ABSTRACT BOOK

ISSN 0390-6078

The abstract book of the 18th Congress of the European Hematology Association is published as a supplement of Haematologica/the Hematology Journal in one volume per year.

All business correspondence and purchase and reprint requests should be addressed either to Haematologica Journal Office, via Giuseppe Belli 4, 27100 Pavia, Italy; phone: +39 0382 27129; fax: +39 0382 394705; e-mail: office@haematologica.org or to the European Hematology Association, Koninginnegracht 12b, 2514 AA The Hague, The Netherlands; phone: +31 (0)70 345 55 63; fax: + 31 (0)70 392 36 63; e-mail: info@ehaweb.org.

The Abstract book is available both at http://www.haematologica.org and http://www.ehaweb.org

EHA-CME new system!

Continuing Medical Education (CME) is a means for hematologists to maintain and develop professional knowledge and skills keeping up-to-date with latest developments within the field.

When spending valuable time at training events and tutorials, it is essential to ensure that you are attending a high quality program. The EHA-CME system has been implemented as a service to European hematologists in response to this need, as accredited events are strictly reviewed by an independent review board and are of the highest quality standards.

In June 2013 at the EHA Congress in Stockholm a new platform will be launched for the EHA-CME system. The process for collecting credit points gets easier and quicker within the new system, current accounts are migrated to the new system and account creating for new users is simple and straightforward.
The new EHA-CME system features:

- link to the European Hematology Curriculum per event
- advanced search for educational programs with certain themes
- individual EHA-CME status access
- automatic calculations following the EHA-CME regulations
- identification and registration of EHA-CME activities
- automatic reminders
- online distribution of certificates

Visit our new website and create an account for yourself, it is simple, easy and free of cost: **eha-cme.org**

Stay on course with your professional development!

EUROPEAN HEMATOLOGY ASSOCIATION

European Hematology Association (EHA)

The European Hematology Association (EHA) aims to promote excellence in clinical practice, research and education in European hematology.
EHA was founded in June 1992 and today – with over 3,000 members from 100 countries – is a consolidated representative of European hematologists.

Our aim

- Become the official European representative of hematology and hematologists – especially where research, education and regulatory issues are concerned – and to become a conduit for European harmonization.
- Promote the creation of a highly attractive market for practitioners and researchers in Europe thus fostering the mobility of hematologists in and to Europe.
- Reach out and offer a platform to countries that wish to further develop excellence in hematology.
- Promote education, training and scientific research in hematology in Europe.
- Exchange and disseminate knowledge and scientific information in the field of hematology.

Our activities

- Organizing of annual scientific and educational congresses in major European cities.
- Dissemination of medical research, both basic and clinic, through Haematologica/The Hematology Journal.
- Collaborating with other leading organizations in the field of hematology and oncology.
- Providing postgraduate education through the annual congress, tutorials and workshops and scientific meetings.
- Supporting junior basic and clinical researchers in the development of their careers through the EHA Career Development Program.
- Strengthening the quality and professional status of hematology throughout Europe by accrediting scientific meetings and providing CME accounts.

EHA Membership

If you recognize the need for a strong European Hematology Association and would like to take advantage of the various activities of the Association, you may wish to become a member of EHA and contribute to its objectives.

Benefits of EHA membership:

- Subscription to Haematologica/ The Hematology Journal, including on-line access
- Discount on EHA Congress registration fee & all other EHA events
- Eligible to apply for the EHA Career Development Program Subscription to the EHA Newsletter, the official newsletter for members of EHA, published in May and November.
- Subscription to the EHA monthly e-bulletin
- Access to EHA membership directory
- Priority access to webcasts of the EHA Annual Congress
- Nomination and voting rights in EHA Board member election Eligibility to EHA Congress travel grants

www.ehaweb.org

EUROPEAN
HEMATOLOGY
ASSOCIATION

Raise the voice of European Hematology:

Join EHA now – every member counts!

Reduced fee of € 20 for Junior Members (up to 36 years of age)

The European Hematology Association is active in various fields of hematology, aiming to enlarge the scope of education, science and advocacy for all hematologists in Europe. EHA's projects include Continuing Medical Education (CME); Career development support through research fellowships and training; Curriculum Passport, advocacy and lobbying; and educational and scientific meetings within and outside of Europe.

Exclusive Membership Benefits are

- Subscription to Haematologica/The Hematology Journal (impact factor 6.424 – monthly hard copy delivery)
- Eligibility to Career Development Program of EHA
- Eligibility to EHA Congress travel grants
- Discount on EHA Congress registration fee & all other EHA events
- Priority access to webcasts of EHA Congress
- Nomination and voting rights in EHA board member election
- Access to EHA membership directory
- Subscription to EHA newsletter (half-yearly hard copy delivery)
- Subscription to EHA e-bulletin

18TH CONGRESS
JUNE 13 -16, 2013
STOCKHOLM

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to present the Abstract Book of the 18th Congress of EHA.

The Scientific Program Committee has compiled an exciting and topical program of Simultaneous Sessions and Poster Sessions from close to 3,000 submitted abstracts. Please join our expert moderators for a walk along the posters in your field of interest on Friday and Saturday. The six best abstracts have been selected for presentation during the Presidential Symposium on Saturday, June 15.

On behalf of the EHA Board, the committees and all the people involved in this years' EHA congress, we thank you for coming to Stockholm.

