mobile unit blood giving, all of the donors are voluntary, non remunerated, and most of them are frequent donors, so they usually are better informed and prepared, compared to the mixed population of voluntary and family replacement donors we deal with at the hospital. In both cases, the deferral rate for women is higher, mostly due to the lower Hb levels. Another fact that needs to be emphasized is the large number of young people (age<35 years) who present to donate blood. This is particularly important in our country, where the problem of ageing population is getting bigger every year.

Granulocytes

B1905
EOSINOPHILIC FASCIITIS
S Akarsu[1*], I Ozercan[2], H Yildirim[3]
[1]Department of Pediatric Hematology, [2]Department of Pathology, [3]Department of Radiology, University of Firat, Faculty of Medicine, Elazig, Turkey

Background: Eosinophilic fasciitis is characterized by edema, painful induration, and progressive muscle weakness. It is more frequently seen in men, and though not an absolute necessity, eosinophilia can be observed in this disease with partially revealed etiology. Scarce number of cases have been reported so far.
Aims: We wanted to present this case considering its scarcity, and critical role in the differential diagnosis of eosinophilic disorders.

Methods: A 12-year old male patient started to suffer from itching, and skin rash all over his body 3 weeks before his admission. Eruptions were as small as pinheads. Later on swellings, and painful skin rashes had emerged on his wrists, elbows, knees, and ankles. His personal, and familial medical history was not remarkable. His physical examination demonstrated edematous eyelids, diffuse subcutaneous nodules all over his body, more numerous on articular areas, and 1-2 mm-sized nodules on his back. In addition a 7 x8 mm-skin lesion with an orange peel appearance was seen on his back. Peripheral eosinophilia (17 %), and a higher eosinophilic cationic protein (ECP) level (42.000 mg/L; normal: 0.00-20.00 mg/L) were detected. Surface ultrasound revealed a minimal amount of subcutaneous edema. On MRI, in sagittal plane a hyperintense lesion measuring 80 x 8 mm localized on the posterior aspect of the left elbow was observed. On T2A-weighted, and also fat-suppressed sequences, this hyperintense lesion was consistent with fasciitis. Histopathologic examination of the biopsy material revealed a nodular lesion characterized with increased collagenous tissue, and irregular contours which infiltrated into subcutaneous adipose tissue almost completely starting from dermal layer, and also fascial layer covering the inferior aspect of the adipose tissue. This local collagenous tissue had patchy areas of myxoid tissue, but it mostly demonstrated a fibrinoid degeneration. This collagenous tissue contained numerous lymphocytes, and occasionally eosinophils.
Results: Methylprednisolone therapy (60 mg/m^2/d) was initiated. One week later any regression of his complaints, and subcutaneous nodules was not observed. Oral methotrexate (20 mg/m^2) therapy was started. A week later his complaints, and subcutaneous nodules disappeared. With weekly dose-tapering protocol, at 5. week of his therapy, his methylprednisolone, and methotrexate doses were reduced to 20 mg/m^2, and 14.58 mg/m^2, respectively which resulted in reappearance of previously regressed lesions on the anterior aspect of the chest. At the 12. week, doses of methylprednisolone, and methotrexate were increased to 25.6 mg/m^2, and 20 mg/m^2 which again brought lesions under control, and his complaints resolved.
Summary / Conclusion: In cases with eosinophilia, underlying causes should be looked for. Eosinophilic fasciitis should be considered among etiological factors of eosinophilia.

B1906
NEUTROPAENIA FOUND ON ROUTINE LABORATORY TESTING – IS FOLLOW-UP REQUIRED?
R Thompson[1], R Irving[1], SWatt[1*]
[1]Department of Haematology, University Hospital of South Manchester, Manchester, United Kingdom

Background: In our teaching hospital laboratory, all full blood count results that demonstrate a neutrophil count of less than 1.0 x 10^9/L are highlighted for the attention of a consultant haematologist. There is little published evidence suggesting what investigation and follow up is required.

Aims: We aimed to follow up all patients identified as neutropaenic during a 3 month period, to build up a picture of patient characteristics and outcomes.
Methods: Between November 2010 and January 2011, 171 patients were identifed as neutropaenic by our laboratory. We performed a retrospective observational study following up each patient over a 2 year time period. We used a combination of hospital case notes, primary care medical histories and our hospital electronic laboratory results system to establish patient outcomes.
Results: Full blood counts came from general hospital wards, outpatient departments and Accident and Emergency (50%), primary care (25%), oncology (19%) and haematology (7%).
Causes of neutropaenia included chemotherapy (24%), infection or subsequent antibiotics (27%), haematological (15%), and drugs (4%). A cause was not identified in 21% of cases; the majority of these were primary care patients who were not further investigated. Excluding patients post-chemotherapy, 31% had a previous diagnosis explaining their neutropaenia. Of the remaining hospital patients, almost all had an attributable cause, most commonly infection; the 10 patients with no obvious cause were either followed up by haematology or were young children who were well, but should have had a repeat full blood count to check resolution of neutropaenia. Of the primary care patients without a previous diagnosis, 59% had a persistent/recurrent mild neutropaenia with no proven aetiology and have remained well. Several of those with new neutropaenia did not have sufficient repeat full blood counts.
There were 35 deaths. 33 patients had an underlying cause for their neutropaenia. There were only 2 deaths in those without a known cause of neutropaenia, both primary care patients in their mid-80s with a persistent mild neutropaenia; cause of death is unclear from the records but we suspect that further investigation would not have altered management.
A significant number (33%) of patients, excluding those post-chemotherapy, had a transient neutropaenia, mostly due to infection or subsequent antibiotics. In around 20% of patients, duration of neutropaenia is unknown. A number were lost to follow up as they moved out of area or were under the care of another hospital; the remainder were assumed to have a transient or benign neutropaenia but did not have sufficient repeat full blood counts to confirm this.
Summary / Conclusion: Almost all hospital patients had either an established reason for neutropaenia, or an obvious attributable cause. Very few needed to be further investigated and those who did require follow up were appropriately referred to haematology.
It is much more difficult to establish causality in primary care patients, due to lack of accessible documentation. However, patients without a diagnosis appear to have a benign cause for their neutropaenia since they remain well.
A small number of patients in both primary and secondary care were assumed to have a transient or benign neutropaenia, but did not have sufficient repeat full blood counts to confirm this. We will ensure that all future neutropaenia blood film reports include a recommendation to repeat full blood count afer around 4 weeks.
Our results suggest that patients with neutropaenia are being followed up appropriately; those who remain without a diagnosis appear to have a benign cause and may not need further investigation in the absence of other signs or symptoms.

B1907
THE CLINICAL FEATURES AND GENETIC MUTATIONS OF CHRONIC GRANULOMATOUS DISEASE: RESULTS FROM A REFERENCE CENTRE AT MIDDLE ANATOLIA
T Patiroglu[1,2*], H Gungor[2], E Unal[1], Y Koker[3]
[1]Pediatric Hematology, [2]Pediatric Immunology, Erciyes University Medical Faculty, [3]Erciyes University, Medical Faculty, Division Of Bone Marrow Transplant Unit, Kayseri, Turkey

Background: Chronic granulomatous disease (CGD) is a rare innate immune deficiency with neutrophil function disorder.
Aims: In this retrospective study, we aimed to evaluate the clinical features of the patients with CGD.
Methods: We presented eight patients (6 boys, 2 girls) with CGD which were evaluated at Erciyes University Medical Faculty hospital between 1996 and 2012. The initial complaints, age at diagnosis, consanguinity of the parents, similar disease history or death of the siblings, physical examination, diagnostic tests, clinical courses, and geneticcharacteristics were analyzed.
Results: The initial complaints were started before the age of one in four patients; whereas only two patients diagnosed before the first birth day. Lymphadenomegally, suppurative infections, pneumonia, diarrhea were the most noted initial complaints. All parents were consanguineous. The clinical features were mild; and the ages of diagnosis were late in patients with p47 and p67 defect. The patient with X linked CGD was diagnosed when he was 3 months old; his clinical course was complicated with chronic otitis media, zygomatic abscess, lung abscess, and facial paralysis. The patient with p22 defect was diagnosed at two months of age; and gastric wall granuloma, inflammation in proximal femur was detected.
Summary / Conclusion: The awareness of the clinicians about CGD will result in early diagnosis and consequently reduce the mortality and morbidity of this disease.

B1908
THE COINCIDENCE OF FAMILIAL MEDITERRANEAN FEVER AND HYPEREOSINOPHILIA IN A PATIENT WITH HEREDITARY ELLIPTOCYTOSIS
M Keklik[1*], A Unal[1], S Sivgin[1], O Kontas[2], L Kaynar[1], B Eser[1], M Cetin[1]
[1]Hematology, Erciyes Stem Cell Transplantation Hospital, Faculty of Medicine, Erciyes University, Kayseri, [2]pathology, Erciyes University, Faculty of Medicine, Kayseri, Turkey

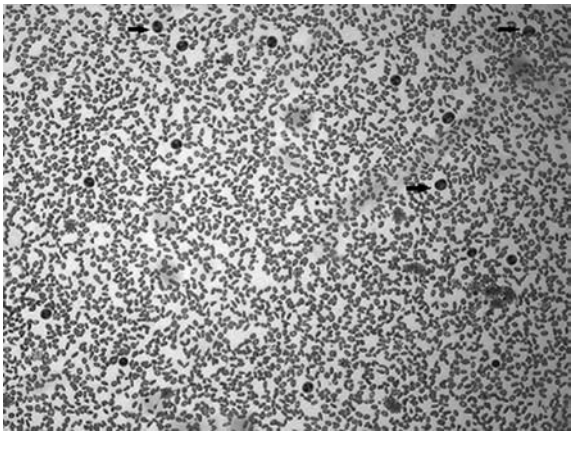
Background: Familial Mediterranean fever (FMF) is a genetic disease with autosomal inheritance characterized by recurrent fever, abdominal pain, and serositis attacks. It is relatively common in the races and ethnical groups around Mediterranean Sea (Sephardic Jews, Armenians, Turks and Arabians).Hereditary elliptocytosis (HE) is common genetic defect of the red blood cell membrane skeleton. In the present study, we reported a HE case accompanied by FMF and hypereosinophilia, as it hasn't been reported in the literature so far.
Aims: This case report describes a Turkish female HE patient who presented

with FMF and hypereosinophilia. The causes of hypereosinophilia and it was considered as reactive hypereosinophilia. Genetic analysis revealed heterozygous mutation in exon 10 of the *MEFV* gene (V726A). The patient was successfully treated with colchicine and steroid treatment with 3 months follow-up. To the best of our knowledge, this is the first report of association between FMF, HE, and hypereosinophilia.

Methods: A 27 years old female patient visited emergency room of Erciyes University for fever, abdominal pain and vomiting. It was found that anemia and splenomegaly was found and she was diagnosed as HE by peripheral blood smear in pediatrics clinic; followed by splenectomy. She had no past another medical history, family history and history of tobacco, alcohol, illegal drug use, and travel. She had been suffering from recurrent periodic fever, abdominal pain, and vomiting every two months since 6 months ago. She complained of abdominal discomfort for three days and fever for two days followed along with whole abdominal pain and vomiting, and then the sympoms resolved spontaneously. Her vital signs were blood pressure 110/70 mmHg, pulse 88/min, respiratory rate 23/min, and body temperature 38.7^0C on admission. In abdominal examination, there was generalized tenderness but not defense or rebound tenderness. Initial laboratory results showed that leukocyte was 35,860/μL (neutrophil28,330/μL, eosinophil5,080/μL), hemoglobin 15.5 g/dL, platelet 521,000/μL, C-reactive protein 53.68 mg/L, and the erytrocyte sedimentation rate 40 mm/h. There were diffuse elliptocytes and increased eosinophils on the peripheral blood smear.In blood sample molecular analysis of patient, the PDGFRA-FIP1L1 was found negative.Her symptoms lasted for around 2 days and then were spontaneously subsided. We performed MEFV gene test for definite diagnosis. Mutational analysis detected gene mutation on one allele in patient, and one missense mutation was detected in the exon 10 of the MEFV gene, V726A in heterozygous. Diagnosis of FMF was determined according to Tel Hashomer criteria for FMF.

Results: The patient is current under treatment with colchicine 1.2 mg/day, oral prednisolone 1mg/kg and hydroxiurea 3 tablet of 500 mg a day. The progress is being followed up with gradually improved severity and duration of the symptoms. Eosinophil count reduced to 0,370/μL at the week 3 after initiation of therapy. Steroid treatment was stopped after 1 month and the patient is now, 3 months after diagnosis, in normal health.

Summary / Conclusion: In the present study, we discussed FMF with adult onset and hypereosinophilia in a patient with HE, and causes of this situation. FMF can be diagnosed based on characteristic clinical patterns, response to treatment for colchicines, and gene test results.In conclusion, this case is considered to be important as it is first case with association of HE, FMF and hypereosinophilia.



B1909

HYPEREOSINOPHILIC SYNDROME: CASE REPORT

E Kazanci[1*], G Kilic[2]

[1]pediatric hematology, [2]pediatric allergy, Bursa Dörtcelik Children hospital, bursa, Turkey

Background: Idiopathic hypereosinophilic syndrome (IHES) is characterized by prolonged eosinophilia in peripheral blood and bone marrow and multiple organ dysfunction. Although the pathogenesis of the disease is not known exactly, its believed that the enzymes released by eosinophils.

Aims: We report a case with cough and urticaria, presented with frequent relapses of clinical signs and idiopathic hypereosinophilia, without known cause. Our patient is admitted to hospital with frequent relapses of pulmonary and skin involvements, which are treated with steroids successfully.

Results: A 4-year old male was referred to our clinic with complaints of fever, cough, wheezing and rash. Five months before the current admission he was treated for allergic dermatitis due to pruritic wheals and edema in his arms and feet. At admission, the child had fever, rash and angioedema. Auscultation of chest revealed bilateral ronchi. The spleen and the liver were palpable 3 cm below the costal margin. Complete blood count revealed an abnormal total leukocyte count of 41.08/μL (neutrophils 18%; lymphocytes 20% and eosinophils 62%), normal hemoglobin level (12.9 g/dL) and normal platelet count (342x103/ μL). The erythrocyte sedimentation rate was 35 mm/h. Serology for hepatitis, HIV, fasciolasis, toxocariasis, syphilis and echinococcosis were negative. Skin prick test were negative. Bone marrow aspiration aspiration revealed a hypercellular bone marrow with the percentage of eosinophils to be 55% among other cells seen. Cytogenetic examination of marrow was normal.We do not detected FIP1L1-PDGFRα fusion gene in our patient. Because of the patient's long lasting peripheral, the multiple-organ involvement and the exclusion of other causes of eosinophilia, a diagnosis of idopathic hypereosinophilic syndrome (IHES) was made. He was treated again successfully with prednisolone.

Summary / Conclusion: Pulmonary involvement can be seen in 40% of cases. The most common respiratory symptom is chronic, persistent nocturnal cough. In our case, the patient had cough and pruritic lesions lasted for more than 18 months. But we could not find any infiltration in chest radiography and thorax tomography. First line therapy for IHES are generally steroids. In our case, we used prednisolone treatments in each admission with clinical and laboratory improvement. In conclusion, our case highlights the importance of IHES, that can be complicated with vital organ involvements and malignities. The disesase is seen rarely but can be admitted to hospital with frequent relapses.

Platelets and thrombocytopenia

B1910

TYPE I GAUCHER´S DISEASE: CLINICAL, EVOLUTIVE AND THERAPEUTIC FEATURES

M Alpoim[1*], A Fernandes[2], P Chaves[3], T Cardoso[3], F Ferreira[1], J Guimarães[1]
[1]Serviço de Hematologia Clinica, [2]Centro Hospitalar de São João, Porto, Portugal, [3]Unidade de Doenças Metabólicas, Centro Hospitalar de São João, Porto, Portugal

Background: Gaucher disease (GD), the most common lysosomal storage disorder is a heterogeneous multisystem condition. Patients with non-neuronopathic (type 1) GD may suffer from hepatomegaly, splenomegaly, thrombocytopenia, bleeding tendency, anaemia, skeletal pathology, growth delay and decreased quality of life (QoL). GD is one of the few inherited metabolic disorders that can be treated by enzyme replacement therapy (ERT). In a majority of series there is a delay of 4 to 10 years between beginning of symptoms and diagnosis.
Aims: To analyze the clinical features, course and treatment response of a group of patients with type I GD.
Methods: Retrospective analysis of nine patients with diagnosis of GD between 1986 and 2012 in a Central Hospital in the North of Portugal. QoL was assessed by SF-36 modified inquiry.
Results: Nine patients with GD were identified (five female and four male) with a median follow-up time of 17 years (range: 5-36 years). The median age of diagnosis was 45 years and the first symptoms appeared around 38 years old. Seven were diagnosed in adulthood and two in childhood. Prior to diagnosis, the main symptoms were anorexia (78%), fatigue (67%), bone pain (44%), abdominal distension (22%), bleeding tendency (22%), and growth delay (22%). Diagnosis was confirmed by low leucocyte acid beta-glucocerebrosidase activity. Morphologic documentation of GD disease in bone marrow aspirate and biopsy was obtained in 44% of the patients. The most frequent genotype was N370S/L444P (56%). At diagnosis, 44% patients were anemic, 66% had moderate to severe thrombocytopenia, 66% moderate to severe splenomegaly and 78% moderate to severe hepatomegaly. Abnormal liver function tests were found in 11% of patients. Bone abnormalities were present in 78%, which included bone marrow infarction (56%), Erlenmeyer flask deformities (44%), osteoporosis (44%), bone pain (44%) and pathologic fractures (22%). ERT with Imiglucerase was performed in eight cases. The median time of Imiglucerase treatment was 10 years. The median time to achieve hematological and visceral therapeutic goals was 24 months. There was an improvement in median hemoglobin concentration from 12g/dL (range: 8.8-14.4 g/dL) to 14.6 g/dL (range: 9.8-16.1 g/dL). Platelet count improved from a median $73X10^9$/L (range: $33X10^9$/L-$236X10^9$/L) at diagnosis to a median $140X10^9$/L (range: $76X10^9$/L-$247X10^9$/L). At the end of follow-up, only 1 (12.5%) patient had moderate thrombocytopenia and 88% anemic patients at diagnosis had normal hemoglobin levels. Only 1 (12.5%) patient had hepatomegaly and 2 (25%) patients had splenomegaly. The majority of patients (87.5%) had stable or poor skeletal response. Women had the worst skeletal response. Self-evaluation of health showed large improvements, 87.5% of patients referred subjective improvement. None of the patients had good QoL prior to treatment, but at the end of follow-up, 4 (50%) patients had good QoL and 3 satisfactory QoL (37.5%). Psychological disturbances were present in 37.5% of patients. Median SSI (Severity Score Index) before and after treatment was 9 (range: 1-14) and 3 (range: 2-9), respectively.
Summary / Conclusion: The hematologic and visceral disorders were the most serious and prevalent manifestations at diagnosis, but also the most changeable with treatment. Despite the poor bone response, patients had clear improvement in QoL and a better SSI score with ERT. Because early treatment can prevent development of irreversible complications, early diagnosis is crucial to improving ultimate outcome. Delay diagnosis was seven years.

B1911

THE CLINICAL SIGNIFICANCE OF PLATELET INDICES IN PATIENTS WITH SEPSIS

R Feng[1*], YLin[2], X Wei[1]
[1]Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Critical Care Medicine, Taiping People's Hospital , Dongguan, China

Background: Platelet activation has both beneficial and potentially harmful effects. Platelet aggregation at sites of inflammation may be responsible for impairing microcirculatory flow in patients with sepsis.
Aims: To investigate the clinical significance of the platelet indices-platelet count (shorted for PC),mean platelet volume (shorted for MPV), platelet distribution width(shorted for PDW), and platelet large cell ratio (shorted for P-LCR) in patients with sepsis.
Methods: Ninety four patients with sepsis were recruited in this retrospective study. All patients were divided into Survivors(n = 71) and non-survivors (n = 23) according to the prognosis□the platelet count was detected andAcute Physiology And Chronic Health Evaluation II(shorted forAPACHE□)score was calculated the day on admission to ICU. All patients were divided into Group A (APACHE □ score <10 points, n = 12), Group B (APACHE□ score 1 to 19 points, n = 39) and Group C (APACHE □ score ≥ 20 points, n = 43) according to the APACHE□ score, the platelet count and mortality were analyzed among the three groups. In addition, all patients were divided into thrombocytopenia group (PC < 100 x 109 / L, n = 39) and non-thrombocytopenia group (PC≥100 x 109 / L, n = 55) according to the platelet count , the incidence of septic shock, APACHE□ score, mortality, days in ICU, MPV, PDW and P - LCR were analyzed between these two groups. All the results were statistically analyzed.
Results: 1)The platelet count was higher in survivors than that in non-survivors□P<0.01□,the APACHE□ score was lower in survivors than that in non-survivors(P<0.01).2) The higher the APACHE □ score was, the lower the platelet count was□and the higher the mortality was□(P<0.01).3) The incidence of septic shock, APACHE □ score, days in ICU, MPV, PDW and P-LCR were higher in thrombocytopenia group than those in non-thrombocytopenia group□P<0.01□. 4) Platelet count and its indices: MPV , PDW and P - LCR were detected dynamicly, the relationship between MPV, PDW, P-LCR and platelet count was negatively correlated.
Summary / Conclusion: Thrombocytopenia could be used as an early warning indicator of severity and prognosis in sepsis. The change of MPV , PDW and P – LCRcould be an indirect sign of bone marrow compensatory hyperplasia ,disturbance in platelet production and activity ,and the prognosis in patients with sepsis, be indicative of the reovery of the platelet count in sepsis with thrombocytopenia.

B1912

RITUXIMAB THERAPY IN REFRACTORY AND RELAPSED THROMBOTIC THROMBOCYTOPENIC PURPURA; A RETROSPECTIVE ANALYSIS OF A SINGLE CENTRE IN QATAR

R Taha[1*], H Omri[1], F Ibrahim[2], I Hijji[1], H Sabbah[1], H Ayoubi[1]
[1]Medical Oncology Department, National Centre for Cancer Care and Research/ HMC, [2]Lab medicine and pathology, Hamad Medical Corporation, Doha, Qatar

Background: Thrombotic thrombocytopenic purpura (TTP) is a life threatening disease that occurs mainly in young adults. Acquired cases are usually a result of antibodies directed against ADAMTS 13, a protease that cleaves the Von Willibrand factor multimers .Plasma exchange is the standard treatment, however some acute severe forms are refractory to plasma exchange and the incidence of relapse is high up to 35% .The mortality remains at 12-20%. The treatment options for refractory and relapsing cases are limited and often unsuccessful. Rituximab , a chimeric monoclonal antibody against CD20 has been recognized as a useful therapy for antibody mediated autoimmune diseases.
Aims: We studied the clinical response to rituximab in 8 cases with refractory or relapsed TTP treated in our center.
Methods: Retrospective analysis of 8 patients diagnosed as refractory or relapsed TTP between 2008 and 2012 and recieved rituximab as a second line therapy. 6 patients were females and 2 were males.7 patients were refractory and 1 patient was a relapse case. The median age of patients was 36 years (17-48).TTP was idiopathic in 5 cases, secondary to pregnancy in 2 cases, and associated with CML in one case. All patients were initially treated with plasma exchange and steroids. Refractory cases were considered after failing a median of 12 sessions of plasma exchange (5-23), the relapsed cases presented after 21 months of complete response. All patients received rituximab 375mg/m2 weekly (4-6 cycles) in combination with the initial therapy
Results: All patients achieved complete response(CR), 2 cases relapsed after 12 and 28 months respectively and responded well to subsequent rituximab therapy, the other 6 are still in CR with a median follow-up of 29 months.
Summary / Conclusion: Rituximab represents an effective second line treatment option for refractory and relapsing TTP, all patients need to be closely monitored for relapse with extended follow up plans.

B1913

A STUDY OF 100 EGYPTIAN CHILDREN WITH INHERITED PLATELET DISORDERS:AN UNDERESTIMATED AND UNDERDIAGNOSED PROBLEM

M Abdelwahab[1*], D khairy[2], A Abdeldayam[3]
[1]PEDIATRIC HEMATOLOGY, [2]Pediatrics, CAIRO UNIVERSITY PEDIATRIC HOSPITAL, Cairo, [3]Pediatrics, El Fayoum University, El Fayoum, Egypt

Background: The true incidence of inherited platelet disorders is not known. Though Glanzmann(GZ) thrombasthenia and Bernard Soulier (BS) syndrome, the commonest platelet function disorders are reported to represent 12% of rare coagulation disorders yet represent 7% in the Egyptian National Registry with 20 cases with GZ. Also, platelet function testing is limited to specialized centers so diagnosis is missed in some children.
Aims: to determine prevalence and baseline epidemiological data of inherited thromasthenias in the biggest tertiary pediatric hospital in Egypt for better understanding of the problem.
Methods: A retrospective study conducted in Hematology outpatient clinic, Cairo University Pediatric Hospita.Records were reviewed and data document-

ed of all children aged 1 to 18 years with diagnosed platelet function disorders over the past ten years.This included age, sex,family history, bleeding spectrum, hospital admissions, treatment recieved and specific diagnosis if known
Results: Inherited thrombasthenias represented 17% of rare bleeding disorders.Patients' mean age was 9.8 years, 60% males and 56% were of consanguineous marriage.Subcutaneous bleeding was initial bleeding symptom in 24%, mucous membrane bleeding in 52% and combined bleeding in 24%. Five patients recieved platelet transfusion, 20 blood transfusion and 5 required hospitalization. Specific diagnosis was reached in 52 children, 39 GZ and 13 BS whilst not reached in remaining 48 children.
Summary / Conclusion: Prevalence of Inherited thrombasthenias is relatively common in Egyptian children though underestimated at the National level so more awareness is needed and better facilities and interantional collaborations to reach specific diagnosis.

B1914
SINGLE CENTRE EXPERIENCE OF THROMBOTIC EVENTS IN PATIENTS TREATED WITH ROMIPLOSTIM
A Chiodini[1*], M Blanco[1], M Expósito[2], M Granell[1], J Arranz[2], J Andres[2], J Gil[1]
[1]Hematology, [2]Hemostasia, Hospital Sant Pau, Barcelona, Spain

Background: Romiplostim is a thrombopoietin analog approved for increasing platelet count in selected patients with chronic immune thrombocitopenia (ITP)
Aims: To assess thrombotic occurrence in patients under romiplostin long term treatment for ITP and myelodisplastic syndromes (MDS)
Methods: Twenty-four patients consecutively treated with romiplostim in our unit between July 2009 and January 2013 were retrospectively reviewed.
Results: The mean age was 65 years (range: 28-87). The indications for treatment were: 17 with ITP, 6 patients with MDS and 1 with bone marrow aplasia. Seven thromboembolic events in 4 patients were identified (16%). The patients were treated with romiplostim during a mean time of 530 days (range: 31-1187) The total follow up was 34.6 patients-year. The incidence of thromboembolic complications was 20% patients-year. Six out of 7 events (86%) were arterial thrombosis (5 strokes and 1 coronary artery occlusion). Only one venous event, a pulmonary embolism in a patient with a previous history of deep vein thrombosis, was observed. All patients with a thrombotic event had ITP. The median platelet count at the moment when the event occurred was 419x109 (99-1453). The mean time since the beginning of treatment with romiplostim until the thrombotic event occurred was 491 days (30-750). Of all patients, 58% had cardiovascular risk factors. All patients that developed thrombosis had at least one cardiovascular risk factor
Summary / Conclusion: In our revision we had a superior incidence of events compared to a phase 3 extent randomized study (Gernsheimer et al. reports an incidence of 2% patients-year). In our series, no patients with MDS developed thrombosis. Our study limitations are: the low number of patients, the follow up time and being a retrospective analysis. Despite the recommended standard control during the treatment, some of the patients that developed a thromboembolic complication had a platelet count higher than >400x x109 at the time of the event. Therefore we think it would be useful to perform a more frequent platelet count control, especially in patients with cardiovascular risk factors. Further studies are needed to establish if romiplostim may increase the incidence of thromboembolic events.

B1915
RETROSPECTIVE EVALUATION OF CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA PATIENTS
D Ozatli[1*], S Aksakal[2], M Atay[1], P Buyukkaya[1], E Kelkitli[1], N Guler[1], M Turgut[1]
[1]Hematology, Ondokuz Mayis University, Medical Faculty, SAMSUN, [2]Immunology, Karadeniz Teknik University, Medicine Faculty, Trabzon, Turkey

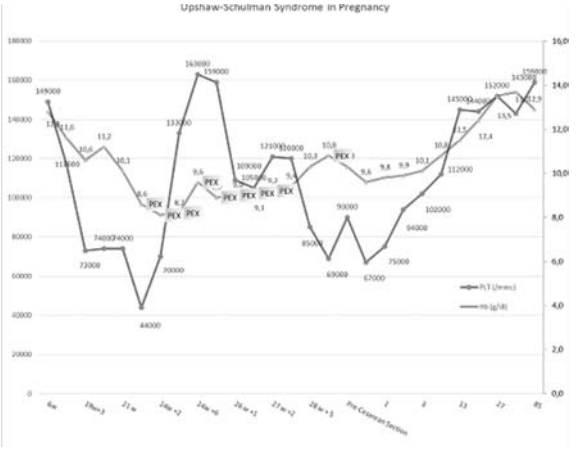
Background: Immune thrombocytopenic purpura (ITP) is an acquired and autoimmune disease characterized by low platelet count and generally mucocutaneous bleedings. In adult, chronic form is usually seen, which spontaneous remission is rare and most often need treatment. Corticosteroids, intravenous immunoglobulin (IVIg) and anti-D therapies are generally considered as first-line therapy in patients with ITP. The patients who fail to respond to those therapies undergo splenectomy. For the patients who don't respond or are not eligible for splenectomy, although rituximab and thrombopoietin receptor agonists (TPO-RAs) have been usually preferred nowadays, immunosuppressive therapy and/or danazole stillare the other treatment alternatives.
Aims: In this study we evaluated the responses to the treatments in the patients diagnosed and/or followed as ITP in our center between 2003-2010 years. In those years, TPO-RAs was not available in our country and rituximab was on used for the treatment of 2 patients in last 2 years of the study.
Methods: In this retrospective study the file of 150 patients diagnosed and/or followed as ITP in our center between 2003-2010 years were reviewed. All patients had chronic ITP, which was defined as a platelet count <150,000/mm3 that had been present for at least 3 months with no clinical or laboratory findings that could account for it. The patients with a platelet count below 30,000/mm^3 and/or bleeding were given therapy. Post-treatment response was considered as complete response (CR) with a platelet count ≥150,000/mm^3 lasting ≥ 4 weeks, as partial response (PR) with a platelet count of 50,000 – 150,000/mm^{3}lasting ≥ 4 weeks and no response (NR) with a platelet count of ≤50,000/mm^3.As first-line treatments, steroids based treatment including standard dose steroids (1 mg/kg/day) and high-dose steroids (30 mg/kg/day steroids for 3 days or 40 mg dexametazon for 4 days) and IVIg were used as medical therapy. For the patients refractory to first-line treatment and the relapsed patients who had NR to a second course steroids treatment splenectomy was done. Immunosuppressive therapy (azathioprine, cyclosporine and rituximab)and/or danazole were given to the patients refractory to splenectomy and steroids treatments
Results: In our study, the mean age of the patients was 44 years (range: 18-91). Female-male ratio was2,57. The median follow-up of 150 patients was 15 months (range 2-83 months). Thrombocytopenia was incidentally detected in 51 (34%) of the cases. During the study period, 21 (14%) the patients were followed up without treatment. As a first line treatment, medical therapy were given to 129 patients. CR were seen in 93 (72%) patients, PR in 14 (11%) patients and NR 22 (17%) patients. High dose steroids therapy had no significant benefit over the standard dose therapy (P=0,59). Of the 107 patients who had response to the treatment, relapse were observed in 48 (45%) of the patients in2,5 years. Fifty-six % of the patients had relapse in one year. Eight patients had platelet counts >30,000/mm^3 and no bleeding, and was followed up without treatment. A second course of steroids based medical treatments were given to 40 relapsed patients. Of 40 patients, there were CR in 15 (38%) patients, PR in 9 (22%) patients and NR in 16 (40%) patients. Splenectomy was performed in 38 patients. Of 38 patients, 22 patients were refractory to the first-line treatment, and 16 patients who had relapsed and had NR to second course medical therapy. CR was achieved in 32 (84%) patients, PR in 2 (%5) patients and NR in 4 (%16) patients. Relapse was observed in 12 (35%) patients of 34 patients responding to splenectomy. Of 12 patients, 2 patients had achieved CR after steroids treatment and 1 patient had platelet count >30,000/mm^3 and no bleeding, and was followed up without treatment.
Severe thrombocytopenia persisted despite steroids therapy and splenectomy in 13 patients. Eleven of 13 patients received azathioprine and 2 patients cyclosporine. Response to azathioprine was seen in 6 patients. Three of 6 patients had platelet count >100,000/mm^3, 1 patient platelet count >50,000/mm^3 and 2 patients platelet counts >30,000/mm^3. Two of 5 patients who had no response to azathioprine achieved PR after cyclosporine plus danazole treatment. One of 5 patients had platelet count >30,000/mm^3 after rituximab. The other 2 patients died from intracranial bleeding.
One of 2 patients given cyclosporine had response (platelet count >30,000/mm^3), and the other had no response, but, had PR after rituximab.
Summary / Conclusion: This study showed that steroids based treatment and splenectomy are very effective treatment in ITP patients. Only 13 (%8.6) patients in our study needed further treatment.

B1916
ATYPICAL PRESENTATION OF UPSHAW-SCHULMAN SYNDROME IN A PREGNANT PATIENT WITH OMOZYGOUS FOR V LEIDEN MUTATION
V Coccini[1*], M Carpenedo[1], E Pogliani[1], S Ornaghi[2], P Vergani[2], C Cecchetti[1]
[1]Hematology, [2]Obstetrics, San Gerardo Hospital of Monza (MI), Monza, Italy

Background: Upshaw-Schulman Syndrome (USS) is a rarely congenital form of thrombotic thrombocytopenic purpura (TTP) that results from mutations in ADAMTS13 gene. Pregnancy can be the trigger event for approximately 5-25% TTP cases (late-onset USS forms or acute acquired TTP).
Aims: During pregnancy TTP may be particularly challenging because of difficult differential diagnosis with other thrombotic microangiopathies (TMAs), such as preeclampsia and HELPP syndrome, and its dramatic consequence on the fetus and its specific therapeutic management.
Methods: ADAMTS13 activity was measured using the residual collagen binding assay (CBA). The detection limit of the assay is 6%. The inhibitor titer (BU/ml) was measured using a procedure based on the Bethesda method (values >1 BU/ml were considered high titer).
Results: We report a case of a 28-year old white pregnant woman, gravida 2 para 0 at 20 weeks of gestation, who presented at our Department for worsening fatigue in the last week. Two years before she underwent an urgent cesarean section at 29 weeks of gestation for an atypical form of HELLP syndrome with perinatal death of a growth restricted fetus. Thrombophilia evaluation revealed omozygous for V Leiden mutation. In the actual pregnancy thromboprophylaxis with LMWH was adopted from the late first trimester. At hospital admission at 20 weeks laboratory data were: Hb 10.7 g/dl, platelets 73 x 10^9/l, schystocyte 12/1000 and LDH 265 U/L. Serum haptoglobin levels, DAT, coagulation test, transaminase, creatinine and blood pressure were normal. The patient was found to have an ADAMTS13 activity of < 6% with the presence of a weakly positivity for antibodies anti-ADAMTS13, confirmed in two following samples. She started oral prednisolone. No clinical sign of TTP or fetal compromise were noted, whereas platelets slowly decreased. Plasma ex-change (PEX) was initiated at 24 weeks' gestation for progressive worsening of laboratory data (Hb 9.5 g/dl, platelets 37 x 10^9/l, schystocyte 65/1000), obtaining a prompt increased of platelet count. A cesarean section was performed without complications at 30 weeks' gestation, after nine PEXs (Hb 9.3 g/dl, platelets 90 x 10^9/l) for progressive onset of allergic reactions to the procedures. A female

neonate of 1440 grams (Apgar score 5) was born in good health condition. After the delivery, a spontaneous progressive normalization of the blood count of the patient was observed. LMWH administering was continued for six weeks postpartum. Nowadays she is in good health condition with a normal blood count. Repeated analysis of ADAMTS13 confirmed a level < 6% with no antibodies. We performed mutational analysis of the ADAMTS13 gene and Upshaw-Schulman syndrome was diagnosed.

Summary / Conclusion: Diagnosis of TTP can be difficult during pregnancy for the potential overlap with other TMAs. The clinical manifestation of Upshaw-Schulman syndrome reported appeared unusual for the weakly positivity of ADAMTS13 antibodies, probably due to pregnancy-related alteration of the immunity system. Furthermore, we supposed that the atypical form of HELLP syndrome reported in her first pregnancy could be a manifestation of the Upshaw-Schulman Syndrome and its prompt recognition and treatment could have been able to avoid the perinatal death that had occurred. It is therefore critical to create a multidisciplinary team involving haematologists, obstetricians, apheresis and genetic counselling physicians to follow patients with thrombotic microangiopathies (TMAs) and to prevent unnecessary mortality both of the mother and the baby.



B1917

AN INVESTIGATION OF PLATELET DISORDERS IN PATIENTS WITH SUBCLINICAL HYPOTHYROIDISM

S Patiakas[1,2*], U Tsiatsiou[3], A Kalikali[2], C Kanonidou[2], K Basilakos[3,4], A Nikolaidou[5]

[1]Blood Donation Department of General Hospital of Kastoria, Kastoria, [2]Hematological Diagnostic center of Thessaloniki "Hemotest", Thessaloniki, [3]General Hospital of katerini, Katerini, [4]General Hospital of Thessaloniki "Theageneion", [5]Hematological Laboratory of University Gneral Hospital of Thessaloniki "ACHEPA", Thessaloniki, Greece

Background: To examine the potential platelet disorders in patients with subclinical hypothyroidism (patients with mild rise of thyrotropin-TSH levels and normal values of FT3 and FT4 hormones), as an effect of the abovementioned abnormality on the coagulation system and possibly on platelet activity has been referred, resulting in an elevation of the risk of thromboembolic-cardiovascular disease.

Aims: A total of 82 participants were enrolled to our study; of those 37 were diagnosed with subclinical thypothyroidism (female/male: 24/13, mean age: 45.8) (Group A) and 45 were healthy subjects (female/male: 28/17, age-matched) (Group B) who consisted the control group.

Methods: In all the participants, the levels of TSH, FT3 and FT4 hormones were measured with chemiluminescent immunoassay. Whole blood parameters such as platelet count (PLT), mean platelet volume (MPV) and platelet distribution width (PDW) were determined with the use of *automated haematology analyser*. The statistical analysis of the results (t-test) was performed with the use of SPSS software.

Results: The results of the performed tests are presented at the table below:
Table: Average (mean±SD) values of PLT, MPV and PDW parameters in patients with subclinical hypothyroidism (Group A) and healthy controls (Group B).

	P	LT (K/μL)	MPV (fL)
PDW (%)			
Group A	262±111	10.84±0.82	12.94±1.68
Group B	271±65	10.23±0.41	11.34±2.48

Summary / Conclusion: The results suggest that in patients with subclinical hypothyroidism, changes in platelet indices confirming the theory of their activation are observed, as both MPV and PDW values were significantly higher when compared to the control group (P=0.05). Platelet parameters were not found to be correlated with thyroid autoantibodies (anti-TPO and anti-TG) in cases to which the relevant data were available.