Jorge Sierra
Chair Scientific Program Committee

INVESTIGATING THE BIOLOGY OF STIL-TAL1 FUSION POSITIVE T-ALL AND ITS GENETIC SUBCLONAL ARCHITECTURE

C Furness[1*] F van Delft[1], M Mansur[1,2], A Ford[1], L Kearney[1], C Harrison[3], M de-Oliveira[2], M Greaves[1]
[1]Haemato-Oncology Research Unit, Division of Molecular Pathology, Institute of Cancer Research, Sutton, United Kingdom, [2]Paediatric Haematology-Oncology Program, Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil, [3]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle, United Kingdom

Background: The *STIL-TAL1* fusion occurs in 25% of T-ALL as a result of a 1p33 deletion which removes the coding regions of *STIL* and places *TAL1* under the control of the *STIL* promoter. Our study aims to investigate the biology of this leukaemia subtype and its genetic sub-clonal architecture in order to aid rational design of future targeted treatment strategies. The hypothesis is that drugs targeted at events occurring at a sub-clonal level will likely fail due to Darwinian evolution and the emergence of drug resistance from a minor subclone selected out by environmental modifiers (drug therapy).
Aims: We aimed to determine the common genetic aberrations occurring in *STIL-TAL1* fusion positive T-ALL in children and young adults (age 1 – 25 years) and to investigate how the leukaemic clone evolves genetically in order to determine the early and founder genetic events amenable to therapeutic targeting. We describe our current approach to this issue using SNP arrays, mutation screening and single cell 4 colour FISH.
Methods: DNA from 17 *STIL-TAL1* fusion positive T-ALL cases and one cell line (RPMI 8402) was screened using the Affymetrix SNP 6.0 platform to detect copy number alterations (CNA) and was sequenced to detect mutations in *NOTCH1* (exons 26,27,34), *FBXW7* (exons 9, 10), *PTEN* (exon 7) and *IL7R* (exon 6). Genomic localisation of copy number alterations using CNAG version 3.3.0 software was used to design in house FISH probes for *STIL-TAL1* fusion and losses of *CDKN2A*, *PTEN*, *LEF1* and *CASP8AP2* in order to permit examination of single cells by multicolour FISH. Interphase FISH was performed on methanol-acetic acid fixed nuclei from diagnostic samples. The FISH probe to detect *STIL-TAL1* fusion consisted of two fosmids whose genomic localisation corresponds to the 1p33 deletion and two control fosmids located downstream of *TAL1*. This reliably detected the deletion in 8 samples screened to date.
Results: The most frequent CNA detected was *CDKN2A* loss (94% of samples). Other frequent CNA were losses of *PTEN* (22%), the region 6q13-6q16 including *CASP8AP2 (*22%), *LEF1 (*11%) and gain of *MYB (*11%). Mutation screening revealed mutation frequencies of 55% for *NOTCH1/FBXW7* and 38% for *PTEN*. Mutations in *IL7R* were not detected in this cohort. Single cell 4 colour FISH performed on 4 patients showed the presence of the *STIL-TAL1* fusion in all cells with an abnormal FISH signal pattern. Scoring of 100 – 200 cells per patient with 3 – 4 differentially labelled FISH probes allowed reconstruction of the evolution of the malignant clone through phylogenetic trees.
Summary / Conclusion: This study provides an overview of key genetic aberrations in this T-ALL subgroup. Results support the hypothesis that, in accordance with other types of leukaemia, the *STIL-TAL1* fusion is a founder event being present in all cells with an abnormal FISH signal pattern. Loss of *CDKN2A* occurred early in the evolution of the leukaemogenic clone in line with its key role in T-ALL. Copy number losses such as *PTEN, CASP8AP2* and *LEF1* occurred sub-clonally to *CDKN2A* loss. *PTEN* inactivation is frequent in *SIL-TAL1* T-ALL with either mutation or copy number losses detected in 50% of samples. Comparison of multicolour FISH results for two patients with *PTEN* loss suggests that the evolutionary timing of this event may vary between patients. Future work will incorporate gene mutations into the single cell analysis to determine the position of key mutations, such as *NOTCH1/FBXW7/PTEN,* in *STIL-TAL1* T-ALL evolution.

P002

DEVELOPMENT OF MINIMAL RESIDUE DISEASE (MRD) ANALYSIS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL) BY NEXT GENERATION SEQUENCING (NGS)

H Williamson[1*] J Hancock[1], J Moppett[2], E Roberts[1]
[1]Bristol Genetics Laboratory, North Bristol NHS Trust, [2]Paediatric Oncology, Bristol Royal Hospital for Children, Bristol, United Kingdom

Background: Detection of sub-microscopic levels of disease (minimal residual disease; MRD) in childhood acute lymphoblastic leukaemia (ALL) after initial treatment is an important prognostic factor. Currently, stratification of therapy for the new frontline trial in childhood ALL (UKALL2011) is provided by MRD analysis using real time quantitative PCR (RQ-PCR) to identify and quantitate patient specific rearrangements of the immunoglobulin (Ig) and T-cell receptor (TCR) genes. Although MRD is a powerful and essential tool in stratification of ALL patients, the current methodology is expensive, time-consuming and complex to perform, and 8% of individuals in the current UKALL2011 trial do not have an informative MRD result.
Aims: Recently, Next Generation Sequencing (NGS) has led to the opportunity to improve Ig/TCR based MRD analysis by revealing the entire Ig/TCR repertoire. In addition, this technology may also have the potential to allow improved quantification of disease, by detecting lower disease levels, resulting in a potential increase in the specificity and sensitivity of MRD analysis in childhood ALL.
Results: To date, this project has concentrated on the IgH locus using the BIOMED 2 primers (van Dongen *et al.,* 2003) for target identification. These primers have been adapted in a novel manner to allow the deep sequencing of this locus using the Illumina MiSeq. Using a simple sequence analysis pipeline, this technology has been used in twelve patients, firstly, to identify the major clones revealed by current methodologies, and secondly, to detect many related and unrelated low-level clones. This NGS methodology has also been used to delineate patterns of IgH rearrangements in two patients previously shown to have oligoclonal rearrangements (greater than two). Such patients represent a time consuming and technical challenge for current technologies as it is important that all targets at the locus are followed by RQ-PCR to provide an informative MRD result. In addition to target identification, this approach can also be used for the quantification of MRD. Logarithmic dilution series of patient DNA in normal PBMC DNA have been analysed using this novel pipeline and reveal that stratification based on a clinical threshold of 1 in 10,000 is possible using this NGS methodology. An important consideration for both MRD target identification and quantification of disease is to undertake an assessment of the normal background repertoire, as well as the repertoire present at the end of induction therapy; both of which represent critical thresholds. Having established this technology it will be used to quantitate disease levels in end of induction samples, previously analysed by RQ-PCR, and the results compared.
Summary / Conclusion: This approach to target identification allows the study of multiple evolved clones, and therefore has the potential to reduce false negative results. Furthermore, this approach also represents a significant time saving (5-7 days) in comparison to established methods (3-4 weeks). Indeed, the interrogation of the entire Ig repertoire will further improve the predictive value of MRD testing. Additionally, further investigation into the clinical utility of NGS for MRD analysis will concentrate on analysing earlier timepoints in treatment and study the potential use of blood rather than bone marrow.

P003

NOVEL COPY NUMBER ALTERATIONS IN INFANTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA (T-ALL)

M Mansur[1,2*] F van Delft[2], S Colman[2], M Pombo-de-Oliveira[1], M Greaves[2], A Ford[2]
[1]Paediatric Haematology-Oncology Program, Instituto Nacional de Câncer - INCA, Rio de Janeiro, Brazil, [2]Haemato-Oncology Research Unit, Division of Molecular Pathology, The Institute of Cancer Research - ICR, Sutton, United Kingdom

Background: Infant Acute Lymphoblastic Leukaemia (I-ALL) is a rare disease associated with *MLL* rearrangements, B cell precursor lineage with $CD10^-$ (pro-B ALL) and prenatal origin. In contrast to infant pro-B ALL, in which an *in utero* origin has been extensively demonstrated, the genetic origin and timing for infant T-cell ALL (T-ALL) has not been fully elucidated. Although very rare in infants, T-ALL is prevalent in older children, this raises the question of whether the aetiology of childhood T-ALL is likely to involve prenatal molecular alterations.
Aims: The overall aims of this study are to elucidate more definitively the early onset of these abnormalities in infants T-ALLs; to delineate the additional genomic hits required to accelerate the emergence of a frank leukaemia; and to compare infant cases with older children/adolescent T-ALL by tracing CNA accumulation.
Methods: The availability to us of a very rare series of 7 infant (≤12 months) T-ALL cases along with 6 remission samples and 4 Guthrie cards allowed us to genetically characterize infant T-ALL (Sanger sequencing, RT-PCR, Q-PCR,

FISH), to trace CNAs and LOH/UPD profiles (SNP-array) and to backtrack prenatal origin.
Results: The main clinical and demographic characteristics observed in our series were a median age of 7 months, no predominance of gender and high WBC count (≥50,000) in 6 out of 7 cases at diagnosis. The infants were treated according to Brazilian GBTLI protocol (n=3), BFM protocol (n=2) and INTERFANT (n=2). All samples have been analyzed at diagnosis for the main T-ALL abnormalities and our results showed 3 cases mutated for *NOTCH1*, all cases were WT for *FBXW7*, *PTEN* and *IL7R* mutations and we did not observe any *SIL-TAL1+* or *TLX3+* cases. *TCRG* & *D* were rearranged in 5 cases, 4 of them also being rearranged for *TCRB*; 1 case presented with only *TCRG* rearrangement and 1 case showed no receptor gene rearrangement at all. This latter case also had a classical ETP profile. *MLL* rearrangements were detected by FISH in 3 out of 6 cases. All diagnostic samples were analyzed by SNP-array to identify genomic losses and gains. As a summary of the SNP results, a recurrent chromosome 3 deletion was observed in 3 cases. This loss results in the complete deletion of *MLF1* and has not previously been described in T-ALL. *MLF1* plays a key role in AML and myelodysplasic syndromes leukaemogenesis. Q-PCR and FISH assays were used to confirm the copy number of *MLF1* in those cases analysed. Akin to paediatric T-ALL we observed a *PTEN* deletion in 1 patient and 2 further cases with a 11p13 deletion that could lead to activation of *LMO2*. Strikingly and unlike childhood T-ALL, none of the infants showed deletions in *CDKN2A*. We confirmed these results using a Q-PCR copy number assay for *CDKN2A* and FISH.
Summary / Conclusion: Since the long term aims of this study include exome sequencing, we cannot rule out the possibility of still having classic and relevant alterations yet to be discovered in these cases, however our preliminary data suggest that infant T-ALL in general presents different genetic abnormalities from childhood T-ALL.