B1918

EVALUATION OF AFFECTING FACTORS FOR PLATELET FUNCTION SCREENING TEST

Y Park[1*], H Lim[1]

[1]Laboratory medicine, Kwandong University College of Medicine, Goyang, Korea, Republic Of

Background: Platelet function screening studies using commercial analyzer are useful and make objective interpretation for the result. With in-vitro measures, principle of the instrument is that anticoagulated whole blood is flowed under high shear force through a narrow hole punched out of a membrane coated with collagen and epinephrine (EPI) or ADP. The combination of biophysical shear and chemical stimulation initially promotes platelet adhesion to the outer edges of the cut membrane, subsequently, platelet-platelet aggregation leads to full occlusion of the channel, which is recorded as closure time. However, platelet function screening test using this commercial analyzer can be affected by hemoglobin level, platelet counts, blood type, venipuncture time, and so on. Several specimen's or patient's factors without these known factors can also affect.

Aims: We investigated the influences of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and mean platelet volume (MPV) about EPI result of platelet function screening test using commercial analyzer.

Methods: Two-hundred seventy-four results among total 874 specimens requested for platelet function screening test during 1 year were selected for this evaluation. Patients' specimens with prolonged prothrombin time or activated partial thromboplastin time, platelet inhibitor treatment, low hematocrit (<30%), low platelet count (<70x10^9/L), and results over maximum closure time were rejected.

Results: Means and standard deviations of each variable were 140.79 and 45.49 for EPI, 22.83 and 21.10 for ESR, 2.58 and 4.86 for CRP, and 7.46 and 0.82 for MPV. Significance values of Pearson correlations were 0.254 for EPI and ESR, 0.001 for EPI and CRP, and 0.33 for EPI and MPV.

Summary / Conclusion: EPI closure time was affected by MPV and ESR values. ESR would affect to EPI results more than MPV, because width of MPV results was lesser than ESR. ESR was considered one of important affecting factor for EPI closure time with hemoglobin level, platelet counts, blood type, venipuncture time, platelet inhibitor drugs, and so on. Therefore, whether increased ESR results should be considered when platelet function screening test do interpret.

B1919

TREATMENT OF REFRACTORY KASABACH-MERRITT PHENOMENON WITH SIROLIMUS

C Mcconville[1*], c cairns[2], k armstrong[3], c macartney[2]

[1]Haematology, Belfast City Hospital, Belfast Trust, [2]Haematology, [3]Dermatology, Royal Belfast Hospital for Sick Children, Belfast Trust, Belfast, United Kingdom

Background: Kasabach-Merritt phenomenon (KMP) is a rare disease, usually in infants, which is characterised by profound thrombocytopenia, haemolytic microangiopathy, a consumptive coagulopathy and an enlarging vascular lesion (either a kaposiform haemangioendothelioma (KHE), or a tufted angioma, or a mixture of both).

Aims: We report a case of sirolimus successfully treating refractory Kasabach-Merritt phenomenon. A male infant of a secundigravida was born at term, and noted to have a large neck mass. Platelet count at birth was 76 x10^9/L, but fell to 27 in 72 hours. Coagulation screen was initially normal. MRI and biopsy of the lesion confirmed the diagnosis of mixed KHE and tufted angioma.

Methods: Treatment, under the supervision of haematology and dermatology, initially with prednisolone was unsuccessful. During the initial phase of treatment, support with platelets and cryoprecipitate was required, but need lessened with the addition of weekly vincristine. Intervention with selective embolisation was required on two occasions within the first year of life. Blood product support was only required for procedural intervention after six months of life. Vincristine frequency varied over a three year period as per clinical need (platelet count, coagulopathy, myofascial pain and tumour size).

Results: Decision was made to commence sirolimus as the thrombocytopenia became more refractory to vincristine. Dose was titrated slowly. The refractory thrombocytopenia responded excellently and has normalised since initiation of therapy.

Summary / Conclusion: There are only a few reported cases of KHE/tufted angioma with refractory KMP responsive to sirolimus therapy worldwide. mTOR inhibitors may prove to be a very important and potent treatment modality in selected cases of refractory Kasabach-Merritt phenomenon.

B1920

VENOUS THROMBOEMBOLIC EVENTS IN PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS AFTER SPLENECTOMY OR DURING THROMBOPOIETIN RECEPTOR AGONISTS (TPORA) THERAPY

I Nichele[1*], M Ruggeri[1], F Rodeghiero[1]
[1]S. Bortolo Hospital, Vicenza, Italy, Vicenza, Italy

Background: Recent epidemiological evidences suggest that chronic ITP patients could have an higher risk of venous thromboembolism (VTE) in comparison to general population.
Between second-line approaches to manage adults with chronic ITP, splenectomy and TPOra, are regarded as the most suitable treatment choices.
Although laparoscopic approach have reduced short- and long- term complications of splenectomy, VTE may occur. Equally, occurrence of VTE was demonstrated in registrative and extend trials with TPOra, raising the question on the potential thrombophilic risk of these new agents. No direct comparisons between splenectomy and TPOra are available in clinical trials.
Aims: A retrospective, monocentric study was carried out to evaluate the rate of VTE in ITP patients after splenectomy and during treatment with TPOra.

Methods: We retrospectively evaluated 37 ITP patients who underwent splenectomy (20 patients) or TPOra (17 patients) between 2008 and 2012 at our Institution.
Among splenectomized patients, 8 (40%) were male and 12 (60%) female, with a median age at diagnosis of 40 years (11-68) and a median age at splenctomy of 45 years (16-78). At splenectomy,14 (70%) patients had a chronic ITP, 5 (25%) a persistent ITP and 1 (5%) patient a newly diagnosed ITP. Median time from diagnosis to splenectomy was 19 months (1-250). Laparoscopy approach was used in all patients.
Among TPOra-treated patients, 6 (35%) were male and 11 female (65%), with a median age at diagnosis of 58 years (11-86) and a median age at the start of TPOra treatment of 64 years (28-89). 5 patients received TPOra because of refractory, splenectomized ITP, while 12 patients were in chronic or persistent phase and not suitable for splenectomy. Median time from diagnosisto TPOra therapy was 84 months (5-246).
The median observation time was 15 months in both groups (range 1-59 and 3-45 respectively).
Results: Two thromboembolic events were recorded in the splenectomized group (cumulative incidence 10%). A splanchnic vein thrombosis (SPT), occurred in a 38-years old male with persistent ITP, while a VTE (pulmonary embolism and deep vein thrombosis at leg) occurred in a 70-years-old female with chronic ITP. Both events occurred after few days from splenectomy, despite peri-surgery thromboprophylaxis with low molecular weight heparin (LMWH). Both patients were treated with full dose of LMWH (for one month then with warfarin for 12 months because of complete remission of ITP in the first case; for 4 months. with suspensions due to relapse of ITP in the second case).
Among TPOra-treated patients, two SPT was recorded (cumulative incidence 11.7%). The events occurred in a 55-years-old female with refractory ITP and in 62-years-old female with chronic ITP, after one month and two years from the beginning of TPOra, respectively. TPOra was interrupted and LMWH started in both cases. In the first case LMWH was temporary interrupted for relapse of ITP, treated with immunoglobulins; in the second patient LMWH was definitively stopped 4-months-later for relapse of thrombocytopenia, refractory to specific therapies; a diagnosis of criptogenetic cirrhosis was made.
Summary / Conclusion: In this small, retrospective study, a similar cumulative incidence of VTE, in a same follow-up period, was observed in two group of chronic ITP patients after splenectomy and during TPOra treatment; 3/4 VTE were SVT, an event quite rare in ITP. In a patient a known risk factor for SVT (hepatic cirrhosis) was diagnosed. However, in absence of a well-designed randomized clinical is not possible to evaluate any difference in thrombogenic risk of splenectomy and TPOra therapy.

B1921

PERSISTENT REMISSION OF CHRONIC IMMUNE THROMBOCYTOPENIA AFTER ROMIPLOSTIM DISCONTINUATION

C Biagiotti[1*], V Carrai[1], R Alterini[1], L Rigacci[1], A Bosi[1]
[1]Hematology, Careggi Hospital, Florence, Italy

Background: Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet count of < 100x 10^9/L in the absence of an identifiable underlying cause of thrombocytopenia. Increased platelet destruction by antiplateled autoantibodies plays a key role in the pathogenesis and may also impair megakaryocyte platelet production; thrombopoietin levels are normal or only slightly elevated in patients with ITP, suggesting that the lack of compensatory stimulation of megakaryocytes may contribute to impaired platelet production. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction. Romiplostim is a Fc-peptide fusion protein (peptibody) that has been shown to produce a dose-dependent increase in platelet counts in individuals and improve platelet counts during both short- and long-term use in patients with chronic ITP. TPO-receptor agonists are currently used for patients at risk of bleeding, who relapse after splenectomy or who have a contraindication to splenectomy and who have already failed at least one other therapy. As far as we know an interruption of treatment with TPO mimetics' is not feasible. In our study we evaluated the feasibility of stopping treatment with Romiplostim.
Aims: In our study we evaluated the feasibility of stopping treatment with Romiplostim.
Methods: We evaluated treatment course with Romiplostim in 27 patients with chronic ITP referred to our institution between 2008 and 2013. Diagnosis of ITP was made according to established guidelines. Median age was 72 years (range 52-93 years), 13 were male and 14 female. Prior starting treatment with TPO mimetic, all patients demonstrated severe ITP and platelet counts were below 20 × 10^9/µl. Romiplostim was started at 1 µg/kg per week and the dose was adjusted to a maximum of 10 µg/kg per week to reach a target platelet-count range of 50-250 × 10^9/L.
Results: At the last follow-up, 22 patients (81%) showed a clinical benefit consisting in achieving a platelet count ≥ 50 × 10^9/L. 4 of 27 (15%) patients were able to maintain a stable platelet response when Romiplostim was stopped. Two patients with a stable platelet count > 250 x 10^9/L discontinued Romiplostim without no dose reduction. At time of interruption one patient was currently treated with 1 µg/kg and the other one with 3 µg/kg per week. With a follow up of 17 and 3 months respectively, they are still off-treatment. 2 patients discontinued treatment after a progressive dose reduction and they showed a stable platelet count > 100 x 10^9/L at 22 and 8 months of follow-up respectively.
Summary / Conclusion: In our limited experience we were able to discontinue Romiplostim in selected patients observing stable platelet counts > 100 × 10^9/µl during the period of observation. Romiplostim seems a very promising therapy for the treatment of refractory forms of ITP; further investigations and specific clinical trials are warranted to explore the feasibility of stopping treatment .

B1922

A CASE OF MYH9 DISORDER WITH KIDNEY DYSFUNCTION SUCCESSFULLY TREATED BY ELTROMBOPAG FOR THE INHERITED THROMBOCYTOPENIA

E Tanaka[1*], N Kinugawa[1], S Kunishima[2]
[1]Hematology, Shonann Kamakura General Hospital, Kamakura, [2]Advanced Dignosis,, Clinical Research center, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: MYH9 disorder is one of the most frequent inherited forms of thrombocytopenia. It is transmitted in an autosomal dominant fashion and derives from mutation of MYH9, the gene for the heavy chain of non-muscle myosin IIA (NMMHC-IIA). Patients present with congenital macrothrombocytopenia with mild bleeding tendency and may develop kidney dysfunction, deafness and cataracts in later life. Here we present a male patient diagnosed as MYH9 disorder with the manifestation of kidney dysfunction nine years after the recognition of macrothrombocytes in the peripheral blood smear. His platelet count normalized with Eltrombopag therapy. We confirmed his MYH9 disorder by using immunofluorescence staining with anti-NMMHC-IIA localization and genetic analysis *MYH9* using PCR and direct DNA sequencing.
Aims: A 58 year-old male patient was transferred because of progressive worsening of kidney function and hypertension (HT). At the initial visit to our hospital, urinalysis showed protein 3+, and hematiuria.2+. Serum creatinine and BUN were elevated 1.91mg/dl and 22.5 mg/dl, respectively. He had a history of diabetes mellitus (DM) and HT for 10 years and had been well controlled. From 7 months before presentation, his blood pressure became uncontrolled with an associate increasing level of serum creatinine. Renal biopsy had been planned, but it was postponed by his low platelet count as 22,000/µl. Past medical history revealed that he had large platelets in the peripheral blood smear 9 years previously. Bone marrow aspirate revealed normocellular marrow, and megakaryocytic hyperplasia, which is compatible with the diagnosis of idiopathic thrombocytopenia (ITP).
Methods: The patient was treated by prednisolone for ITP but his glycaemia control worsened. Reduced dose of prednisolone with Eletrombopag restarted and the platelet count increased to 138,000 /µl which was sufficient for performing a renal biopsy. This was performed 8 months after his initial visit, when the serum creatinine level was 2.7mg/dl. At that time his daughter was referred to the hematology department because of asymptomatic thrombocytopenia during surveillance check-up for her pregnancy. Her peripheral blood smear stained with May-Giemsa, which confirmed the presence of large platelets and granulocyte inclusion bodies that resemble DÖhle-like bodies which suggested the diagnosis of May-Hegglin anomaly. Additional medical history from his sister was revealed the diagnosis of May-Hegglin anomaly (data are not available). To further characterize this, we analyzed his blood sample with immunofluorescence staining against anti-NMMHC-IIA localization in granulocytes and direct DNA sequencing of *MYH9*, after informed consent for genetic analysis was obtained from the patient.
Results: The findings of light microscopy revealed destruction of one third of the kidney gromeruli and the mesangial cell proliferation. His kidney function deteriorated progressively and at the age of 59 years he was diagnosed as chronic kidney disease stage 4 in association to sensorineural hearing loss. Immunofluorescence analysis showed abnormal NMMHC-IIA accumulation.

Direct sequencing analysis of the MYH9 gene revealed a heterozygous E 1841 mutation.
Summary / Conclusion: The term May-Hegglin Anomaly, encompasses four autosomal-dominant thrombocytopenias that were previously described as distinct disorders into four categories, namely the May-Hegglin Anomaly, Sebastian, Fechtner and Epstein syndromes. However, they are not distinct entities, but represent a variable expression of a single illness. Although the variable expressions of the immunofluorescence test for NMMHC-IIA distribution within the granulocyte are detected, these four categories are all derived from mutations of the *MYH9* gene. Regarding the genotype-phenotype correlation, the MYH9 disorder with E 1841K amino acid mutation generally shows a mild to intermediate risk of developing renal impairment. In our case, the onset of renal impairment was relatively late, in his sixth decades, but the progression of dysfunction was very rapid.
It is necessary to maintain high surveillance in order to recognize cases to therefore investigate the genotype-phenotype correlation in the MYH9 disorder.

B1923
THE EFFECTIVNES AND SAFETY OF THE THROMOPOETIN(TPO) RESEPTOR AGONISTS IN THE TREATMENT OF ADULTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA(ITP) REFRACTORY TO OTHER TREATMENTS
K Abdulkadyrov[1*], I Zotova[1]
[1]Clinical department of hematology, Russian Research Institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: ITP is an acquired autoimmune disorder characterized by low platelet counts (increased platelet destruction and suboptimal platelet production) and an increased risk of bleeding. The goal of treatment is to eliminate symptoms of bleeding, and to maintain a platelet count ≥50 x 10^9/L. Initial therapy consists of corticosteroids or intravenous immunoglobulin (IVIg). For most children, ITP is a self-limiting disease; however, for some children and most adults, thrombocytopenia can become chronic. Patients with chronic refractory ITP (CRITP) might undergo splenectomy. Adults with ITP fail to respond to conventional therapies in almost 30% of cases, developing CRITP. Newer therapies for ITP include rituximab and TPO receptor agonists. Rituximab is a useful second-line therapy and may be splenectomy-sparing. TPO agonists have demonstrated large treatment effects in many randomized studies with respect to increasing platelet levels. In 2008, the FDA approved the use of two new TPO mimetic agents, romiplostim and eltrombopag. Both medications are registered in Russian Federation.
Aims: To evaluate the efficacy and safety of romiplostim in adult CRITP patients from a single institution.
Methods: Adult patients (n=27) were prospectively treated with romiplostim. 25/27 (93%) patients were women and had a mean age of 53 years (range, 30 – 71), with a median time from their initial diagnosis being 13 years (range, 1.5 – 47). All the patients entered into the study had insufficient response to previous therapies. The most common first-line treatments were corticosteroids and IVIg (17 patients, 63%), 10 patients (37%) were treated with second-line therapies including splenectomy (4 patients). Six patients (22%) were receiving concurrent corticosteroid therapy (prednisolone with daily dose ranged from 5 to 30 mg) at the start of romiplostim. Baseline platelet count was 18x10^9/L (range, 1–47x10^9/L). Romiplostim was administered as a subcutaneous injection weekly. The initial dose was 1 mcg/kg/wk, with adjustments up to 10 mcg/kg/wk to maintain platelet counts ≥50x10^9/L. The primary end point was a durable platelet response (≥50x10^9/L). Response was classified as sustained (SR) when it was stable for a minimum of 6 months. No other immunosuppressive drugs were used.
Results: The median duration of romiplostim therapy was 25 weeks (range, 4 to 118). The median dose of romiplostim used during SR was 3.9 microg/kg/wk. A durable and sustained platelet response (≥50x10^9/L) wasachieved in 24/27 patients (89%) after four weeks of treatment. The platelet response is seen to be between 50 and 470x10^9/L. Symptoms of bleeding were eliminated in all the patients (in whom a SR and even less than SR was achieved). Prednisolone was successfully tampered in 4/6 patients in 4 – 17 weeks from initiation of romiplostim. The most common adverse events were not severe: ecchymosis at the injection sites (30%), headache (20%), arthralgia (10%), and skin rash (5%). Serious adverse events were not registered.
Summary / Conclusion: Romiplostim administration has been associated with a durable platelet response in patients with CRITP. Romiplostim has been found to be well tolerated. Overall SR achieved was high, long term, and with no risk of severe adverse events. In conclusion, romiplostim therapy is effective and safe in adult patients with CRITP. No other illnesses have been recorded in this group of patients during the ongoing follow-up period.

B1924
REFRACTORY CYCLIC THROMBOCYTOPENIA
S Ahmed[1*], J Quinn[1], P Murphy[1], P Thornton[1]
[1]Haematology, Beaumont Hospital, Dublin, Ireland

Background: Cyclic thrombocytopenia (CTP) is a rare disorder of regularly oscillating platelet count and variable bleeding tendencies. Possible aetiologies include immune platelet destruction, insufficient platelet production, hormonal disturbance and T cell clonal disease.
Aims: We report a case of CTP refractory to multiple modalities of treatment that include corticosteroids, rituximab, Intravenous immunoglobulins (IVIG), anti D, cyclophosphamide, cyclosporine, azathioprine and romiplostim. We reviewed 53 cases of CTP reported in the literature to highlight the characteristics of this under reported disease.
Methods: The patient was 21 -year- old Caucasian lady, presented with excessive bruising, heavy menstrual periods and isolated low platelet count. She was diagnosed with Idiopathic thrombocytopenic purpura (ITP). Over the following three years she failed multiple modalities of ITP treatments including corticosteroids, rituximab, Intravenous immunoglobulins (IVIG), anti D, cyclophosphamide, cyclosporine and azathioprine. Consequently she had a bone marrow aspiration and trephine biopsy that showed absence of megakaryocytes. It was noticed that the patient has marked oscillation of platelet count between 1700 x 10^9/L and 0 in 5 week's cycles. When the platelet count fall the patient develops severe bleeding that requires treatment with platelet transfusion and pulses of recombinant factor VIIa (NovoSeven). The diagnosis of CTP was made and the patient received treatment with danazol, eltrombopag and then romiplostim without response.
Results: Patients with CTP present with symptomatic thrombocytopenia and frequently misdiagnosed as ITP. Platelet count fluctuates in cycles ranged between 1 week and 10 weeks and the average cycle is 4 weeks. Platelets fluctuate between a nadir that can reach zero and a peak that can exceed the normal limit of platelet count and the maximum reported platelet count was 2300 X10^9/l. CTP is more common in females with a female: male ratio of 3:1 and more common in Japanese. The age at diagnosis varies from infants to patients at their 80s. The mean age at diagnosis is 40 years. Not like ITP, the bone marrow in CTP shows absent or low megakaryocytes during the nadir phase of the cycle and normal or increased megakaryocytes during the thrombocytosis phase. There were several reports of isolated associations including Sjögren syndrome, LGL Leukaemia, H.Pylori, polycythemia vera and Clonal T cell. Conclusion: Most patients with CTP including our case fail to respond to conventional ITP treatments; nevertheless few reported cases responded to cyclosporine, corticosteroids, IVIG, azathioprine, low dose hormonal contraception and romiplostim. There is a reported case of CTP improved after H.Pylori eradication and there are also reports of spontaneous recovery.
Summary / Conclusion: Cyclic thrombocytopenia is an underreported cause for thrombocytopenia and need to be considered in the differential diagnosis of ITP. We report a case of CTP refractory to multiple modalities of treatment which highlights the need for better understanding of the disease and more effective treatments.

B1926
THROMBOCYTOPENIA DURING LONG-TERM LOW-MOLECULAR-WEIGHT HEPARINS (LMWH) FOR CANCER-ASSOCIATED VENOUS THROMBOEMBOLISM (VTE): TROPIQUE, A PROSPECTIVE, MULTICENTER, OBSERVATIONAL STUDY
F Cajfinger[1*], D Bancel[2]
[1]Hospital de la Salpetriere, 75013 Paris, [2]Saint Louis Hospital, 75010 Paris, France

Background: Long-term treatment with LMWH is the recommended standard for treatment of venous thromboembolism (VTE) in cancer patients [1]. LMWH are known to be associated with the occurrence of thrombocytopenia. However, malignancy by itself, chemotherapy and radiotherapy increase the risk of thrombocytopenia in patients with cancer. Few prospective data are available on thrombocytopenia during long-term prescription of curative doses of LMWH in patients with cancer in real clinical practice
Aims: The study aims at documenting the prescription and use of curative doses of LMWH in patients with cancer in routine clinical practice. Clinical outcomes such as VTE recurrence, bleeding and thrombocytopenia will be recorded. Also, the study will assess whether the occurrence of thrombocytopenia may result in treatment discontinuation.
Methods: This is an ongoing prospective, observational, multicenter study in cancer patients with symptomatic VTE and an indication for treatment with LMWH for at least 6 months. Adult patients, aged 18 years or more, willing to participate, with diagnosed malignancy and recent symptomatic VTE in whom a treatment with LMWH has been initiated within less than 7 days, are consecutively included in the study. Patients already treated with LMWH for more than 7 days or with a contra-indication to LMWH are not eligible to participate. Main study outcome measures include VTE recurrence, bleeding, thrombocytopenia and adherence to recommended standards [1]. Assuming a normal patient distribution and the unfavorable hypothesis that only 50% of patients are treated according to the national recommendations, 384 patients are needed to

obtain conclusive results with a precision of 5% and a risk error of 5%. Incidences of 7% of VTE recurrence and 6% of major bleeding are expected. A total of 400 patients are therefore planned to be included in the study.
As of end of February 2013, 70 sites were activated and 136 patients were enrolled. Completion of enrollment is expected by June 2013.
Results: The results obtained from this study will add significantly to the knowledge regarding the long-term treatment safety of LMWH to prevent recurrent cancer-associated VTE in real clinical practice and will document whether thrombocytopenia influences treatment management.
Summary / Conclusion: Important prospective safety data on the long-term management of cancer patients with symptomatic VTE will be generated, and analyses of clinical parameters will add important information that may help to further tailor therapy and improve compliance with established recommendations.

B1927

SLOW "DELAYING AND TAPERING" ROMIPLOSTIM ADMINISTRATION COULD ALLOW ITS DEFINITIVE SUSPENSION AND STABLE COMPLETE REMISSION IN PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS

M Carpenedo[1*], V Coccini[1], M Fedele[1], E Pogliani[1]
[1]Hematology and Transplantation Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Italy, Monza, Italy

Background: Various lines of evidence indicate that Primary Immune Thrombocytopenia (ITP) is due to impaired thrombopoiesis in addition to the traditionally recognized autoantibody-mediated mechanism of platelet destruction. Thrombopoietin-receptor (TPO-r) agonist have demonstrated to be effective in ITP patients, given the high rate of sustained response while on long-term treatment.
Aims: We report 8 cases of patients treated with the TPO-r agonist romiplostim (R) for ITP unresponsive to different lines of therapy, that achieved a complete response while on-treatment, that have subsequently undergone a "delaying & tapering" (D&T) phase of R administration to ascertain if definitive suspension of the drug could be possible without relapse.
Methods: A retrospective observation of a single institution case series of ITP patients treated with R between Jan 2010 and Jan 2013 was performed.

Romiplostim remission induction in eight patients: main characteristics

Patien data, plt baseline	ITP duration before R	Prior treatment	R duration/ n tot doses admin	Current Plt count	R Off therapy (weeks)
M, 20y, 1x10^9/L	2 months	S, IVIG	15 wks/12	227x10^9/L	116
M, 67y, 1x10^9/L	2 months	S, IVIG	21 wks/17	194x10^9/L	84
M, 66y, 12 x10^9/L	2 years	S, IVIG, CSA, spl	22wks/13	235x10^9/L	74
F, 69y, 3x10^9/L	3 months	S, IVIG, rtx	37wks/32	132x10^9/L	12
F, 51y, 2x10^9/L	2 months	S, IVIG	64wks/60	156x10^9/L	23
F, 55y, 11x10^9/L	4 months	S, IVIG, azathiop	122wks/ 92	267x10^9/L	4
F, 41y, 5x10^9/L	2 months	S, IVIG	58 wks/55	202x10^9/L	4
M, 42y, 1x10^9/L	2 months	S, IVIG	14 wks/11	257x10^9/L	5

R: Romiplostim, S: steroid, IVIG: intravenous immunoglobulin, CSA: Cyclosporin, Azathiop: azathioprine, spl: splenectomy; wks: weeks

Results: Ten women and six men have been treated with first line steroid and IVIG and second or third line treatment (4 with azathioprine, 4 cyclosporin, 4 splenectomy, 2 rituximab) and considered non responders, so they started R administration. Eight patients (4 women and 4 men) received R for a mean of 42,6 weeks (11 to 101) and they all experienced a complete response (plt >100 x 10^9/L). Instead of continuing the scheduled weekly administration as indicated by the manufacturer, under strict weekly lab check, we started to delay of 7 days the expected dose. Additional weeks of delay were given if the platelet count remained > 50 x 10^9/l. In four out of eight patients we observed a drop of the platelet count under 50 x 10^9/lt without any bleeding and we resumed R treatment once at the same last given dose, then we tapered the dose of 1 mcg/kg the week after and so on until we stopped the treatment, and we observed a spontaneous rising of the platelet count to a normal value in all four patients. The other 4 patients showed a good stability during the "delaying period" of R treatment, and they did not need to resume the drug administration because their platelet remained normal. Eight patients were not considered for D&T procedure because of the following reasons: One woman was treated with R until platelet count rose and than splenectomy was performed with complete response achieved. One patient developed antibody against R: she lost the response after 48 weeks of ongoing treatment with sudden platelet drop and she was treated with rituximab that allowed a new complete response until now. One patient while on R treatment (14 months) experienced an acute myocardial infarction when platelet count was 89 x 10^9/L. A percutaneous transluminal coronary angioplasty was performed, and a bare metal stent was placed. R was suspended and we started rituximab when platelet count dropped, until we reached a safe platelet count for aspirin treatment. One patient is on chronic TPO-r ongoing treatment and her platelet count shows a complete dependence to R. One patient refused to continue R as chronic therapy because of a fluctuating response. Three other patients are currently under weekly R administration since few weeks now, with unstable response.
Summary / Conclusion: TPO-R Romiplostim is a handy treatment for ITP patients in different phases of the disease. A cautious attemp of "delay and tapering" of R administration in well stabilized responders could help to recognize patients potentially cured by the drug, that can be safely weaned from it and left without any therapy and a normal platelet count. Nonetheless attention has to be paid for possible adverse events.

B1928

SUCCESSFUL TREATMENT WITH THE TPO AGONIST ROMIPLOSTIM OF A YOUNG PATIENT WITH MYH9 RELATED THROMBOCYTOPENIA

L Simeone[1*], F Chiurazzi[1], V Russo[1], C Candido[1], F Pane[1]
[1]Hematology, University "Federico II" Naples, Italy, Naples, Italy

Background: MYH9 related platelet disorders are rare autosomal dominant syndromes characterized by macrothrombocytopenia with leukocyte inclusion bodies associated with mutations in MYH9, the gene for the nonmuscle myosin heavy chain IIA. Platelet transfusion is currently the primary medical treatment to improve hemostasis in symptomatic patients.
Aims: To evaluate the increase of platelet count in a patient with a severe thrombocytopenia associated with *MYH9* mutations (*MYH9*-related disease) treated with Romiplostim, a parenteral thrombopoietin mimetics.
Methods: a 39 years old female with symptomatic MYH9 related thrombocytopenia diagnosed at the age of 37 with indirect immunofluorescence and then molecular analysis of MYH9 gene. Platelet count before starting was 11x10^9/L (range 7- 23) with WHO grading of bleeding severity 2. She was treated with romiplostim once weekly by subcutaneous injection.
Results: romiplostim treatment was commenced at a starting dose of 1 mcg/kg, as recommended, by weekly subcutaneous injection performed in our outpatient department. The weekly dose was stepwise increased by 1 mcg/kg during the second and third week to improve platelets. At the beginning of the fourth week platelet count exceeded 50x10^9/L and Romiplostim treatment were continued at the dose of 3 µg/kg. Persistent platelet increase during the following weeks with disappearance of the bleeding manifestations allowed the progressive reduction of steroids. Romiplostim was well tolerated. The patient started home self injection during the fourth week. On sixty week the platelet count was 96x10^9/L, WHO grading of bleeding severity was 0.fl. Balduini et al. (Blood 2010) reported their experience on oral thrombopoietin mimetics of twelve adult patients with MYH9-RD with significative response on most, but not all patients (major responses were obtained in 8 patients, minor responses in 3. One patient did not respond).
Summary / Conclusion: At our knowledge, this could be the first case of MYH9 related platelet disorders treated with parenteral thrombopoietin mimetics (Romiplostim). Although performed on a single case, our experience suggest potential efficacy of such a treatment in this rare patients, thus offering new openings in the treatment of inherited thrombocytopenias both in chronic treatment and as preparation to surgical operations.

B1929

A COMPARATIVE STUDY OF NEW PLATELET INDICES IN PATIENTS WITH IRON DEFICIENCY AND HOMOZYGOUS OR HETEROZYGOUS SICKLE CELL DISEASE

A Nikolaidou[1*], S Patiakas[2,3], U Tsiatsiou[4], C Kanonidou[2], K Megalou[5]
[1]Hematological Laboratory of University Gneral Hospital of Thessaloniki "ACHEPA", [2]Hematological Diagnostic center of Thessaloniki "Hemotest", Thessaloniki, [3]Blood Donation Department of General Hospital of Kastoria, Kastoria, [4]General Hospital of katerini, Katerini, [5]General Hospital of Serres, Serres, Greece

Background: The determination of platelet parameters, such as mean platelet volume (MPV), platelet distribution width (PDW), plateletcrit (PCT) and immature platelet fraction (IMF), is provided easily by modern automated hematologic analyzers as a component of complete blood count, facilitating their further evaluation in patients with hematopoietic disorders.
Aims: The aim of the study to examine these platelet indices in patients with sickle cell disease and in those with iron deficiency anemia.
Methods: A retrospective study of 15 heterozygous (8 females, 7 males), 88 homozygous (52 females, 36 males) for sickle cell disease subjects and 47 iron deficient patients (29 females, 18 males) was conducted. Data were recorded and analyzed using Student's t test and Pearson's correlation test. P values <0.05 were considered as statistically significant.
Results: The participants were matched for age and gender. The mean PCT

value was 0,2611±0,121% in heterozygous, 0,4153±0,1198% in homozygous individuals and 0,2950±0,12203% in iron-deficient ones. PCT value was found to be significantly higher in homozygous patients when compared to the heterozygous (P<0,001) and sideropenic participants (P<0,001). IPF values were positively correlated with MPV (r=0,682, P<0,001) and PDW (r=0,759, P<0,001) in homozygous patients. A similar correlation was observed in subjects with iron deficiency [(r=0,694, P<0,001) and (r=0,739, P<0,001) respectively].
Summary / Conclusion: The study indicates that PCT levels were significantly higher in patients homozygous for sickle cell anemia than in heterozygous and iron-deficient ones. Regarding the relationships between the various platelet parameters, IPF was found to be positively correlated with MPV and PDV indices not only in homozygous sickle cell disease but in iron deficiency anemia as well.

B1930
COMPARISON OF MANUAL AND AUTOMATED PLATELET COUNTS IN THROMBOCYTOPENIA
D Gunawardena[1*], D Gunaratne[2], G Vidyaratne[2]
[1]Heamatology, [2]Allied Health Sciences, University of Sri Jayawardenapura, Colombo, Sri Lanka

Background: Reliable platelet count is of prime importance in clinical management of thrombocytopenia where platelet transfusion, splenectomy, therapeutic or any appropriate intervention is concerned. Still most of the methods which accurately estimate the number of platelets remain at research or highly specialized laboratory set up. Automated analyzer count is based on impedance and optical technology whereas the manual chamber count method is based on phase contrast and naked eye observation. Results of the automated counts especially in severe thrombocytopenia seem to be uncertain and less reliable.
Aims: Determine how reliable the platelet count is in automated analyzer reports in thrombocytopenia, and how it compares with manual assessment of the platelet count.
Methods: In this research, a descriptive cross sectional study was carried out at the study setting of haematology clinic at Colombo South Teaching Hospital on 83 samples from patients with thrombocytopenia to determine the differences between the automated analyzer method and manual chamber count method especially in severe thrombocytopenia. Data record sheets were analyzed and stratified into two strata as moderate thrombocytopenia (<=150,000–50,000/mm^3) and severe thrombocytopenia (<=50,000/mm^3). Pearson Correlation and Levels of Agreement were carried out at each stratum according to the Bland and Altman comparison method.
Results: Pearson Correlations(R) was 0.897 as a whole and 0.78 at moderate thrombocytopenia where as it was low as 0.60 at severe thrombocytopenia. There was a tendency of around 20,000/mm^3 deviation of automated counts from the true count at moderate thrombocytopenia and that was 13,000/mm^3 at severe thrombocytopenia.
Summary / Conclusion: Pearson correlation was satisfactory and the levels of agreement were clinically acceptable at moderate thrombocytopenia. Both correlation and levels of agreement at severe thrombocytopenia were significantly beyond the clinically acceptable levels.

B1931
SAME DIAGNOSIS, DIFFERENT PROBLEMS, VARIABLE CLINICAL PROGRESS: IMPRESSIONS RELATING TO ELTROMBOPAG TREATMENT WITH 4 CASES
F Sahin[1*], M Comert[1], G Saydam[1]
[1]Haematology, Ege University, School of Medicine, Izmir, Turkey

Background: Eltrombopag treatment is indicated in chronic immune trombocytopenia (ITP) which is resistance or unresponsible to steroids or immunosuppressive treatments. In spite of the illness and the drug name is same, clinical progress and response to treatment is variable in every patient. In this abstract we present 4 chronic ITP cases who were unresponsible to steroid and immunosuppressive treatments and also each of these cases has different clinical progress and also have different kinds of problems .
Aims: To introduce the variable clinical progress and different problems of eltrombopag treatment
Methods: Case 1: Fifty-six year-old female was diagnosed as ITP at 2006. She was unresponsible to steroid, immunosupressive and azathiopurine treatments. Splenectomy was not performed because of reluctancy of patient and conflict of surgeon due to 300-1000 µL thrombocyte levels. The patients thrombocyte level was under 1000/µL when her nose bleeding was started. After these bleedings 50 mg/day eltrombopag treatment was started at September 2011. After two weeks of follow up process, patients thrombocyte levels was still low (1000-2000/ µL) and we increased the eltrombopag dose to 75 mg/day. Patients bleedings was stopped when her thrombocyte level increased to 10-15.000/ µL. The patients is still being followed with the same thrombocyte levels and 75 mg/day eltrombopag treatment without bleedings. Case 2: Thirty-three year-old female patient was diagnosed as ITP at 1987. Splenectomy was performed after five months from the diagnosis because of unresponsibility to steroid treatment. Accesory splenectomy was also performed 7 months later. Steroid, cyclophosphamide and azothiopurine treatment was given to the patient who was also unresponsible to splenectomy. Immunosupressive treatments was stopped at 2010 because of low thrombocyte levels (10.000/ µL). Rituximab treatment was started with the approval of the ministry of health. A partial response was achieved and the patient was followed without treatment. 50 mg/day eltrombopag treatment was started when the patient's thrombocyte level was 12.000/ µL at August 2012. Thrombocyte level was increased to 360.000/ µL in first week. The patient is still being followed in our clinic with the same treatment. Case:3 Forty-nine year-old female patient was diagnose as ITP at 2006. Splenectomy was performed at 2007 because of unresponsibility to steroid treatment. Azothiopurine treatment was given to the patient who was also unresponsible to splenectomy. Accesory spleen was detected at 2011 but the patient did not accept the surgery. 50 mg/day eltrombopag treatment was started at January 2012 when the thrombocyte level was 15.200/ µL. One month later thrombocyte level was 117.000/ µL but it was reduced to 15.000/µL in the second month. Because of that patient's diet and additional drug treatments was questioned. It was noticed that the patient was using oral calcium because of osteopenia. Her diet was changed and eltrombopag treatment was continued. Thrombocyte level was increased to 120.000/µL. The patient is still being followed in our clinic with the same treatment. Case 4: Forty-four years old male patient was diagnosed as ITP at 2011. Splenectomy was performed because of fail of response to steroid treatment. IVIG and vincristine treatments was given but thrombocyte levels was still low. 50 mg/day eltrombopag was started when the thrombocyte was 14.500/µL. Thrombocytes was still low and the dose of eltrombopag was increased to 75 mg/day. Follow of process cervical lymphadenopathy was detected and excisional biopsy was performed. Diffuse large B cell lymphoma was reported. Eltrombopag treatment was stopped and R-CHOP treatment was given. Thrombocyte level was > 100.000 /µL in the tenth day of the R-CHOP treatment.
Results: We presented 4 cases with different clinical progress and different problems.
Summary / Conclusion: In international guidelines, the response criteria for cronic ITP treatment of thrombocyte level criteria is defined under 5000/µL. But the resistant cases like our firs case, occurance of bleeding is more important than the guideline numbers. furthermore, 2500% at thrombocyte level was still under 5000/µL, should poiint that patient is unresponsible to eltrombopag treatment according to guidelines. But the ending of the bleedings directly means that the patient is well responded to the treatment. So when we are looking for references from guidelines, we should remember the word 'there is no illness, there is patient' and the response criteria to the treatment should be individualized. If response fails to the eltrombopag treatment occurs, diet and additional drug usage of the patient should be questioned. As in our third case, calcium usage and excessive calcium diet seems to cause response fail to eltrombopag. Unexpected decreases of thrombocyte levels from formely well responded patients, should be questioned about diet and additional drug usage again. Although not initially identified in chronic ITP,it should be noted that malignant disease may occur in the follow-up process like our fourth case.
The impression which we get from our four cases is that different problems and different clinical progress can be seen with the same diagnoses and same medicine usage.