P004

THE ROLE OF THE JANUS-FACED TRANSCRIPTION FACTOR PAX5-JAK2 IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA
D Denk[1*] K Fortschegger[1], M Kauer[1], S Anderl[1], R Kofler[2], S Strehl[1]
[1]CCRI, Children's Cancer Research Institute, St. Anna Kinderkrebsforschung e.V., Vienna, [2]Tyrolean Cancer Research Institute, Biocenter - Division of Molecular Pathophysiology, Innsbruck Medical University, Innsbruck , Austria

Background: In B-cell precursor acute lymphoblastic leukemia (BCP-ALL) the transcription factor PAX5, a master regulator of B-cell commitment and maintenance, is fused to several different partner proteins including other transcription factors, structural proteins, and the tyrosine kinase JAK2. Mutations and translocations affecting JAK2 are found in a variety of hematopoietic malignancies and lead to its constitutive activation and cytokine-independent JAK-STAT signaling.
Aims: In this study, we aimed to determine the functional consequences of the chimeric PAX5-JAK2 protein, which contains the DNA binding paired domain of PAX5 and the JH1 kinase domain of JAK2.
Results: Indirect immunofluorescence displayed nuclear localization of PAX5-JAK2. Furthermore, the chimeric protein retains the ability to bind to wild type PAX5 target loci and to activate some PAX5 target genes, like *CD79A* but not *CD19*, as shown by chromatin immunoprecipitation and reporter gene assays, respectively. This suggests that the fusion protein has an influence on PAX5 target gene expression. In order to determine whether PAX5-JAK2 is tyrosine phosphorylated and whether it is capable of activating STAT proteins, intracellular phosphoprotein analyses using flow cytometry and / or Western blotting of different transfected cell lines were performed. Our data provide compelling evidence that PAX5-JAK2 itself is phosphorylated and acts as an active kinase, which in turn phosphorylates and activates downstream STAT proteins. Gene expression profiling of PAX5-JAK2 positive samples revealed high similarities with BCR-ABL1 and JAK2-mutated BCP-ALLs, further supporting an activation of the JAK-STAT pathway. Importantly, the kinase activity of the fusion can be efficiently blocked by JAK2 inhibitors rendering it a potential target for therapeutic intervention.
Summary / Conclusion: Together, our data show that PAX5-JAK2 may deregulate the PAX5 and the JAK-STAT transcriptional network at the same time and thus, by interfering with these two important pathways, may promote leukemogenesis.
This project is funded by the Austrian Science Fund FWF (P21554).

P005

THE PRE-B-CELL RECEPTOR PATHWAY IS A THERAPEUTIC TARGET IN SPECIFICALLY TCF3-REARRANGED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA
A Van Der Veer[1*] V van der Velden[2], M Willemse[1], P Hoogeveen[2], E Petricoin[3], H Beverloo[4], G Escherich[5], M Horstmann[5], R Pieters[1], M Den Boer[1]
[1]Pediatric Oncology, Erasmus MC - Sophia Children's Hospital, [2]Immunology, Erasmus MC, Rotterdam, Netherlands, [3]Applied proteomics and molecular medicine, George Mason University, Manassas, United States, [4]Genetics, Erasmus MC, Rotterdam, Netherlands, [5]COALL study group, University Medical Center Eppendorf, Hamburg, Germany

Background: *TCF3*-rearranged B-cell precursor (BCP) ALL displays high levels of cytoplasmic Igm (CyIgm) which is a known component of the pre-B-cell receptor (pre-BCR).
Aims: We investigated whether an activated pre-BCR pathway in *TCF3*-rearranged BCP-ALL that may serve as therapeutic target.
Methods: The rearrangement pattern of immunoglobulin heavy chain (*IGH*), and light chains (*IGK* and *IGL)* was analyzed by multiplex PCR in leukemic cell samples of 190 non-*TCF3*-rearranged and 22 *TCF3*-rearranged childhood BCP-ALL patients. Expression levels of pre-BCR pathway components (EBF1, ZAP70, SLP65, BTK, PI3K-p110δ and IRF4) were measured by reverse-phase protein assays. Cytotoxicity of Ibrutinib (a BTK inhibitor) was determined in six *TCF3*-rearranged and six non-*TCF3*-rearranged cases by methyl-thiazol-tetrazolium (MTT) assays. The effect of Ibrutinib on Erk expression levels was tested by western blot.
Results: 84.6% (11/13) of *TCF3*-rearranged cases was highly positive for CyIgm-expression compared to 20.9% (68/325) of non-rearranged cases (P<0.001). The Ig-rearrangement pattern of the majority (86.4%) of *TCF3*-rearranged cases was arrested at IGH level without further processing of IGK/IGL genes. In contrast, only 17.9% of non-*TCF3* rearranged cases was blocked at *IGH* level (P<0.001). Expression levels of pre-BCR pathway proteins (ZAP70, SLP65, BTK, PI3Kd110, IRF4 and EBF1) were 1.2 to 5.2-fold higher in *TCF3*-rearranged compared to non-rearranged samples (P<0.05). The concentration of Ibrutinib lethal to 50% of primary leukemic cells was 16.7mM for *TCF3*-rearranged cases and >50 mM for non-rearranged cases (P<0.001). Ibrutinib effectively reduced the expression of Erk in the MHH-CALL3 (*TCF3*-rearranged) leukemic cell line whereas this level remained unaffected in the non-rearranged cell lines NALM6 and MHH-CALL4 .
Summary / Conclusion: This study indicates that *TCF3*-rearranged BCP-ALL is characterized by an immature pre-BCR signature with a concommitant activated pre-BCR signaling pathway. Inhibition of this pathway selectively reduced the cell viability of *TCF3*-rearranged BCP-ALL. These findings warrant clinical application of pre-BCR inhibitors (such as Ibrutinib) in the treatment of *TCF3*-rearranged BCP-ALL.