B1932
PSEUDOTHROMBOCYTOPENIA ASSOCIATED WITH GRAVES' DISEASE
E Beyan[1], D Ertugrul[1], M Dagdeviren[1], C Beyan[2*]
[1]Department of Internal Medicine, Kecioren Training and Research Hospital, [2]Department of Hematology, Gulhane Military Medical Academy, Ankara, Turkey

Background: The association between hyperthyroidism and thrombocytopenia was described firstly in 1931. The shortened platelet life span, increased reticuloendothelial phagocytic activity, immune thrombocytopenia related to thyroid autoantibodies, genetic predisposition to the concurrence of immune thrombocytopenia and hyperthyroidism are most commonly reported mechanisms. Pseudothrombocytopenia (PTP) is a condition caused by anti-platelet antibodies in which agglutination of platelets in the complete blood count tube leads to incorrectly low platelet counts. It should be considered first in patients with low platelet counts without a bleeding diathesis. This phenomenon could be observed in healthy subjects, but it could also accompany certain diseases. The incidence is 0.09–0.21%. Misdiagnosis of PTP as true thrombocytopenia leads to unnecessary laboratory tests and unwarranted exposure to transfusion and related complications. Graves' disease, an autoimmune disease characterized by antibodies against the thyroid stimulating hormone (TSH) receptor, is the most common cause of hyperthyroidism. Graves' disease may be associated with autoimmune hematological disorders such as immune thrombocytopenic purpura. Association of PTP with Graves' disease was reported in only one case and the course of PTP was not defined in this paper.
Aims: A case with PTP associated with Graves' disease was presented in this report. After clinical healing and normalization of thyroid stimulating immunoglobulin, PTP was resolved completely.
Methods: A 27 year old woman admitted with palpitation, sweating and weight loss complaints. These complaints have started since six months. She had weight loss of 3 kg in spite of good appetite in this period. She had no fever or

diarrhea. Body temperature was 37.2 °C, arterial blood pressure was 120/60 mmHg and pulse was 104/min and rhythmic. The skin was moist. She had the nervous appearance. The thyroid gland was diffusely enlarged and painless. White blood cell count was 6.8 x10^9/L, red blood cell count 4.55 x10^{12}/L, hemoglobin 11.9 g/dL, hematocrit 35.2%, mean corpuscular volume 77.4 fL, mean corpuscular hemoglobin 26.3 pg and platelet count 33 x10^9/L in complete blood count with ethylenediaminetetraacetic acid (EDTA). Biochemical analysis, erythrocyte sedimentation rate and urine analyses were normal. Tests for thyroid disease were free T_3 16.63 pg/mL (2.2-4.2), free T_4 5.23 ng/dL (0.65-1.7), TSH 0.004 μIU/mL (0.4-4.2), and thyroid stimulating immunoglobulin (TSI) 69.42 U/L (0-14), anti-thyroglobulin antibody (anti-Tg ab) 5 IU/mL (5-100) and anti-thyroid peroxidase antibody (anti-TPO ab) 1.49 IU/mL (1-16). Thyroid ultrasonography revealed diffuse enlargement in the thyroid gland. Anti-nuclear antibody and anti-double strand DNA antibody were negative. Platelet clumps were seen sufficiently in peripheral smear examination. Platelets were counted mean 16.2 numbers in microscopic evaluation with x1000 augmentation. Complete blood count was repeated with heparin and platelet count was found to be 180 x10^9/L. PTP associated with Graves' disease was diagnosed and propylthiouracil 600 mg/day and propranolol 40 mg/day were started.

Results: Drugs' doses were adjusted with regular controls. White blood cell count was 5.8 x10^9/L, red blood cell count 4.61 x10^{12}/L, hemoglobin 11.5 g/dL, hematocrit 35.8%, mean corpuscular volume 77.6 fL, mean corpuscular hemoglobin 25.0 pg and platelet count 167 x10^9/L in complete blood count with EDTA after three months from diagnosis. Platelet count was found as 168 x10^9/L with heparin. Free T_3 3.21 pg/mL (2.2-4.2), free T_4 0.825 ng/dL (0.65-1.7), TSH 1.37 μIU/mL (0.4-4.2), TSI 15.37 U/L (0-14), anti-Tg ab 5 IU/mL (5-100) and anti-TPO ab 3.98 IU/mL (1-16) were found. Platelet clumps were observed in peripheral smear.

	Platelet count (with EDTA)	Platelet count (with heparin)	Free T_3 (2.2-4.2)	Free T_4 (0.65-1.7)	TSH (0.4-4.2)	TSI (0-14)	Anti-Tg ab (5-100)	Anti-TPO ab (1-16)
At diagnosis	33 x10^9/L	180 x10^9/L	16.63 pg/mL	5.23 ng/dL	0.004 μIU/mL	69.42 U/L	5 IU/mL	1.49 IU/mL
After three months	167 x10^9/L	168 x10^9/L	3.21 pg/mL	0.825 ng/dL	1.37 μIU/mL	15.37 U/L	5 IU/mL	3.98 IU/mL

Summary / Conclusion: PTP is frequently misdiagnosed which lead to inappropriate treatments. Therefore, this situation should be kept in mind primarily in the evaluation of thrombocytopenic patients.

B1933

CORRELATION BETWEEN PLATELET ACTIVATION INDICES AND METABOLIC PARAMETERS.

S Patiakas[1,2,3], B Kelesiadou[2], A Nikolaidou[4*], B Stavrou[5], A Kalikali[6], C Charalampous [7]

[1]Blood Donation Department , General Hospital of Kastoria, [2]Blood Donation Department of General Hospital of Kastoria, Kastoria, Greece, [3]Blood Donation Department of General Hospital of Kastoria, Blood Donation Department of General Hospital of Kastoria, Kastoria, [4]Hematological Laboratory of University general Hospital of Thessaloniki "ACHEPA", Hematological Laboratory of University general Hospital of Thessaloniki "ACHEPA", [5]Hematological and Biochemical Laboratory, General Hospital of Thessaloniki "Theageneion", [6]Hematological Diagnostic Center of Thessaloniki "Hemotest", [7]Outpatient Obesity, Hypertension and Dyslipidemia Clinic of the Department of Internal Medicine of the Psychiatric Hospital of Thessaloniki , Thessaloniki, Greece

Background: As we know diabetes mellitus and hyperlipidemia often present thromboembolic events. The calculation of the platelet activation indices, such as mean platelet volume (MPV) and platelet distribution width (PDW), is very easy with nowadays hematologic analyzers.

Aims: The aim of this study is to determine the possible correlation between platelet activation indices, such as mean platelet volume (MPV) and platelet distribution width (PDW), with different metabolic parameters,such as glycosylated hemoglobin level (HbA1c) and total cholesterol (CHOL).

Methods: In all, the results of the complete blood count (MPV and PDW) in 92 patients' cases were examined. These patients presented with diagnosed Metabolic Syndrome (MS) and were treated at the Outpatient Obesity, Hypertension and Dyslipidemia Clinic of the Department of Internal Medicine of the Psychiatric Hospital of Thessaloniki (group I). At the same time 95 random samples of the general population (group II) coming from various areas were examined. In all the samples the levels of glycosylated hemoglobin and total cholesterol were determined, while the results' statistical analysiswas performed with the use of the SPSS.

Results: In group II ofthe general population mean values and standard deviations of the examined parameters were: MPV: 9,51±1,18 fl, PDW: 16,22±2,17, HbA1c:6,49±1,88% and CHOL: 214±86 mgr/dl. Respectively, in group I the following values arose: MPV: 9,74±1,182 fl, PDW: 17,09±2,82, HbA1c:8,18±2,93 % and CHOL: 239±115 mgr/dl. Further statistical analysis revealed that for group I the correlation coefficient among HbA1c and MPV and PDW values was 0,33 and 0,39 respectively, while for group II the equivalent values of the correlation coefficient were 0,25 and 0,29.

Summary / Conclusion: It takes its toll that even though MPV and PDW measurements are useful, its sole determination is not enough for the estimation of the thromboembolic risk in relation to the HbA1c and CHOL values, since in no case (not even in group I of the patient suffering of MS), a statistically significant correlation between HbA1c and CHOL and the MPV and PDW valueswas observed. It is proved that thromboembolic incidents are multifactorialprocessesin which apart from platelets and other factors are involved, such as the endothelium and the coagulation factors and consequently there is no direct correlation between the platelet indices and biochemical findings, such as glycosylated hemoglobin and total cholesterol.

B1934

EFFICACY AND SAFETY OF TPO-R AGONIST IN NEUROSURGICAL SETTING: SUCCESSFULLY PERIOPERATIVE ROMIPLOSTIM TREATMENT OF A THROMBOCYTOPENIC PATIENT UNRESPONSIVE TO FIRST LINE THERAPY

M Carpenedo[1*], V Coccini[2], E Pogliani[2]

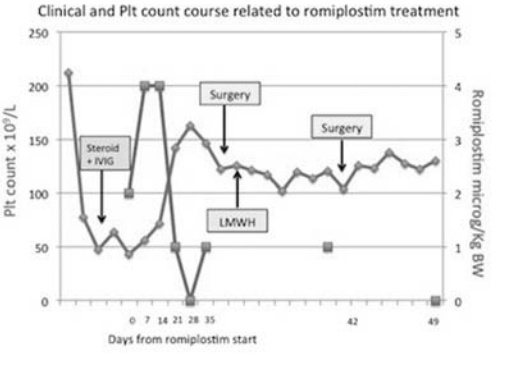
[1]Hematology and Transplantation Unit, [2]A.O San Gerardo di Monza and University of Milan Bicocca, Italy, Monza, Italy

Background: Neurosurgery interventions should be performed with a normal or near normal platelet count to avoid serious bleeding complications, also in the postoperative period. Therefore thrombocytopenic patients requiring neurosurgery for expansive lesions are a difficult challenge because the need of a safe intervention is not always well balanced by the response to available therapies. Thrombopoietin-receptor (TPO-R) agonists have been used in different surgical/invasive procedure settings, mostly in patient with Primary Immune Thrombocytopenia (ITP) before splenectomy or in liver disease-related thrombocytopenia

Aims: We describe the case of a man with multiple brain lesions requiring surgical removal that developed a thrombocytopenia unresponsive to steroid and intravenous immunoglobulin (IVIG), safely and successfully treated with romiplostim in order to achieve and maintain a safe platelet count before, during and after the neurosurgical intervention

Methods: Clinical description of a neurosurgical thrombocytopenic patient treated with romiplostim in the perioperative period.

Results: A 63 years old man was admitted to our Neurosurgical Dept. with three newly diagnosed brain lesions. A total body CT scan excluded a solid metastatic cancer as explanation of the cerebral lesions and their surgical removal was scheduled, but patient started to develop a mild thrombocytopenia (54 x 10^9/L). We performed a bone marrow aspiration and biopsy to exclude myelophthisis. Megacaryocites are well represented and no pathological features were described in the bone marrow specimens. We excluded other common causes of thrombocytopenia (virus-related, autoimmune diseases-related) so we could conclude for an Immune Thrombocytopenia likely tumor-related. We started high dose dexamethasone (40 mg/day for 4 days, than 8 mg t.a.d) and IVIG in order to reach the required surgical platelet count (at least 100 x 10^9/L) without platelet transfusion. We didn't observe any response, and platelet count dropped to 43 x 10^9/L, so we decided to start romiplostim administration (2 microgr/kg as first dose), in order to avoid any immunosuppressant therapy. After 4 weeks of treatment the surgical removal of two lesions was performed when platelet count was 143 x 10^9/L, without complications. Low molecular weight heparin (4000 IU enoxaparin) was introduced as thromboprophylaxis and platelet count remained normal. A new surgical session, for the last brain lesion, was scheduled after 7 days, so romiplostim was administered once again the day before the procedure. Histological examination confirmed that a glioma was the reason of the expansive lesions, so chemotherapy was scheduled. Platelet count has remained normal after the last romiplostim dose so far, thus confirming the possible relationship between the cancer lesions and the thrombocytopenia.



Summary / Conclusion: Selected thrombocytopenic patient in surgical setting could be successfully treated with romiplostim, if first line therapy shows no effect, avoiding platelet transfusion thus allowing even neurosurgery to be performed without bleeding complications. Wide clinical studies are needed to provide more information about safety and efficacy of TPO_R agonist in this field.

B1935

RETROSPECTIVE ANALYSIS OF THERAPEUTICAL RESULTS IN IMMUNE THROMBOCYTOPENIC PURPURA

I CLAUDIU[1*], I IOANA[1], C LIVIU[1], O DACIAN[1], C MARIA[1], I MIHAI[1], C DESPINA[1], P OVIDIU[1], I HORTENSIA[1]
[1]Hematology, UNIVERSITY OF MEDICINE AND PHARMACY „VICTOR BABEŞ", TIMIŞOARA, Timisoara, Romania

Background: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely.
Aims: To evaluate the treatment of ITP patients in Departament of Hematology, County Hospital, Timişoara.
Methods: A retrospective study for 380 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient's medical charts for the 12 months prior to their most recent visit.
Results: The mean age was 47,1 years with 59% women and 41% men. Median time from the diagnosis of ITP to the start of the observational period was 25 months. Prior to the observational period, 39% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (60%), followed by bleeding symptoms (49%). Corticosteroids represented 61% of treatments, followed by IVIg (17%), azathioprine (12%) and rituximab. Splenectomies (7% of patients) and platelet transfusions (25% of patients) were performed during the observational period. For monitoring the platelet levels, 76% of patients visited their hematologist 1 to 8 times during the observation. Main reasons for a visit were a low platelet count (40% of visits) and bleeding (31% of visits). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13,5 days.
Summary / Conclusion: The retrospective study of 380 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

B1936

THE EFFICACY OF REVOLADE(ELTROMBOPAG) IN IDIOPATHIC AUTOIMMUNE THROMBOCYTOPENIC PURPURA(ITP)-SINGLE CENTER EXPERIENCE:

R Mihaescu[1*], G Borzak[2], A Stoian[2], R Buzas[1]
[1]Medical Semiology, University of Medicine and Pharmacology"V.Babes", [2]Haematology, Oncomed, Timisoara, Romania

Background: ITP occurs when platelets undergo premature distruction as a result of autoantibodies or immune complex deposition on their membranes and there are no known etiologic factors. It is a diagnosis of exclusion and it is characterized by peripheral thrombocytopenia,normal or increased number of megakaryocytes in the bone marrow and absence of splenomegaly.
Aims: To demonstrate the efficacy of Revolade (Eltrombopag), a Tpo receptor agonist in treatment of ITP.
Methods: Thirty patients, ages between 35-56 years old, followed between 2010-2013,22 women(73,3%) and 8 men(26,6%);all received pulse-therapy with corticosteroids more then once and 17 (56,6%) had splenectomy. We started the treatment with 50mg ,od,when platelets count <30000/mm^3 and,then, lowered the dose to 25mg,od, when platelets >150000/mm^3. Five (16,6%) patients reached the level of platelets >250000/mm^3 with 50 mg od and needed to stop the medication for one week, than restarted with 25 mg od.
Results: All patients had platelets>50000/mm3 after the first week, no thromboembolic events; 7(23,3%)reported mild/moderate headache and 5(16,6%) had minor elevation of liver enzymes. No need to increase the dose to 75mg,od.
Summary / Conclusion: Revolade is a very strong option both for patients with ITP and splenectomy and for those who have contraindication for splenectomy. The medication is very well tolerated, despite the food restrictions(no mineral or diary products four hours before and four hours after the treatment with Revolade).

B1937

THE ANTIPHOSPHOLIPID ANTIBODIES, A RISK FACTOR TO DEVELOPED ANTIPHOSPHOLIPIDE SYNDROME OR SYSTEMIC LUPUS ERYTHEMATOUS IN THE PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP)

A Gaman[1*], G Gaman[2], I Rotaru[2]
[1]Pathophysiology, Hematology, [2]Hematology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: *Background*: The presence of antiphospholipid antibodies has been reported in immune thrombocytopenic purpura (ITP), but their role in the pathophysiology of disease is still unclear.
Aims: *Aim of study*: to evaluate the presence of antiphospholipid antibodies in ITP and the risk of developing an antiphospholipide syndrome or systemic lupus erythematous in patients with ITP.
Methods: *Methods*: we studied 49 patients with ITP hospitalized in Clinic of Hematolohy of Craiova (Romania) between 2007-2012. The diagnosis of ITP were established based on history, physical examination, complete blood count and reticulocyte count, bone marrow examination; 29 patients were tested for helycobacter pylori, HCV, antiphospholipid antibodies (APA- CLIA method), antinuclear antibodies (ANA-FEIA method).
Results: *Results:* the median age of patients was of 34 years, 80% were female and 20% were male. At diagnosis, 60% of them had a platelet count < 50 x10^9/L and 40% had a platelet count ≥ 50 x 10^9/L. The presence of APA was detected in four patients and ANA in seven patients (three of them had both APA and ANA). During the follow-up period (5 years), one patient with APA developed antiphospholipide syndrome and four patients with ANA (three of them both APA and ANA) developed systemic lupus erythematous, one of them with central nervous system manifestations.
Summary / Conclusion: *Conclusion*: the estimation of APA in patients with chronic immune thrombocytopenic purpura is indicated for the identification of patients who risk to develop an antiphospholipide syndrome or an autoimmune systemic disease.

B1938

MANAGEMENT OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) THERAPY - A RESTROSPECTIVE STUDY ON 49 PATIENTS

A Gaman[1*], I Rotaru[2], G Gaman[2]
[1]Pathophysiology, Hematology, [2]Hematology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background: *Background*: Primary immnune thrombocytopenia (ITP) is characterized by a low platelet count which is the result of both increased platelet destruction and deficient platelet production. The development of autoantibodies in the pathophysiology of ITP still remains a problem.
Aims: *Aim of study*: to evaluate the response at therapy of 49 patients with ITP.
Methods: *Methods*: we studied 49 patients with chronic immune thrombocytopenia hospitalized in the Clinic of Hematology of Craiova (Romania) between 2007-2012. The diagnosis of chronic ITP was established based on history, physical examination, complete blood count and examination of the peripheral blood and bone marrow smear. All patients were initially treated with corticosteroids and the patients who did not respond were treated with Danazol, vinca alkaloid regimens, splenectomy or thrombopoietin receptor agonist as second line therapy.
Results: *Results*: 49 patients were initially treated with corticosterids (prednisone 0,5-2 mg/kg/day for 2-4 weeks or Dexamethasone 40 mg daily for 4 days every three weeks) and more than a half of them responded to this therapy; the patients who did not respond were treated, as second line therapy, with Danazol (two), Vinca alkaloid regimens (three), splenectomy (nine) or thrombopoietin receptor agonist (nine patients with refractory or relapsed chronic ITP and platelet count < 30.000/µl).
Summary / Conclusion: *Conclusion:* corticosterids remain the first line therapy in patients with chronic ITP but when they do not respond, a second line treatment option may be considered: Danazol, Vinca alkaloid regimens, splenectomy or thrombopoietin receptor agonist.

THE RESULTS OF THE SAUDI NATIONAL SCREENING PROGRAM FOR FACTOR VIII AND IX HEMOPHILA INHIBITORS

T Owaidah[1,2*], M Saleh[3], h alzahrani[4], a almusa[3], f alkasim[5], A Tarawah[6], R Alnouno[1], F AL Batniji[7], f alothman[8], a alomari [9], S Abuherbish [10], M RIASH[4], M Ahmed[1], A ALMOMEN[2]
[1]pathology, KFSHRC, [2]medicine, king Saud university, [3]pedatric hematology, [4]oncology, KFSHRC, [5]pedatric hematology, ministry of health, Riyadh, [6]pedatric hematology, ministry of health, madina, [7]pedatric hematology, military hospital, [8]pedatric hematology, security force hospital, [9]pedatric hematology, national gaurd hospital, [10]oncology, security force hospital, Riyadh, Saudi Arabia

Background: Hemophilia A is an X-linked disease that affects males at prevalence of 1:5000-10000 while the prevalence of hemophilia B is 1:34,500 male. Although these disorders are rarely observed; it can be very serious (life threatening) and costly for families and countries. The development of factor inhibitor is a consequence of administration of blood products or manufactured factor concentrate. The reported prevalence of inhibitors for Hemophilia A ranges from 3.6-27% whereas for Hemophilia B very low 3-5%. There are few reports about the prevalence of these inhibitors in Arabs
Aims: we are reporting the final data analysis of a saudi screening survey for factor VIII and factor IX inhibitors.
Methods: A screening program for Hemophilia A and B inhibitor prevalence in Saudi Arabia had been launched in 2008 as a cross-sectional study. Seven centers in the country had participated in this survey. After approval of the proposal from research and ethical committee of each center, a representative from that center was included in a steering committee. Patients were requited from each center in addition to several Hemophilia awareness days were done to identify cases. All patients had been interviewed for clinical data collection and then subjected to confirmation of the disease in a central laboratory by measuring factor levels using standard chromogenic coagulation tests. Patients with confirmed Hemophilia A and Hemophilia B were included in the study and tested for presence of Factor inhibitors by Quantitative assay to measure Bethesda units (BU).
Results: Over 5 years 267 patients with diagnosis of hemophilia A or B were included in the study. Only 214 and been included in analysis, 53 patients were excluded mainly for incorrect diagnosis (most of these patients were von willebrand disease misdiagnosed as Hemophilia A). There were 158 hemophilia A (15 mild, 9 moderate and 134 severe) and 56 with hemophilia B (13 mild, 5 moderate and 38 severe). There were 208 males and only 6 female with hemophilia with mean age at diagnosis 1.6 years (range 0-20 years). Most of these patients 152 (71%) received treatment based on episodic bleeding and only 45 (21%) were on prophylaxis, while more than 100 (47%) received plasma derived clotting factors and 44(21%) recombinant concentrate still around 27 (13%) received Fresh frozen plasma. Chronic joint disability was encountered in 106 (50%) of patients with most commonly involved joints were Knees followed by elbows and ankles. The mean level of PTT was 86 sec. Factor VIII inhibitors were detected in 43 (28%) patients, of these 38 (88%) were detected in severe cases. Out of these patients 8 (19 %) had FVIII inhibitor level (1-5 BU), 23 (53%) titer (>5 BU) and in 12 (28%) titer was (< 1 BU). The total prevalence of inhibitors (> 1 BU) was 21%. Only one patient (1.8%) with severe hemophilia B had inhibitor at level of 135 BU.
Summary / Conclusion: we are reporting for the first time the prevalence of hemophilia A and B inhibitors in a cohort of Saudi patients. We found that the inhibitor level is similar with what had been reported in other ethnicity. We had detected 28 % with very low level of inhibitors which most likely representing transient inhibitor. We will conduct a follow up study to determine the frequency of development of high-level inhibitor in this group of patients.

B1940

LARGE INTER-INDIVIDUAL VARIABILITY OF THE RESPONSE TO NEW ORAL ANTICOAGULANTS

S Bloemen[1*], M de Laat[1], M Ninivaggi[1], T Lenderink[2], M Leers[3], B de Laat[1], C Hemker[1], R Al Dieri[1]
[1]Synapse BV, CARIM, Maastricht, [2]Department of Cardiology, [3]Department of Clinical Chemistry and Hematology, Atrium Medical Centre, Heerlen, Netherlands

Background: New, direct inhibitors of thrombin and factor Xa (FXa) show more stable pharmacokinetics than vitamin K antagonists do. Before the conclusion can be drawn that this warrants standard dose treatment it should be ascertained that the pharmacodynamic characteristics of the agents are predictable as well.
Aims: To investigate the response of the plasma from healthy subjects and patients with atrial fibrillation (AF) to a fixed dose of conventional and new anticoagulants.
Methods: Thrombin generation (TG) was determined by calibrated automated thrombinography (CAT). Platelet poor plasma (PPP) of 44 healthy, consenting subjects was spiked with otamixaban (direct FXa inhibitor), melagatran (direct thrombin inhibitor), unfractionated heparin, dermatan sulfate and pentasaccharide at concentrations around IC50. Thrombin generation was measured at 5 pM tissue factor and 4 µM phospholipids. The effect on TG of rivaroxaban (direct FXa inhibitor) in five consenting patients with AF was assessed in whole blood, platelet rich plasma (PRP) and PPP before therapy and in the 1st and 2nd week of therapy, three hours after ingestion of the drug.
Results: In the PPP of 44 healthy subjects the coefficients of variation (CV's) were 18% for the uninhibited endogenous thrombin potential (ETP) and 16% for the uninhibited peak height. A dose-dependent inhibition of all anticoagulants was observed in both ETP and peak height. The concentration of anticoagulant that inhibited ETP and peak around 50% was added to the individual plasmas. After inhibition the variation increased to 20-24% (ETP) and 24-43% (peak) for conventional and modern anticoagulants alike.
In the patients, both after 1 and 2 weeks of therapy, the ETP in PPP, PRP and whole blood decreased to a highly variable extent. The least variation was seen in PPP. The individual values of the response to rivaroxaban of the ETP were (1st week (%)/2nd week (%)): 21.9/29.3; 33.4/38.9; 9.1/11.3; 50.4/40.8 and 34.6/0.5. The values are to disparate and the number of patients too small to draw any quantitative conclusion, but it is obvious that the inter-individual variation is enormous. The differences in inhibition between the first and the second week in the same individual appear more similar than the inter-individual differences, which suggests that there may exist high and low responders.
Summary / Conclusion: This study indicates that the new anticoagulants cause quantitative changes in thrombin generation, that are as variable as those brought about by administration of vitamin K antagonists or by heparin treatment. The first results in patients suggest that, before relying on the effect of a fixed dose, the dose response in a patient should be determined.

B1941

POLYMORPHISM OF THROMBIN-ACTIVATABLE FIBRINOLYSIS INHIBITOR AND RISK OF INTRACRANIAL HEMORRHAGE IN FACTOR XIII DEFICIENCY

A Dorgalaleh[1*], S Alizadeh[1], M Naderi[2], A Kazemi[1], STabibian[1], Z Khatib[1]
[1]Hematology Department, Allied Medical School, Tehran university of Medical sciences, Tehran, [2]Departement Of Pediatrics Hematology & Oncology, Ali Ebn-e Abitaleb Hospital Research Center for Children And Adolescents Health [RCCAH], Zahedan University Of Medical Sciences, Zahedan, Iran , Zahedan University of Medical Sciences, Zahedan, Iran, Islamic Republic Of

Background: Factor XIII deficiency is an extremly rere coagulation disorder with estimated prevalence of 1/2000000 worldwide. The clinical manifestations of the disease are delayed wound healing, recurrent spontaneous miscarriage, severe bleeding and spontaneous intracranial hemorrhage as the main cause of death in these patients.
Aims: This study aimed to evaluates effect of a common polymorphism of thrombin activatable fibrinolysis inhibitor (TAFI) as a *antifibrinolytic factor in occurrence of* spontaneous intracranial *hemorrhage in patients with severe factor XIII deficiency.*
Methods: This case control study conducted on 34 factor XIII deficient patients with ICH and 36 patinents with factor XIII deficeincy but without history of ICH as control group. Initially all patients were moleculary analyzed for factor XIII deficiency and after confirmation of disorder both groups were assess for common TAFI Thr 325Ile polymorphism. And finally obtained data was analyzed by SPSS software.
Results: Molecular analysis for *TAFI* Thr 325Ile polymorphism revealed that almost all patients with ICH (89%) had this mutation that in 67% of patients was homozygot while in control group 18.7% was homozygot for Thr 325Ile polymorphism. There is a significant relationship between Thr 325Ile polymorphism in homozygote manner with incidence of ICH in severe factorXIII deficienty.
Summary / Conclusion: Co-existance of 325Ile polymorphism in homozygote manner with severe factor XIII deficiency increase risk of ICH about 20 fold.

B1942

THROMBIN GENERATION TEST FOR IDENTIFICATION OF PATIENTS AT HIGH THROMBOTIC OR BLEEDING RISK

V Shmeleva[1*], O Golovina[1], Y Namestnikov[1], O Matvienko[1], N Saltikova[1], V Soldatenkov[1], L Papayan[1]
[1]Russian Research Institute of Hematology and Transfusion, Saint-Petersburg, Russian Federation

Background: Thrombin generation test parameters, particularly endogenous thrombin potential (ETP), obtained in plasma by the use of a fluorogenic substrate seems to reflect overall haemostasis better than traditional coagulation tests. Prognosis of patients with myeloproliferative neoplasmas is strongly affected by disease-related hemostatic complications and it is important for them to choose proper thrombosis prophylaxis without increasing risk of hemorrhages.
Aims: Aim of our study was to compare ETP in patients on low and optimal intensity vitamin K antagonists (VKA) treatment and to evaluate correlation

between ETP and international normalized ratio (INR) - standardized method of wide clinical utility.
Methods: The study involved 28 controls and 54 patients (M/F 30/24, mean age 58,2±14,8 yrs), treated with warfarin at list for 6 months and INR range of 0,9 to3,3. ETP in platelet poor plasma was measured using the Calibrated Automated Thrombogram (CAT), according to Hemker et al. both in the presence and in the absence of thrombomodulin (TM), which allow to assess influence of VKA treatment on the protein C system.STATISTICA 6.1 was used, data are given as mean±SD.
Results: Lag time, ETP, peak thrombin and time to peak obtained with and without TM demonstrated strong positive correlation (R between 0.93 and 0.98, P<0,05). Both in the absence and in the presence of TM strong inverse correlation with INR was found for ETP (R =-0,85 and R =-0,79, respectively, P<0,05) and peak height (R =-0,84 and R =-0,79, respectively, P<0,05). In patients with INR1,5-1,9 ETP (nMmin),obtained both with and without TM, was significantly (P<0,0001) higher (481,2±106,8 and 642,8±129,7 respectively) vs. those with INR2,0-3,3 (293,2±167,4 and 358,0±210,3, respectively), but significantly (P<0,0001) lower than corresponding parameters in controls (932,8±272,6 and 1731±253,6 respectively). None of the patients with INR1,5-1,9 had increased ETP, (i.e above 95th percentile measured in controls: >2114 nMmin in the absence of TM and >1433 nMmin in the presence of TM). In patients with INR 0,9-1,4 ETP was very close to controls (1487,4±210,3 without TM and 880,6±167,4 with TM). Two patients (both with INR =1) had increased ETP. In one case increased ETP in the absence of TM was accompanied by normal result in the presence of TM, and during the following18 months of observation patient did not demonstrate recurrent thrombosis. In the other patient with ETP 2343 nMmin in the absence of TM and 1603 nMmin in the presence of TM (i.e. increased) rethrombosis took place. In one patient with polycythemia vera, (INR 2.8), ETP and peak thrombin either in the absence or presence of TM were markedly decreased (73 and 71 nMmin ;4,6 and4,9 nM respectively), lag-time and time to peak were markedly prolonged (31,0 and 24,3 min; 41,6 and 34,3 min respectively), so the dose was corrected.
Summary / Conclusion: There is a strong correlation between ETP and INR both in the absence and in the presence of TM, but in some patients with INR within therapeutic range high risk of bleeding and/or rethrombosis can be better assessed by CAT and these patients could benefit from monitoring by this method. In some cases low intensity VKA is possible in aim of reduced risk of bleeding without increasing risk of recurrent thrombosis. Our data support the position that thrombin generation test may allow individualized approach when assessing the balance between bleeding and thrombotic risk and its modification by antithrombotic treatment.

B1943
NOVEL ORAL ANTICOAGULANTS - PROTOCOL TO MINIMISE BLEEDING AND EDUCATE DENTAL SURGEONS
M Giffen[1*]
[1]Oral surgery, NHS Portsmouth, Portsmouth, United Kingdom

Background: As many patients attending dental surgery are taking medications which alter their bleeding tendency it has been a topic which receives much attention. In March 2004, the British National Patient Safety Agency (NPSA) issued a protocol for patients requiring invasive dental surgery while taking the coumarin anticoagulant warfarin. This has become an important aspect of patient safety and professional are aware of their responsibility for monitoring these patients' International Normalised Ratios (INR). Dental surgeons operate to these guidelines and are aware of a patient's potential increased bleeding risk and how to minimise the impact it will have following an invasive dental procedure, often by using simple local haemostatic measures. Eight years later, in March 2012, the British National Institute for Health and Clinical Effectiveness (NICE) approved the use of Dabigatran Etexilate for the prevention of stroke and systemic embolism for patients with nonvalvular atrial fibrillation and defined additional risk factors. Dabigatran Etexilate is one of the Novel Oral Anticoagulant group of drugs (NOAC) which have the potential to impact on dental surgeons providing invasive oral surgery both in primary care and in the hospital setting and currently there is little evidence and effective means of measuring patients' bleeding tendencies on these drugs.
Aims: To establish a working protocol for assessing and optimising patients receiving treatment with a NOAC drug who require invasive oral surgery procedures or conventional dental deep nerve blocks as part of their treatment in order to minimise their bleeding risk.
Methods: Current literature, national guidance and international experience was compared to the opinion of consultants in the region. A panel was established to review the literature develop expanded guidance given by the drug manufacturers. The functions of the panel were to review the evidence and to consider the implications in dental surgery practice in order to establish a safe working protocol for patients requiring dental and oral surgery while treated with NOAC drugs.
Results: The opinion of consultants from various specialties in the region varied greatly in both their experience of NOAC drugs and their advice on managing a patient requiring invasive dental treatment taking NOAC drugs. Through discussion with the haematology team a working protocol was established for patients requiring oral surgery within the Oral and Maxillofacial Surgery department.
Summary / Conclusion: Where new drugs are added to the formulary following approval by the National Institute for Health and Clinical Effectiveness the risk they pose to other healthcare professionals should be assessed. Within the hospital we have established a multidisciplinary team to examine the evidence and establish a protocol for the safe treatment of patients requiring oral and dental surgery while receiving treatment with drugs from the NOAC family. This information requires dissemination to colleagues providing care in both primary care and secondary care. The protocol will evolve with the further evidence, discussion and where more cases of increased bleeding and adverse events come to light.

B1944
MANAGEMENT OF DENTAL INVASIVE PROCEDURES IN HEMOPHILIA A/B AND VON WILLEBRAND DISEASE OUTPATIENTS
V De Padua[1], D Gaglioti[1], C Santoro[2*], R Bosco[1], F Riva[1], E Baldacci[2], L Parlanti[2], R Foà[2], M Mazzucconi[2]
[1]Department of Oral Surgery, George Eastman Hospital, [2]Cellular Biotechnology and Hematology, Hematology, Sapienza University, Rome, Italy

Background: Dental procedures in hereditary bleeding disorders affected patients can be complicated by excessive bleeding. Replacement prophylactic therapy and local measures dramatically reduce the risk of complications in these surgical procedures. Moreover, self-infusion and home-treatment reduce therapy cost.
Aims: To describe the dental procedures performed in a group of hemophilia A/B and von Willebrand Disease outpatients utilizing systemic prophylactic therapy and local measures.
Methods: During the last six years, in our Dental Department, we performed one hundred and fifty four surgeries on forty nine patients (41 M, 8 F; median age 48 years, range 11-82) affected by hereditary bleeding disorders: 15 severe, 7 moderate, 10 mild hemophilia A; 2 severe, 2 mild hemophilia B; 6 type1, 1 type 2A, 3 type 2B, 3 type 3 von Willebrand Disease. The Hemophilia Center provided personalized therapeutic schemes, on the basis of the type/severity of the coagulopathy and type of surgery. Factor VIII concentrates were administered in severe, moderate and few cases of mild hemophilia A; FIX concentrates in severe and mild hemophilia B; desmopressin in mild hemophilia A, von Willebrand Disease type 1 and type 2A; FVIII/VWF concentrates in von Willebrand Disease type1, in case of low response or contraindication to Desmopressin, type 2B and type 3. One hundred and twenty one dental and roots extractions, ten third molar surgical extractions, one excisional biopsy, two cysts enucleation, eighteen scaling and roots planing, one gingival graft, one hypertrophic gingival tissue removal were performed under local and locoregional anesthesia. Local hemostasis was ensured by applying gelatine packing, fibrin glue, absorbable suture, fifteen-minute compression with tranexamic acid saturated gauzes. In the post-operative period, patients were treated with antibiotics and continued the self-infusion of concentrates/desmopressin for an average period of 5 days (3-7). Tranexamic acid mouthwashes (three times a day for 3 days) were prescribed; acetaminophen was used as the only pain-relief treatment.
Results: We observed no hemorrhagic or infectious complications. All patients completed the post-surgery management by home-based treatment.
Summary / Conclusion: A tailored prophylactic treatment ensures a good hemostasis in patients affected by hereditary bleeding disorders undergoing dental procedures. A strict collaboration between the hematologist and the dental surgeon is requested.A multidisciplinary approach allows to manage coagulopathic patients without bleeding complications; home-treatment reduces management costs.

B1945
PROPHYLAXIS WITH ACTIVATED PROTHROMBIN COMPLEX CONCENTRATE (FEIBA) IN CHILDREN WITH SEVERE HAEMOPHILIA A (HAEMA) AND HIGH RESPONDING FVIII INHIBITORS BEING ON IMMUNE TOLERANCE INDUCTION (ITI)
H Pergantou[1*], A Komitopoulou[1], P Xafaki[1], M Avgeri[2], Z Kapsimali[2], M Mazarakakis[2], E Adamdtziki[2], H Platokouki[2]
[1]Haemophilia Centre/Haemostasis Unit, Aghia Sophia Children's Hospital, [2]Haemophilia Centre/Haemostasis Unit, Aghia Sophia Children's Hospital, Athens, Greece

Background: About one third of children with severe HaemA, mainly previously untreated patients, develop inhibitory antibodies towards infused factor VIII (FVIII) concentrates. The development of high–titer FVIII inhibitors [>5 Bethesda Units (BU)] renders treatment of patients problematic as they no longer respond to standard FVIII replacement. By passing agents are used to control or even prevent bleeding in these patients. Activated prothrombin complex concentrate (aPCC: FII, FIX, FX, activated FVII; FEIBA, Baxter, Vienna-Austria), licensed for use in our country in 2011;it has been suggested as preventive treatment in patients with severe HaemA and FVIII inhibitors in order to avoid serious and devastating haemorrhages
Aims: The safety and efficacy of FEIBA given as preventive treatment were evaluated in 4 children with severe HaemA and high responding FVIII inhibitors

(mean value: 342 BU, normal values < 0.6 BU), aged between 16 months and 5 years, being already on various ITI protocols (100 U/kg of FVIII concentrates for 3 or 4 times / week – 200 U/kg/24h) with different FVIII products (recombinant FVIII:3, plasma derived FVIII:1) for a median period of 15 months (1.5-37 months). Prophylactic treatment with FEIBA was administered for a period of 2-7.5 months in a dosage of 70 u/dl ±15 u/dl/day, and a frequency of 3 - 7 times/week, due to recurrent serious hemorrhagic episodes.
Methods:
Results: During the observational period, all patients showed improvement of their clinical status, as a threefold reduction of the mean number of haemorrhages under FEIBA prophylaxis was observed in comparison with those before FEIBA initiation (3, range 0-5 versus 9, range: 4-19 respectively). Neither new target–joint nor life-threatening haemorrhage was reported in all four children. It is worthy to note that one out of four boys had already suffered one serious episode of extensive haemothorax and two episodes of intracranial haemorrhage before initiating prophylaxis with FEIBA. No thromboembolic complications or any drug-related adverse reactions occurred during the period of prophylaxis while D-dimers were found negative in consecutive evaluations. All patients remained negative for HCV and HIV while they had maintained high titers of anti-HBs antibodies due to vaccination for hepatitis C. Elimination of FVIII inhibitors was reported in all four patients. Nevertheless, only additional administration of rituximab (MabThera, Rhoche) resulted in successful ITI and FVIII inhibitor eradication in one patient. Treatment with FEIBA was stopped when each patient's FVIII levels were measured >10 u/dl in a 30 minute post-infusion sample.
Summary / Conclusion: In our small series, FEIBA prophylaxis decreased the overall bleeding rate, and target-joint evolvement in children with severe HaemA and high responding FVIII inhibitors. In spite of the concomitant use of FVIII on any ITI protocol and infusions of FEIBA, a product containing activated FVII, no adverse events, mainly thromboembolic, were observed.

B1946
THE SIGNIFICANCE OF TEG AND TGA IN THE EVALUATION OF HEMOSTASIS IN CHILDREN WITH CYANOTIC AND ACYANOTIC CONGENITAL HEART DISEASES
C Balkan[1*], S Gokce[1], N Karadas[1], D Karapinar[1], Z Ulger[2], K Kavakli[1]
[1]Pediatric Hematology, [2]Pediatric Cardiology, Ege University School of Medicine, Izmir, Turkey

Background: Patients with cyanotic congenital heart disease (CHD) have hemostatic abnormalities, which result in an increased risk of bleeding. The cause is unknown, but recent studies have indicated that an elevated hematocrit, which is present in cyanotic patients, could be an important factor.
Aims: In this study, we aimed to evaluate the hemostatic state of children with cyanotic and acyanotic CHD by using thromboelastography (TEG) and thrombin generation assay (TGA).
Methods: Seventy four patients with CHD (39 acyanotic, 35 cyanotic; ages were between 0-18 years) were enrolled in this study. Twenty nine, age matched, healthy children were enrolled as a control group. Hemogram, PT, aPTT, TEG and TGA results were evaluated in all patients before angiography and cardiac surgery.
Results: In the cyanotic group, as expected, hematocrit levels were significantly higher than acyanotic and control groups (P=0.000). When compared to the acyanotic patients, PT anda PTT results were significantly higher in the cyanotic group (P=0.011 and P=0.037 respectively).
When TEG parameters were analyzed, TEG-R values were significantly longer in cyanotic patients than acyanotic and control groups (P=0.000 for both groups). Alpha-angle degree and maximum amplitude (MA) values were significantly lower in cyanotic group than acyanotic (P=0.001) and control (P=0,005) groups.
When TGA parameters were analyzed, peak thrombin levels were significantly lower in cyanotic group than acyanotic and control groups (P=0.000, P=0.000 respectively). When compared to control group, peak thrombin time results were significantly longer in cyanotic and acyanotic groups (P=0.014, P=0.028 respectively). Endogenous thrombin production was significantly lower in cyanotic group than acyanotic and control groups (P=0.000, P=0.000 respectively).
Summary / Conclusion: While it is well known that high hematocrit levels increase the tendency for thrombosis in cyanotic heart disease, TEG and TGA results in our study show that there are also coagulation disturbances in these patients.

B1947
INTRACRANIAL HEMORRHAGE IN HEREDITARY BLEEDING DISORDERS: THE EXPERIENCE OF ÇUKUROVA
I Sasmaz[1*], B Antmen[1], B Karagun[1], G Leblebisatan[1], D Yılmaz[2], Y Kilinc[1]
[1]Pediatric Hematology, [2]Neurosurgery, Cukurova University, Adana, Turkey

Background: Intracranial hemorrhage (ICH) is a life threatening complication of hereditary bleeding disorders in childhood resulting in high rates of mortality and disabling sequelae.
Aims: In this study, we evaluated our patients with intracranial hemorrhage and compared with literature.
Methods: From 1995 to 2012, 21 patients with intracranial hemorrhage were diagnosed and evaluated in Çukurova University Hemophilia Center. ICH episodes, the findings of physical examination, CT scan or MRI and treatment strategies including surgical interventions were reviewed retrospectively.
Results: We evaluated 22 episodes of ICH from 21 patients with hereditary congenital factor deficiencies (CFD). Age range was from 9 days to 12 years. There were 15 patients with hemophilia A, 2 patients with hemophilia B, 2 patients with factor VII deficiency, 1 patient with factor X deficiency, 1 patient with von Willebrand disease. Two patients with factor VII deficiency, 1 patient with factor X deficiency and 1 patient with von Willebrand disease were female. Except one patient with factor X deficiency, all patients had one bleeding episode. Two patients had a high titer inhibitor against factor VIII. The most important factor was trauma. A history of recent trauma was documented in 10 patients. Intracerebral and subdural hematoma were more frequently seen. The most frequent symptoms were seizure and headache. The diagnosis of hemophilia was established in 5 patients after intracranial hemorrhage who referred to our center with ICH . In 9 patients, hematoma was evacuated. Three hemophilia patients died due to ICH and 4 patients presented late sequelae.
Summary / Conclusion: Intracranial hemorrhage is the most serious complication in childhood, especially for hereditary bleeding disorders. Urgent establishing diagnosis and treatment with prompt doses of factors to initially maintain a normal concentration of circulating factor is mandatory. Despite the prompt treatment, death and late sequelae can be seen in this patients group.

B1948
HEMATURIA IN CONGENITAL COAGULATION FACTOR DEFICIENCIES
N Karadas[1], C Balkan[1*], D Karapinar[1], K Kavakli[1]
[1]Pediatric Hematology, Ege University School of Medicine, Izmir, Turkey

Background: Spontaneous gross hematuria or subclinic microscopic hematuria is not an uncommon manifestation in severe hemophiliacs and has been thought to reflect tubular damage.
Aims: In this retrospective study, we evaluated the prevalence of hematuria in hemophiliacs and other congenital factor deficiencies in a comprehensive care center.
Methods: All medical records of hemophiliacs who attended this comprehensive hemophilia care centre between 1990 and 2012 were evaluated. 629 patients with congenital hemorrhagic diathesis (383 hemophilia A (HA), 77 hemophilia B (HB), 99 type-1, 16 type-2 and 14 type-3 vonWillebrand's Disease (VWD), 16 FVII deficiency, 8 FV deficiency, 5 FX deficiency and 11 rare factor deficiencies) were evaluated retrospectively in this study.
Results: Hematuria was determined in 39 of 383 HA patients, 12 of 77 HB patients, 5 of 129 VWD patients and 3 of 40 patients with the other factor deficiencies. The first attack of hematuria occurred at the age of 3-34 years (mean 15,5±6,9 years). Hematuria was seen in 59 of all hemophilia patients. Thirty four of these hemophiliacs had only one hematuria episode, 8 had two, 4 had three, 3 had four episodes and 10 had five and more episodes. Hematuria was seen in 29 severe, 20 moderate and 2 mild FVIII and FIX deficiencies. Inhibitors were positive in 7 of these patients.
While there were no significant findings in ultrasonography in 41 of 59 patients (70%) who had hematuria, nephrolithiasis was observed in seven patients (12%), pyelocaliectasis in one patient (1.7%) and renal cyst in one patient (1.7%). Ultrasonography was not performed in 9 patients.
While 8 patients (13.6%) received only hydration therapy, 43 patients (72.9%) received both hydration and factor replacement therapy. Five patients (8.5%) received hydration and factor replacement therapy. Two patients (3.4%) received fresh frozen plasma and 1 patient (1.7%) received fresh frozen plasma with combined prednisone therapy.
No cause for hematuria was identified in 46 of these patients (78%). Nine patients (15.3%) had nephrolithiasis, 1 (1.7%) had poststreptococcal glomerulonephritis, 2 (3.4%) had urinary tract infection, 1 (1.7%) had renal cyst.
Summary / Conclusion: Our results are consistent with the other investigations which rarely demonstrate urinary system abnormalities in these patients. The long-term outcome of hematuria is largely unknown.

B1949
MAJOR SURGICAL INTERVENTIONS IN CHILDHOOD RARE FACTOR DEFICIENCIES:A SINGLE-CENTER EXPERIENCE FROM TURKEY
D Tugcu[1*], Z Salcioglu[1], A Akcay[1], G Aydogan[1], F Akici[1], M Demirkaya[1], M Gokce[1], Z Baslar[2]
[1]Pediatric Hematology-Oncology, Kanuni Sultan Suleyman Education and Research Hospital, [2]Internal Medicine, Hematology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

Background: Rare factor deficiencies(RFD) are autosomal recessively inherited coagulation factor deficiencies with an incidence ranging from one in 500 thousand to 2 million.
Aims: Data regarding to major surgical interventions of RFD are based on case reports and records of guidelines.There are not well-documented and separately prepared directories related to presurgical and prophylactic

approaches of surgical interventions of these deficiencies.
Methods: This study retrospectively reviewed 20 individuals with RFD who received 24 major surgical intervention selected among those who were monitored and treated by our clinic between 1990-2012. We retrieved information from patient records and the records contained in the dataprocessing environment introduced in 2005.
Results: Our retrospective study had consisted of 171 rare factor deficiencies that were followed up in our clinic and of whom 20 had 24 major surgical interventions between 1990-2012. Age range was 5-19 years and male/female ratio was 17/7 (71/29%).Seventeen (71%) of the major surgeries were performed for patients with FVII deficiency, 4 (17%) for FV deficiency, 2 (8%) for FXI deficiency and one (4%) for afibrinogenemia. Of the patients who underwent major surgery, 13 (54%) were asymptomatic and 11 (46%) symptomatic.In factor VII deficient patients, ventriculoperitoneal shunt insertion(n=1), ventriculo peritoneal shunt valve replacement(n=1), undescended testicle(n=1), adenotonsillectomy (n=3), tonsillectomy(n=2), hernioplasty(n=5), splenectomy(n=1), subdural haematoma discharge (n=1), fracture repositioning(n=1), adenoidectomy(n=1) operations were performed. In FV-deficient patients hernioplasty(n=2), subdural haematoma discharge(n=1), bone repositioning(n=1) operations were performed. In FXI-deficient patients, cleft lip (n=1) and hernioplasty operations were performed. In the afibrinogenemia patient, cochlear implant insertion was performed.In factor VII deficient patients, rFVIIa was used for 7(41.2%) of the major surgical interventions, FFP for 2 (11.8%), and FFP and rFVIIa was coadministered in one case (5.8%). No replacement therapy was administered in 7 interventions(41.2%). Six (60%) of the patients who received replacement for Factor VII deficiencies were symptomatic and 4(40%) were asymptomatic. rFVIIa was used at 15-35mcg/kg for 3-83 times (4±31) and in 4-12 hour intervals. Cases involving FFP treatments were before 2002, after which rFVIIa and rFVIIa stable at room temperature were used. The number of doses used in ventriculoperitoneal shunt operations was 83, and 60 doses of rFVIIa were used for replacement of the VP shunt valve of the same patient. For the two hernioplasty patients, it was not possible to control the bleeding with 9 doses of FFP in one of them with FVII:C 42% and haemostasis could be achieved with 4 additional doses of rFVIIa. During the other hernioplasty procedure, 4 doses of rFVIIa were sufficient for haemostasis. In one case of adenotonsillectomy and one case of tonsillectomy, haemostasis was achieved with 3 and 4 doses of rFVIIa, respectively. In undescended testicle operation, replacement with 3 doses of rFVIIa was required.In four FV-deficient patients, FFP at 20ml/kg was used every 24-36 hours. Number of doses ranged between 1 and 10.In two FXI-deficient patients, single dose (20ml/kg) of FFP were sufficient.In the afibrinogenemia patient, fibrinogen was used at 50 mg/kg/ in 2-4 day intervals for a total of 3 administrations.
Summary / Conclusion: Surgical interventions to RFD patients, which represent a population with varying characteristics, should be performed in hospitals with experienced haematology centers. Patients as well as the surgery and anaesthesia teams should be prepared and encouraged prior to the intervention.

B1950
RECURRENT NEONATAL INTRACRANIAL HEMORRHAGE AS THE SOLE INITIAL PRESENTING SYMPTOM OF ACQUIRED FACTOR II DEFICIENCY: A CASE REPORT IN AN EGYPTIAN CHILD WITH TYROSINEMIA TYPE1
M Abdelwahab[1*], R ELSAYAD[2]
[1]PEDIATRIC HEMATOLOGY, [2]PEDIATRIC HEPATOLOGY, CAIRO UNIVERSITY PEDIATRIC HOSPITAL, Cairo, Egypt

Background: Hypoprothrombinemia can be congenital or acquired due to another disorder as liver disease. Severe bleeding including intracranial hemorrhage typically occurs when prothrombin level (FII) is below 5%. Type 1 tyrosinemia is a severe metabolic disorder often presenting with liver disease or liver failure with a subsequent coagulopathy.
Aims: To report that acquired hypoprothrombinemia secondary to hepatic affection can present initially with the severe bleeding symptoms without any clinical or laboratory evidence of hepatic involvement.
Methods: A one year old boy of consanguineous marriage presented with recurrent intracranial hemorrhage and recieved replacement . He was investigated for an underlying coagulopathy, diagnosed and started on weekly prophylaxis.He was doing very well till he developed very mild jaundice several months later when he was invetigated for an underlying hepatic affection.
Results: Patient's hematological assessment showed mild FII deficiency whilst hepatological evaluation revealed mild hepatosplenomeagly and prominent pelicalyceal system on abdominal ultrasound.This in association with the transient hepatic dysfunction and coagulopathy raised the possibility of being a case of tyrosinemia. Investigations revealed high plasma lactate dehydrogenase, alkaline phosphatase, succinylacetone, tyrosine, methionine and alphafetoprotein. So investigations were consistent with the diagnosis of tyrosinemia type 1 but patient died while being prepared for hepatic transplantation.
Summary / Conclusion: Liver cell failure with a secondary coagulopathy is one of the known presentations of tyrosinemia but initial clinical presentation with a severe coagulopathy in the absence of clinical manifestations of liver disease is not recognized as the initial presenting symptom of this condition.

B1951
A CASE STUDY OF POSTPARTUM HEMOPHILIA: HETEROGENICITY IN CLINICAL PRESENTATION, THERAPY REQUIREMENTS AND THERAPY ADVERSE EFFECTS
P Klonizakis[1], S Vakalopoulou[2], A Agapidou[2*], S Chissan[2], C Xadjiaggelidou[2], T Papadopoulou[2], M Tzimou[2], I Stoupis[2], V Garypidou[2]
[1]Second Department of Internal Medicine, [2]Second Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Acquired hemophilia A is an extremely rare hemorrhagic disorder. Postpartum hemophilia A is considered to be relatively benign. The haemorrhage episodes are rarely fatal and mortality is usually associated with the immunosuppression therapy side effects. First and second line therapy recommendations include corticosteroids, with or without cyclophosphamide, and Rituximab respectively.
Aims: To exhibit the heterogeneity of postpartum haemophilia A regarding clinical presentation, therapeutic requirements and therapy related complications.
Methods: We present three women with postpartum haemophilia A. In each case we describe the clinical presentation, the diagnostic findings, the therapeutic choices and final outcomes.
Results: Patient 1. A 27-year-old primigravida presented with extensive subcutaneous haemorrhage, low blood pressure and melena two months after an uncomplicated delivery. A week ago the initial spontaneous subcutaneous haematomas were misdiagnosed and therapy with salicylic acid 100 mg was given by an orthopedician. Further investigation revealed severe anaemia and intra-abdominal haemorrhage. Patient 2. A 29-year-old primigravida presented with an abrupt onset of subcutaneous haematomas at the left upper extremity and finger numbness six months after an uncomplicated delivery. Clinical evaluation revealed appartement syndrome at the left forearm. Abdominal CT scan revealed a splenic haematoma. Patient 3. A 34-year-old admitted to our department because of the appearance of spontaneous ecchymoses of the upper extremities and of the right calf, eleven months after a third delivery by caesarian section. She had also mentioned the appearance of similar but spontaneously resolved superficial ecchymoses and episodes of haematuria three months ago. Laboratory tests showed in all three patients isolated prolongation of PTT, low factor VIII levels and the presence of a FVIII inhibitor by mixing studies. There were no findings of malignancy, autoimmune disease or antiphospholipid syndrome. Treatment with the by-passing agent FVIIa was administered only in patients 1 and 2. All three patients initially received immunosuppressive treatment with prednisone 1mg/Kg. Patient 1 did not respond well to prednisone and received additional immunosuppressive therapy with cyclophosphamide 1000mg. A normal FVIII activity and inhibitor eradication was achieved on day 90. The same patient developed Listeria Monocytogenes meningitis and later on bilateral femoral bone necrosis. Patient 2 responded to prednisone therapy without any complications and exhibited a normal FVIII activity on day 45. Patient 3 is in the first week of prednisone therapy and exhibits a gradual increase in FVIII activity.
Summary / Conclusion: Diagnosis of postpartum hemophilia A is based on spontaneous haemorrhagic manifestations, which develop during the first twelve months post labour, and is confirmed by low FVIII levels and the presence of a FVIII inhibitor by mixing studies. Although, the incidence is higher in primigravidas diagnosis cannot be ruled out in subsequent pregnancies. Interestingly, in postpartum haemophilia A the inhibitor may spontaneously disappear, so less immunosuppression therapy may be needed and this may indeed explain the lower mortality rate. Nevertheless, patient 1 required intensive immunosuppressive treatment and exhibited serious therapy related complications. We conclude that early diagnosis and management of postpartum haemophilia A is crucial and careful patient monitoring should be recommended during the immunosuppression period.

B1952
ILIOPSOAS HEMORRHAGE IN CONGENITAL FACTOR DEFICIENCIES:THE EXPERIENCE OF ÇUKUROVA UNIVERSITY, ADANA , TURKEY
B Antmen[1*], I Sasmaz[1], B Karagun[1], G Leblebisatan[1], Y Kilinc[1]
[1]Pediatric Hematology, Cukurova University, Adana, Turkey

Background: Iliopsoas hemorrhage is a serious complication of bleeding disorders that occurs most commonly in patients with severe hemophilia and less commonly von Willebrand disease and Factor V deficiency and is considered as potentially life threatening condition and significantly associated with morbidity. Despite its clinical importance, there are few reports on the mode of presentation, treatment and sequela. In this study, we presented our experience about iliopsoas hemorrhage in patients with severe bleeding disorders.
Aims: In this study, we evaluated our patients with iliopsoas hemorrhage and compared with literature.
Methods: From 1995 to 2012, 19 patients with iliopsoas hemorrhage were evaluated in Çukurova University, Hemophilia center. The findings of physical examination, pain locations, complications were assessed. Iliopsoas hematomas were confirmed by ultrasonography, CT or MR scan. The treatment strategies were noted.
Results: We evaluated 29 episodes of iliopsoas bleeding from 19 patients with

congenital factor deficiencies (CFD). There were 13 with hemophilia A, 4 with hemophilia B, 1 with factor V deficiency, and 1 with von Willebrand disease. Age range was from 45 days to 19 years. Fourteen patients had one episode, three had two episodes, one had three episodes, one patient with severe hemophilia A with inhibitor had 6 episodes. Three patients had a high titer inhibitor against factor VIII. Iliopsoas hematomas were confirmed by ultrasonography in all patients. Five patients needed erythrocytes transfusion. The mean duration of therapy was 11,55±3,54 days, and the duration of hospitalization was 10,50 ±3,54 days. Patients with inhibitors were treated with by-passing agents. In 6 bleeding episodes of 1 severe hemophilia A patient with inhibitor treated with recombinant factor VIIa (rFVIIa). Activated prothombin complex concentrates (aPCC) was given in two episode in two severe hemophilia A patients with inhibitor. Long term complications included paresthesia in 5 patients in the distribution of femoral nerve and quadriceps atrophy in 4 patients.
Summary / Conclusion: Iliopsoas hematoma is a serious bleeding event in patients with hereditary clotting disorders. In this report, we present our experience and treatment modality in 28 episodes of serious iliopsoas hematoma in hereditary congenital factor deficiencies.

B1953
OUR CASES DIAGNOSED AS HEMORRHAGIC DISEASE OF THE NEWBORN
S Akarsu[1*], O Hancerli[2]
[1]Department of Pediatric Hematology, [2]Department of Children's Health and Diseases, University of Firat, Faculty of Medicine, Elazig, Turkey

Background: The nomenculature used for the entity called hemorrhagic disease of the newborn secondary to vitamin K deficiency which occurs in 1 % of the infants has been replaced by vitamin K deficiency bleeding of the newborn (VKDB), because this disease is not only caused by vitamin K (VK) deficiency**.** In 0.1-2 % of the healthy term newborns not receiving VK prophylaxis, classical VKDB occurs within the first 2 weeks of their lives.
Aims: We wanted to analyze our cases diagnosed as VKDB, and share our results in comparison with incidence rates of this disease cited in the literature.
Methods: Demographic data, information on medical history, clinical, and physical examination findings, bleeding sites, laboratory test results, treatment modalities, and their outcomes were analyzed in 21 cases with VKDB whom we followed up in the Division of Pediatric Hematology between 07.25. 2003, and 09.24.2012,
Results: These cases demonstrated clinical manifestations of early stage (n=2; 9.52 %), classical (n=3; 14.28 %), and late- type (n=16; 76.19 %) VKDB. The oldest infant with late-type VKDB was 2 years old. The infants with VKDB were born in the hospital (n=14; 66.66 %66.66) or at home (n=7; 33.33 %). They had (n=12; 57.14 %) or had not (n=7; 33.33 %) received vitamin K therapy, while in 2 cases (9.52 %) uncertainty existed. These infants were term (mature) (n=17; 80.95 %) , premature (n=3; 14.28 %), and postmature (n=1; 4.76 %) babies. They were receiving breast milk (n=16; 76.19 %), formula (n=2; 9.52 %), formula, and breast milk (n=2; 9.52 %). Neurological sequelae developed in 5 (23.8 %) cases, and 2 (9.52 %) infants died. Both of the deceased infants were in their early stage of VKDB..
Summary / Conclusion: Even though vitamin K therapy is mandatory during the neonatal period, currently in Turkey 33.33 % of the babies are still delivered at home, 33.33 of them don't receive vitamin K therapy, and 9.52 % of the infants die because of VKDB.

B1954
PERCUTANEOUS TRANSLUMINAL AORTIC VALVE IMPLANTATION (TAVI) FOR SEVERE AORTIC VALVE STENOSIS IN PATIENT WITH HEMOPHILIA A
G Giuffrida[1*], N Parrinello[1], R LOMBARDO[1], E Di Francesco[1], G Sortino[1], A Scandurra[2], S Mangiafico[2], A Arcidiacono[2], F Di Raimondo[1]
[1]Division of Hematology, [2]Division of Cardiology, Università di Catania, Italy

Background: Hemophilia is caused by the deficiency of coagulation factor VIII (A) or IX (B).The development of FVIII or IX inhibitors is the most severe and costly complication in the treatment of hemophilia.
The management of cardiovascular events in elderly hemophiliacs necessarily differs from that of non-hemophilic patients.
Aortic stenosis (SA) is the most common degenerative valve disease in Western countries, and its incidence increases with age. Nowadays, the surgical aortic valve replacement is the gold standard. However, approximately 30% of patients with severe symptomatic SA do not undergo surgical treatment because they are considered at high surgical risk because of advanced age and co-morbidity often coexist.
Aims: The TAVI has rapidly become an important treatment option for patients who are not candidates for surgical valve replacement or with high surgical risk.
Methods: A 56-years-old man with a severe hemophilia A with HCV-related chronic liver disease was admitted to hospital due to dyspnea on moderate exertion .A history of arterial hypertension, hyper-thyroidism and diagnosis of severe aortic valve stenosis was present in anamnesis. Electrocardiogram showed sinus rhythm, heart rate of 81 beats/min. An echo-colorDoppler excluded the presence of stenosing plaque in the right and left iliac and femoral arteries. During the hospital stay patient underwent coronarography which showed coronary arteries without any hemodynamically significant lesions, but dominant right coronary showed an abnormality of origin, deriving from ascending aorta. Aortic valve replacement was indicated, and because of the contraindication of surgery and his comorbidity, patient was subjected to TAVI that was performed in the cardiac catheterization laboratory under mild sedation and local anesthesia with fluoroscopic guidance. Echocardiographic analysis was repeated 24 hours after the TAVI procedure to assess prosthetic function and positioning and to exclude other complications. The outcome of the procedure was satisfactory. The patient did no experience any adverse events during and after the procedure. During hospitalization, under the supervision of haematologists, patient was treated with rFVIII 80 UI/Kg (Kogenate) bolus before surgery and then at a dose of 40 UI/Kg every 12 hours after surgery. During the procedure, heparin bolus 5000 UI. has been administered. Patient has continued home therapy as prophylaxis with recombinant FVIII infusion every 12 hours for 15 days and prophylaxis with EBPM 100 U/Kg/day.
Results: One year after TAVI procedure, patient maintains a satisfactory response in terms of cardiac outcomes and symptoms. The patient did not report any thrombotic or hemorrhagic events. Indeed, long-term follow-up has not revealed any complication.
Summary / Conclusion: The TAVI has rapidly become an important treatment option for patients who are not candidates for surgical valve replacement or with high surgical risk. The elderly patient is therefore an ideal candidate for percutaneous implantation especially in haemophiliac patients with high bleeding risk.

B1955
TRANEXAMIC ACID AS PROPHYLAXIS IN A YOUNG HAEMOPHILIA PATIENT WITH INHIBITOR PRESENCE
M Economou[1*], A Teli[1], A Papagianni[1], V Gourtsa[1], F Papachristou[1], N Gompakis[1]
[1]1st Department of Pediatrics, AUTH, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Inhibitor management remains a challenging issue in haemophilia patients. Tranexamic acid, an antifibrinolytic agent, is widely used both in inhibitor and non-inhibitor haemophilia patients as adjunctive therapy to factor replacement.
Aims: To report the clinical course of a 4 year old hemophiliac with persistent and exceptionally high inhibitor titers on a non-conventional prophylactic monotherapy with tranexamic acid.
Results: This is a report of a young haemophiliac diagnosed with severe FVIII deficiency (1%) soon after birth. During the first months of life he presented with repeated bleeding episodes requiring substitution therapy and by the age of 8 months inhibitor presence was established. Bleeding episodes were initially managed with recombinant activated factor VII, which subsequently became unavailable due to hospital economic reasons. ITI was planned, but due to poor venous access and difficulties in maintaining a central venous line (the child pulled off his Hickman catheter twice) was not started until the age of 2. During 12 months of ITI, the inhibitor titer rose from 128 B.U./ml to 2000 B.U./ml and ITI was discontinued as unsuccessful. The child continued to bleed frequently, with minimal access to factor VII as a result of hospital budget cuts. At the age of 3 a non-conventional non-established regimen of daily tranexamic acid prophylaxis was decided. During the months that followed the child demonstrated a dramatic change in clinical course, with great reduction in number of bleeds, almost none of which were of spontaneous nature. The child has now been on prophylaxis with tranexamic acid for 15 months, maintaining an unbelievably good joint status and an almost normal lifestyle.
Summary / Conclusion: Although not evidence-based or properly established, prophylactic treatment with tranexamic acid has proven extremely efficacious for this young haemophiliac patient who, as a result of the economic situation in Greece, cannot have access to appropriate treatment.

B1956

PERCUTANEUS TRANSLUMINAL ANGIOPLASTY (PTA) FOR AORTIC COARCTATION (COA) IN PATIENT WITH HEMOPHILIA A AND HIGH INHIBITORS TITRE USING FACTOR VIII INHIBITOR BYPASS ACTIVITY (FEIBA®)

G Giuffrida[1*], N Parrinello[1], R Lombardo[1], E Di Francesco[1], R Cingari[1], D Ussia[2], A Triolo[1], F Di Raimondo[1]
[1]Division of Hematology, [2]Division of Cardiology, Università di Catania, Italy

Background: Hemophilia is caused by the deficiency of coagulation factor VIII (A) or IX (B).The development of FVIII or IX inhibitors is the most severe and costly complication in the treatment of hemophilia. Controlling bleeding during and after surgery in haemophilia patients with inhibitors remains a challengefor physicians. Published studies demonstrate the efficacy, safety and tolerability of FEIBA in a variety of major and minor surgeries. CoA can be defined as a variable degree of narrowing of the aorta, resulting in pathologic obstruction of blood flow from the systemic ventricle to the systemic circulation. Treatment options depend on age and how aorta is narrowed and include surgical and transcatheter interventions. Recent developments in endovascular stent technology have extended the treatment options available and seem cost effective. The complications were represented by aortic aneursysm, aortic wall dissection/rupture, stent migration, embolic event, injury to access vessels, hematoma, bleeding, fistula formation.
Aims: We present a case report of a severe hemophilia A patient with inhibitors treated with FEIBA for the management of bleeding during transcatheter intervention (primary stenting) for post-isthmic CoA.
Methods: A 54-year-old man with severe hemophilia A and a high inhibitor titre (12 BU) and HCV-HBV related chronic liver disease referred to us because of acute pulmonary edema. A history of arterial ipertension and diagnosis of CoA were present in past anamnesis. Electrocardiogram showed atrial fibrillation, heart rate of 90 beats/min and complete left bundle branch block.
Because of the contraindication of surgery (high bleeding risk), PTA with stent implantation was performed in the cardiac catheterization laboratory, under deep sedation and local anesthesia with fluoroscopic and transesophageal echocardiographic guidance. Repeated echocardiographic examinations were performed 24 hours after the procedure to evaluate stent localization and the presence of residual gradients. The acute outcome of procedure was satisfactory. The patient had no adverse events during both the procedure and hospital stay. Before PTA 70 UI/Kg of FEIBA have been given to patientas a bolus and the same dose was repeated every 12 h for 7 days. As the coagulation factors was stable over time, and no bleeding was recorded during or after surgery, it was decided of increase the time intervals of administration from 12 h at 24 h for another 7 days, then move to prophylaxis regime for further 7 days.
Results: At 6 months after procedure, the patient has maintained a satisfactory response in cardiological profile and no thrombotic adverse events.
Summary / Conclusion: Endovascular stenting for the treatment of native and recurrent CoA appears to be a feasible, safe and efficient method in patients with hemophilia. Stent placement is a procedure that has a lower complication rate than balloon angioplasty and surgery. In patients with inhibitors, the administration of FEIBA at standard doses could be the gold standard for the management of bleeding.

B1957

FOLLOW-UP AND PROGRESSION OF HEMOPERITONEUM DEVELOPED IN A TYPE 3 VON WILLEBRAND PATIENT SECONDARY TO THE HEMORRHAGIC RUPTURE OF CORPUS LUTEUM

S Akarsu[1*], R Atilgan[2], M Altun[3]
[1]Department of Pediatric Hematology, University of Firat, Faculty of Medicine, [2]Department of Gynecology, Fırat University , [3]Department of Children's Health and Diseases, University of Firat, Faculty of Medicine, Elazig, Turkey

Background: Haemoperitoneum can occur as a result of the rupture of a bleeding follicle and a few cases have been reported in patients with type 3 von Willebrand's disease. Adequate information is not available related to the treatment, and follow-up period of this condition.
Aims: We wanted to present treatment modality, ultrasonographic evaluation (US), and the process of complete cure of our case.
Methods: A 15.5-year-old female adolescent who had been diagnosed as type 3 von Willebrand disease started to suffer from abdominal pain, and dysuria 10 days before her due date of menstruation. Her physical examination of the patient with complaints of constipation and fever revealed an abdomen with its normal convexity, tendernes at suprapubic region, and both lower quadrants. Abdominal defence was detected at the left lower quadrant. Somewhat attenuated bowel sounds were auscultated. Urgent US could not demonstrate the left ovary clearly. A hemorrhagic cyst measuring 39 x 37 mm, and surrounded by a free fluid zone in the left adnexial region was detected. Doppler US demonstrated normal blood supply of the cyst. Dense free fluid collection was observed in the Douglas recess, and pelvic region. Contrast-enhanced CT disclosed hemoperitoneum, and a hemorrhagic-ruptured corpus luteum cyst. Hemoglobin (Hb) value was 12.1 g/dl. She was monitored for bleeding episodes. A concentrated solution which contained FVIII, and von Willebrand factor was administered at a dose of 20 IU/kg at 8 hour-intervals for a period of 24 hours, and then for 3 days at every 24 hours. Besides prednisolone (2 mg/kg/d), and desmopressine spray were given for 3 days. In addition, the patient received IV tranexamic acid (15 mg/kg) at 8-hour intervals for 3 days, then its oral doses were maintained for 7 days. During follow-up period, her Hb regressed to 10.6 g/dl. After recovery of normal menstrual cycles, oral contraceptive therapy was initiated.
Results: Daily US controls were performed, and on the 10. day, a hemorrhagic follicle in the left ovary measuring 16 x 25 mm , and minimal fluid collection in the Douglas recess, and around the left ovary were observed. Then she was discharged, and sent home with the recommendation of oral contraceptive use for at least 6 months. Her monthly US controls were performed, and at the end of the 6. month, her hormonal test results were assessed to be within normal limits. Another problem was not observed.
Summary / Conclusion: Conservative management in a type 3 von Willebrand's disease has been succesfull in avoiding surgery. If recognized early, this could be a way to avoid surgery.

B1958

EXPERIENCE WITH PROTHROMBIN COMPLEX CONCENTRATES FOR PROPHLAXIS AND TREATMENT OF BLEEDING

F Keren[1*], O Balcık[2], Eda sİMSEK[2], A Kosar[2]
[1]Internal medicine, [1] Turgut Ozal University School of Medicine Department of Internal Medicine, Ankara, TURKEY, [2]Hematology, Turgut Ozal University School of Medicine Department of Hematology, Ankara, Turkey

Background: PCC is currently indicated for the treatment of bleedings and prevention (during surgery) caused by the congenital or acquired lack of vitamin K-dependent coagulation factors II, VII, IX and X in the blood.
Aims: In this presentation we discussed PCC and fresh frozen plasma (FFP) efficiency and side effects for prophylaxis and bleeding.
Methods:
From May-2012 to October 2012 total 50 patients evaluated retrospectively in our hospital. Twenty five patients used PCC and 25 patients used FFP for prophylaxis and bleeding.
Results: Patient characteristics and results are summarized in table 1.The PCC group was older than FFP group and this was statistically significant (P=0,021). No statistically significant for gender and indications both of the groups (P=0,773 and P=0,115). In PCC group before and after treatment prothrombin time (PT) was higher than FFP group (P=0,001 and P=0,001). Decreasing PT was higher in PCC group (P=0,001). In PCC group before and after treatment INR was higher than FFP group (P=0,001 and P=0,001). Decreasing INR was higher in PCC group (P=0,002). In PCC group before and after treatment active partial thrombin time (aPTT) was higher than FFP group (P=0,012 and P=0,048). No statistically significant for before and after treatment aPTT both of the groups (P=0,077). Efficiency time was lower in PCC group and statistically significant differences (P=0,011). But length of hospital stay wasn't different (P=0,762). There wasn't any side effect in both groups.

Table 1. Patient characteristics and results

		FFP	PCC	P value
Age		57,7 ± 19,4	70,1 ± 17,5	[a]0,021*
Gender	Women n(%)	16 (%64)	14 (%56)	[c]0,773
	Men n(%)	9 (%36)	11 (%44)	
Indications	Bleeding n(%)	15(%60)	21(%84)	[c]0,115
	Prophylaxis n(%)	10(%40)	4(%16)	
Before-PT		29,6 ± 17,0	61,1 ± 29,7	[b]0,001**
After -PT		19,8 ± 4,5	27,9 ± 6,8	[b]0,001**
PT difference		10,4 ± 13,4	33,2 ± 27,8	[b]0,001**
Before-INR		3,2 ± 2,2	7,2 ± 3,7	[b]0,001**
After-INR		1,5 ± 0,4	2,7 ± 0,8	[b]0,001**
INR Difference		1,7± 2,0	4,5 ± 3,4	[b]0,002**
Before-aPTT		67,0 ± 46,6	80,8 ± 37,5	[b]0,012*
After-aPTT		41,2 ± 13,0	46,8 ± 13,2	[b]0,048*
aPTT difference		27,7 ± 39,1	33,9 ± 39,4	[b] 0,077
Hospitalisation(day)		7,5 ± 11,6	7,4 ± 10,5	[b] 0,762
Efficiency time(hour)		32,6 ± 15,3	25,5 ± 17,0	[b]0,011*

[a] Student t Test [b] Mann Whitney U Test [c] Yates Continuity correction
*p<0,05 **p<0,01

Summary / Conclusion: We used PCC for the patients who were older and have higher coagulation parameters. It showed effect in a shorter time and corrected coagulation parameters more than FFP. PCC is an effective treatment for prophylaxis and bleeding. To achieve a precise results we need further studies with more patients.

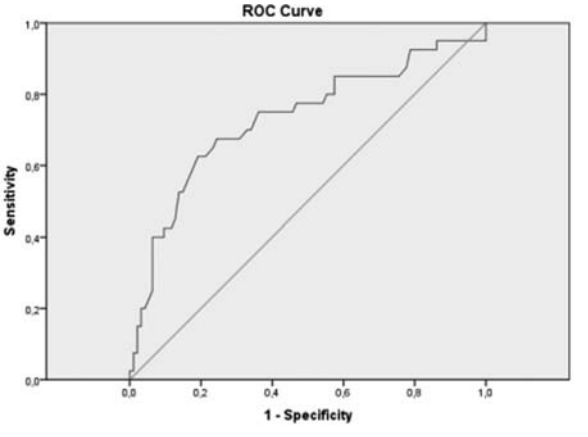
B1959
SPONTANEOUS DUODENAL HEMATOMA IN A PATIENT WITH GLANZMANN'S THROMBASTHENIA
H Tokgoz[1*], U Caliskan[1]
[1]Pediatric Hematology, Necmettin Erbakan University, Konya, Turkey

Background: Glanzmann's thrombashtenia (GT) is a rare congenital disorder of platelet function associated with a prolonged bleeding time, a normal platelet count, abnormal clot retraction and defective platelet aggregation. Mucocutaneous bleedings including gastrointestinal bleeding are common in GT patients but spontaneous intramural duodenal hematoma is extremely rare.
Aims: We report a child who had GT presented with signs and symptoms of duodenal obstruction. We aimed to pay attention a rare presentation of GT patients.
Methods: A five-year-old boy with a known GT was brought to the pediatric emergency room by his parents. The patient had been complainting of the acute onset of periumblical and right upper quadrant pain and vomiting. There was no melena and hematemesis in admission. No history of trauma was present. The abdomen was flat with tenderness in the midepigastrium and right upper quadrant without evidence of peritoneal irritation. Rectal examination reveled black stool.
Results: Abdominal ultrasonography revealed appearent intramural duodenal hematoma and ileoileal invagination. Invagination was resolved via rectal barium application. Intramural hematoma was resolve recurrent administration of thrombocyte suspension. Erythrocyte suspension was given because of deep anemia. The patient did not need further surgical intervention. Intramural hematoma completely regressed on day 10.
Summary / Conclusion: Intramural duodenal hematoma is generally seen after abdominal trauma. It has been reported spontaneous intramural duodenal hematoma in coagulation disorders such as Von Willebrand disease, immune thrombocytopenic purpura, polyartheritis nodosa, hemophilia A (1-3). Only one report about GT and intramural duodenal hematoma was found in the literature and GT (1). The diagnosis of duodenal hematoma should be considered in any patient who has abdominal pain and a coagulation disorder. İntramural hematoma may be abundant even requiring blood transfusion. Nonoperative management of an obstructing duodenal hematoma was successful and potentially life-threatening surgery was avoided.

Thrombosis and vascular biology

B1960
PROTEIN C SERUM LEVELS ARE DECREASED IN HEART FAILURE: A GLIMPSE AT THE PULMONARY SIDE OF THE EQUATION?
C Costa[1*]
[1]Hematology, Instituto Português de Oncologia Francisco Gentil - Lisboa, Lisboa, Portugal

Background: Protein C (PC) is a fundamental piece of the endogenous anticoagulant system. It also has a role in inflammatory response, in endothelial permeability and in vessel remodeling through its receptor EPCR. The author has hypothesized that PC may be depleted in cases of pulmonary stasis and, thus, lower the threshold to pulmonary edema by increasing capillary permeability.
Aims: Assess the relation between levels of PC and the severity of heart failure.
Methods: Retrospective analysis of a series of consecutive patients who attended the emergency department of a Portuguese community hospital from September 2009 to September 2011.
Results: Patients with hematological diseases, coagulation disorders or hepatic dysfunction were excluded. A total of 149 patients were studied; median age 50 years (range 1-90), 46.5% females. The most prevalent primary diagnoses, as listed by the attending physician, were myocardial infarction (64 patients, 44.7%), stroke (16 patients, 11.2%) and heart failure (8 patients, 5.6%). Levels of PC (expressed as percentage of activity) are significantly lower in patients with levels of NT-proBNP superior to 2000 pg/ml (compatible with decompensated heart failure): average level 82.2 vs. 103.6 ng/ml in other patients, P<0.001, 95%CI of the difference: 11.9 to 30.9. Results of transthoracic echocardiography are available for 58 patients. Patients with PC levels in the lowest quartile have a significantly lower left ventricle systolic shortening fraction (P=0.011, 95%CI of the difference: -14.2 to -1.2). Receiver-operator characteristic curve for PC and heart failure has an area under the curve of 0.73.



Summary / Conclusion: PC levels are decreased in cases of severe systolic dysfunction. Although limited by sample size and missing data, these results support that PC may have a role in the pathogenesis of heart failure, concerning specifically episodes of exacerbation. Further studies are needed to confirm this novel hypothesis, as well as the possible role of PC as a biomarker.