P006

ACUTE LYMPHOBLASTIC LEUKEMIA RECOGNITION BY NATURAL KILLER CELLS: CLINICAL AND THERAPEUTIC IMPLICATIONS
G Torelli[1,*] N Peragine [1], S Raponi[1], D Pagliara[2], W Barberi[1], A Vitale[1], A Guarini[1], G Basso[3], F Locatelli[2], R Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, Sapienza University, [2]Department of Pediatric Hematology/Oncology, Ospedale Pediatrico Bambino Gesù, Rome, [3]Department of Pediatric Onco-Hematology, University of Padova, Padova, Italy

Background: Natural killer (NK) cell recognition of malignant targets is finely tuned by activating and inhibitory receptors. The major receptors with activating functions are NCRs, NKG2D and DNAM-1. NCRs are orphan receptors, MICA/B and ULBPs are ligands for NKG2D, PVR and Nec-2 for DNAM-1. The pathway of NK cell-acute lymphoblastic leukemia (ALL) recognition is unclear. Differences in NK cell killing susceptibility among age-related subgroups of ALL patients have been described in the haploidentical stem cell transplant (SCT) context. Possible differences in the expression of NK cell activating ligands among molecularly defined subgroups of ALL patients have been also hypothesized.
Aims: In this study, we aimed at analyzing the pathways of NK-ALL recognition and at verifying whether differences in NK cell activating receptor ligands' expression among groups defined by age of patients or presence of cytogenetic/molecular aberrations correlate with susceptibility to NK cell recognition and killing.
Methods: We analyzed 103 newly diagnosed ALL patients: 46 adults, median age 34 years (18-74); 57 children, median age 4 years (0.1-17). Ninety patients had B cell precursor (BCP)-ALL: 39 were adults (15 BCR-ABL+, 7 MLL-AF4+, 2 E2A-PBX1+, 15 negative) and 51 children (6 BCR-ABL+, 3 MLL-AF4+, 1 MLL-ENL+, 10 TEL-AML1+, 31 negative); 13 patients had T-ALL (7 adults and 6 children). Phenotypic analyses to evaluate the expression of NKG2D and DNAM-1 ligands (MIC-A/B, ULBP1-2-3, Nec-2 and PVR) on primary ALL blasts and of NKG2D and DNAM-1 on a population of activated NK cells of donor origin were performed. Cytotoxic activity of activated NK cells against primary ALL blasts was also evaluated. For blocking experiments, NK cells were pre-treated with anti-NKG2D or anti-DNAM1 neutralizing mAbs. Student's paired *t* test was used for statistical analysis.
Results: ALL blast cells of children showed a higher expression of Nec-2 (P=.03), ULBP-1 (P=.01) and ULBP-3 (P=.04) compared to adult ALL samples (Figure 1A). The differential expression between adults and children was confined to BCP-ALL blasts with no known molecular alterations. The analysis performed within molecularly defined subgroups of ALL cases revealed a high surface expression of NKG2D and DNAM1 ligands on BCR-ABL+ blasts, regardless of the age of patients. In line with the phenotypic results, pediatric

BCP-ALL without molecular markers showed a higher susceptibility to NK cell killing than molecularly negative adult samples. In addition, primary blasts from BCR-ABL+ ALL appeared significantly more sensitive to NK-dependent lysis than BCP-ALL blasts without molecular aberrations (P=.01) (Figure 1B). Finally, when performing cytotoxic assays in the presence of neutralizing mAbs, the NK cell killing potential was significantly inhibited with the use of anti-DNAM-1 (P=.006), thus indicating a possible pathway of recognition of ALL blast cells in the setting of the Nec-2/DNAM-1.

Summary / Conclusion: For the first time a possible biological explanation responsible for the different role played by alloreactive NK cells in pediatric and adult ALL is suggested. The high expression of these ligands in BCR/ABL+ ALL cases, with the highest levels of cytotoxicity exerted by NK cells targeting this subgroup of ALL blasts, indicate a new possible immunotherapeutic strategy based on the *in vivo* infusion of activated NK cells for controlling/eradicating minimal residual disease in this subgroup of patients. The possible correlation between the level of activating receptor ligands' expression and susceptibility to lysis may help to identify those patients that may maximally benefit from NK-based immunotherapy and from NK alloreactive donors in the haploidentical SCT context.

KRASG12D INITIATES ACUTE T-CELL LYMPHOBLASTIC LEUKEMIA IN COOPERATION WITH LOSS OF THE WILD-TYPE KRAS ALLELE

A Staffas[1,*] C Karlsson[2], L Palmqvist[1], M O Bergö[2]
[1]Biomedicine, [2]Medicine, University of Gothenburg, Gothenburg, Sweden

Background: Activating mutations in RAS (NRAS, KRAS and HRAS) are found in patients of all major subtypes of hematopoietic malignancies including acute myeloid leukemia (AML), myeloproliferative disease (MPD) and acute lymphoblastic leukemia (ALL). Activation of KRAS in hematopoietic malignancy has been studied using the Mx1-*Cre*;*Kras*$^{LSL-G12D}$ mouse model, where expression of oncogenic *Kras*^{G12D} is induced by injection of polyinosinic-polycytidylic acid (pIpC). Injection with pIpC leads to rapid development of a 100% penetrant MPD. Surprisingly, when bone marrow from these MPD-mice is transplanted to wild-type recipients this leads to development of acute T-cell lymphoblastic leukemia (T-ALL). The cause for this lineage switch is not known. Injection with pIpC in the primary mice leads to expression of Kras^{G12D} also in non-hematopoietic tissues including the liver, colon and in the skin, which may affect the malignant phenotype. Alternatively, during transplantation, Kras^{G12D} tumor initiating cells of myeloid and T-lymphoid lineage might home differently.

Aims: In addition to understanding the cause of this lineage switch, this mouse model also gives an ideal situation for studying the effects of KRAS-activation both in myeloid and in T-lymphoid cells.

Methods: To investigate this and to address what causes the lineage switch we have performed cross bone marrow transplantations between Mx1-*Cre*;*Kras*$^{LSL-G12D}$ and wild-type mice.

Results: Expression of *Kras*^{G12D} has a greater proliferative driving force in myeloid compared to T-lymphoid cells. Expression of *Kras*^{G12D} also increases differentiation of myeloid cells which leads to induction of the primary MPD-phenotype. In parallel, expression of *Kras*^{G12D} expands immature T-cell populations in the thymus leading to a pre-leukemic state in T-cells. pIpC injected Mx1-*Cre*;*Kras*$^{LSL-G12D}$ cannot be rescued by transplanting wild-type bone marrow meaning that the cause of death in the primary mice is unrelated to their MPD. Transplanting the *Kras*^{G12D} bone-marrow extends the lifetime of the tumor, creating time for additional mutations to occur that transforms the pre-leukemic state into T-ALL. One of these additional mutations is loss of the wild-type *Kras* allele.

Summary / Conclusion: The effects of *Kras*^{G12D} expression differs between myeloid and T-lymphoid cells. In myeloid cells activated Kras increases proliferation and differentiation which induces MPD without the ability to transform into AML. In T-lymphoid cells expression of *Kras*^{G12D} leads to a pre-leukemic state with expanded immature populations that with time and additional mutations transforms into T-ALL. This indicates that activation of Kras in the development of acute leukemia, is a potent first genetic hit in the T-lymphoid lineage, but not in the myeloid lineage. Also, loss of the wild-type *Kras* allele in the T-ALL tumors indicates a tumor-suppressive role for wild-type *KRAS* in T-cell tumorigenesis.

P008

FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF COPY NUMBER ALTERATIONS (CNA) IN HIGH-RISK B-LINEAGE ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS ENROLLED IN RISK-ADAPTED PROTOCOLS

J Ribera[1,*] M Morgades[1], L Zamora[1], J Nomdedeu[2], S Brunet[2], M Pratcorona[3], J Esteve[3], M Tormo[4], M Collado[4], J Martinez[5], P Martinez-Sanchez[5], J Hernandez-Rivas[6], M Gonzalez[6], J Gonzalez-Campos[7], P Trujillo[7], I Gómez-Seguí[8], P Montesinos[8], E Genescà[1], N Ruiz-Xivillé[1], I Granada[1], S Marcé[1], M Cabezón[1], F Solé[1], J Juncà[1], F Millá[1], E Feliu[1], J Ribera[1]
[1]Institut de Recerca contra la Leucèmia Josep Carreras, Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Badalona, [2]Hospital de la Santa Creu i Sant Pau, [3]Hospital Clínic de Barcelona, Barcelona, [4]Hospital Clínico Universitario de Valencia, Valencia, [5]Hospital Doce de Octubre, Madrid, [6]Hospital Clínico Universitario de Salamanca, Salamanca, [7]Hospital Universitario Vírgen del Rocío, Sevilla, [8]Hospital Universitario de La Fe, Valencia, Spain

Background: In the last years, great advances in the understanding of ALL biology have been achieved. Several studies in pediatric patients have identified copy number alterations (CNA) in genes involved in cell differentiation, tumor suppression, cell cycle control and apoptosis as markers with prognostic significance. The frequency and prognostic value of CNA in adult ALL are less studied.

Aims: To analyze the frequency and prognostic significance of CNA in B-cell development genes in a series of high-risk B-lineage adult ALL patients enrolled in high-risk protocols from the Spanish PETHEMA Group.