B1961
THROMBOEMBOLISM PROPHYLAXIS AFTER CESAREAN SECTION (PRO-CS) TRIAL
F Algahtani[1*], h al dohami[2], s harbesh[2], a gader[1], A Aleem[1]
[1]Medicine, King Saud University Hospital, [2]Medicine, security, Riyadh, Saudi Arabia

Background: Background: Pregnancy and the post partum are well-established risk factors for venous thromboembolism, with higher risk if delivered via cesarean section. However, current evidence cannot justify deep vein thrombosis thromboprophylaxis on the basis of caesarian section alone in all women with different risk factors especially low risk, thus cannot be recommended for the time being. This study was conducted to determine the efficacy and safety of DVT prophylaxis in low risk women who delivered via cesarean section, and to identify the risk factors. The study regesisted in clinical trial, NCT01321788.
Aims: This study was conducted to determine the efficacy and safety of DVT prophylaxis in low risk women who delivered via cesarean section, and to identify the risk factors

Methods: Methods: Prospective, randomized study of adult female patients aged 18 – 35 years old presenting to OB-Gyn Department of Security Forces hospital, Riyadh Saudi Arabia who delivered via cesarean section were included in the study. Subjects were randomized into two groups; a) Drug group – received Tinzaparin 4500 IU subcutaneously once daily 12 - 24 hours after cesarean operation and, b) placebo group – received once daily 12 – 24 hours after cesarean operation for tow weeks. Both groups received mechanical prophylaxis using graduated compression stockings. Patient's demographics, physical data, obstetrical history, medical histories for thrombosis, presence or absence of clinical signs and symptoms of deep vein thrombosis and co-morbidities were all noted. Laboratory tests were done to all patients. Patients were observed within one week of hospital stay for signs and symptoms of DVT, minor and major bleeding events. After discharge patients followed-up after two weeks, at 6th week, at 3rd month and 6 months interval thereafter for one year.
Results: Results: A total of 200 patients (mean age: 28.6 years) consented for the study. The demographic data was similar to both groups. There were only one incidences of deep vein thrombosis in the 200 placebo group in comparison to 100 tinzaparin study group . There has been no record of death after 1 year of follow-up.
Summary / Conclusion: Conclusion: Our study showed the low risk caesarian section are not at risk of developing DVT as will no benefits of LMWH confirm no safety and efficacy of thromboprophylaxis using LMWH.

B1962

THROMBELASTOMETRY IN DUAL ANTIPLATELET TREATMENT IN PATIENTS WITH ACUTE CORONARY SYNDROME

L Duraj[1*], M Samoš[2], M Fedor[2], I Škorňová[2], J Staško[2], F Kovář[2], P Kubisz[2]
[1]Clinic Haematology and Transfusiology, [2]Jessenius Faculty of Medicine, Comenius University Martin, Martin, Slovakia

Background: Dual antiplatelet therapy (acetylsalicylic acid (ASA) and thienopyridins) has an important role in the management of patients with acute coronary syndrome (ACS) undergoing coronary intervention. However, there can be a high individual variability in response to antiplatelet therapy.
Aims: We initiated this study to investigate the utility of thrombelastometry in assessing the response to dual antiplatelet treatment in patients presenting with acute coronary syndromes (ACS) and to compare these results with established monitoring techniques.
Methods: Our study included 20 patients with ACS (13 men, 7 women, mean age 67.6 years) who received a loading dose of ASA (400 mg, n=20) and clopidogrel (600 mg, n = 15) or prasugrel (60 mg, n = 5). The control group consisted of 21 healthy blood donors (17 men, 4 women, mean age 50.1 years). The first sampling was conducted to monitor the loading dose of antiplatelet drugs prior to the implementation of selective coronarography. The second sampling served to monitor the efficacy of antiplatelet therapy in maintenance doses. As laboratory methods served optical agregometry and rotation thromboelastometry (ROTEM).
Results: Optical aggregometry showed a significant decrease in platelet aggregation between the first and second sampling after stimulation by arachidonic acid (33.2% vs. 21.1%, controls 74.6%) as well as by adenosine diphosphate (51.4% vs. 37, 1%, controls 72.7%). There was found a significant decrease in aggregation for the antiplatelet combination clopidogrel-ASA (57.3% vs. 45.1%, P=0.05) and even more significant decrease was seen for combination prasugrel-ASA (35.0% vs. 17.5% p <0.001). The standard parameters of ROTEM (CT, MCF) didn´t record significant results.
Summary / Conclusion: In our study the treatment with prasugrel was more effective than clopidogrel in patients with ACS as measured by optical aggregometry. Conversely, standard parameters of ROTEM do not seem to be sufficiently sensitive for monitoring the antiplatelet therapy. The role of ROTEM in this field requires further studies.

B1963

CONTRIBUTORY RISK FACTORS FOR DEVELOPMENT OF THROMBOSIS IN CHILDREN WITH NEPHROTIC SYNDROME

B Tavil[1*], S Aytac[2], F Kara[3], S Unal[2], M Cetin[1], R Topaloglu[3], F Gumruk[2]
[1]Pediatric Hematology/BMT Unit, [2]Pediatric Hematology Unit, [3]Pediatric Nephrology Unit, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Diagnosis and treatment of thrombosis is important in the management of children with nephrotic syndrome (NS).
Aims: The aim of this study was to evaluate the prevalence of thrombosis and contributory risk factors for development of thrombosis in children with NS.
Methods: Nephrotic syndrome registry data was retrospectively evaluated since July 2008 in Hacettepe University. Among 187 children with the diagnosis of NS (80 girls and 107 boys; mean age 12.4±5.5 years) followed up in Hacettepe University Faculty of Medicine, Pediatric Nephrology Unit; 17 children (16 boys and 1 girl) with the mean age of 11.6±6.7 years (1.3-24.0) identified as having thromboembolic complications. All 17 children with NS and thrombosis screened for laboratory risk factors for thrombosis (protein C, S, and antithrombin III, homocystein, lipoprotein, triglyceride and cholesterol levels, antiphospholipid antibodies (APA), factor V Leiden, prothrombin, MTHFR 677 and 1298 mutations, plasminogen activator inhibitor (PAI) polymorphisms, factors II, V, VII, VIII, IX, XI, and XII levels). The diagnosis was confirmed by cranial magnetic resonance imaging (MRI), doppler ultrasonography (USG), and echocardiography.
Results: The mean age of the 17 children was 4.5±3.2 years (0.08-11.0) at the time of NS diagnosis and that was 7.1±4.9 years (0.25-14.0) at the time of thrombosis. Among 17 children with thrombosis; 4 had catheter related thrombosis in jugular veins, 2 had cerebral infarct, 2 had portal venous thrombosis, 2 had intracardiac (right ventricle and right atrium; respectively) thrombosis, 3 had sagittal sinus thrombosis, 1 had cerebral infarct and intracardiac thrombosis at tricuspid valve and patent ductus arteriosus, 1 had left sigmoid and transverse sinuses thrombosis, 1 had superficial right femoral vein thrombosis, and 1 had cephalic vein thrombosis. Inherited risk factors for thrombosis were identified in 16 (94.1%) children. High factor VIII levels was detected in 11/17, high factor V levels in 4/17, decreased protein C level in 3/17, decreased protein S level in 2/17, antithrombin III deficiency in 5/17, high homocystein level in 4/17, high lipoprotein a level in 4/17, antiphospholipid antibodies in 1/17, anticardiolipin antibodies in 2/17, factor V Leiden heterozygote mutation in 2/16, MTHFR 677 heterozygote mutation in 6/16, MTHFR 677 homozygote mutation in 1/16, MTHFR 1298 heterozygote mutation in 3/13, MTHFR 1298 homozygote mutation in 1/13, PAI (4G/5G) polymorphism in 2/13, and PAI (4G/4G) polymorphism in 1/13 child. Two children had1, seven children had2, three children had3, and four children had 4 inherited risk factors for thrombosis. Furthermore; 4 children had central venous catheters, 2 had infection, and 1 had rejection episode of transplanted kidney as clinical risk factors for thrombosis. Most of the children (n:13, 76.4%) treated with only low molecular weight heparin (LMWH). Thrombectomy was performed for 2 children. The duration of anticoagulation therapy was 6 months for most of the children (n:13, 76.4%). Only 1 child received 12 months therapy and other 3 children received 3 months therapy. Twelve children (70.5%) had complete recovery from thrombosis, whereas 3 had partial recovery with sequela and 2 had died due to sepsis and multiple organ dysfunction syndrome and other systemic diseases except for thrombosis.
Summary / Conclusion: It should be kept in mind that children with NS and additional inherited risk factors should be followed up carefully for development of thrombosis. The early diagnosis and appropriate intervention can improve outcomes, reduce mortality and morbidity significantly.

B1964

FIBRINOGEN GENETIC VARIABILITY AND PROTHROMBOTIC PROFILE IN PATIENTS WITH HYPERTENSION

Z Pallantza[1*], D Tousoulis[2], M Kozanitou[3], A Varsamis[3], N Papageorgiou[2], M Liosi[3], C Tassos[3], K Toutouzas[2], C Stefanadis[2]
[1]Haematology Department, Hippokration Hospital, Athens, Greece, ATHENS, [2]1st Cardiology Unit, [3]Haematology Department, Hippokration Hospital, Athens, Greece

Background: The G455A fibrinogen polymorphism is associated with the risk of coronary artery disease. However, it remains unknown whether it affects the prothrombotic profile of patients with hypertension (HT). We aimed to examine the impact of this polymorphism on fibrinogen, D-dimers, factor V (fV) and factor X (fX) levels in hypertensive patients.
Aims: Fibrinogen Genetic Variability And Prothrombotic Profile In Patients With Hypertension
Methods: The study population consisted of 457 HT and 224 non HT. The G455A polymorphism was determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique, while circulating levels of fibrinogen were measured by the von Clauss method. D-dimers levels, fV and fX levels were measured by standard coagulometry techniques.
Results: Genotype distribution for non HT and HT was GG: 50.9%, GA: 41.8%, AA: 9.7% and GG: 51.5%, GA: 37.6%, AA: 10.9% respectively. There was no significant difference in fibrinogen levels (mg/dl) between 455AA homozygotes and 455G allele carriers in non HT patients (448.3±34.6 vs 395.4±9.9, P=NS). Importantly, 455AA genotype presented with much more elevated levels of fibrinogen compared to the GG+GA in HT patients (535.4±25.3 vs 414.2±8.0, P<0.001). Moreover, HT 455AA homozygotes had significantly increased D-dimers levels (μg/l) compared to 455G allele carriers (640.3±83.6 vs 485.5±27.2, P<0.05). No difference was observed for non HT regarding D-dimers between the 455AA genotype and GG+GA (477.6±74. vs 450.8±40.7, P=NS). Interestingly, 455AA genotype presented with higher fV(%) and fX(%) levels compared to GG+GA in HT patients (133.6±5.8 vs 117.8±3.3, P<0.05, for fV) and (101.9±4.6 vs 92.2±2.4, P<0.05, for fX). However, no difference was observed in fV and fX levels between 455AA and GG+GA in non HT (105.8±11.6 vs 118.7±4.4, P=NS for fV) and (95.8±8.0 vs 119.4±29.1, P=NS for fX).
Summary / Conclusion: The G455A fibrinogen genetic polymorphism has a remarkable impact on prothrombotic profile of patients with hypertension, by affecting fibrinogen, D-dimers, factor V and factor X levels. These findings provide evidence that this polymorphism modifies further the atherosclerotic effects of hypertension via alterations in the coagulation cascade.

B1965

IDIOPATHIC PURPURA FULMINANS, DIFFERENTIAL DIAGNOSIS OF CUTANEOUS THROMBOSIS IN CHILDHOOD, ANTITHROMBOTIC THERAPY AND MONITORING

I Murillo-Flórez[1*], I Martíez-Martínez[2], M Andrade-Campos[1], J Quintero-Gutierrez[1], N Fernandez-Mosteirin[1], C Salvador-Osuna[1], Jl de la Calle[2], F Lucía[1], M Torres[1], D Rubio[1]
[1]Department of Hematology, Miguel Servet University Hospital, Zaragoza, [2]Department of Hematology and Medical Oncology, Regional Blood Donation Center - Morales Messeger General Universitary Hospital, Murcia, Spain

Background: Purpura fulminans (PF) is a thrombotic skin disorder, usually caused by a deficiency of Protein C or S-mediated autoimmune mechanism, characterized histologically by extensive venous thrombosis of the dermis with hemorrhagic infarction of adjacent tissues. There are three clinical situations described: neonatal PF, infectious PF, and idiopathic PF. Differential diagnosis must be done with hypo/dysfibrinogenemia and disseminated intravascular coagulation (DIC).
Aims: We describe a case of a patient who had idiopathic PF; diagnosis, treatment and monitoring.
Methods: Case report
Results: 2 year old Moroccan male patient with no medical history, admitted by fever 48 hours of evolution associated with rejection of the motion and two lower extremity purpura. After admission rapid progression of lesions coalesce in 6 hours, with a central area and very painful ischemic, prothrombin activity noticeable decrease to 16.3%, establishing initial treatment with vitamin K and antibiotics. Because clinical suspicion of coagulopathy, coagulation test were extended revealing normal antithrombin (85%), fibrinogen (Claus von: 0.2 g/L), and protein C (121%) levels. The ethanol test was negative, prothrombotic polymorphisms (FV Leiden and prothrombin G20210A) were absent, and a weak positive lupus anticoagulant was detected. As expected, D-dimer levels were high (32,550 ug/dL). Relevantly, severely reduced protein S (4%) determined by *functional assay Protein S HemosIL TM*. A protein S inhibitor is suspected because after mixing with normal plasma this parameter was not corrected completly. Parents' protein S levels were normal. Cultures pharyngeal, blood, urine and skin negative and seronegative (HAV, HBV, HCV, mycoplasma, Varicella - zoster IgG and IgM, CMV, EBV and parvovirus B19). Skin biopsy: thrombotic vasculopathy compatible with PF, fibrinoid thrombosis in practically all and venular capillaries of the dermis and adipose tissue, hematic extravasation between dermal collagen bundles.
After diagnostic confirmation of PF anticoagulation with enoxaparin 1.5 mg/kg/12 hours was started performing titration by determining levels of anti-Factor Xa (therapeutic levels from 0.5 to 1.0 IU/mL) and fresh frozen plasma therapy, thus obtained a progressive increase in serum levels of protein S and clinical improvement.
The patient fully recovered without sequelae, and after 3 months anticoagulant therapy was discontinued. We highlight a relevant decrease of protein S levels during a new infectious event, but because the absence of clinical symptoms, no treatment was required.
Surface Plasmon Resonance on protein S-CM5 chips, revealed no anti-protein S antibodies in patient's plasma at any infectious event. Moreover, western blot of plasma protein S revealed normal total protein S levels of similar size than in controls. Finally, molecular analysis of *PROS1* gene revealed no significant mutation.
Summary / Conclusion: 1) Despite its low incidence, the PF is an entity to be considered in the differential diagnosis of cutaneous thrombosis in childhood, 2) In this framework, it is necessary to carry out early histological analysis to find evidences sustaining a definitive diagnosis. 3) Anticoagulant therapy should be initiated at an early stage to prevent damage; 4) In addition to anti-protein S antibodies; other factors triggered by infections may interfere with the anticoagulant activity of this protein C cofactor. Further studies are required to identify this factor in this patient.

B1966

MONITORING OF LOW-MOLECULAR-WEIGHT HEPARIN IN HIGH RISK PREGNANCY

I Murillo[1*], J Quintero[1], I Parra[1], M Andrade[1], N Fernández-Mosteirín[1], E Colorado[1], C Coello[1], C Salvador-Osuna[1], M Torres[1], J Lucía[1], D Rubio-Félix[1]
[1]Hematología y Hemoterapia, Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: The molecular-weight Heparin (LMWH) is the preferred anticoagulant for the prevention and treatment of pregnant women with high risk of venous thromboembolism (VTE) and adverse pregnancy outcomes**.** Dosing of LMWH based on weight alone is standard for most non-pregnant patients, the concept of using a target antifactor Xa level for VTE prophylaxis during pregnancy remains controversial, with currently alternatives including: previously defined prophylactic dose, intermediate-dose or periodic monitoring of antifactor Xa activity.
Aims: To describe demographic and clinical characteristics, and to evaluate the dosing requirements and monitoring patterns when LMWH is used during pregnancy in our institution.
Methods: A retrospective, observational, cohort study of patients who were given prophylactic or therapeutic LMWH during pregnancy and who were monitored with antifactor Xa between January 2011 to February 2013. We analized demographic parameters, history of congenital or acquired thrombophilia, obstetric and/or VTE history, treatment monitoring and dose adjustment, complications and obstetric outcomes.
Results: Data were obtained on 46 pregnancies in 46 women. Median age 34 years (18-45). Table below shows observed LMWH parameters.
Trimester LMWH was started N (%)
First 33 (71.7%)
Second 12 (26.1%)
Third 1 (2.2%)

Starting dosis

Enoxaparin 40 mg/24 h 40 (86.9%)
Enoxaparin 60 mg/24 h 5 (18.9%)
Enoxaparin 60/12h 1 (2.2%)
Indications for LMWH prophylaxis/treatment
Adverse pregnancy outcomes 5 (10.9%)
Antiphospholipid syndrome 12 (26.1%)
Thrombophilia, no VTE 19 (41.3%)
History of VTE and thrombophilia 3 (6.5%)
History of VTE 5 (10.9%)
Current VTE 1 (2.2%)
A mean of 2.3 (ranges 1-16; median: 6) antifactor Xa levels were obtained for each patient. The mean antifactor Xa level was 0.343 UI/mL (range 0.07-0.87). 18 patients (39.1%) required dose changes (increasing dose) , 6 of them requires more than one dose change (both increase and decrease). Complications (embolic events and/or hemorraghe) were not observed. 1 patient (2.2%) under target antifactor Xa levels presented fetal death at 37 week due to eclampsia.
Summary / Conclusion: LMWH dose cheges throughout pregnancy according to antifactor Xa levels were common in our patients, similar to data refered in literature. Increase in the LMWH dosage requirements suggest that more frequent monitoring may be appropiate to achieve a predetermined target or antifactor Xa levels. Although dosing recommendations for LMWH in pregnancy are fairly well described, monitoring guidelines to attain acceptable anticoagulant safety and efficacy are still needed.

B1967

THROMBIN-LIKE AMIDASE ACTIVITY IN PLASMA REMAINS HIGH AFTER LUNG DISEASES EXACERBATIONS

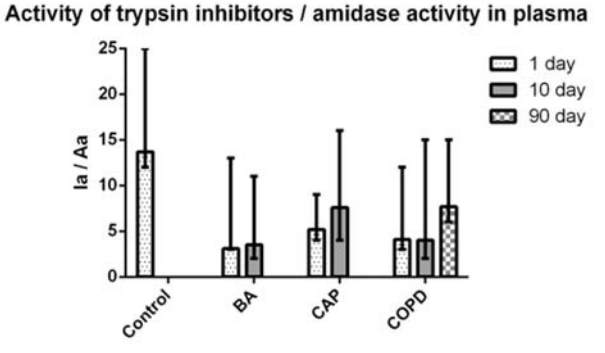
N Koretskaya[1*], G Tkachev[2], J Gaverova[1], T Vavilova[1]
[1]department of biochemistry, University / Research institute MSMSU named after A.I.Evdokimov, [2]Institute of Clinical Cardiology, Federal State Institution "Russian Cardiology Research and Production Complex" of the Ministry of Health of the Russian Federation, Moskow, Russian Federation

Background: It is known, patients with chronic obstructive pulmonary disease (COPD) are at an increased risk of venous thromboembolism. Courses of hypercoagulable state in this case are not clean. Protease imbalance plays key role in COPD pathogenesis and coagulation cascade is enzymatic cascade consist mainly of serine proteinases with trypsin-like activity. Besides thrombin, such proteinases, as kallikrein or trypsin can carry out factor XII activation. Serine and other proteases modify the properties of angiogenic growth factors and cytokines able to degrade of the endothelial and interstitial matrix. Theese proteases can cleavage of amino acid bond in BApNA (Na-benzoyl-L-arginine p-nitroanilide) and it is possible chromogenic assay of amidase activity.
Change of plasma thrombin-like amidase activity (Aa) can reflect system reaction on hypoxia or relate to systemic inflammation.
To analize whether any airflow limitation is a course of the imbalance between the procoagulant and anticoagulant pathways we analysed plasma samples of COPD, bronchial asthma (BA) and community-acquired pneumonia (CAP) patients.
Aims: To measure amidase activity and activity of serine protease inhibitors in plasma of patients with COPD, BA, CAP to estimate risk of thrombotic complications.
Methods: Informed agreement was received from all patients. There were two times to blood assay – the 1-st day (exacerbation) and 10-th day at a hospital. COPD patients visit us at 90-th day too. They received standart therapy in City clinical hospital No. 70 of Department of Healthcare of Moscow. A total of 15 patients (mean age 43±10) were on study. There were 7 COPD, 5 BA and 3 CAP patients. Control group include 10 subjects, age 40±11. Blood samples were collected in 4 ml tubes, 60 USP Units of Lithium Heparin, after processing plasma samples stored frozen. The ability of the plasma samples to catalyse the hydrolysis of BApNA is referred to as Aa. Simultaneously in microwell plate the activity of trypsin inhibitors in plasma (Ia) was measured using BApNA hydrolysis. In microwell plate in duplicate we added 50 µl of samples at a dilution of 1:25, 200 µl of a 1 mg/ml BApNA solution in 0,1 M tris-HCl buffer at pH 7.65, 50 µl and 50 µl buffer (Aa analysis) or 50 µl trypsin solution with activity 225 U/ml (Ia analysis). 1 U corresponds to the amount of enzyme which increases the absorbance at 410 nm by 0.001 per minute at pH 7.65. We read

absorbance of each microwell on a spectro-photometer using 410 nm as the primary wave length (620 nm as the reference wave length). The plate was incubated at 25°for 30 minutes on a microplate shaker set at 100 rpm. After that was the second absorbance reading using 410 (ref. 620) nm and the difference of absorbances (ΔOD) was found. We created a standard curve by plotting ΔOD for each standard on the ordinate against the standard trypsin activity (from 899 U/ml to 14 U/ml and 0 U/ml) on the abscissa. Calculated Aa was multiplied by the dilution factor. Ia was calculated using abscissa $\Delta OD_Z = (\Delta OD_{225} + \Delta OD_{Aa}) - \Delta OD_{Ia}$ to consider proteinase activity of the sample. We didn't use soybean trypsin inhibitor to this analysis because ratio Ia/Aa was evaluated to estimate proteinase imbalance.

Results: We examinated proteases and serpins activity in the presence of heparin that inhibition of thrombin by antithrombin was accelerated.

All COPD, BA, CAP samples showed a markedly increased Aa in comparison with conrol group. So lung inflammation and airflow limitation are the sufficient reasons to the changing plasma Aa activity within 10 days after exacerbation of lung disease. For example, it can be a consequence of kallikrein activation. We assumed that increasing of Ia testifies to reaction to Aa increasing. But Ia showed tendency to increase only in COPD group (Mann-Whitney's criterion, P=0,065). We next examined Ia/Aa ratio. Results of long-term follow-up study are presented in Figure. This ratio in 10 day BA and CAP groups and even in 90 day in COPD group didn't reach control value. Smoking status and other COPD risk factors were not analyzed and it is limitation of the study.



Summary / Conclusion: The current study demonstrates continuous proteinase imbalance in plasma of patients with lung diseases. It can be cause to pay attention to the procoagulant activity after CAP or exacerbations of chronic lung diseases.

B1968

STUDY OF CONSTITUTIONAL THROMBOTIC RISK FACTORS AND ACQUIRED RETINAL VEIN THROMBOSIS. EXPERIENCE A CENTER.

N Garcia[1*], J Suarez[1], J Fernandez[1], E Magro[1], M Callejas[1], M Rubio[1], E Flores[1], C Casco[1], N Espinazo[1], S Marcellini[1], M Cortti[1], C Burgaleta[1]
[1]Hematologia, Hospital Universitario Principe de Asturias, Alcala de Henares, Spain

Background: Retinal vein thrombosis (RVT) has been associated with vascular disease and the main risk factors associated are hypertension (HT), diabetes mellitus (DM) and atherosclerosis. Thrombophilia caused by hemostasis disorders is a well known cause of the increase of risk for suffering thrombotic events in your people as a consequence its role in the RVT is being investigated.

Aims: We conducted a retrospective study ofthrombophilia abnormalities in patients with RVT in order to see the association of molecular pathology or plasma associated thrombotic risk in this group of patients.

Methods: We analyzed a database of our Service with 818 patients during 8 years. Adquired risk factors were identified as: HT, obesity, DM, smoking, dyslipidemia, family history of thrombosis (FT), oral contraceptives, and immobility; and presence of possible alterations that cause thrombophilia as: mutation for Factor V Leiden (FVL), G20210A prothrombin gene (P20210A), and plasma deficits such as protein S deficiency, protein deficiency C, resistance to activated protein C (APCR) and lupus anticoagulant.

Results: We identified 26 patients with TVR, 16 women and 10 men, with a mean age of 43.46 years (range 13-73). 34% patients did not collect any risk factors in the medical record. Of the remaining patients, 53% had one risk factor: 4 smoking, 2 FT, 2 HT, 1 obesity; and 35.3% had two or more (FT with smoking, obesity and DM). Regarding thrombophilia studies findings were : - Heterozygous for FVL mutation in 7.7% (2 patients), one patient had a family history of thrombosis. - Heterozygous mutation for P20210A by 3.8% (1 patient), and obesity asociated. - In the analysis of the deficits of plasma factors, the 88.46% of the results were normal, in other cases, one patient had protein S deficiency and one cases a lupus anticoagulant, not associated with other risk factors.

Summary / Conclusion: Our results reveal an incidence in population diagnosed of RVT similar to the normal population and confirm the association of RVT with age ≤ 45 years, family history of thrombosis or cardiovascular risk factors. However, it seems necessary to conduct prospectives studies in patients with RVT to determine the role of hereditary and acquired thrombophilia in these patients.

B1969

EVALUATION OF HEALTH LITERACY AND ADHERENCE TO THROMBOPROPHYLAXIS IN PREGNANCY

C Noone[1*], R O'Shea[2], S O'Shea[1], L Sahm[3]
[1]Haematology, Cork University Hospital, cork, [2]School of Medicine, [3]School of Pharmacy, University College Cork, Cork, Ireland

Background: A report carried out in 2002 by the National Adult Literacy Agency stated there is a critical need for additional Irish research into health literacy. There has remained a paucity of work in this area. Thromboembolic disease remains a leading cause of morbidity and mortality in pregnancy and puerperium as evidenced by statistics gathered such as in the Centre for Maternal and Child Enquiries (CMACE) report 2010.

Aims: The primary goal of this research was to analyse the relationship between health literacy and adherence rates to LMWH (low molecular weight heparin) thromboprophylaxis in pregnancy.

Methods: The Rapid Estimate of Adult Literacy in Medicine (REALM) was used to measure health literacy in pregnant patients on LMWH thromboprophyalxis. A second questionnaire entitled the Beliefs in Medicines Questionnaire (BMQ) was also administered to assess patient beliefs, concerns and knowledge surrounding their medication. Both of these are standardised tools widely used in research. With patient consent, their pharmacies were contacted and information gathered regarding their prescription collection. This information was used as a surrogate indicator of adherence.

Results: Of the 24 patients studied, 25% were found to have inadequate health literacy. Of the thirteen patients for whom information was available, eight were found to have incomplete adherence. The BMQ showed that in general participants believed that their medication was necessary, and their concerns did not outweigh theses beliefs. Patient knowledge surrounding their medication was relatively good. Analysis was carried out to look for possible associations between inadequate health literacy and adherence, along with patient beliefs, concerns and knowledge.

Summary / Conclusion: Results suggest that the level of inadequate health literacy may even be higher than expected. Adherence to LMWH regime is suboptimal in the majority of cases. We postulate that there is a significant relationship between health literacy levels and adherence. This is a pilot study in one centre with a small sample size. Indications are that further studies would be useful and that implementation of services such as focused information leaflets and a text messaging reminder service may result in higher rates of adherence to LMWH in these patients.

B1970

LOCAL EXPERIENCE IN THE DIAGNOSIS AND TREATMENT OF DEEP PELVIC SEPTIC THROMBOPHLEBITIS

J Coll[1*], M Paloma[1], A Redondo[1], J Arguiñano[1], A Perez[2], T Zudaire[1], M Hamdi[3], C Larrañaga[2], M Mateos[1], M Ardaiz[1], Y Burguete[1], M Perez[1], M Goñi[1], I Ezpeleta[1]
[1]Hematology B, [2]Gynecology, [3]Complejo Hospitalario de Navarra, Pamplona, Spain

Background: There are two types of septic pelvic thrombophlebitis (SPT): ovarian vein thrombophlebitis (OVT) and deep septic pelvic thrombophlebitis (DSPT). Patients with DSPT usually present within a few days after delivery or surgery with unlocalized fever that persists despite antibiotics, in the absence of radiographic evidence of thrombosis.

A variety of factors (Cesarean section, Pregnancy, Pelvic infection eg, postpartum endometritis, pelvic inflammatory disease, Induced abortion, Pelvic surgery, Uterine fibroids, Underlying malignancy. Hormonal stimulation) confer increased risk for SPT.

The diagnosis of SPT can be challenging and is often a diagnosis of exclusion. In the absence of definitive diagnostic findings, many clinicians presume SPT in patients with appropriate risk factors and persistent fever despite antibiotic therapy who defervesce within 48 hours of empiric systemic anticoagulation.

There have been no studies to determine the optimal duration of anticoagulation therapy in SPT. In the absence of documented thromboses or underlying hypercoagulable state, most clinicians favor discontinuing anticoagulation following resolution of fever for at least 48 hours.

Aims: To review the experience in our center regard concerning patients with suspected DSPT.

Methods: Medical records from patients with suspected DSPT in the last year were reviewed to obtain relevant data.

Results: We present three cases in which DSPT was suspected. In all them fever was unresponsive to antibiotics and appeared in the immediate postpartum period associated with increased levels of acute phase reactants. Blood

cultures showed no bacterial growth in all three cases and abdominal CT scans were normal except where noted. Patient #1: a 29 year old woman complained of fever 24h after a vaginal delivery complicated with fetal distress. Once DSPT was suspected sodium heparin was started at therapeutic doses. Fever disappeared soon after heparin therapy. Patient #2: a 34 year old woman complained of abdominal pain and febricula 9 days after an uncomplicated vaginal delivery. On clinical suspicion of DSPT, LMWH was started with good clinical response. A study of thrombophilia performed afterwards detected a lupus anticoagulant as well moderately increased IgM anticardiolipin antibodies. Low dose AAS was administered onwards. A subsequent pregnancy went uncomplicated under antithrombotic prophylaxis. Patient #3: a 39 year old had undergone cesarean section due to premature rupture of membranes; fever started seven days after the procedure. In abdominal CT scan only a previously known leiomyoma was noticed. LMWH was started due to suspicion of DSPT but in this instance anticoagulation did not solve the clinical problem. CT scan was repeated showing red degeneration of myoma and thus this patient was not considered to have DSPT.

Summary / Conclusion: Although SPT is usually diagnosed by obstetricians, this entity must be known by hematologists, since antithrombotic therapy leads to diagnosis as well as clinical resolution.

B1971

THROMBOPHILIC STATUS IN PATIENTS WITH EXTRA-HEPATIC PORTAL HYPERTENSION

E Sysoeva[1*], E Jakovleva[1], I Fevraleva[1], A Sudarikov[1], S Vasiljev[1], E Kitsenko[2], E Lukina[1]

[1]Hematogy Research Center, [2]National Research Center of Surgery, Moscow, Russian Federation

Background: The extra-hepatic portal hypertension due to portal thrombosis was belived to be a rare condition (about 10-20% of all cases of portal hypertension). Chronic myeloproliferative disorders (MPD) were considered to be the main cause of thrombotic complications in adult patients (pts), and thrombophilia - to be a predisposing factor.

Aims: To compare the rate of antiphospholipid syndrome and mutations causing predisposition to thrombophilia in patients with portal vein thrombosis (PVT) associated with chronic myeloproliferative disorders (MPD) and without MPD.

Methods: 183 patients (77 males, 106 females, Median age – 41 years) with portal thrombosis confirmed by Doppler sonography were included into this study. The period from the first manifestation of portal hypertension (splenomegaly, gastro-esophageal varices, variceal bleedings) to examination in our Center varied from 6 to 480 months (Median 60 months). Only 73 (40%) patients had bone marrow morphology of chronic myeloproliferative disorders(MPD+ group) The other patients had normal pattern of bone marrow, normal blood picture or cytopenias (MPD- group). The both groups were comparable by age, sex and duration of disease.

All patients were screened for heritable thrombophilic gene mutations (G1691A Factor V Leiden, G20210A prothrombin, C677T MTHFR mutations, polymorphism of PAI-1gene (4G/5G, 4G/4G) and lupus anticoagulant with antiphospholipid antibodies (APL-Abs).

Results: Homozygous C677T MTHFR mutation was found in 1% of pts in MPD+group and in 9%>in MPD-group, heterozygous factor V Leiden mutation – in 13,5% and 13% pts, respectively, heterozygous G20210A prothrombin gene mutation – in 3% pts in MPD+group and 8% in MPD-group. 4G/4G PAI-1 polymorphism was revealed – in 11% and 13%, 4G/5G – in 30% in MPD+group, in 19% in MPD-group. The combination of 3 and more thrombophilic gene mutations was found in 35% patients. Lupus Anticoagulant was found in 62% MPD+ pts, and in 55% pts without MPD. The antiphospholipid antibodies (APL-Abs) to membranes phospholipids and β2-glycoprotein I were studied in 37 pts. APL-Abs were found in 22 pts LA+ and in 15 pts LA-, most frequently in pts with cytopenias. Statistically significant difference in MPD+ group and patients without MPD was not revealed.

Summary / Conclusion: The use of molecular diagnostic methods reveals the high frequency of mutations causing predisposition to thrombophilia in patients with portal vein thrombosis (PVT) associated with chronic myeloproliferative disorders and without MPD. Antiphospholipid syndrome was diagnosed in 58% patients with MPD and 65%> without MPD. Patients with portal thrombosis due to hereditary and acquired thrombophilia have a high risk of recurrence, and so prescribing anticoagulant/antiaggregant therapy in patients without MPD should be necessary.

B1972

THROMBOPHILIC RISK FACTORS AND THE EFFICIENCY OF PROPHYLACTIC ANTICOAGULATION THERAPY IN CHILDREN WHO UNDERWENT RENAL TRANSPLANTATION

B Tavil[1*], S Aytac[1], B Gulhan[2], F Aki[3], S Unal[1], M Cetin[1], N Besbas[2], F Gumruk[1]

[1]Pediatric Hematology/BMT Unit, [2]Pediatric Nephrology Unit, [3]Department of Urology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: In pediatric renal transplantation, graft loss due to thrombosis is a major problem. Although thrombosis has been identified as the most important risk factor for early graft loss, there is limited data about the effect of prophylactic anticoagulation therapy on graft survival, rejection episodes, and graft function in childhood.

Aims: The aim of this study is to evaluate inherited and acquired risk factors for thrombosis and the efficiency of anticoagulation treatment protocol used in our center for renal transplant recipients.

Methods: Twenty-two children (10 boys and 12 girls) with the mean age of 14.2±3.7 years (6.8-18.9) were underwent renal transplantation in Hacettepe University Faculty of Medicine between 2009 and 2012. All 22 children screened for inherited and acquired risk factors for thrombosis (protein C, S, and antithrombin III, homocystein, lipoprotein, triglyceride and cholesterol levels, antiphospholipid antibodies (APA), factor V Leiden, prothrombin, MTHFR 677 and 1298 mutations, plasminogen activator inhibitor (PAI) polymorphisms, factors II, V, VII, VIII, IX, XI, and XII levels) to extend prophylactic anticoagulation therapy in those with an increased risk for thrombosis. Prophylactic anticoagulation therapy protocol using in our center include intravenous heparin administration at a dosage of 10 U/kg/h for approximately 2 weeks start after the procedure and continue during hospitalization and switch to low-molecular-weight heparin (LMWH) at a dosage of 1 mg/kg after discharged from the hospital for at least 3 months. LMWH prophylaxis has extended to 6 months for children with thrombophilic risk factors. The effect of this protocol on incidence of acute rejection episodes has also been analyzed.

Results: No thrombosis occurred in early post-transplant period in these 22 children who underwent renal transplantation. Thrombophilic risk factors were identified in 17/22 (77.2%) of these children. High factor VIII levels was detected in 9/16, decreased protein C level in 2/14, decreased antithrombin III level in 1/14, high homocystein levels in 4/14, high lipoprotein a level in 4/14, high triglyceride levels in 6/22, high cholesterol levels in 2/22, factor V Leiden heterozygote mutation in 1/18, MTHFR 677 homozygote mutation in 3/18, MTHFR 1298 homozygote mutation in 2/7, PAI 4G/5G polymorphism in 2/7, and PAI 4G/4G polymorphism in 2/7 children. The mean follow up duration for these children who underwent renal transplantation was 24.6±12.5 months (3-48). Acute rejection episode and graft loss was not observed in any children during this follow up period. Macroscopic hematuria was observed in one patient after 10 days of transplantation and heparin was decreased to the dosage of 5 unit/kg/h until discharge from the hospital. Other two patients had thrombosis in their arteriovenous fistula 2 months and 1 year after transplantation. These patients received LMWH treatment for an additional 6-month for thrombosis.

Summary / Conclusion: Children with thrombophilic risk factors should be identified before renal transplantation. Prophylactic heparin at a dosage of 10 U/kg/h approximately 2 weeks during hospitalization and LMWH therapy at a dosage of 1 mg/kg at least 3 months should be administered for all renal transplant recipients, whereas LMWH treatment should be extended for children with identified thrombophilic risk factors. This prophylactic anticoagulation therapy will decrease the risk of thrombosis in renal transplant recipients.

B1973

ANTITHROMBOTIC PREVENTION IN NEUROSURGERY

F Sasvary[1*], R Rusnak[2], M Sproch[2], F Sasvary[3], P Bielik[4], L Marsik[5]

[1]Hematology, Hospitale, Sahy, [2]Neurosurgery, Central Military Hospital, Ruzomberok, [3]Medical School, Comenius University, Bratislava, [4]Hospital, Lucenec, [5]University Hospital, Bratislava, Slovakia

Background: Venous thromboembolism (VTE) is a serious but preventable disease with possible acute and chronic complications. VTE is one of the leading causes of deaths in Europe. VTE leads to hospitalizations or prolongation of hospitalizations. Quality of life of the VTE patients is worth mainly due to chronic complications such as postthrombophlebitic syndrome and pulmonary hypertension.

Aims: To describe the necessity and benefits of risk stratification and perioperative antithrombotic prophylaxis in neurosurgery patients.

Methods: All 54 patients operated at Neurosurgery department in month January 2013 are evalulated ex post. The group of patients consisted of 17 male and 37 female, aged 19-81 years, average age 53 years. The operations performed were: intracranial tumor extirpation (2 cases), hemilaminectomia or laminectomia (7), dorsal lumbal somatic fusion (23), anterior lumbal somatic fusion (2), anterior cervical somatic fusion (5), baloon kyphoplastic (5), nerve decompression (9). Patients´ risk status was evaluated for intermediate or high risk. No low risk patient was identified because of recent neurosurgery intervention. Into the high risk group were considered patients with oncologic diagnose, long-term immobilization and previous VTE episode. No inherited trombophylia markers were tested. Prophylactic low-molecular-weight heparin was considered for all patients. In those at intermediate risk lower dose fo the time of hospitalization (maximum up to 14 days) and in those at high risk high dose for the hospitalization periode followed by lower dose for up to 6 weeks.

Results: No VTE event has been observed in the reported group of patients during the hospitalization periode and in the close follow up (4-8 weeks).