Methods: Bone marrow or peripheral blood samples at diagnosis from 78 high-risk B-lineage adult ALL patients were studied by MLPA for the following genes: *IKZF1, IKZF2, IKZF3, EBF1, CDKN2A/B, PAX5, ETV6, BTG1, RB1,* X/Y PAR region genes (*CRLF2*, *CSF2RA* and *IL3RA*), 14q32.33 region genes (*IGH D*, *MTA1* and *KIAA0284*) and *hsa-miR-31*.

Table 1. Frequency of CNA in 78 higt-risk B-lineage adult ALL patients enrolled in PETHEMA protocols.

	Deletion, n (%)	Duplication, n (%)	Normal, n (%)
IKZF1	29 (37)	1 (1)	48 (62)
EBF1	8 (10)	3 (4)	67 (86)
CDKN2A/B	30 (38)	0	48 (62)
PAX5	27 (35)	1 (1)	50 (64)
hsa-miR-31	17 (22)	0	61 (78)
ETV6	3 (4)	0	75 (96)
BTG1	6 (8)	1 (1)	71 (91)
RB1	13 (17)	0	65 (83)
14q32.33 region	15 (19)	4 (5)	59 (76)
X/Y PAR region	6 (8)	9 (12)	63 (80)
IKZF2	0	3 (4)	75 (96)
IKZF3	1 (1)	4 (5)	73 (94)

Results: The median age was 46 [15-74] years, 40 (51%) males, median WBC count 15.4 x10^9/L [0.4-388]. Immunophenotype: 8 pro-B (10%), 44 common (57%), 15 pre-B (20%), 8 mature-B (10%), 3 undetermined (3%). Cytogenetics: 13 normal (17%), 6 hyperdiploid (8%), 2 hypodiploid (3%), 17 t(9:22) (22%), 5 t(1;19) (6%), 5 11q23/*MLL* (6%), 7 t(8;14)/*C-MYC* (9%), 1 complex (1%), 9 other translocations or deletions (12%), 13 no growth (17%). CNA results reported by MLPA are shown in table 1. Deletions of *IKZF1* were significantly associated with older age and Ph+ ALL. Patients with *EBF1* or *RB1* deletions showed higher WBC count at presentation and *RB1* deletions were associated with

high frequency of CNS infiltration. *IKZF1* deletions were also significantly associated with *EBF1* deletions. In the 9p region, we observed a high codeletion rate of *CDKN2A/B* with *PAX5*, *CDKN2A/B* with *hsa-miR-31* and *PAX5* with *hsa-miR-31*. We also observed concomitant deletions of *PAX5* with *BTG1*, *BTG1* with 14q32.33 region, *PAX5* with 14q32.33 region and *PAX5* with X/Y PAR region. Seventy six patients were evaluable for prognosis. In the whole and in the Ph-negative cohorts, patients with *BTG1* or those with ETV6 deletions had a significant lower complete remission (CR) rate than those not deleted. Concerning overall survival (OS), deletions of *IKZF1, CDKN2A/B*, *hsa-miR-31*and X/Y PAR region CNA were associated with significantly lower OS rates in the entire cohort. In Ph-negative patients, *IKZF1* deletions were also associated with lower OS, and X/Y PAR CNA showed a trend to reduced OS (P=0.052). In terms of CR duration, patients with deletions of *IKZF1* or *CDKN2A/B* showed significantly higher relapse rates in both the whole and the Ph-negative cohorts.
Summary / Conclusion: In high-risk B-lineage adult ALL patients the frequency of CNA is similar to that reported in childhood ALL. Resistance to therapy is associated with *BTG1* and *ETV6* deletions. *IKZF1* and *CDKN2A/B* deletions are associated with lower CR duration, and deletions in *IKZF1*, *CDKN2A/B*, *hsa-miR-31* as well as X/Y PAR CNA correlated with poorer OS.

P38ALPHA/BETA INHIBITION PREVENTS ALL PROLIFERATION *IN VIVO*
S Strube[1,*] S Krause[1], C Vokuhl[2], K Timm-Richert[1], M Schrappe[1], M Stanulla[1], D Schewe[1]
[1]Pediatrics, [2]Childrens Pathology, Universitätsklinikum Schleswig-Holstein, Kiel, Germany

Background: P38α/β stress-activated protein kinase (SAPK) has been described as an important regulator of dormancy and tumor cell dissemination in different epithelial malignancies. However, p38α/β also regulates other cellular processes such as inflammation, differentiation, apoptosis and, rarely, cell cycle progression.
Aims: Here, we study the role p38α/β as a targetable mediator of acute lymphoblastic leukemia (ALL) proliferation.
Methods: We performed *in vitro* and *ex vivo* flow cytometric analyses to study the role of p38α/β in ALL growth in cell lines. Biochemical analyses were conducted by Western Blotting. For *in vivo* studies, ALL xenografts were created by injecting fluorescently labeled ALL cells into large vessels in the chorioallantoic membrane of fertilized avian embryos (domestic turkey, *Meleagris gallopavo*). Engraftment in target organs was measured by flow cytometry and immunohistochemistry after 11 days. For *in vitro* and *in vivo* p38α/β inhibition, the kinase inhibitors SB203580 and BIRB-796 were used.
Results: P38α/β was highly phosphorylated during log-phase of ALL cell growth in culture. Importantly, intracellular flow cytometric analyses found that high phosphorylation of p38α/β correlated with the S-and G2/M-phases of the cell cycle and low phosphorylation of p38α/β with G0/G1. Remarkably, maximal p38α/β activation was found in ALL cells proliferating in permissive microenvironments like the bone marrow of avian xenografts. Additionally, growth suppressive measures such as L-Asparaginase therapy lead to an abrogation of p38 signaling while other MAPK pathways remained unaffected. Inhibition of p38α/β with SB203580 and BIRB-796 causing accumulation of cells in G0/G1 *in vitro*, markedly suppressed engraftment and proliferation *in vivo*.
Summary / Conclusion: We propose p38α/β as a mediator of important growth-stimulatory mechanisms in ALL cells and suggest p38α/β inhibition as a potential adjunct therapeutic approach in the treatment of this disease entity warranting further mechanistic exploration and validation in patient samples.