No bleeding or other complications were reported in the observed group of patients.

Summary / Conclusion: Authors describe their philosophy in VTE risk evaluation and prophylaxis, based on most recent national and international guide-

lines. The right risk stratification of patients, selection of the proper method, timing, dosage and duration of antithrombotic prophylaxis can minimize the occurence of VTE events in neurosurgery patients.

B1974

DEEP VENOUS THROMBOSIS SECONDARY TO MAY-THURNER SYNDROME: A CASE REPORT

K Acosta[1*], M Ganzon[2], E Esposo[1], R Carino[3]
[1]Department of Medicine, [2]Cardiovascular Medicine, [3]Cardiovascular Surgery, St. Luke's Medical Center, Quezon City, Philippines

Background: We report a case of a 31 year-old female with pain and swelling of the left lower extremity as the initial presentation of acute deep venous thrombosis (DVT) secondary to May-Thurner Syndrome, a rare case with unknown overall prevalence, that is due to an anatomical anomaly where the left common iliac vein is compressed between the right common iliac artery and the lumbar vertebrae. She had a two-day history of pain and swelling of the left lower extremity, warmth and difficulty in ambulation. On examination, the left lower extremity had purplish discoloration, varicosities, grade three pitting edema, warmth, tenderness from the medial part of the thigh to the calf and limitation of movement. Its circumference was greater than the right lower extremity by 10 cm. Pulses, reflexes and sensory were intact with no inguinal lymphadenopathy.
Aims: May-Thurner Syndrome is often unrecognized due to the prevalence of other more easily recognized risk factors for DVT. A more invasive study, such as venography is necessary to correctly identify and manage this anomaly to prevent debilitating sequelae.
Methods: Duplex scan of lower extremities showed acute DVT partially occluding the left common iliac and distal external iliac veins, proximal to distal femoral vein, and popliteal vein. CBC, PT and PTT were unremarkable. She had elevated Factor VIII levels at 201%, and low protein S level at 19%, prompting investigation for thrombophilia which yielded negative findings. On further workup, venography revealed stenotic, anomalous vein originating from the left iliac vein, obstruction from the left common iliac vein to mid-proximal femoral vein and collaterals in the common femoral vein to the left common iliac vein. Workup for anti-phospholipid antibody syndrome, systemic lupus erythematosus, malignancy, lymphedema, and infection were negative.
Results: Management was aimed at clearing the thrombus present and correcting the underlying compression of the left iliac vein. Methods of clearing the thrombus include anticoagulation and thromboreductive strategies. Initial anticoagulation with Enoxaparin was overlapped with Warfarin for long-term anticoagulation. She also underwent catheter-directed thrombolysis with Alteplase, and ilio-femoral, popliteal, and posterior tibial thrombectomy after IVC filter insertion; however, treatment failed as evidenced by persistence of pain and swelling on the left lower extremity and occurrence of pulmonary embolism. Subsequently, femoro-femoral vein bypass using cross-over great saphenous vein and arteriovenous fistula creation to the femoral venous bypass graft were successfully performed, followed by chronic anticoagulation with Rivaroxaban. Clinical improvement was noted with completely resolved pain and swelling on the left lower extremity after 6 months. Follow-up duplex scan of lower extremities also showed marked improvement.
Summary / Conclusion: A comprehensive diagnostic approach is essential to accurately identify May-Thurner Syndrome as a cause of iliofemoral DVT, especially in a young female with unilateral pain and swelling of lower extremity. Long-term anticoagulation and thromboreductive strategies, while indicated, are not adequate to prevent long-term sequelae in this condition, and a more invasive therapeutic approach, surgery, is indicated.

B1975

WARFARIN-INDUCED BREAST NECROSIS ASSOCIATED WITH FV LEIDEN, PROTEIN S DEFICIENCY AND PROTHROMBIN G20210A MUTATION

M El-Ali[1*], T Theodoridis[1], A Karyda[1], V Christopoulou-Cokkinou[1]
[1]Hematology Laboratory, Evangelismos General Hospital, Athens, Greece

Background: Warfarin induced skin necrosis is a rare side effect of warfarin therapy. It occurs in only 0.01-0.1% of patients taking the drug and is frequently associated with low levels of protein C,S or FV Leiden mutation.
Aims: The investigation of a 28 year-old obese woman admitted for cholecystectomy. She had a history of deep vein thrombosis (DVT) during a pregnancy (4th month of gestation) and a subsequent still birth. Two days after the operation, oral anticoagulation was initiated without a preceding heparin administration. Six days after the onset of warfarin the patient complained for a strong pain in her right breast and on the next day in the left breast as well. Both breasts were painful, with a red color which quickly developed to a blue-purplish. A few days later a large necrosis was observed in the left breast and the patient underwent mastectomy.
Methods: Postoperative haematological investigation and thrombophilia profile waw ordered.
Results: INR: 3.9, D-dimers: 13.6 μg/ml, AT: 89%, protein C: 91%, protein S (total): 51%, pro C global FV. N.R.: 0.46, factor V Leiden: present (homozygous), prothrombin 20210A mutation: present (heterozygous).
Summary / Conclusion: The patient had multiple genetic factors predisposing to thrombotic events. It is worth noting that her mother who had low protein S levels, was heterozygous for FV Leiden and prothrombin variant 20210A, presented no thromboembolic events and had given birth to four children. Reinstitution of low dose warfarin therapy to our patient was successful, starting under simultaneous cover with LMWH.

B1976

THROMBOSIS PREDICTORS IN SAUDI PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A PRELIMINARY STUDY

F Algahtani[1*]
[1]Medicine, King Saud University Hospital, Riyadh, Saudi Arabia

Background: Recent studies report that inflammatory bowel disease (IBD) is associated with an increased risk of vascular complications. The most important of these complications are arterial and venous thromboembolism, which represent a significant cause of morbidity and mortality in IBD patients, yet there is no clear evidence who is at risk to develops thromboembolic event and what are the risk factors. The incidence of thromboembolism in IBD ranges between 1% and 7.7% in clinical studies. Many IBD patients with thromboembolic disorders either have active disease or have undergone recent major abdominal surgery. Most of the studies on thrombosis in the Saudi population were retrospective. The main purpose of this prospective study was to identify main thrombosis predictors in Saudi patients with IBD.
Aims: Recent studies report that inflammatory bowel disease (IBD) is associated with an increased risk of vascular complications. The most important of these complications are arterial and venous thromboembolism, which represent a significant cause of morbidity and mortality in IBD patients, yet there is no clear evidence who is at risk to develops thromboembolic event and what are the risk factors. The incidence of thromboembolism in IBD ranges between 1% and 7.7% in clinical studies. Many IBD patients with thromboembolic disorders either have active disease or have undergone recent major abdominal surgery. Most of the studies on thrombosis in the Saudi population were retrospective. The main purpose of this prospective study was to identify main thrombosis predictors in Saudi patients with IBD.
Methods: This was a prospective, cohort study conducted in tertiary care teaching hospital in Riyadh. Patients with IBD, were invited to participate in this study. Patient recruitment lasted over a year. Study patients had a definitive diagnosis of UC or CD that had been confirmed by radiological, endoscopic, and histological studies. Patients on any medication that might have caused platelet or coagulation abnormalities during the last eight (8) weeks before blood sampling, had Impaired renal or liver functions, had myeproliferative disorders, or diagnosed with cancer were excluded. None of the study participants had any previous thrombotic episode. Appropriate ethical approval was obtained. Baseline characteristics were summarized using descriptive statistics. Categorical variables were examined using the Pearson $\chi 2$ test or the Fisher's Exact test, as appropriate. The designated level of significance was .05.
Results: A total of 100 Saudi patients with IBD were followed up and included in the analysis, 51 were women. Average age was 32 years (min, max), 73 had Crohn's disease, and 27 had ulcerative colitis. No mortality was reported so far. Eight patients (8%) had at least one thrombotic event. Predictors of thrombosis in this sample were mainly family history of deep venous thrombosis (DVT), P=.072 and pulmonary embolism (PE), P=0.05.
Summary / Conclusion: The main predictor of thrombosis in this patient population was family history of Thromboembolic event.

B1977

LIPOPROTEIN(A) AND ISCHEMIC STROKE IN CHILDREN: A SINGLE CENTER EXPERIENCE IN SOUTH AMERICA

M Garanito[1*], J Carneiro[1], V Filho[1]
[1]Pediatric Hematology and Oncology, Instituto da Criança – Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background: Ischemic stroke is a rare and heterogeneous disease in childhood, with an incidence of approximately 5/100.000 individuals per year and has a significant impact on morbidity and mortality. Clinical presentation and risk factors are not the same as in adults and the most frequently reported risk factors are congenital heart malformations, acquired heart diseases, hemoglobinopathies, collagen vascular diseases, some rare inborn metabolic disorders, trauma, infection and thrombophilia.
Aims: The aim of this study was a retrospective analysis of inherited prothrombotic risk factors in pediatric patients with first ischemic stroke.
Methods: Data from all patients admitted in our service from 2008 to 2012 were identified. Heart diseases, hemolytic anemia, vasculitis, vasculopathies, structural anomalies of the cerebrovascular system and trauma were excluded. Elevated homocysteine, lipoprotein (a) [Lp(a)] and factor VIII; antithrombin, protein C and protein S deficiency; factor V Leiden; factor II G20210A and antiphospholipid antibodies were evaluated.
Results: Ten patients (five girls and five boys), younger than 18 years were

studied. The median age was6,07 years, ranging from 0,6 to 13 years. In seven patients (Table 1) were detected increased levels of Lp(a) [cut-off 30mg/dL, in at least two samples and dyslipidemia was excluded]; one patient had sinusitis associated and three had a family history of ischemic stroke. The clinical presentation was hemiparesis (4 patients) and convulsion (3 patients). One patient was treated with low molecular weight heparin for 6 months and six patients received aspirin in the acute treatment. All patients are using aspirin for secondary stroke prevention and until now no one had stroke recurrence. Two patients present neurological sequelae (hemiparesis and epilepsy).

Tabe 1: Patients characteristics

Patient	Age	Gender	Clinical presentation	Treatment	Lp(a) mg/dL patient	Lp(a) mg/dL parents	Infection	Family history	Sequelae
1	12y11m	F	Hemiparesis and convultion	Aspirin	47 / 41	mother 56 father 33	no	ischemic stoke father's family	no
2	7m	F	Convultion	Aspirin	200 / 91	father 83	no	ischemic stroke mother's family	no
3	5y1m	M	Convultion	Aspirin	163 /269	unknowm	sinusitis bilateral	unknowm	lost following
4	1y7m	F	Convultion	Aspirin	30 / 70	mother 37	no	no	hemiparesis
5	3y6m	M	Hemiparesis	Enoxaparin	90/128	mother 203	no	ischemic stroke mother's family heart attack father's family	no
6	5y1m	M	Hemiparesis	Aspirin	269/137	father 145	no	no	epilepsy
7	13y	M	Hemiparesis	Aspirin	70/78	mother 73	no	no	lost following

Aspirin 1-5mg/kg/d
Enoxaparin 1mg/kg/BD

Summary / Conclusion: Although the association between circulating levels of Lp(a) and stroke is well established in childhood and the measurement of Lp(a) should be included in screening programs in children suffering from arterial ischemic stroke, no uniform approach exists for the treatment and the recommendations in children are extrapolated from adult guidelines.
Further studies are needed to understand the underlying mechanisms involved and thereby improve primary and secondary prevention of childhood stroke.
In our service, we use aspirin as secondary prophylaxis.

B1978

THE INCIDENCE OF VENOUS THROMBOEMBOLISM IN UNSELECTED MYELOMA PATIENTS ATTENDING A TERTIARY REFERRAL CENTRE

M Crowley[1*], O Gilligan[1], S O' Shea[1]
[1]Haematology, Cork University Hospital, Cork, Ireland

Background: Multiple myeloma is a malignant disorder characterized by clonal proliferation of plasma cells. VTE is one of the leading causes of death in patients with cancer. Patients with haematological malignancies have the highest risk, adjusted for age and sex. Myeloma therapies such as thalidomide and lenalidomide (IMiDs) further increase the risk. There are few dedicated studies in the literature looking at the incidence of VTE in myeloma patients. Almost all published data is extrapolated from treatment studies where they look at the incidence of thrombotic side effects in highly selected populations. Myeloma is a disease of the elderly and in this population, co-morbidities are inherent. Therefore, looking at the rate of VTE in randomised controlled trials designed to evaluate treatment efficacy may not be generalisable.
Aims: To estimate the prevalence of VTE in a 'real world' myeloma population and to assess the risk factors associated with VTE.
Methods: The medical charts of patients with a diagnosis of myeloma attending a tertiary referral centre between Jan 2007 and Dec 2012 were retrospectively reviewed.
Results: 217 patients were identified. The average age was 65±12 years. 62% (n=134) were men. The median follow-up per patient was 35 months (Range 1-231 months).Myeloma subtypes included IgG 53%, IgA 24%, Light Chain 17%, Non secretory 4%, IgD 2% and IgM <1%. The ISS stage was known for 77% - 28% (49/168) were stage I, 49% (82/168) were stage II and 23% (39/168) were stage III. 66% (n=143) received 1-2 lines of therapy, 32% (n=69) received 3-4 and 2% (n=5) received >4. 69% (n=149) received IMiDs and 98%(n=146) of these were administered with either high dose steroids or chemotherapy. 7% had a second malignancy. 12% (n=27) had an episode of VTE (7% PE, 5% DVT). Non-parametric tests were performed to see if there was an association between the use of IMiDs, co-existing malignancy, number of treatment courses and the occurrence of VTE in this population but none were significant.
Summary / Conclusion: The prevalence of VTE in this population was similar to previously published reports. Myeloma patients have many risk factors for VTE but in this population, no one was predictive. As myeloma therapies and outcomes are rapidly changing, a dedicated prospective study is required to evaluate all risk factors to mediate prophylaxis of VTE.

B1979

EXCESS BLOOD CLOTTING FACTOR VIII AND THE RISK OF THE INFRINGEMENT OF CEREBRAL CIRCULATION

I Davydkin[1*], I Kurtov[1], A Nizyamova[1]
[1]The department of hospital therapy with course of hematology, The Samara State Medical University, Samara, Russian Federation

Background: Currently, an important role in the development of disorders of the arterial and venous circulation belongs to thrombophilia. Definite interest thrombophilia is associated with excess content of blood clotting factors. The increasing level of factor VIII in the blood is one of the major risk factors for arterial and venous thrombosis. The increasing level of factor VIII over 150% reflects a 6-fold risk of venous thromboembolism, compared to those where the level of antihemophilic factor is less than 100%. Causes of these disorders have not been fully elucidated. These patients have the likelihood of recurrence of venous thrombosis.
Aims: Determine the clinical significance of increasing factor VIII in patients with cerebral stroke and possible association with other disorders of hemostasis.
Methods: A total of 56 patients, including 46 women and 10 men aged 22 to 50 years, mean age - 30.8 years. Most of women had miscarriage in early pregnancy, as well as the failure of in vitro fertilization, 4 women had a history of acute ischemic stroke, and 1 - arterial thrombosis fingers. In men, the treatment causes were: 1 patient had pulmonary embolism, thrombosis of the femoral artery - 1 patient, repeated acute ischemic stroke - 3 patients, thrombosis of the internal carotid artery of one patient, venous thrombosis of the lower limbs - 4 people. Research methods included the identification of indicators of hemostasis: activated partial thromboplastin time, international normalized ratio, fibrinogen, thrombin time, the level of protein C, protein S, antithrombin III, plasminogen, factor VIII, factor IX, von Willebrand factor, platelet count, determination platelet aggregation under the influence of inducers, such as ADP and collagen. RT-PCR method is determined by genetic mutations of blood coagulation: MTHFR C677T, MTRR Ile22Met, prothrombin G20210A, inhibitor of the plasminogen activator PAI-1, platelet receptor ITGB3 Leu33Pro, fibrinogen 455G/A, FV Leiden Arg506Gln.
Results: Group of patients with a factor VIII level more than 150% (normal value of 50 - 150%) consisted of 24 patients, including 18 women and 6 men. The level of factor VIII in the group was 224.7±4.2% (P <0.05). A group of patients with normal antihemophilic globulin were 32 patients, including 28 women and 4 men. The average content of factor VIII in the comparison group was 104.4%±2.2%. Of the patients examined all seven people, that is 29.2% with acute ischemic by ischemic type, enter a group with a high content of antihemophilic globulin. In the comparison group of violations of cerebral blood flow was observed. In these seven patients, the average level of factor VIII was 231.6%±2.4%. Among other hemostatic disorders in these patients revealed a polymorphism of PAI-1, 5 - homozygous variant, at 1 - heterozygous. 1 patient had a heterozygous polymorphism MTRR Ile22Met, at 1 - MTHFR C677T and heterozygous fibrinogen 455G/A, 2 patients had homozygous polymorphism MTHFR C677T, 1 patient - heterozygous polymorphism ITGB3 Leu33Pro and elevated von Willebrand factor (190%), one patient - a heterozygous mutation in the prothrombin G20210A.
Summary / Conclusion: Thus, the increase in factor VIII in the blood is an additional risk factor for vascular events in the vessels of the brain. Increase in factor VIII is more than 200% to 29.2% increased risk of acute ischemic even in young patients. A combination of excess factor VIII procoagulant with other defects of hemostasis is unfavorable for such patients, in particular, with the polymorphism of PAI-1. Thus, a comprehensive study of the blood coagulation system, including the determination of factor VIII in the blood, is advisable at patients, especially with cerebral accident.

Quality of life, palliative care and ethics

B1980

TO ADMIT OR NOT TO ADMIT HEMATOLOGIC PATIENTS IN THE ICU? THAT'S THE QUESTION!

T Maia[1*], A Marques[2], S Beirão[2], P Coutinho[2], M Ribeiro[1]
[1]Hematology, [2]Intensive Care Unit, CHUC - Hospital geral, Coimbra, Portugal

Background: The admission of patients with hematological diseases to the Intensive Care Unit (ICU) has been an issue of controversy for many decades. In the 80s the mortality rates of these patients were 80%, but newer studies have shown an improved outcome (mortality of 50-60%). Nevertheless, due to the serious complications that these patients commonly develop and their difficult management, ICU specialists are still reluctant to admit them.
Nowadays, the therapeutic advances improved the long-term prognosis of these patients and it is now urgent to evaluate their predictor outcomes in the ICU, in order to facilitate the challenging decision to admit an hematological patient.
Aims: Characterize the hematological patients (Hp) admitted to a polyvalent ICU, evaluate their mortality and prognostic factors and compare their evolution and predictor outcomes with a paired sample of non-hematologic patients (nHp).
Methods: Observational, retrospective study in Hp admitted in a polyvalent ICU from March 2007 to March 2012. Statistical workup was done using SPSS® v19.0. The group of non-hematological patients (nHp) was selected during the same period and matched to the Hp group by sex, age (±1), Acute Physiology and Chronic Health Evaluation score II (APACHE II) (±5), Simplified Acute Physiology Score (SAPS) (±5) and cause of admission.
Results: During the analyzed period we have treated in our ICU 24 Hp (1,6% of all admissions), median age 65 years, 7 (29%) female. Hematological diagnosis: 9 Myeloproliferative/Myelodisplastic Syndromes, 8 NonHodgkin lymphomas/Multiple Myelomas, 2 Aplastic Anemias, 5 benign disorders. The main reason for admission was respiratory infection (67%). Median APACHE 17±8,9, SAPS 36,3±10,9. Median ICU length of stay 11,5±13,7 for Hp and 9,2±5,9 for nHp. The mortality rate in ICU of the Hp was 45,8% and the nHp 54,2%.
In order to evaluate mortality influencing factors, several predictors of outcome (PO) were tested between both groups (Hp and nHp) using Fischer Test: (APACHE, SAPS, reason for admission, neutrophil and platelet count, required ventilatory, renal and inotropic support, duration of mechanical ventilation, sepsis and transfusional needs), but we only found statistical significance for sepsis (P=0,03) as a predictor of mortality. When analyzing the relative risk (RR) of death, for the different PO, they were similar in both groups and the need for inotropic support had the highest RR (3,4).
Summary / Conclusion: When comparing the Hp to nHp admitted to ICU for the same reason, with similar age and scores (APACHE and SAPS), the Hp had a lower mortality than the matched group of nHp. Selection bias was excluded using T-student test. The hematological characteristics of the Hp (neutropenia, anemia and thrombocytopenia) *per se* did not influenced mortality in our group of patients. The Hp had similar RR of death as the nHp in all the tested PO. This study shows that despite historical bad outcomes, the Hp should have the same admission criteria as nHp.

B1981

METRONOMIC THERAPHY IN VERY OLD PATIENTS : WHEN TO TREAT AT HOME BED IT'S NOT SO BAD.

G Giordano[1*], d traficante[2], f d'amico[3], m de maria[1], f tomei[2], a d'aveta[1], p assalone[4], f calista[4], l di lullo[2]
[1]oncology, Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [2]oncology, veneziale hospital, isernia, [3]Foundation "J. Paul II" - Campobasso - Italy, Campobasso, [4]veneziale hospital, isernia, Italy

Background: Patients 80 years old or older frequently are affected by aggressive B or T lymphomas. Which is the best treatment in these patients is still unclear, because standard treatment are complicated by an higher toxicity and mortality.
Aims: Aim of this study is to verify if metronomic therapy, already used in solid tumours, is not inferior and less toxic than standard chemotherapy in treatment of aggressive lymphomas of very old patients.
Methods: We considered 26 patients from 2009 to 2013. To calculate frailty of patients CHARLSON, CIRS-G, CRASH and GISL score were used.
In group A patients were treated at home with metronomic therapy with cyclophosfamide 50 mg days 1to5, etoposide 50 mg days1-3-5, prednisone 25 mg days 1to7, lenalidomide 10 mg days 1to21, all orally, every 28 days for 9-12 cycles (Large B Cell Lymphoma and Mantle Cell Lymphoma), or with cyclophosphamide 50 mg days 1to3, fludarabine 25 mg days 1to3, etoposide days 4to6, prednisone 25 mg days 1to15, all orally, methotrexate 15 mg im day15, every 28 days for 9-12 cycles (T cell Lymphoma). In group B patients received at hospital i.v. Rituximab 375 mg/sqm day1, Cyclophosphamide 750 mg/sqm day1, adryamicin 50 mg/sqm day1, prednisone 50 mg/sqm orally day 1to5 (Large B Cell Lymphoma, T cell lymphoma and Mantle Cell Lymphoma). In group A M/F:8/8, median age was 85.5 years (R85-94), TNHL/DLBCL/MCL:5/4/1, median IPI 4(R2-5),median follow-up was 6 months(R2-13), 9 patients showed 1 comorbidity (56%), 7 patients 2 or more (44%); CHARLSON>5:12pat(75%),CIRS-G=4:9pat.(56%),CRASH>9: 7pat(43%),GISL FRAIL:12pat.(75%). In group B M/F:4/6, median age was 85 years (R85-91), TNHL/DLBCL:2/8, median IPI 4(R2-5),median follow-up was 6 months(R1-24), 2 patients showed 1 comorbidity (20%), 2 patients 2 or more (20%), 6 patients no comorbidities (60%) CHARLSON>5:4pat(40%),CIRS-G=4:5pat.(50%),CRASH>9:3pat(30%),GISL FRAIL:5pat.(50%). SF8 questionnaire was used to evaluate quality of life of patients.
Results: In group A median hospitalization was 0 weeks (R0-12), complete remission 4 patients (25%), partial remission 8 patients (50%), progression of disease 4 patients (25%), G3/G4 toxicities (hematologic 25%, not hematologic 25%,infection 37%, transfusion 19%,death 37.5%), days of hospitalization/days of global survival 5%(R0-25), cost per month of survival € 5000 (R250-9100), SF8 60 (R40-100). In group B median hospitalization was 9 weeks (R3-17), complete remission 5 patients (50%), partial remission 2 patients (20%), progression of disease 3 patients (30%), G3/G4 toxicities (hematologic 70%, not hematologic 50%,infection 40%, transfusion 80%,death 60%), days of hospitalization/days of global survival 33%(R20-100), cost per month of survival € 21000 (R5000-37000), SF8 40 (R20-50). At Kaplan-Mayer analysis median survival was 18 months for both groups.
Summary / Conclusion: Metronomic therapy is cost-effective and warrants a good quality of life and survival in very old patients.

B1982

IMPROVEMENT OF QUALITY OF LIFE AND INCREASE HEMOGLOBIN CONCENTRATION IN ANEMIC PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS TREATED ERYTHROPOIESIS-STIMULATING AGENTS

N Romanenko[1*], I Kostroma[1], I Karmatskaya[1], N Potikhonova[1]
[1]Hematology, Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background: Anemia is a frequent and under-appreciated complication lymphoproliferative disorders (LPD) and antitumor therapy decreasing survival rate and overall quality of life (QoL). Anemia's pathogenesis is based on suppression by proinflammatory cytokines, decreasing erythroid precursor's sensitivity to serum erythropoietin and the myelosuppressive effects of chemotherapy. Therefore erythropoiesis-stimulating agents (ESA) are used as effective pathogenetic treatment of anemia in LPD patients significantly increasing hemoglobin concentration, reducing a number of red blood cell (RBC) transfusions and improving QoL.
Aims: To study the efficacy of ESA, to compare increasing Hb concentration in LPD patients with anemia whom were administrated ESA treatment versus similar patients without ESA (control group), to find out improvement of QoL in group ESA patients.
Methods: We performed this interventional prospective study in LPD patients (n=135) with anemia (Hb 3.9-10 g/dl). Median age of patients was 66 years (range 26-88). ESA (n=88) group included patients with low-grade non-Hodgkin's lymphoma (NHL, n=11), chronic lymphocytic leukemia (CLL, n=21) and multiple myeloma (MM, n=56). A control group (n=47) included similar patients with low-grade NHL (n=7), CLL (n=10) and MM (n=30). ESA was administrated subcutaneously. Epoetin alfa (n=39) on 40.000 IU weekly, Epoetin beta (n=27) on 30.000 IU weekly and Darbepoetin alfa (n=22) 500 µg once per three weeks. All patients had received two or more cycles of antitumor treatment before start of ESA treatment. If Hb concentration was <8.0 g/dl, it was treated by RBC transfusion before ESA administration. The target Hb level was 11-12 g/dl. Positive response was estimated as increasing Hb concentrating ≤2.0 g/dl (without RBC transfusions) or achieving target Hb level during 8-16 weeks of ESA therapy. QoL was assessed using the FACT-Anemia subscale questionnaire.
Results: Mean baseline Hb concentration was similar in both groups ESA and control (8.89±1.20 g/dl and 8.54±1.51 g/dl, respectively, P>0.05). On the whole in the ESA group Hb concentration increased from baseline to 11.18±2.21 g/dl (P<0.001). We observed positive response at 60 patients (68.2%) in the ESA group, their Hb concentration increased from 9.03±1.14 g/dl to 12.24±1.15 g/dl (P<0.001). In non response grope Hb concentration was almost the same (from 8.68±1.26 g/dl to 8.44±1.16 g/dl). Having compared efficacy of different ESA we didn't find out significant statistical difference between of them. Epoetin alfa showed positive response in 26/39 patients (66.7%), Epoetin beta – in 19/27 (70.4%), Darbepoetin alfa – in 15/22 (68.2%). Positive response in the control group was observed at 14/47 patients (29.8%), it's significant less than in ESA group (P<0.05). However Hb concentration increased from 8.54±1.51 g/dl to 10.48±1.19 g/dl in the control group of patients. We compared QoL in ESA patients before and after ESA therapy and observed improvement in the most items but statistically significant improvement (P<0.05) was found out only in the next items: 1) I feel fatigued; 2) I feel weak all over; 3) I feel listless ("washed out"); 4) I feel tired; 5) I have trouble starting things because I am tired; 6) I have trouble finishing things because I am tired; 7) I need sleep during the day; 8) I have been short of breath; 9) I have pain in my chest.
Summary / Conclusion: In this prospective study was shown the efficacy of ESA therapy improving QoL and increasing Hb in LPD patients with anemia.

B1983

DISSOCIATIVE DISORDERS IN STRUCTURE OF PSYCHOGENIC REACTIONS AT THE BLOOD SYSTEM DISEASES PATIENTS

D Vybornykh[1*], E Parovichnikova[1], V Savchenko[2]
[1]Bone Marrow Transplantation, [2]Director, National Research Center for Hematology, Moscow, Russia, Moscow, Russian Federation

Background: There are some types of psychogenic reactions at the blood system diseases patients necessary to study for development of the therapeutic techniques directed on correction of these disorders
Aims: Clinical studying of the dissociative disorders revealed at patients with blood system diseases patients, and development of the therapeutic techniques directed on correction of these disorders
Methods: 192 patients with various blood system diseases were studied by the psychopathological method. Dissociative psychogenic reactions were revealed at 86 (44,8%) patients.
Results: 2 types of psychogenic reactions with dissociative symptoms are revealed – anxious-dissociative (n=67 (77,9%) and schizophrenic dissociative (n=19, (22,1%) ones.
Anxious-dissociative reactions:
- Proceed with the phenomena of real blood system disease alienation and signs of the latent somatizing anxiety, being accompanied by abnormal behavior in illness (Barsky A.J. Klerman G.L., 1983). Into the forefront the consciousness fragmentariness (dissociative disorder of identity (DSM-IV-R) acts. Alienation of blood system disease signs is associated with significant depersonalization and derealization. The events occurring in a hospital connected with diagnostics and treatment of blood system disease are perceived as though from outside. Patients categorically deny any fears connected with illness outcome. Thus the dissociation covers basically cognitive aspect of reaction («cognitive dissociation»). There are doubts concerning existence of blood system disease, correctness of the diagnosis, statement of absolute recovery, ignoring of the somatic status deterioration symptoms, or their interpretation as manifestation of less serious illness. - persons with shizoid and anancastic personality traits prevail. Dissociative schizophrenic reactions: - the phenomenon of blood system disease alienation, a complete negation of the fact of a disease dominates, patients completely refuse further care, motivating it with that they are almost healthy and don't need the specialized help. As a rule, such patients repeatedly ask for the help only at emergence of the complications which are directly menacing to life. - persons with schizotypal disorder (DSM-IV) (n=15) or with the personality changes at juvenile one catadrome schizophrenia (n=4) prevail. The basic principles of the revealed mental disorders therapy were: - empirical selection of medications taking into account specific features - prescription of psychotropic drugs according to their main indications on the basis of the clinical picture analysis of psychopathological disorders - choice of psychotropic drugs on the basis of an assessment of risk/advantage proportion with taking into account the tolerance and safety profile, and also potential medicinal interactions. Efficiency of psychopharmacotherapy with of drugs standard dosages using depended on the type of psychogenic reaction. At the anxious-dissociative disorders the quantity of responders reached 76,1%, and at the schizophrenic dissociative reactions – 68,4%.
Summary / Conclusion: Dissociative reactions at patients with blood system diseases are rather frequent and accompanied considerable resistance to psychopharmacotherapy

B1984

HEALTH-RELATED QUALITY OF LIFE AND PRODUCTIVITY IMPACT OF MYELODYSPLASTIC SYNDROMES (MDS): THE PATIENT PERSPECTIVE

R Komrokji[1], D Mahmoud[2*], S Hudgins[3], F Taylor[4], F Pompilus[4], S Hwang[4], C Beach[5]
[1]Department of Hematologic Malignancies, Moffitt Cancer Center, Tampa FL, [2]Global Pricing and Market Access, Celgene Corporation, Summit NJ, [3]Health Care Analytics, [4]Endpoint Development and Outcomes Assessment, Adelphi Values, Boston MA, [5]Hematology/Oncology Clinical Research & Development, Celgene Corporation, Summit NJ, United States

Background: One of the most important clinical features of myelodysplastic syndromes (MDS) is the presence of chronic anemia which is directly related to fatigue. Patients' experiences of fatigue associated with chronic anemia are well-documented in the literature; however, consensus on measurement of fatigue is lacking.
Aims: To perform a qualitative interview study to understand the effect that fatigue has on the health-related quality of life (HRQL) of MDS patients, and the economic burden of the disease.
Methods: Following a targeted review of the existing literature, 60-minute face-to-face in-depth qualitative interviews were conducted with MDS patients (n=17) in the US with a clinically confirmed diagnosis according to the World Health Organization (WHO) 2008 classification Interviewer questions were open-ended and focused on patients' HRQL and indirect costs associated with the disease. The 12-item Short-Form Health Survey (SF-12v2®) was administered after the interview to gain further insight into the impact on patients' HRQL. Qualitative data were analyzed using a grounded theory approach that combined semi-quantitative and qualitative methods.
Results: The mean age of patients interviewed was 70.8 years (range: 42.2 to 85.5 years); 59% of patients were male. The median time from diagnosis was 3.8 years; (range: 0.2 to 8.7 years). The sample included patients of each WHO 2008 classification subtype; the most common diagnosis was refractory cytopenia with multilineage dysplasia (47%). Based on the International Prognostic Scoring System (IPSS), 59% and 41% of patients were diagnosed with low and high risk MDS, respectively, with 76% of patients currently taking treatment for their MDS. Current treatments included erythroid growth factor support (53%), hypomethylating agents (18%), and lenalidomide (6%). One patient reported transfusion-dependence (≥2 transfusions in the past eight weeks) – however the number of patients receiving occasional transfusions was not recorded. The most frequently reported comorbidities included diabetes (53%), high blood pressure (35%), and cancer (24%). This qualitative study found that MDS is associated with a considerable financial impact to patients. Based on the qualitative interviews with patients, the indirect financial costs reported (i.e., decreased work activities) were equally as burdensome to patients as their direct medical cost for treatment. Seven patients (41%) discussed the impact of MDS on their ability to work, either as a result of fatigue or their constant need for treatment. Patients reported being unable to complete work activities, taking time out of work for medical appointments, and reduced productivity during working hours. Patients also reported financial impacts associated with travel to medical appointments (n=11, 65%), and caregiver assistance with daily activities that patients had difficulty completing as a result of their disease (n=5, 29%). A total of 30 HRQL concepts within 11 domains (Table 1) were spontaneously reported by patients during the interviews, with the largest HRQL impairment being physical activity (n=16, 94%) directly related to patients' fatigue. These results are consistent with findings from the SF-12v2® questionnaire, on which patients scored a mean Physical Functioning domain score of 37.5 (SD 30.28) on a scale from 0-100 where a higher score indicates a better health status. The national norm for the US is a mean of 50.0 with a standard deviation of 10 for the Physical Functioning domain score. MDS patients also frequently reported the social (n=12, 71%), sleep (n=11, 65%), functional (n=10, 59%), and emotional (n=9, 53%) impacts of the disease.

Table 1. Number of patients who reported impacts in HRQL domains during qualitative interviews

HRQL domain	n (%) N=17
Physical	16 (94)
Social	12 (71)
Sleep	11 (65)
Functional	10 (59)
Emotional	9 (53)
Cognitive	7 (41)
Activities of daily living	7 (41)
Consumption of time	4 (24)
Ability to travel	4 (24)
Leisure activities	3 (18)
Self-care	2 (12)

Summary / Conclusion: These qualitative findings provide additional insight into the HRQL and financial impact of MDS which has been considered yet not fully articulated in the literature for these patients. Specifically, in addition to decline in HRQL, fatigue and the constant need for treatment in MDS appear to impact patients' work activities as well as their productivity within society.

B1985

AUDIT MORTALITY WITHIN 30 DAYS OF CHEMOTHERAPY IN A DISTRICT GENERAL HOSPITAL IN UK

F Elamin[1*], S Tueger[1]
[1]Department of Haematology, Countess of Chester Hospital, chester, United Kingdom

Background: Over the last three decades, there has been a large increase in both the number of chemotherapy. Over the last three decades, there has been a large increase in both the number of chemotherapy treatments available for patients with haematological malignancy and its usage. There is clear evidence of the beneficial effects of these treatments. There is also considerable experience and in grading and managing toxicities associated with these treatments. In UK there are no national benchmark figures for early mortality due to chemotherapy unlike for surgical interventions. NCEPOD (National Confidential Enquiry into Patient outcome and death) published a document in 2008 which has reviewed the care of patients who died within 30 days of receiving systemic anti-cancer therapy. The document recommended that all deaths within 30 days of chemotherapy should be considered at morbidity and mortality or clinical governance meetings.

Aims: The aim of the study was to monitor all deaths within 30 days of chemotherapy in patients with haematological malignancies at the Countess of Chester Hospital, a district general hospital in Chester, UK covering population of 250,000 residents.
Methods: Databases were searched for all deaths within 30 days of chemotherapy in those patients who received one or more cycles of chemotherapy between Jan & Dec 2012. Information regarding treatment intention-curative or palliative-, cause of death, number of previous treatment was collected from patients' case notes and Somerset cancer register (national database application which contain clinical cancer data).
Results: Between January2012 and December 212, 17 deaths occurred within 30 days of chemotherapy. Of these, 9 deaths (53%) were due to disease progression. Eight (47%) deaths were related to chemotherapy, of which 5 (29%) were due to neutropenic sepsis. 11 0f the 17 deaths occurred in patients who were receiving potentially curative chemotherapy. Performance status prior to chemotherapy was not documented anywhere in the notes in 8 (47%) of patients.
Summary / Conclusion: The authors believe regular collection of this data including accurate recording of performance status may add weight to the decision-making process. We feel this is an audit system that could be used for haemo-oncology centres nationally. We practice this form of audit yearly and feedback to the treating teams so that deaths are discussed and practice monitored.

B1986
QUALITY OF LIFE AND DISEASE UNDERSTANDING: IMPACT OF ATTENDING A PATIENT CENTERED CANCER SYMPOSIUM
L Padrnos[1*], R Emanuel[1], A Dueck[1], R Mesa[1]
[1]Mayo Clinic Hospital Arizona, Scottsdale, United States

Background: Various instruments have been developed to measure quality of life (QOL) among cancer patients. Components of QOL assessment include symptoms (e.g., fatigue), physical function, social interactions and financial burden. To date no studies have evaluated the effect of a cancer symposium as an educational intervention to improve quality of life among cancer patients.
Aims: The aim of this study is to evaluate the impact of a patient centered cancer symposium on a broad population of cancer patients.
Methods: Surveys were distributed to attendees of the Mayo Clinic "Living with Cancer" patient symposium in January 2013. Surveys items included the EORTC QLQ-C30, questions regarding disease comprehension (response options of not at all, a little, quite a bit, and very much), and Distress Thermometer. Attendees also completed validated disease-specific questionnaires based on cancer type. These questionnaires included the MPN-SAF, EORTC disease-specific modules, and FACT disease-specific scales.
Results: 158 patients completed the pre-convention survey. There was equal gender representation among participants (51%F). Median age was 67.5 years (range 30-86). Disease type included 37% hematologic malignancies, 23% breast cancer, 23% prostate cancer, and 17% other. The large majority of respondents were greater than 1 year from cancer diagnosis (76%) with 40% greater than 3 years from diagnosis. Most respondents endorsed understanding their disease quite a bit (54%) or very much (29%). Most respondents reported disease comprehension of "quite a bit" or greater in regards to treatment options (84%), screening modalities (83%), disease symptoms (74%), and cancer-related side effects (71%). The lowest percentage of understanding ("quite a bit"/"very much") was reported for legal issues of disease and treatment (27%), managing disease related fatigue (41%), risk factors of disease (49%), and managing disease related stress (49%). Subjects with heme malignancies (N=58) had significantly less understanding of risk factors (31% vs 60% in nonheme, Jonckheere-Terpstra [JT] P<0.001) and treatment options (78% vs 89% in nonheme, JT P=0.03) with a trend for less understanding of treatment side effects (66% vs 75% in nonheme, JT P=0.07). 158 respondents completed the QLQ-C30 with mean scores of 84.4 (SD=16.6) for physical functioning, 83 (SD=22.3) for role functioning, 80.7 (SD=22.9) for social functioning, and 72.7 (SD=20.2) for global health status. The three symptoms with highest mean scores were insomnia (mean=35.5, SD=32.4), fatigue (mean=29.3, SD=22.4), and pain (mean=22.7, SD=24.7). Mean distress was 3.8 (SD=2.8) with respondents identifying a median of 5 problems. Subjects with heme malignancies had statistically significantly lower physical functioning (mean 80.6 vs 86.7 in nonheme, t-test P=0.02) but did not significantly differ on any other QLQ-C30 scale. Mean distress among subjects with heme malignancies was 3.5 (SD=2.6) with respondents identifying a median of 6 problems neither being statistically different from nonheme subjects.
Summary / Conclusion: Cancer patients had high baseline disease understanding and appeared motivated for an educational teaching program via a patient centered cancer symposium. However, subjects with heme malignancies reported less understanding of risk factors, treatment options, and treatment side effects. Heme respondents also reported worse physical functioning than nonheme respondents. Further results of cancer knowledge and QOL following the symposium are being assessed.

B1987
THE FACTORS OF KETAMINE THAT AFFECT SEDATION IN CHILDREN WITH HEMATOLOGY/ONCOLOGY PROCEDURES: PARENT SATISFACTION PERSPECTIVE
C Traivaree[1*], W Jindakam[1], C Monsereenusorn[1], P Thaoyot[1], R Lumkul[1]
[1]Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background: The pain and its complication during sedation with ketamine remains a significant problem for children with hematologic malignancy.
Aims: The purpose of this study is to further evaluate the parental satisfaction for procedural sedation and analgesia during pediatric hematology/oncology procedures performed by pediatric hematologist in the department of pediatrics, Phramongkutklao hospital.
Methods: A prospective audit of intravenous ketamine use in department of pediatrics requiring invasive procedures. Children received intravenous of ketamine 1 mg/kg. The informed consents and assents were obtained .The procedure was assessed by way of a physician completed form and by evaluation of questionnaires given to parents to estimate levels of pain by using a 0 to 10 mm Visual Analog Scale (VAS).
Results: A total of 46 children aged 6 months to 15 years were observed at pediatric unit for a total of 46 procedures. The indications for procedural sedation and analgesia included lumbar puncture and intrathecal chemotherapy (50%), bone marrow aspiration or biopsy (21.7%), and both procedures (28.3 %). The mean VAS scale during oncology procedures were 3.39±2.39 which was expressed by all the parents/guardians of the children treated. Adverse effects were observed in all children include hallucination (39.1%),nausea (30.4%),hypersalivation (26.1%), vomiting (21.7%)No child required admission to hospital and there were no serious complications.
Summary / Conclusion: Intravenous ketamine 1 mg/kg is effective for invasive procedures in children with malignancy. The use of intravenous ketamine may produce psychedelic effects in children. These adverse effects may alter the child's comfort and parental satisfaction especially in the age group which are younger than 10 years old**.**

B1988
IMPACT OF HYPOMETHYLATING AGENTS ON THE BLOOD PRESSURE OF THE PATIENT WITH HEMATOLOGIC MALIGNANCIES: SAFETY AND RECOMMENDATIONS FOR USE.
B De Gusmao[1*], M Nogales[2], I Gonzalez[1], M Quintana[1], E Perez-Persona[1], A Campeny[1], J de Castro[1]
[1]Department of Hematology, [2]Department of Pharmacy, Hospital Universitario de Álava, Vitoria - Gasteiz, Spain

Background: DNA hypomethylating agents are currently important drug in the therapeutic approach from myelodysplastic syndromeand myeloblastic leukemias. Alikhani-Koopaei (j. Clin. Invest. / 2004) and S. Friso(Atherosclerosis 2008) demonstrated the relationship of epigenetic in arterial hypertension (AH) and the effect of agents such as 5-azacytidine as regulatory hypomethylation of the gene of 11-beta-hydroxysteroid dehydrogenase, involved in AH epigenetic control.
Aims: Determine the relationship of blood pressure with hypomethylating agents and assess the security and management of hypotension in patients with hematologic malignancy treated with azacitidine. We consider hypotension a decrease of 20 mmHg with respect to your baseline blood pressure.
Results: We have reviewed 109 treatment cycles of azacitidine of 26 patients (14 men, 12 women) with a median age of 74.5 years (range 39-83) treated by hematological malignancies (16 AML, MDS-10).50% of the patients receiving treatment for chronic hypertension. In our Center 18 of the 26 patients (69.23%) presented an episode of hypotension, but stratifying by groups, in the 46 first cycles of azacitidine is have found an incidence of 73.9 %(N=34) of arterial hypotension. After the high rate of adverse effects, we customize our Protocol, by removing antihypertensive in the week receiving azacitidine, decreasing the total incidence of 73.9% to 30.3% (P<0.001) respectively.
Summary / Conclusion: Our data confirm the role of hypomethylation of DNA in the epigenetics of hypertension described by Alikhani-Koopaei (j. Clin. Invest. / 2004) and S. Friso (Atherosclerosis 2008). Azacitidine, as agent hipometilante, presents a synergistic effect with drugs used in the treatment of high blood pressure. After monitoring and surveillance at our Center, we suggest blood pressure control all patients treated with agents hipometilantes and avoid the concomitant use of antihypertensive /azacitidina in the week of treatment, improving security, tolerance and avoiding adverse effects potentially serious.

B1989

SECOND PRIMARY MALIGNANCY IN HEMATOLOGY PATIENTS IS A RARE ENTITY?

K Palla[1*], A Kolovou[1], G Tsirakis[1], N Pantieras[1]
[1]Hematology, Chania General Hospital, Chania, Greece

Background: The reported incidence of multiple primary cancer (MPC) is rare, and it is even less common to observe hematological malignancy with solid tumor. The etiologic implicating factors are a first primary tumor itself, genetic predisposition, environment exposures, chemotherapy(CT), radiotherapy(RT), hormonotherapy(HRT), immunosuppresion and also a better overall and prolonged survival achieved due to improved treatment.
Aims: To evaluate occurrence of second primary malignancy (SPM) in hematology patients.
Methods: We retrospectively studied the files of 563 (307men, 256 women)with median age 62years (43-81) and a male to female ratio 1.7:1 who were consecutively admitted in our unit.Between January 2010 and January 2013, 8(1.42%)patients developed metachronous second primary malignancy(SPM), 5(1.62%)men and 3(1.17%)women .
Results: The median interval time to the diagnosis of the SPM was 94 months (14-216). Half of the SPM occurred between 14 and 33months while the others were detected after a 5-year interval. 5/8 cases were associated with a first hematologic malignancy, and 3/8 with solid tumor. These cases included myeloproliferativesyndrome/ polycythaemia vera with lung cancer, chronic lymphocytic leukemia with lung cancer,myelodysplastic syndrome/acute myeloid leukemia with lung cancer , chronic myelomonocytic leukemia with lung cancer, lung cancer with myelodysplastic syndrome, prostate cancer with myelodysplastic syndrome, melanoma with gastric MALT lymphoma, B- chronic lymphocytic leukaemia with breast cancer.5/8 cases had diagnosis lung cancer as primary or second malignancy. 5/8 pts had treatment for the first malignancy which included CT, only Hydreoxyurea (HU),RT, surgery, HRT and 3/8 did not receive any treatment. 3/5 pts with lung cancer were heavy smokers.
Summary / Conclusion: The risk of developing SPM among hematology pts surviving>5 years was low in our series, considering the prevalence of MPC varying between 0.73% and 11.7% Based on small numbers, an unexpected presence of solid tumors was reported.Lung cancer was the commonest site of metachronus tumour. Our findings support a role for a shared susceptibility(genetic, enviroment) that predisposes to certain solid tumors.We did not find prevalence of lymphoid or myeloid malignancies as second tumor in contrast to the references.The administration of chemotherapy and or irradiation did not seem to increase the risk.

B1990

ROMANIAN PEOPLES OPINION ABOUT THE UTILITY OF CHEMOTHERAPY IN ACUTE LEUKEMIC PATIENTS

R Mihaila[1*], C Far[2], G Popa[2]
[1]Faculty of Medicine, Lucian Blaga University of Sibiu, [2]Hematology Department, Emergency County Clinical Hospital Sibiu, Sibiu, Romania

Background: It is useful to regularly test the opinion of Romanian people according to the various issues raised by medical practice. The problems about the management of leukemic patients are among them. Their responses can provide starting points for improving it.
Aims: We aimed to study the opinion of Romanian inhabitants about the issues related of acute leukemia chemotherapy.
Methods: A transversal study was performed on a sample of 221 Romanian inhabitants: 62 consecutive hospitalized patients in January 2013 and all those 159 subjects who responded to a questionnaire on the management of acute leukemic patients posted on Internet. The results were analyzed and they have allowed conclusions that we hope to have implications for clinical practice.
Results: The mean age of surveyed patients was 40.64+/-19.31 years. Distribution by gender: women 58.37%, men 41.63%. Most responders (78.13%) agreed with chemotherapy in acute leukemic patients. 88.69% of them agreed to idea that all chemotherapeutics for leukemic patients must be present in hospitals and their treatment must be free of charge. Unfortunately, essential drugs for their treatment are missing in Romania in the last months. If the responders were in their situation, almost half of them could not buy them and 33.94% of them would not know what to do. Only 47.06% felt that they could buy them from other countries and 32.58% had no idea how to buy them. More than half of them didn't agree to the idea that chemotherapeutics could be replaced by herbal medicine and 33.03% had no idea about this. The vast majority of those surveyed (80.54%) felt that chemotherapy delay may worsen leukemic patient outcome. Only 27.15% didn't agree to the idea that resveratrol could replace chemotherapeutics and 65.16% didn't know this drug. Most (77.38%) feel that the government is responsible for the absence of chemotherapeutics in hospitals. If they have a leukemic child 71.94% of them would go abroad to treat him. 85.07% of them, would agree to donate blood for these patients, even if they could not receive chemotherapy, as palliative treatment. To avoid the absence of chemotherapeutics in the future, 52.49% of them felt that these drugs should be made in Romania and only 17.19% agreed with their import. Most (71.04%) were optimistic: they felt that public opinion could influence the solving of chemotherapeutics absence, but only 34.84% of them agreed to the idea that the popularization of this problem on Internet could sensitize authorities to solve the vital drug absence; 35.29% weren't sure, 15.38% didn't know, and 14.48% didn't agree to this idea.
Summary / Conclusion: Most people are aware of the importance of chemotherapy made in time for effective treatment of leukemic patients, and agree to buy missing chemotherapy drugs or go abroad for their child treatment. They agree, as blood donors, to participate voluntarily in helping them. Most responders were optimistic regarding the influence of public opinion on solving the chemotherapeutics absence but only third of them felt that Internet is the right place to discuss and solve this problem.

B1991

PALLIATIVE CARE FOR CHILDHOOD CANCER IN COUNTRIES WITH LIMITED HEATH RESOURCES: CURRENT CHALLENGES

G Mokhtar[1], S El-Habashy[1], I Ragab[1*], Y El-Henawy[1], O El-Safty[2], H Ahmed[3]
[1]Pediatrics, [2]Anasthesiology, [3]neuropsychiatry, Ain Shams University, Cairo, Egypt

Background: Cancer patients suffering from a terminal illness require special care and support. There is deficiencies in the current practice guidelines and lack of quality assurance in the provision of these services. The main target in that group focus on symptoms management, psychological rehabilitation.
Aims: The study aimed to plan a standard of care in our center aiming at assessment and management of all symptoms encountered in children with terminal childhood cancer, to provide maximum comfort to patients and families, to compare with the previous service provided over the preceding period and to highlight the deficiencies in the current provision of care.
Methods: The study was conducted prospectively (Group A=20 patients) on terminal cancer patients recruited from Oncology Unit - Pediatric Hospital- Ain-Shams University in the period from JAN2009 through JAN 2011.This group was compared to (Group B= 13 patients),studied retrospectively from patients hospital records over the previous 2 years prior to study . They were enrolled based on less than 10% predicted overall survival in international results and/or progressive, refractory disease or relapse with standard of care protocol and second line salvage protocol. Parental consents were obtained. Patients were subjected to proper assessment of type of malignancy, detailed review of all given therapies and their response thorough clinical examination and system review. Pediatric palliative care overview included anticancer therapy and symptoms management. Integral assessment for all symptoms (gastrointestinal, respiratory, neurological, pain, anorexia/cachexia), together with psychiatric evaluation of parents and patients were carried in three phases: initial screening, assessment and interventions and reassessment
Results: The frequency of various symptoms were pain in 80% of patients, GI in 65% , anorexia / cachexia (50%) , Cancer related fatigue (35%), neurological (15%) and respiratory (40%); the duration of patients on palliative care was 12.37±9.807 months in group A compared to group B(4.250 ±2.527 months)(P<0.001). Marked symptoms focus improvement was detected in group A after implementation of the program. In group A, 62.5% were given analgesia around-the-clock (ATC) and 37.5% were given analgesia PRN. All patients in group B were given analgesia PRN. Depression and anxiety was present in6, 10 (30, 50 %) of group A patients before treatment which dropped to2,2(10, 10%) respectively after treatment. Group B was not subjected to any psychological rehabilitation. Ten patients had weight loss, and 10 had more than 10% weight loss in group A , after rehabilitation all 20 patients had normalized weight.
Summary / Conclusion: Timely and planned management of pain and other symptoms is effective in relieving patients and parents distress and improving their quality of life.

Health economics

B1992

THE COST OF PRODUCING A UNIT OF BLOOD IN GREECE: AN ECONOMIC ANALYSIS FOR THE CASE OF "AGIOS SAVVAS" REGIONAL CANCER HOSPITAL

V Fragoulakis[1*], E Grouzi[2], K Stamoulis[3], P Minogiannis[2], N Maniadakis[1]
[1]National School of Public Health, [2]Agios Savvas" Regional Cancer Hospital, [3]National Blood Centre (EKEA), Athens, Greece

Background: The economic burden of blood collection and processing is substantial and there are many studies which have provided useful insights and estimates in this field in several different healthcare settings across the world.
Aims: Given that healthcare resources are scare, especially in the presence of the current crisis in Greece, an economic analysis was undertaken to determine the mean cost of "producing" a unit of blood from a hospital and societal perspective. This abstract describes the preliminary findings of a project which attempts to estimate the cost of a blood unit across all the public hospitals nationwide.
Methods: In accordance with official guidelines, an activity based costing model with five steps was adopted, to produce more accurate results than conventional approaches. In this light, the cost of blood "production" from a hospital perspective accounted for a) the cost of collection, b) the cost of processing, c) the cost of laboratory testing, d) storage cost, and e) the cost for elimination of a blood unit if a component fails for any reason. In addition, from a societal perspective, indirect cost comprises the donor's productivity loss, assuming that each individual expends half of a working day per unit donated. The cost associated with donor recruitment, pre-transfusion preparation and administration, follow up due to adverse events or other relevant resources consumed in the long-term were not taken into consideration. It must be noted that in Greece there are not separate blood bank centers, which may operate as a supplier for local hospitals, and thus, the storage cost was estimated specifically for "Agios Savvas" hospital. As an allocation parameter for distribution of institutional overhead costs we used the square meters (m^2). The calculation of the medical equipment's depreciation was assumed to be fifteen years, with a discount rate at 3.5%. Main input parameters of the model include personnel cost, reagent costs, equipment related cost, percentage of wastage of blood units, institutional overheads, yearly blood production, the cost of Nuclear Acid Tests (NAT), other exams and relevant consumables. Data were collected through a structured questionnaire filled with data obtained by the blood centre of "Agios Savvas" Regional Cancer Hospital, the database of National Blood Centre of Greece, the National School of Public Health and the Ministry of Health. All data referred to the year 2012.
Results: The mean cost for "producing" a blood unit from a hospital perspective was estimated at €224.70. In particular, the cost of personnel was estimated at €99.18, the cost of institutional overheads at €8.52, the cost of consumables at €3.34, the cost of computerization at €0.80, the cost of blood bag (different types) at €28.30, the cost of examinations at €47.29, the cost of NAT at €37, the cost of blood distruction at €0.19 and the cost of equipment at €0.08. The indirect cost per blood unit was estimated at €31.67. Hence, the total societal cost per blood unit was estimated at €256.37.
Summary / Conclusion: The preliminary findings of this study represent an update of previous estimates, as well as an advance in the methodology used for the determination of the cost of blood unit in Greece. It must be mentioned that several cost elements which are associated with the cost of transfusion are missing from the present analysis and their consideration will certainly lead to higher estimates. A common issue in studies which use similar methodologies relates with the fact that the estimation of blood cost was based only at the Red Blood Cells production, without taking into consideration the rest of blood products, such as the Fresh Frozen Plasma or the platelets.

B1993

UNDERSTANDING PATTERNS OF ORDERING COMMON BLOOD TESTS IN PATIENTS ADMITTED TO HOSPITAL – AN AUDIT TO EVALUATE NUMBER AND FREQUENCY OF COMMON BLOOD TESTS IN ADMITTED PATIENTS IN A MEDIUM SIZED DGH

H Ahmad[1*], R Proud[1], C Grzesiowski[1], T Lennerova[1], A McDougall[1], C Spence[1]
[1]Haematology, Burton Hospitals NHS Foundation Trust, Burton on Trent , United Kingdom

Background: Blood tests play a very important part in the diagnosis and management of most diseases and pathology costs form significant proportion of the health service budget. The Independent Review of Pathology Services in the National Health Service UK by Lord Carter postulated that savings of £500 million annually are possible by reducing wastage.
In cost reduction strategies most savings are predicated on economies of scale and service redesign, creating larger pathology units with Hub and Spoke models to reduce waste and improve efficiency by up-scaling automation and down-scaling staffing levels etc.
However, inappropriate and unnecessary blood tests also contribute significantly to waste but there is a dearth of literature or guidance on this subject.
Aims: The aim was to evaluate number, frequency and appropriateness of common blood tests in adult patients admitted to the hospital in order to assess for possible wastage
Methods: In our study we conducted a retrospective audit on approximately four hundred patients admitted to a medium sized District General Hospital. Obstetric and paediatric patients were excluded from this study. The remaining 309 patients were evaluated using the electronic patient records. . The purpose was to study the number and frequency of common blood tests e.g. Full Blood Count, Renal and Liver blood tests. The data on Length of stay was also evaluated. The cohort was subdivided into following subgroups for data analysis: Medicine, Care of the Elderly, Orthopaedics & Surgery.
Results: Our results showed that over 50% of admitted patients were medical patients who also had a longer average length of stay than the surgical cohort. Consequently, average number of tests per patient was higher in medical patients but frequency of repeating blood tests appeared broadly similar in medical and surgical groups. The repeat ordering of blood tests did not appear to be influenced by abnormal results as similar frequency of repeat blood tests was noted in patients with normal and abnormal results.
The repeat ordering appeared to follow a recurring pattern rather than being reactive to the results of the previous test. There was significant wastage as blood tests were frequently repeated even when recent results were within normal range. On the contrary in some patients repeat tests were not ordered despite abnormal results. It was also interesting to note that there was no significant difference in repeat ordering of blood tests between cases showing severe abnormalities of Full Blood Count and those with milder abnormalities.
Summary / Conclusion: Although our audit had a number of limitations, it highlights the need for further studies to evaluate the pattern of ordering common blood tests in hospitalised patients with a view to identify wastage and minimise it.
There is also need for developing evidence-based consensus on how to reduce unnecessary testing without compromising patient safety. Published literature on this subject is limited and much innovative research is possible.

B1994

WORTHINESS OF BONE MARROW TRANSPLANTATION AS A TREATMENT OPTION FOR THALASSEMIA PATIENTS IN DEVELOPING COUNTRIES

M Missiry[1*], M Dubali[2]
[1]Department of Internal Medicine , National research center, Cairo, Egypt, [2]International Center of Bone Marrow Transplantation, Rome, Italy

Background: Thalassemia is a serious prevalent chronic genetic disorder worldwide, with carrier rates reaching 9% in some countries as Albania and Egypt. The long life course of thalassemia causes continuous suffering for the patients, parents and community. The problem aggravates more in developing countries where there are limited financial and human resources capable to cope with increasing numbers of patients and their needs. Treatment of thalassemia is of two types. The first is long life course treatment in the form transfusion and chelator administration. The other is the conclusive only cure for the disease, which is Stem cell transplantation, from which the most recommended type is bone marrow transplantation.
Aims: We aimed to study thalassemia in Albania and Egypt, as an example of developing countries with different circumstances.
Methods: Data collection and calculations for treatment costs in Albania and Egypt.
Results: We found that long life treatments of patients can reach 25, 400 and 12,300 euros in each country respectively. In Albania, there are no enough treatment facilities for the long life demanding patients, most importantly, lack of adequate blood and treatment costs that approaches European standards. Similar situation is present in Egypt where there is no enough resources to overcome the annually increasing number of patients. Moreover, and due to high carrier rate with lack of preventive program, increase of disease is found to be uncontrollable as well. Accordingly, curing thalssemia in young age by bone marrow transplantation; as a once per life treatment, can be the solution for the long life health and financial suffering for the disease.
Summary / Conclusion: Curing thalassemia in early age with - once in life - bone marrow transplantation can be the solution to avoid progressing health and financial problems.

B1995

SURVIVAL AND TREATMENT RELATED DEATHS IN PEDIATRIC ONCOLOGY PATIENTS: A SINGLE CENTER RETROSPECTIVE COHORT STUDY

G Mokhtar[1*], A Abdelmaksoud[1], S Elarab[2], A Alam[2]
[1]Pediatric hematology and oncology, [2]Ain Shams University, Cairo, Egypt

Background: Improved survival for pediatric cancer patients is one of the great success stories of the late 20th century.
Aims: To estimate survival, event free survival (EFS) and causes of treatment related deaths in childhood malignancies.
Methods: A retrospective review of patients' data from Hematology Oncology

Clinc, Children's hospital, Ain Shams University in the period from 1999 to 2008.
Results: 506 patients were included. The 5-year survival rate of the studied childhood malignancy was 49%. Patients were divided into; leukemia group (307 patients): 71% ALL, 22.5% AML, 0.2% biphenotypic and 4.3% chronic leukemias. The 5-year survival rate of these groups was 55, 23, 33 and 14% respectively, while; the 5-year EFS was 48.1, 25.2, 31 and 18% respectively. Lymphoma group (85 patients) included; Hodgkin disease (41%) and non Hodgkin lymphoma (59%), their 5-year survival rate was 81 and 57% respectively, and the 5-year EFS was 78 and 90% respectively. The solid tumors group (114 patients), comprised 43% with neuroblastoma and 27.2% with wilms' tumor, their 5-year survival was 19 and 60% respectively, and the 5-year EFS was 66 and 71% respectively. Infection was the most common cause of treatment related death representing 25.3% in leukemia patients, 30.7% in lymphoma patients, and 20.4% in solid tumor patients. Deaths related to progressive disease ranged from 25 to 45%. The commonest complication of chemotherapy was infection requiring hospital admission in 95% of leukemia patients, 82% of lymphoma patients and 85% of solid tumor patients. The commonest infections were febrile neutropenia and bronchopneumonia.
Summary / Conclusion: The highest survival rate was in patients with Hodgkin disease followed by those with wilms' tumor, while the lowest survival rate was for chronic leukemia followed by neuroblastoma and AML. More attention should be given to supportive care and infection control for oncology patients.

B1996
MORBIDITY RATE OF MALIGNANT NEOPLASMS OF LYMPHOID AND HEMATOPOIETIC TISSUE IN SAINT PETERSBURG
L Zhiguleva[1*], K Abdulkadyrov[1]
[1]Hematology, Russian Institute of hematology and Transfusiology, St.Petersburg, Russian Federation

Background: The analysis if the indexes of morbidity rate of malignant neoplasms of lymphoid and hematopoietic tissue in certain regions allows detecting of disease risk factors, forecasting morbidity level, planning hematological aid, evaluating its quality and detecting organization gaps.
Aims: To determine morbidity of malignant neoplasms of lymphoid and hematopoietic tissue in St.Petersburg in 2000-2010 y.
Methods: The research of morbidity rate indexes was performed for the period of 2000 – 2010, based on the state statistic account form No. 7 "Data of the diseased with malignant neoplasms", with involvement of the data from population cancer registry of Saint Petersburg and of Federal State Statistics Service about number, basic demographic trends of the population and morbidity rate indexes in Russia and Saint Petersburg.
Results: In the period of 2000 – 2010 the number of the newly diagnosed diseased with malignant neoplasms of lymphoid and hematopoietic tissue increased on 39%, while the number of the newly diagnosed diseased with all malignant neoplasms increased in Saint Petersburg on6,6% (and 15,2% in Russia). It provides evidence of high rates of malignant neoplasms of lymphoid and hematopoietic tissue morbidity rate increase in Saint Petersburg. The morbidity level among men exceeded the morbidity level among women. In the morbidity rate structure the lymphomas head the list: the standardized ratio of non-Hodgkin's lymphomas in 2010 was equal to 4.64 per 100 000 of population, of Hodgkin's lymphomas – 2.31. Next to it chronic lymphocytic leukemia ranked (2.23 per 100 000), the next was multiple myeloma and immunoproliferative diseases (2.14 per 100 000 of population), acute lymphocytic leukemia (1.48 per 100 000 of population), chronic myeloid leukemia (1.35 per 100 000), acute myeloid leukemia (1.17 per 100 000). The morbidity rate increase in the last 10 years took place due to the morbidity rate increase of non-Hodgkin's lymphomas (from 3.65 to 4.64 per 100 000), multiple myeloma (from 1.48 to 2.14 per 100 000), acute myeloid leukemia (from 0.83 to 1.17 per 100 000) and chronic myeloid leukemia (from 1.26 to 1.35 per 100 000 of population).
Summary / Conclusion: High levels of malignant neoplasms of lymphoid and hematopoietic tissue morbidity rate in Saint Petersburg result from a variety of causes, the main of which are: maintaining of the trend of senior and old people in the city population structure, ecological factors typical for large industrial cities, climate conditions that exacerbate the effect of the ecological factors. The morbidity rate indexes level is influenced also by the quality of primary diagnostics and optimality of the registration and account of the detected diseases. The quality is provided in Saint Petersburg by operation of the population cancer registry.

B1997
GOOD SURVIVAL RATES IN ELDERLY PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA COME AT A PRICE
A Gatt[1*], N Refalo[2], D Camilleri[1]
[1]Haematology-Oncology and Pathology, MATER DEI HOSPITAL AND UNIVERSITY OF MALTA, MALTA, Msida, [2]Haematology-Oncology , Boffa Hospital, Floriana, Malta

Background: Cases of lymphoma are on the rise in view of our ageing population. Haemato-oncologists are often faced with the dilemma of how aggressive one should be when treating very elderly patients hereby defined as >70 years, since very often similar patients have multiple comorbidities and relatively poor performance status.
Aims: The aims of this retrospective review were to define the survival rate and patient characteristics including costs of care of an unselected group of patients who were over 70 years old when diagnosed with Diffuse Large B-Cell Lymphoma (DLBCL) from January 2010 to February 2013 in Malta.
Methods: This was a case note review of 19 consecutive patients over 70years old with DLBCL including those with transformed follicular NHL. We looked at patient characteristics such as stage, gender, treatment regimes, ECOG performance status, costs of care.
Results: Mean age was 78.4 years (range 72-89years). 68.4% were female with an average ECOG performance status of 2. The mean Stage of the DLBCL was 2 with elevated LDH at 392. The eGFR was as expected at similar ages with a mean of 75 and mean albumin normal at 40.
All but 2 patients were treated with standard infusional chemotherapy (mainly reduced doses of Rituximab, Cyclophosphamide, Adriamycin, Vincristine and prednisolone or dexamethasone (R-CHOP). In patients with pre-existing cardiac problems the anthracycline was substituted with Etoposide (R-CEOP). The other 2 patients received radiotherapy only since one had a very poor performance status and the other only had minimal disease in one groin (Stage 1 A) and multiple co-morbidities including cardiac arrhythmias and severe ischaemic heart disease. 5 patients died with a mean survival of 354.2 days (24-830). 3 patients died in remission of conditions unrelated to the DLBCL and 2 died of complications of chemotherapy. 73.7% are alive with a mean follow-up time of 377 days. Only 14% of bone marrow biopsies were positive for lymphoma. The mean number of days of hospitalisation was 43.3 days with many requiring antibiotic and GCSF support.
Summary / Conclusion: It is evident that very elderly patients still have an excellent survival against DLBCL using tailored therapy. However, a large proportion required prophylactic GCSF and in-patient therapy±longterm care due to their multiple co-morbidities and lack of appropriate support in the community. This should be taken into consideration when one is planning future haemato-oncology services.

B1998
A PROSPECTIVE STUDY ON THE COST AND UTILIZATION OF AZACITIDINE IN A CANADIAN PROVINCE: IMPLICATIONS FOR BUDGET IMPACT ANALYSIS (BIA)
R Kumar[1,2*], P Skrabek[1,2], P Burns[3], B Lozar[4], M Geirnaert[3], V Bourrier[3], S Navaratnam[1,2]
[1]Medical Oncology and Hematology, CancerCare Manitoba, [2]Internal Medicine, University of Manitoba, [3]Pharmacy, [4]Information Services, CancerCare Manitoba, Winnipeg, Canada

Background: Cost effectiveness analysis (CEA) and incremental cost effectiveness ratio (ICER), based on data generated by Phase III trials, are often used to fund expensive drugs. Innovative drugs with proven efficacy may not be approved if they exceed arbitrary thresholds. The UK agency NICE initially did not recommend use of azacitidine (AZA) despite clinical efficacy and survival advantage based on a phase III trial. (Fenaux et al. Lancet Oncol 2009; 10:223-32).
Aims: To study the use and cost of azacitidine in the province of Manitoba (MB) and implications for cost analysis.
Methods: In MB (population 1.2 million), AZA became available in 2009 on compassionate basis and was later funded through CancerCare Manitoba. All Pts who were started on AZA from March 2009 to 30 April 2012 were prospectively studied. Drug utilization included any administration until 30 June 2012. Responses were as per IWG 2006 criteria, until 31 July 2012. Use was considered an 'approved indication' (AI) if it met Health Canada criteria: Intermediate-2 and high risk MDS or AML with 20-30% blasts. All other use was classified as a non-approved indication (NAI). Those on clinical trial were excluded. The cost of AZA per 100 mg vial was taken as $628 (listed price in Canada).
Results: A total of 27 Pts (8 females), received one or more doses of AZA for 20 AIs and 9 NAIs. In AIs, the diagnoses were: RCMD in5, RAEB-1 in3, RAEB-2 in 7 and AML (RAEB-t) in 5. The overall response was 50%: CR in 3 (15%), marrow CR with hematologic improvement (HI) in 2 (10%), and stable disease with HI in 5 (25%). Diagnoses in NAIs were: (a) RCMD (Int risk-1) in 2 (b) AML (blasts >30%) in 5 (with relapse after CR, failure of standard chemotherapy, or as a bridge to BMT) and (c) Relapse after BMT in 2 (these Pts had earlier received AZA for AIs). Response in NAIs was 11% (Stable disease with HI in 1). Detailed utilization and cost analysis is shown in Table 1. In the AZA 001 tri-

al, a median of 9 cycles were given at a schedule of 75mg/m^2 per day for 7 days, every 4 weeks. For an adult with BSA ≥1.4 mg/m^2, 2 vials of 100mg/day are needed (including wastage). Hence the estimated cost per cycle is $8,792. The projected cost of treatment per Pt is $ 79,128. Our study showed that the actual cost per Pt for AIs was $ 51,464. The median number of cycles given was less than in the AZA 001 trial (5 vs. 9) and in 33% cases, the doses were reduced or cycles attenuated. Our results are similar to a larger study from France, where patient received a median of 6 cycles (Itzykson et al. Blood 2011. 117: 403-11) Use in NAIs represented 18.9% of the cost incurred in AIs.

Utilization of Azacitidine in Manitoba over 3 years

Indications for AZA use	Median cycles (range)	Total cycles	Reduced dose or duration	Total vials used	Total cost ($)	Cost per cycle ($)	Cost per Patient ($)
Approved (n=20)	5(1-25)	141	33%	1639	1,029,292	7300	51,465
Non-Approved (n=9)	3(1-5)	23	9%	311	195,308	8492	21,701
AZA,azacitidine; $, Canadian dollars							

Summary / Conclusion: The importance of opportunity costs and budget impact have not received emphasis in recent economic literature. For decision makers, budget impact may have more relevance than ICER alone. The critical factors in a budget impact analysis (BIA) are the number of patients utilizing the drug and the magnitude of use. Data from RCTs may overestimate the amount of drug used per patient, while any information on the anticipated numbers for an orphan drug is likely to be unreliable. Moreover, clinical trials cannot provide information on the NAIs after licensing. To generate reliable data for BIA, phase IV studies are essential. For drugs which have proven clinical efficacy, conditional approval may be granted to generate phase IV data, before a final pharmaco-economic evaluation.

B1999

OVARIAN FUNCTION IN FEMALE SURVIVORS OF CHILDHOOD MALIGNANCIES

A El-shalakany[1*], M Ali[2], A Abdelmaksoud[2,3], S Ab-Elghany[2,3], E Hasan[1]
[1]obstetric &gynecology, [2]Ain Shams University, Cairo, Egypt, [3]pediatrics, Ain Shams University, Cairo, Egypt

Background: Chemotherapy-induced infertility is a common side effect observed in women of fertile age after treatment for malignant disease
Aims: to study gonadal function and fertility in female survivors of childhood malignancies.
Methods: Study included 30 female cancer survivors and 30 age matched healthy females as a control group. Data collected regarding; type of malignancy, age at diagnosis, duration on and off treatment, treatment received (radiation or chemotherapeutic regimens), sexual, menstrual, pregnancy and fertility histories were also recorded. Laboratory investigations included; T4, TSH, LH, FSH and AMH. Pelviabdominal ultrasound was done to estimate the mean ovarian volume.
Results: Among patients; 80% had normal menarche and 6 (20%) had delayed menarche (P>0.05). There was higher LH and FSH levels and lower AMH levels in patients (P<0.05) with no significant difference in thyroid function tests (P>0.05). Lower mean ovarian volume was observed among female survivors (6.32±2.31 cm^3) (P=0.041). There was a higher FSH & LH levels among female survivors of solid tumors compared to those with hematological tumors (P=0.05 and 0.04 respectively). There was a significant positive correlation between FSH level and patients' age at start of malignancy (r=0.65, P=0014), age of menarche (r=0.74, P=0.036) and duration of treatment (r=0.54, P=0.025).There was a significant negative correlation between age of menarche and AMH level (r=-0.61, P=0.03).
Summary / Conclusion: Female survivors of childhood malignancies had reduced ovarian reserve and reduced mean ovarian volume, especially those with older age, older age of menarche and longer treatment duration.

B2000

CHEMOTHERAPY ORDERING, PREPARATION AND ADMINISTRATION USING COMPUTERIZED OREDR ENTRY SYSTEM – HOSPITAL AMPANG (MALAYSIA) EXPERIENCE

T Ong[1*], K Chang[1], Y Guan[1]
[1]Haematology, Hospital Ampang, Malaysia, Pandan Mewah, Malaysia

Background: Chemotherapy errors are serious as cytotoxics have very narrow therapeutic window, are toxic even at therapeutic dosages and cancer patients are generally a vulnerable group. The complexity of regimen and drug schedule predisposes to medication error, one study showed hemato-oncology has the highest error rate.
Aims: We developed a stand-alone application using Microsoft Access to order, prepare and administer chemotherapy in Hospital Ampang. The application is built to suit the work process and automating calculation process. The final chemotherapy request and administration form complies with most of the standard recommendations by American Society of Oncology safety standards on chemotherapy.
Results: From Feb 2011 to end of 2012, a total of4,567 chemotherapy regimens, comprising 27,842 cytotoxic drug items were requested and processed via this application. 99% of chemotherapy order was made via electronic ordering. Regular meetings and surveillance are conducted to rectify and prevent error in programmed formula. Users' survey conducted after 24 months showed 100% satisfaction over the old manual prescription process.

Summary / Conclusion: With the introduction of computerized order entry system, we experience marked improvement in efficiency of ordering and processing chemotherapy requests. Since chemotherapy regimens and doses are computerized and autocalculated, improved safety via minimizing errors by manual ordering is also achieved. We strongly recommend centers handling chemotherapy treatment to develop a similar system that is customized to suit the work process in their practices. It is worthwhile to invest time and money to develop such an application as it reduces medication errors and potential litigation, which are both costly and potentially fatal.

Acute lymphoblastic leukemia – Clinical

B2001

EVALUATION OF SERUM LEVELS OF MULTIPLE CYTOKINES AND ADHESION MOLECULES IN PATIENTS TREATED FOR ACUTE MYELOID LEUKEMIA

T Kupsa[1,2*], J Horacek[1,2], M Vasatova[3], L Jebavy[1,2], P Zak[2]
[1]Department of Internal Medicine, University of Defence, Faculty of Military Health Sciences, [2]4th department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, [3]Institute of Clinical Biochemistry and Diagnostics, University Hospital, Hradec Kralove, Czech Republic

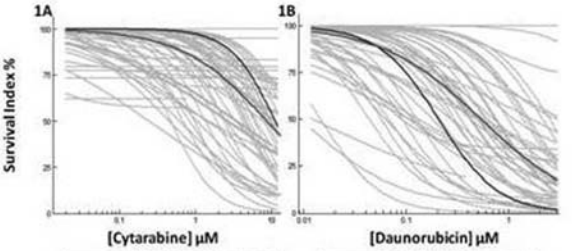
Background: Acute myeloid leukemia (AML) shows a high degree of heterogeneity due to a variety of mutations and mechanisms involved in leukemogenesis. This heterogeneity is often not fully reflected in standard treatment approaches. Cytokines are soluble molecules that take part in intercellular communication, with a specific role in cell proliferation control. Postconsolidation immunotherapy with interleukin-2 and histamine dihydrochloride improved the leukemia-free survival of adult patients with acute myeloid leukemia in complete remission. Increased levels of soluble adhesion molecules have been shown to correlate with better outcome. Further knowledge gained from multiple cytokine and adhesion molecule analysis should allow better diagnosis and disease management.
Aims: The aim of our study was to evaluate serum levels of multiple cytokines and adhesion molecules and changes related to disease activity in patients treated for AML.
Methods: A total of 20 AML patients, mean age 53.5±11.8 years, median 55.4, 7 males and 13 females, 4 with better risk, 7 with intermediate risk, 9 with high risk according to cytogenetics and molecular genetics, treated with cyclic chemotherapy (3+7, 2+5, HiDAC) alone or in combination with high-dose chemotherapy (FIAG-Ida, preparative regimen Bu/Flu/ATG) followed by allogeneic hematopoietic stem cell transplantation in 5 cases were studied. We evaluated serum levels of the following 22 cytokines and adhesion molecules: interleukins (IL-1 alpha, IL-1 beta, IL-2, IL-3, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-23), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-alpha), interferon-gamma (IFN-gamma), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1), E-selectin, L-selectin, P-selectin, intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox) at the diagnosis of AML (active leukemia) and in durable complete remission (CR) at circa 6 months after completion of chemotherapy.Probability values (p) < 0.01 were considered statistically significant.
Results: Comparing serum cytokine and adhesion molecule levels in active leukemia and in durable CR, we found significant increase in serum IL-7 (6.43±4.91 ng/L vs. 21.36±7.72 ng/L; P<0.00005), EGF (17.52±16.01 ng/L vs. 48.66±28.15 ng/L; P<0.0001) and VEGF (65.48±41.33 ng/L vs. 158.92±60.75 ng/L; P<0.0005). On the other hand, we found significant decrease in serum L-selectin (2430.93±1032.85 mcg/L vs. 1340.15±308.27 mcg/L; P<0.0005) and IL-13 (6.97±3.41 ng/L vs. 4.02±4.02 ng/L; P<0.01). Serum levels of other evaluated cytokines and adhesion molecules were without significant differences.
Summary / Conclusion: Our results indicate that serum levels of some cytokines and adhesion molecules (IL-7, EGF, VEGF, L-selectin, IL-13) are significantly altered in patients treated for AML, reflecting activity of the disease. Whether these alterations could serve as a prognostic marker for AML is not known. To assess their predictive value for patient outcome, further studies comparing cytokine and adhesion molecule levels with established prognostic markers (cytogenetics, molecular genetics) in a larger number of patients is necessary.
The work was supported by Specific research project "Analysis of defined prognostic factors in acute myeloid leukemia" (FMHS) and by a long-term organisation development plan 1011 (FMHS).

B2002

PREDICTION OF CLINICAL RESPONSE USING A PERSONALIZED MEDICINE *ex vivo* TEST IN A PATIENT DIAGNOSED WITH MIXED PHENOTYPE T/MYELOID ACUTE LEUKEMIA

J de Oteyza[1*], A Serrano[1], E Panizo[1], M Bengochea[1], E Rodrigo[1], S Alvarez[1], F Garcia[1], P Montesinos[2], F Moscardó [2], D Cuadrón[2], M Sanz[2], J López[3], D Primo[4], P Hernández-Campo[4], J Gorrochategui[4], T Bennett[4], J Nobell[4], B Liébana[4]
[1]Haematology, Hospital de Madrid Norte Sanchinarro, Madrid, [2]Haematology, Hospital Universitari i Politecnic La Fe, Valencia, [3]Haematology, Hospital Universitario Doce de Octubre, [4]Vivia Biotech, Madrid, Spain

Background: Mixed phenotype acute leukemia, T/ myeloid, is a rare entity accounting for less than 1% of leukemias. Treatment of these entities is not well defined, since response to standard chemotherapy regimens is usually poor. A patient presenting with this mixed lineage leukemia was part of a multicenter, prospective, non-interventional study of the PETHEMA group conducted by Vivia Biotech.
Aims: The objective of the study is to determine the validity of a personalized drug sensitivity test to predict clinical response based on the analysis of leukemic cell death *ex vivo* in rare leukemias.
Methods: A bone marrow sample was collected at diagnosis and processed in the Vivia lab. The sample was diluted in its entirety (retaining erythrocytes and plasma) and plated with the drugs, each at 8 concentrations. The plates were incubated 48-hours, then analyzed by our automated flow cytometry-based ExviTech© platform. Malignant cell death was determined via labeling with appropriate monoclonal antibodies and AnnexinV-FITC. Dose-response curves for 16 drugs were generated, including Cyt, Dau, Flu and idarubicin (Ida) were run. The key parameters are the efficacy of the drug to deplete cells, and the potency of the drug measured as the concentration at which 50% of the cells are eliminated (EC50). A survival index is computed for each drug, calculating the percentage of malignant cells remaining. The lower the survival index, the more effective the drug is in eliminating the malignant population. The Effective Maximum (Emax) is the maximum possible effect for the drug, thus an Emax of 0% indicates that there are no surviving malignant cells. Vivia's results were not used to drive treatment.
Case report: A 77 year old man presented with a WBC of 37.54 x 10^9/L , Hemoglobin 12.7 gr/dl and platelets 64 x 10^9/L. Bone marrow aspirate showed 80% blast cells, and a diagnosis of mixed phenotype acute leukemia, T/ myeloid, was established. Cytogenetic studies showed two clones: 46, XY, del(5)(q15q33)[3] and 46, XY, del(5)(q15q33), del(6)(q15q25)[17]. Furthermore, oligolonal T-cell receptor rearrangement (VjA/VjB) was found. Induction chemotherapy with fludarabine (Flu) plus cytarabine (Cyt) was initiated. Twenty days later the patient remained in grade IV pancytopenia. Bone marrow aspirate showed persistence of 60% blasts, demonstrating chemo resistance. A DAOP chemotherapy including daunorubicin (Dau), Cyt, vincristine plus prednisone was administered. After 20 days, the patient showed complete neutrophil and platelet recovery. A bone marrow aspirate showed absence of leukemic blasts indicating that CR was achieved.
Results: Figure 1A displays the dose-response curves from 121 patients to Cyt (grey). The response of the patient referenced above (blue) to this drug was much worse than the average (red) with the drug having a survival index of only 48.3%, indicating that it was able to eliminate only 50% of the malignant cells. However, the patient appeared to be particularly sensitive to Dau, as seen in figure 1B. Shown are Dau dose-response curves from 102 patients (grey), with the patient's response in blue and the average response in red. Dau was both more potent (lower EC50) and very effective (survival index = 0) than the average patient response. The patient's sample also tested moderately sensitive to Ida but resistant to Flu and all other drugs tested.
Summary / Conclusion: Vivia's *ex vivo* analysis was able to predict the clinical response in this patient. This type analysis could prove useful in cases such as this where incidence is rare and standard treatment protocols are not known



Cyt	EMAX	EC50
Average,Red	22.1%	6.03µM
Patient, Blue	48.3%	11.2µM

Dau	EMAX	EC50
Average, Red	12.3%	0.80µM
Patient, Blue	0%	0.21µM

Chronic lymphocytic leukemia and related disorders

B2003

SERUM FREE LEPTIN, LEPTIN RECEPTOR AND INSULIN IN RELATION TO B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA RISK

M Dalamaga[1], A Lekka[2], M Triantafilli[2*], J Chamberland[3], K Karmaniolas[4], A Dionyssiou-Asteriou[1], C Mantzoros[3]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, NIMTS Hospital, Athens, Greece, [3]Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Internal Medicine, NIMTS Hospital, Athens, Greece

Background: Excess weight is now considered to be a risk factor for many types of cancer, including leukemia and lymphoma. Leptin, an adipocyte secreted hormone, and particularly free leptin, the biologically important form of leptin, reflecting accurately the body fat mass, modulates glucose and fat metabolism by improving insulin sensitivity and reducing intracellular lipids. Leptin has also been proposed to have a role in hematopoiesis and was not studied in depth in B-cell chronic lymphocytic leukemia (B-CLL).
Aims: In this case-control study, we attempted to investigate the contribution of serum free leptin, leptin receptor and insulin to B-CLL risk, taking also into account potential confounders including the family history of lymphohematopoietic cancer (LHC) and the body mass index (BMI). We also attempted to ascertain whether a relationship between free leptin and prognostic markers exists amid patients with B-CLL diagnosis.
Methods: Blood samples were collected from 95 cases with incident B-CLL, and 95 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Serum insulin and leptin were determined by radioimmunoassay (Millipore and Linco Research, Inc. respectively). Serum leptin receptor levels (sOB-R) levels were measured using a commercially available ELISA (BioVendor Laboratory Medicine). Free Leptin Index (FLI) was calculated as the ratio of leptin to sOBR. Furthermore, serum lactate dehydrogenase (LDH), β_2-microglobulin (BMG), lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocyteswere assessed. The statistical analysis of the data was performed using IBM-SPSS® version 20 for Windows.
Results: Patients with B-CLL presented on average a higher BMI as compared to control participants (27.8 vs. 26.7 kg/m^2; P<0.01). Significantly, more cases than controls had a family history of LHC (13 vs. 3 controls; P<0.01). Circulating leptin was significantly lower in cases as compared with controls (10.03 vs. 13.89 ng/mL, P<0.01). FLI was lower in cases than in controls (P=0.003). Cases with B-CLL exhibited higher sOB-R levels though not statistically significant at α=0.05. Among patients, FLI was positively associated with insulin (r=0.26, P=0.01). Also, FLI was negatively correlated with Binet stage, BMG, total lymphocyte count, LDH and atypical lymphocyte morphology (P<0.05). Finally, lower FLI was associated with B-CLL risk in unadjusted analyses as well as after controlling for age, gender, date of diagnosis, family history of LHC, BMI and insulin levels (OR: 0.23, 95% C.I.0.09-0.57; P=0.001).
Summary / Conclusion: FLI was found to be lower among cases as compared to controls, despite cases exhibiting a higher BMI. It has been recently shown that hypoleptinemia but not hyperleptinemia is linked to the risk for several malignancies. These results need to be confirmed in larger study populations, but if reproduced, they may suggest that leptin becomes dysregulated, or that other factors such as inflammatory cytokines secreted by lymphocytes suppress leptin expression at later stages of B-CLL process.

B2004

THE RESPONSE TO CHEMOTHERAPY AND IMMUNOCHEMOTHERAPY AMONG PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACCORDING TO THE NUMBER OF CELLS WITH A DELETION OF 13Q14

T Zagoskina[1*], V Ovsepyan[1], E Zotina[1], S Baranchikova[1], I Grishina[2]
[1]Kirov Research Institute of Hematology and Blood Transfusion, [2]Kirov State Medical Academy, Kirov, Russian Federation

Background: Nowadays, among patients with chronic lymphocytic leukemia (CLL), the response to the modern therapy depends on its type and the various prognostic factors, including chromosomal abnormalities. It is well-known, that the number of cells with a deletion of 13q14 (del13q14) affects the clinical course of CLL.
Aims: Assess the response to chemotherapy and immunochemotherapy in patients with CLL according to the number of cells with del13q14.
Methods: We identified 77 patients with CLL with the only del13q14. The median age was 61 years. Patients were divided into 2 groups according to the type of received treatment. The first group (n=35) was treated by the regime FC (fludarabine, cyclophosphamide), the second one (n=42) – by the regime RFC (rituximab, fludarabine, cyclophosphamide). Chromosomal abnormalities were determined by FISH during the time of diagnosis before specific therapy. Patients were divided into 2 subgroups according to the number of cells with del13q14. The first subgroup included 41 (53%) patients with del13q14 in ≥ 60% of cells, the second one – 36 (47%) patients with del13q14 in < 60% of cells.
Results: A complete remission (CR) was achieved in 7 (44%) patients among the 16 patients with del13q14 in < 60% of cells, received treatment FC, a partial remission (PR) – in 8 (50%) patients, no effect was observed in 1 (6%) patient. CR and PR were achieved among 3 (16%) and 7 (37%) patients accordingly from 19 ones of the first group with del13q14 ≥ 60% of cells. The lack of therapeutic effect was observed in 9 (47%) patients (p=0.021). Median follow-up of patients was 68 months. Median overall survival (OS) in patients with del13q14 in < 60% of cells, received treatment FC, has not been achieved, and in patients with del13q14 in ≥ 60% of cells it was 53 months (P=0.014). Median time to progression (TTP) in patients with del13q14 in < 60% of cells was 30 months, and with del13q14 in ≥ 60% of cells – 19 months (P=0.021). The effect of the therapy RFC was independent of the number of cells with del13q14. CR was achieved in 15 (75%) patients among the 20 patients with del13q14 in < 60% of cells, received treatment RFC, PR – in 4 (20%) patients; CR and PR were achieved in 14 (64%) and 6 (27%) cases respectively (P=0.644; p=0,849) among 22 patients with del13q14 in ≥ 60% of cells. Medians OS of patients received treatment by RFC, and having a different number of cells with del13q14, have not been achieved during the follow-up (P=0.438). However, the TTP was dependent on the number of cells with del13q14. Thus, median TTP in patients with del13q14 in < 60% of cells was 62 months; among patients with del13q14 in ≥ 60% of cells it was 43 months (P=0.041).
Summary / Conclusion: Determination of the number of cells with del13q14 among patients with CLL has an important clinical significance and can be used as additional prognostic factors of response to the therapy, as well as for the selection of appropriate treatment programs.

B2005

SERUM FETUIN-A/A2HS-GLYCOPROTEIN LEVELS IN PATIENTS WITH B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

M Dalamaga[1], A Lekka[2], M Triantafilli[2*], J Chamberland[3], K Karmaniolas[4], A Dionyssiou-Asteriou[1], C Mantzoros[3]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, NIMTS Hospital, Athens, Greece, [3]Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Internal Medicine, NIMTS Hospital, Athens, Greece

Background: Obesity and overweight may be considered as risk factors for many types of cancer, including leukemia and lymphoma. A significant association of excess body weight with insulin resistance (IR), characterized by hyperinsulinemia has been well documented. There is also evidence that IR is involved in several malignancies related to obesity. Fetuin-A, also known as α2HS-glycoprotein, a hormone synthesized mainly in the liver reflecting ectopic hepatic fat deposition, could cause IR via inhibition of insulin signaling; modulate adipocyte function by downregulating adiponectin expression; and interact with various growth factors influencing tumor initiation and progression.
Aims: In this case-control study, we explored the role of serum fetuin-A in conjuction with insulinemia in relation to B-cell chronic lymphocytic leukemia (B-CLL) risk. We also investigated its association with several established prognostic factors for B-CLL.
Methods: Blood samples were collected from 95 cases with incident B-CLL, and 95 hospital controls, admitted for non-neoplastic and non-infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2001 and 2007. Serum insulin was determined by radioimmunoassay (Millipore). Serum fetuin-A levels were measured using an enzyme linked immunosorbent assay (Biovendor R&D). Moreover, serum lactate dehydrogenase, β_2-microglobulin, lymphocyte morphology and the surface expression of CD38 in >30% of B-CLL lymphocyteswere determined. The statistical analysis of the data was performed using IBM-SPSS® version 20 for Windows statistical software package.
Results: Patients with B-CLL had a higher body mass index (BMI) compared to controls (27.8 vs. 26.7 kg/m^2; P=0.01). Circulating fetuin-A was significantly lower in cases as compared to controls (241.9 vs. 288.8 μg/mL, P=0.005). In multivariate analysis, the highest tertile of circulating fetuin-A levels is associated with an odds ratio of 0.21 (95% CI: 0.08-0.52) compared with the lowest tertile adjusting for age, gender, date of diagnosis (matching factors), body mass index (BMI), family history of LHC, and serum insulin levels. Because BMI is a significant risk factor for B-CLL in this dataset, stratifying by BMI revealed that only among overweight/obese subjects (BMI≥25 kg/m2), those with hypofetuinemia presented a higher risk for B-CLL before and after adjustment with matching factors, family history of lympohematopoietic cancer and insulin levels. Finally, no significant association was observed between fetuin-A and B-CLL prognostic markers (P>0.05).
Summary / Conclusion: This study suggests that low serum fetuin-A may be associated with B-CLL risk in the context of overweight/obesity. In B-CLL patients, fetuin-A levels were lower, possibly due to a compensatory response to the upregulation of other inflammatory cytokines/factors which may be ontologically linked to B-CLL. The mechanisms underlying fetuin's role in B-CLL etiopathogenesis require further investigation.

Myeloma and other monoclonal gammopathies – Clinical

B2006

THE POTENTIAL ROLE OF DEXA-BEAM IN MULTIPLE MYELOMA FOCUSING ON EXTRAMEDULLARY DISEASE – A CASE SERIES

L Rasche[1*], S Strifler[1], J Duell[1], A Rosenwald[2], A Buck[3], U Mäder[4], H Einsele[1], S Knop[1]

[1]Internal Medicine, Hematology and Oncology, University Hospital Wuerzburg, [2]Pathology, University Würzburg, [3]Nuclear Medicine, University Hospital Wuerzburg, [4]Tumor registry, University Wuerzburg, Wuerzburg, Germany

Background: Extramedullary (e) disease in multiple myeloma (MM) is characterized by an aggressive biology and an adverse prognosis especially when occurring at relapse. Published therapeutic regimens are inconsistent and results contradictory, especially regarding use of the "novel compounds". Due to the high proliferation found in eMM lesions we analyzed outcome data of patients treated with a non novel-agent-based therapy, the Dexa-BEAM protocol which is usually used in relapsed high grade lymphoma.

Aims: Evaluating the potential role for applying lymphoma-directed treatment to extramedullary multiple myeloma.

Methods: Retrospective analysis of MM patients having received Dexa-BEAM (including dexamethasone, carmustine, cytarabine, etoposide and melphalan) at a single center in the years 2007-2012. In all, 18 patients were identified, 11 of whom had extramedullary disease.

Results: Objective responses (≥PR) after Dexa-BEAM were achieved in more than half of patients with extramedullary disease (6/11); furthermore, a high-dose consolidation strategy with autologous or allogeneic stem cell transplantation improved upon the depth of remission in two-thirds of eMM patients (4/6) with ongoing remissions in three patients. In contrast all patients without consolidation relapsed. Progression-free survival after Dexa-BEAM was short in both patient groups with intramedullary or extramedullary myeloma with a median of 3 and 4 months, respectively. Toxicity was relevant with one treatment-related death and grade 3 and 4 toxicities in all 18 patients.

Summary / Conclusion: Dexa-BEAM may be an effective induction regimen in medically fit patients with extramedullary manifestations to regain disease control prior to an intended auto or allogeneic transplantation. For Patients who are not eligible for transplantation, alternative therapies should be chosen.

Myeloproliferative neoplasms – Clinical

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm (MPN) characterized by ineffective hematopoiesis and symptomatic burden such as cytopenias, and splenomegaly. The prevalence of MF symptoms is relatively uniform across the 3 main subtypes: primary MF (PMF), post – polycythemia vera MF (PPV MF), and post – essential thrombocythemia MF (PET MF). The only potentially curative therapy is allogeneic hematopoietic stem cell transplantation (HSCT) but treatment-related mortality remains high. Recently ruxolitinib an oral Janus kinase 1/2 inhibitor (JAK-1/2) has been approved to treat patients with MF. The safety and efficacy of Ruxolitinib has been evaluated 528 patients from COMFORT I and COMFORT II trials

Aims: To report the first clinical experience in a CUP with an oral JAK–1/2 Inhibitor (ruxolitinib) in 88MF patients in Mexico

Methods: PMF patients and PPV/PET MF eligible for the ruxolitinib CUP, were diagnosed according to 2008 WHO criteria, irrespective of JAK2 mutation status; classified as high risk; intermediate risk level 2; or, intermediate risk level 1 with an enlarged spleen; with a peripheral blood blast count of < 10%; adequate renal and liver function, platelet count >100x10^9/L. Therapy with ruxolitinib was administered to all patients. Doses were adjusted according to the platelet counts.

Clinical and demographic characteristics were assessed at baseline and during the follow-up. The analyzed characteristics were: Demographic: age, gender; Clinical: Risk group, Bone marrow fibrosis grade, spleen size, ECOG, MPN subtype, JAK mutation, CBC counts; Spleen size at baseline and at week 52 of treatment

Results: The median age was 64.2 (Interval 41 – 75). Gender distribution was 46% female and 54% male. IPSS risk category distribution: 10% low risk; 53.3% intermediate – 1 risk; 26.7 % intermediate – 2 risk; and 20% high risk. Bone marrow fibrosis grade distribution was: Grade I 46.15%; Grade II 23.07%; Grade III 30.76%. Spleen length below costal margin: <10 cm, 80.7%; 10 to ≤20 cm, 11.5% and > 20 cm, 7.7% of patients. Spleen Average size was 9.58 cm below costal margin at the beginning of treatment. ECOG 0 was present in 15% of patients; $ECOG_1$, 73%; and $ECOG_2$, 12% of patients. The disease subtype distribution was: PMF 45%; PPV-MF 19% and PET-MF 36%. JAK mutation was positive for 46% of patients, 19% were negative, and 35% did not have mutation analysis.

The findings from the baseline to week 52 were: Splenomegaly decreased from 9.58 cm (avg) to 2.8 cm (avg) (70.77% of reduction); Median Hemoglobin level was 13.2 gr/dL at baseline versus 10.24 gr/dL (22.42% of decrease). Median Platelet count was 437,000/mm^3 at baseline versus 341,503/mm^3 at week 52 of treatment

Summary / Conclusion: Data showed demonstrate principal characteristics of subjects. This analysis shows that continuous oral ruxolitinib therapy can reduce splenomegaly in MF patients. Besides, efficacy of treatment on low risk and

intermediate-1 patients is shown for the first time with good results.
Further follow-up is needed to assess the long-term outcomes with respect to efficacy and safety symptoms in this cohort of Mexican patients.

B2008

SAFETY PROFILE OF RUXOLITINIB IN PRIMARY MYELOFIBROSIS, POST-POLYCITEMIA VERA MYELOFIBROSIS AND POST-ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS IN A COMPASSIONATE USE PROGRAM (CUP) IN MEXICO

P Guzman[1*], G Agreda[1], P Vargas[2], R Ovilla[3], M Alvarado[4], J Solis[5], S Silva[6], J Kassack[7], S Zavala[8], A Morales [9], A Herrera [9], M Rodriguez [10], X Lopez[1], E Reynoso [11], G Ruiz [12], P Sobrevilla[2], M Garcia[6], J Aguilar [13], R Morales [14], E Barrera [15], A Osuna [16], J Rodriguez [17], G Silos [18], A Vega [19], S Cuin [20], M Mora [21], C Best [22], E Murillo [23], L Loarca [24], O Perez [25], J Pachicano [26], E Baez [27], J Montemayor [28], D Barrera [29], J Garcia [30], L Peraza [30], S Baltazar [27], R Ramirez [31], L Iniguez [31], K Nacho [31], T Romero [31]

Background: Since the discovery of JAK2 in 2005, JAK inhibitors have been the subject of multiple clinical trials in primary myelofibrosis (PMF), post-essential thrombocythemia myelofibrosis (PET-MF) and post polycythemia-vera myelofibrosis (PPV-MF). Ruxolitinib (INCB018424) is a JAK1, JAK2 and JAK3 inhibitor. Phase III studies (COMFORT-I and COMFORT-II) have demonstrated its effectiveness and a suitable safety profile, being anemia and thrombocytopenia the most common adverse events, but they rarely led to discontinuation of the drug.
Aims: Describe the safety profile of ruxolitinib in CUP for patients with PMF, PET-MF and PPV-MF in Mexico.

Table 1. Hematologic and nonhematologic adverse events observed in patients treated in Compassionate Use Program with Ruxolitinib in Mexico.

Event	Ruxolitinib (N=88) Total events = 21 (23.8%)			
Grade	All grades (%)	Grade 3 or 4 (%)	Intervention	Final outcome
Nonhematologic	(14.7)	(4.5)		
Nausea	1 (1.13)	1 (1.13)	DS	W
Alopecia	1 (1.13)	0	None	Resolved
Septic shock	2 (2.27)	2 (2.27)	DS	W/Death
Pruritus	1 (1.13)	1 (1.13)	O	Resolved
Tuberculosis	2 (2.27)			
Pulmonary	1 (1.13)	NA	TS	Resolved
Nodal	1 (1.13)	NA	DS	W
Pneumonia	1 (1.13)	NA	O	Death
Superior respiratory tract infection	1 (1.13)	NA	O	Resolved
Zoster reactivation	2 (2.27)	NA	O	Resolved
Complicated urinary tract infection	1 (1.13)	NA	O/DS	W/Death
Basocellular carcinoma of the ear	1 (1.13)	NA	¥	Resolved
Hematologic	(9)	(2.27)		
Cytopenias	4 (4.54)	2(2.27)		
Thrombocytopenia	2 (2.27)	2 (2.27)	TS	Resolved
Anemia	2 (2.27)	0	None	None
Disease progression	4 (4.54)			
AML	3 (3.4)	NA	DS	W/Death
CMML	1 (1.13)	NA	DS	W

AML: acute myeloid leukemia. CMML: chronic myelomonocytic leukemia. TS: temporal suspension of ruxolitinib. NA: Not applicable. DS: definite suspension. W: withdrawal from the program. ¥ Topical treatment with 5-fluoracil. O: Other treatment (antihistaminics, antibiotics).

Methods: Descriptive, retrospective and multicentric study addressing the safety profile of 88 patients with primary or secondary myelofibrosis (WHO criteria), intolerant or non-responding to previous treatments, not eligible for allogenic transplantation and enrolled in a CUP with ruxolitinib was analyzed.
Results: Eighty-eight patients that received at least one dose of ruxolitinib were included in the analysis, from September 2011 to February 2013. In this group, the incidence of adverse events was 23.7% (20/88 patients) and both hematologic and non-hematologic grade III and IV events were present in 6.8% (6/88 patients). Grade III thrombocythopenia developed in 2.27% (2/88 patients) and self-resolved with temporarily suspension of treatment. Grade I and II anemia also developed in 2.27% (2/88 patients) requiring transient transfusion support. Infectious complications presented in 10.2% (9/88 patients), 2 cases of septic shock (without microbiologic isolation), 2 cases of tuberculosis reactivation (pulmonary and nodal), 2 cases of zoster reactivation, 2 cases of respiratory tract infections and last a case of pyelonephritis. Disease progression during treatment was present in 4.54% (4/88 patients), 3 patients progressed to acute myeloid leukemia (AML) and 1 patient to chronic myelomonocytic leukemia. At last follow up the rate of withdrawal from the program was 10.2% (9 patients), being disease progression the main cause. Seven deaths (7.9%) have been reported so far (three cases of AML progression and four associated to infectious complications).
Summary / Conclusion: Adverse events were monitored continuously during the program. According to these results safety profile of ruxolitinib in CUP proved to be manageable, associated with few grade 3 or 4 adverse events and the percentage of patients who discontinued treatment due to adverse events was small (10.2%). Infectious complications were the most frequently reported non-hematologic adverse events. Interestingly in this population there were two cases of reactivation of tuberculosis (nodal and pulmonary), one resolved with conventional treatment and was able to continue in the study, and the other (nodal) had to discontinue the drug and was withdrawn from the program. In summary, this data showed that oral ruxolitinib therapy has a tolerable safety profile in patients with myelofibrosis, as previously reported in other international clinical trials.

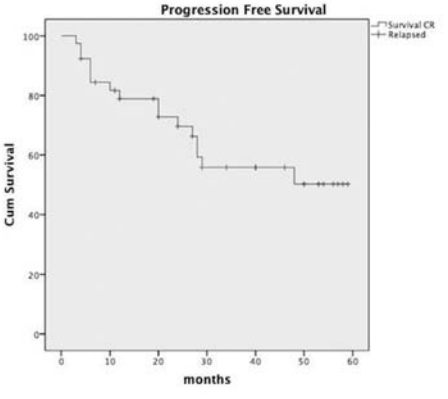
Non-Hodgkin lymphoma – Clinical

B2009

EFFICACY AND SAFETY OF THERAPY WITH 90Y IBRITUMOMAB TIUXETAN, IN B CELL NHL PATIENTS OVER 65 YEARS OLD.

M Campos[1*], A Limon[1], I Florez[1], J Grasa[2], T Baringo[3], P Giraldo[4]
[1]Department of Haematology and Hemotherapy, [2]Miguel Servet University Hospital, Zaragoza, Spain, [3]Department of Nuclear Medicine, [4]Department of Haematology and Hemotherapy / Translational Research Unit, Miguel Servet University Hospital, Zaragoza, Spain

Background: 90Y Ibritumomab tiuxetan (90Y-IT) has become an efficient option to therapy in B-cell non-Hodgkin Lymphoma (NHL).
Aims: To analyse our updated information of patients treated with 90YIbritumomab/tiuxetan in a prospective study according clinical practice setting and to analyse treatment outcome in elderly patients.
Methods: A total of 39 B cell NHL patients were included in a clinical protocol conducted by a multidisciplinary team and treated in the same centre. According to the inclusion criteria: patients over 65 years old diagnosed as CD20+ NHL with neutrophils ≥1,5 x 10^9/L, platelets ≥ 100 x 10^9/L, bone marrow lymphocytes CD20+ ≤ 25%. All patients received 0,3 or 0,4 mCi /kg IV (88%) of 90YIbritumomab/tiuxetan and response evaluation was performed 12 weeks after. Period of study: September 2005/February 2013. The 90Y-IT was administered as consolidation of first line therapy (Rituximab alone, R-COP, R-CHOP21) or in relapsed/refractory status. Endpoints: objective response rate (ORR), time to relapse (PFS) overall survival (OS) and safety. Other clinical prognostic factors were observed to assess their possible influence upon treatment value.



Results: At the end of February 2013, 39 patients over 65 years old, had received treatment with 90YIbritumomab/tiuxetan and completed the evaluation protocol and were considered to analysis; M/F: 18/21, mean age 72.8 years (65-87); ECOG 0-1 92.3%. According OMS classification: NHL-follicular 27 (69.2%), mantle cell Lymphoma 7 (17.9%), DLBCL 4 (10.3%) and 1MALT (2.6%). Score distribution: low risk 19 (48.7%), intermediate 12 (30.8.2%) and advanced 8 (20.5%). Previous therapy schedules ≤2 (66.7%), >2 (33.3%). The median follow-up time: 46.0 months (95% CI: 4.0; 88.0), mean PFS: 39.5 months (95% CI: 32.2; 46.8) median NR (see Fig 1.). 13 patients received 90Y-IT as consolidation of first line therapy (33.3%) and 26 relapsed/refractory (66.6%). ORR was 84.6 % CR: 29 (74.3%); PR 4 (10.2%) and 6 failures (15.4%) in relapsed/refractory disease. Mean estimated OS since ^{90}Y-IT: 63.1 months (95% CI: 51.7; 74.4) and mean estimated OS since diagnosis 158 months. Median PFS was NR. The mean PFS for patients in consolidation therapy was 52.1 months (95% CI: 44.4; 59.7), but any NHL-follicular patients in consolidation (11) have been relapsed even dead. Safety: thrombocytopenia being the most frequent, G3-4 (35.9%), median time to developed haematological toxicity: fourth week, and neutropenia G3-4 (41.0%), the median time to recover normal values was 4.2 and 2.6 weeks respectively. In 5 (12.9%) of patients red blood cell transfusion was required, and 10 platelet transfusions (25.6%). The most frequent non haematological toxicity was asthenia. One patient developed a severe mucositis. Four patients have concomitant associated tumours (colon, breast, lung and prostate) and two patients over 77 years developed a rectum carcinoma after 18 months of 90Y-IT and another prostate and renal tumour after 8 years. Non-mortality related therapy was registered, at the end of study 10 patients have died, 6 of them in relapse.
Summary / Conclusion: In our experience 90Y Ibritumomab tiuxetan is a safety and effective therapy in patients with NHL over 65 years. According to obtained PFS results, it seems like the use of this kind of therapy as used in early part of therapy offers good and maintained response rate with lower toxicity in this fragile population. The OS in this population was not inferior to observed in younger NHL patients.

Stem cell transplantation – Clinical

B2010

ALLOGENEIC VERSUS AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR NON PROMYELOCYTIC ACUTE MYELOID LEUKEMIA: 30 YEARS EXPERIENCE IN A SINGLE CENTER

M Carmen[1*], G Perez-Vazquez[1], A Cuesta[1], Z Diez[1], A Bermudez[1], C Richard[1], E Conde[1]
[1]Hematology, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: The optimal post-remission treatment for Acute Myeloid Leukemia (AML) remains uncertain. Traditional comparisons of Allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT) versus Autologous Hematopoietic Stem Cell Transplantation (auto-HSCT) noted higher TRM (Treatment Related Mortality) but lower CIR (Cumulative Incidence of Relapse), with discordant results in Overall Survival (OS).
Aims: Retrospective study of 274 patients diagnosed of AML (Acute Promyelocytic Leukemia excluded) who underwent Hematopoietic Stem Cell Transplantation (HSCT) in our center between 1982 and 2011. We compared CIR, TRM, OS and Disease Free Survival (DFS) when receiving allo or auto-HSCT.
Methods: Cumulative incidences were used for CIR and TRM whereas Kaplan Meier curves and log-rank test were used for OS and DFS. Multivariate analysis with Cox Regression was used for controlling confounding factors.
Results: Patient and disease characteristics in allo (162p) and auto-HSCT (112p) were respectively: median age of 37,8(IQR 30-52) and 44,5(IQR 36-56), secondary AML in 20,2% and 9,8%, failure after Induction course in 15,8% and2,8%, complete remission pre-HCST in 87,1% and 97,3% and year of HSCT ≥2005 in 46,9% and 14,3% .There was no statistical difference in any other characteristic (cytogenetic risk and WBC count at diagnosis, included).
The CIR in allo and auto-HSCT was respectively: 17,7%(CI 12,1-24,2) and 31,7%(CI 23,3-40,5) at 1 year and 24,2%(CI 17,5-31,5) and 50,0%(CI 40,2-59,0) at 5 years, with no statistical difference if the HSCT was perfomed before or after 1997(start to quantify the pre-HSCT minimal residual disease by flow citometry). The cumulative incidence of TRM in the earliest period (≤1996) for allo and auto-HSCT was respectively: 30,0%(IC 16,8-44,4) and6,5%(IC1,7-16,1) at 1 year and 35,0%(IC 20,8-50,0) and8,7%(IC2,8-18,9) at 5 years. However, the cumulative incidence of TRM in the latest one (>1997) was respectively: 16,4%(IC 9,8-24,4) and1,7%(IC 0,1-8,0) at 1 year and 25,2%(IC 14,3-37,7) and3,5%(0,7-10,8) at 5 years. The OS in the earliest period for allo and auto-HSCT was respectively: 39,6%(CI 26,6-52,4) and 60,8%(CI 46,1-72,6) at 1 year and 28,3%(CI 17,0-40,7) and 45,1%(CI 31,2-58,0) at 5 years. And the OS in the latest one was respectively: 65,6%(CI 55,8-73,8) and 70,3%(CI 57,1-80,2) at 1 year and 46,8%(CI 34,1-58,5) and 47,7%(CI 34,0-60,1) at 5 years. Any significant results in the multivariate analysis neither in the log-rank test regarding OS differences between allo and auto-HSCT were observed. Covariates such as elderly, elevated WBC count at diagnosis, high cytogenetic risk, early period of HSCT or secondary AML showed worse prognosis, but only MRD was a strongly outcome predictor. The DFS in the earliest period for allo and auto-HSCT was respectively: 50,0%(CI 33,8-64,2) and 65,2%(CI 49,6-77,0) at 1 year and 37,5%(CI 22,9-52,1) and 45,6%(CI 30,8-59,1) at 5 years. And the DFS in the latest one was respectively: 66,9%(CI 56,5-75,3) and 63,2%(CI 49,2-74,2) at 1 year and 51,7%(CI 37,3-64,3) and 46,5%(CI 32,6-59,4) at 5 years. 74% of the patients who underwent auto-HSCT have ECOG 0 the date of the last follow-up and 6 patients over 14 who relapsed after auto-HSCT were rescued with allo-HSCT.
Summary / Conclusion: In our series, we have found no statistical difference between allo and auto-HSCT in OS and DFS in any period. Despite the higher CIR, we have observed a higher survival in auto-HSCT in the earliest period which turns to get similar nowadays because of the decrease in TRM, more significative in allo-HSCT.

Hematopoiesis, stem cells and microenvironment

Background: Local hematopoietic renin-angiotensin system (RAS) affects the essential steps of hematopoiesis in the bone marrow (BM) microenvironment. Malignant blood cells, including multiple (MM) myeloma cells, are derived from the clonal neoplastic stem cells within a complex series of pathological proliferative steps. Local BM RAS could affect neoplastic tumoral blood cell production. Local RAS is effective even in the embryonic hematopoiesis.The prominent functions of local RAS in primitive hematopoiesis further support the hypothesis that local autocrine BM RAS could also be active in the neoplastic hematopoiesis.
Aims: The aim of this study is to search critical RAS elements in normal CD34+ hematopoietic stem cells and multiple myeloma-related progenitor cells. For this aim, CD34+ hematopoietic cells obtained from the healthy allogeneic hematopoietic stem cell transplant (Allo-HSCT) donors and from the MM patients undergoing autologous stem cell transplantation were analyzed via qRT-PCR. Normal BM cells obtained from hematologically normal people were also searched to detect the impact of precursor cell compartment on the RAS expressions. Elucidation of the status of the local RAS molecules in the early and neoplastic hematopoiesis represents a clinically relevant basic research area for better understanding the biology of the diseases.
Methods: The study group comprised the total bone marrow cells (CBM) and the CD34+ stem cell samples (CD34+CBM) of 9 healthy donors for allogeneic peripheral stem cell transplantation, and the CD34+ stem cell samples (CD34+MM) of 9 multiple myeloma (MM) patients undergoing autologous peripheral stem cell transplantation. The diagnoses of multiple myeloma were reached based on the criteria of the International Myeloma Working Group. At the time of the sample collection, all of the patients were in good health and well hydrated. We searched for the gene expression of the major RAS components (ACE I, ACE II, RENIN and ANGTS) in healthy hematopoietic cells and myeloma cells by qRT-PCR.
Results: RENIN, ANGTS, and ACE I mRNA expression levels of CBM were significantly higher than those in myeloma patients (P=.03, P=.002, and P=.0008, respectively). Moreover, RENIN and ANGTS mRNA levels were significantly higher in CD34+ stem cell samples of healthy allogeneic donors compared to those in myeloma patients (P=.001 and P=.01). However, ACE I expression levels were similar in CD34+CBM and CD34+MM groups (P=.89). Other 'RAS pathway members' (ACE II, AGTR I and AGTR II) expressions were also examined and expressions of those were not at detectable levels, and no significant differences were determined between all groups.
Summary / Conclusion: RENIN and ANGTS mRNA expressions were significantly higher in normal CD34+ hematopoietic stem cells of in comparison to the myeloma-related progenitor cells (P=0.001 and P=0.01, respectively). Likewise, RENIN, ANGTS, and ACE I mRNA expression levels of CBM were significantly higher than those in the myeloma patients (P=.03, P=.002, and P=.0008, respectively). However, ACE I expression levels were similar in CD34+CBM and CD34+MM hematopoietic cells (P=.89) . Those findings support our original hypothesis that there is a biologically active local RAS in the hematopoietic system in normal and pathological states. BM AT1r expression levels of myeloma patients showed a positive correlation with their BM infiltration pattern and tumor load, indicated by serum Beta 2 Microglobulin levels.Our results about myeloma-related progenitors in this study provide an additional clue for the local RAS effects in the pathobiology of multiple myeloma.

Background: There is preliminary evidence that local BM RAS could affect neoplastic hematopoiesis. Over-expression of the angiotensin-converting enzyme (ACE) (CD 143) surface antigen in leukemic myeloid blast cells have been detected by flow cytometric analyses. Moreover, a positive correlation has been found between the ACE and BM blast count. ACE and p53 expressions were detected in the CD34+cells of patients with acute leukemia during and after induction chemotherapy. ACE-expressing macrophages in lymph nodes of Hodgkin's disease have been detected. The renin system is present in the K562 leukemic cell line in vitro model. Multipotential, hematopoietic malignant K562 leukemic blast cells also exhibited significant expressions of *RENIN, ANGIOTENSINOGEN (ANGTS)* and *ACE*.
Aims: The purpose of this study is to research mRNA expressions of the essential RAS elements (*RENIN, ANGTS, ACE1* and *ACE2*) in myeloid and lymphoid hematological neoplastic disorders. Elucidation of the presence of local RAS in the neoplastic myeloid and lymphoid pathological hematopoiesis is important because targeting the actions of local RAS may represent a valuable therapeutic option for the management of cancer.
Methods: Forty-six patients with newly diagnosed myeloid (AML, biphenotypic leukemia, CML) or lymphoid (CLL, NHL, B-ALL, T-ALL) hematological disorders were included in the study. Samples from BM were collected prior to the chemotherapy administered to each patient.We searched for the gene expression of the major RAS components (*ACE1, ACE2, RENIN* and *ANGTS*) in myeloblasts and lymphoid hematopoietic cells by qRT-PCR.
Results: In the lymphoid group, the median expression values of *RENIN, ACE1, ACE2* and *ANGIOTENSINOGEN (ANGTS)* mRNAs were 1.96%, 0.42%, 0.00% and 0.00%, respectively; in the myeloid group, 0.73%, 1.55%, 0.04% and 0.006%, respectively. In the lymphoid group, *RENIN* levels were significantly higher (*P*=0.001), whereas *ACE1* and *ACE2* levels were significantly higher in the myeloid group (*p* values were 0.013 and 0.010, respectively). *ANGTS* levels were similar in both groups. In patients with non-ALL lymphoid malignancies, *RENIN* expressions were significantly higher when compared to ALL patients (*P*=0.004). All patients with active disease had significantly higher *RENIN* mRNA expression levels than patients without active disease (2.03% vs 0.30%) (*P*=0.034).
Summary / Conclusion: These data support the original hypothesis that there is a local RAS in the BM affecting physiological and pathological hematopoiesis. The result indicates that the activities of local RAS may differ in distinct disease states such as leukemia and lymphomas.