P010

A UNIQUE FAT1 CADHERIN ISOFORM REGULATES THE PROLIFERATION OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (T-ALL) CELLS
C de Bock[1,2,*] A Boyd[3], G Burn[1], J Cools[2], R Thorne[1]
[1]Cancer Research Unit, University of Newcastle, Callaghan, NSW 2308, Australia, [2]Center for the Biology of Disease, VIB Center for the Biology of Disease / KU Leuven, Leuven, Belgium, [3]Leukaemia Foundation Laboratory, Queensland Institute of Medical Research, Herston, QLD, Australia

Background: The large 550 kDa FAT1 protein is a member of the cadherin superfamily and an ortholog of the Drosophila fat protein, which is implicated in cell proliferation during development. We recently reported that FAT1 cadherin is expressed by a range of leukemia cell lines, but not by normal peripheral blood and bone marrow cells from healthy donors. *In silico* analysis of expression data revealed significant expression levels of FAT1 in 11% of acute myeloid leukemia, 29% of T-ALL and 63% of B-ALL, and little or no transcript in normal blood cells. Using RNA-sequencing and Northern blot analysis of T-ALL cell lines, we now have identified a novel isoform of FAT1, which is unique to T-ALL and bears striking similarity to the drosophila allele Gull, an antimorph of the drosophila Fat.
Aims: To characterize the expression and function of FAT1 and the smaller unique isoform using *in vitro* and *in vivo* models.
Methods: RNA-seq data from a panel of leukemic T-ALL cell lines in combination with Northern blotting was mined focusing on members of the FAT cadherin family for mutations. Transcript and Protein expression of FAT1 and the isoforms was assessed through qPCR and Western blotting on both T-ALL lines and bone marrow aspirates from both primary B-ALL and T-ALL samples. The function of one of the isoforms, gulFAT1, was analysed *in vitro* using cell proliferation, colony forming and soft agar assays. To study the effects of the FAT1 isoforms *in vivo*, we expressed the gulFAT1 construct as well as the FAT1 cytoplasmic tail only in mouse hematopoietic cells through viral transduction. Transduced cells were injected into sublethally irradiated recipient mice.
Results: Using Northern blotting, we identified two novel FAT1 isoforms that occur as truncated transcripts at the RNA level (12 kb and 2.8 kb) compared to the wild type full length FAT1 mRNA (15 kb). The smaller truncated transcripts were found to be both unique and specific to T-ALL. RACE analysis showed the smaller 2.8 kb is the result of a cryptic transcription start site incorporating a retained intron and predicted protein to have a novel N-terminus. Interestingly the sequence is the striking ortholog of a gene mutation in drosophila (Gull) that results in developmental abnormalities of the wing [JC1] and we have therefore named this smaller human equivalent as gulFAT1. In murine NIH3T3 fibroblasts, gulFAT1 expression caused a significant increase in proliferation, which was abrogated upon removal of the carboxyl-terminal PDZ binding peptide. We have found that this motif can specifically bind to the DLG1, MAGI3 and SCRIB, proteins, which have previously been indicted in the etiology of T-ALL. Transient siRNA knockdown in human T-ALL lines decreased cellular proliferation, and on going experiments with expression of gulFAT1 in the bone marrow cells of mice caused increased white blood cell count.
Summary / Conclusion: The FAT cadherins have recently been implicated in a number of cancers, and our results have identified a short FAT1 transcript gulFAT1 that is potentially involved in the leukomogenesis of T-ALL. The exact role of gulFAT1 it yet to be determined, but may act by sequestering PDZ binding proteins from their normal function. With the expression of the shorter FAT1 isoforms unique to leukemic cells they could be considered as markers for diagnosis and minimal residual disease, and potentially future therapeutic targets.

P011

COMMON AND DISTINCT FEATURES OF PAX5 FUSION PROTEINS
S Anderl[1,*] K Fortschegger[1], D Denk[1], S Strehl[1]
[1]CCRI, Children's Cancer Research Institute, St.Anna Kinderkrebsforschung e.V., Vienna, Austria

Background: In B-cell precursor acute lymphoblastic leukemia PAX5, a transcription factor pivotal for B-cell commitment and maintenance, is frequently affected by genetic alterations including deletions, mutations, and chromosomal rearrangements. The latter result in the expression of chimeric proteins that retain the PAX5 DNA-binding paired domain at the N-terminus, which is fused to the C-terminal domains of a heterogeneous group of partner proteins. PAX5 fusion proteins are hypothesized to act as aberrant transcription factors antagonizing wild-type PAX5 function.
Aims: To characterize PAX5 fusions we investigated the biochemical and functional properties of PAX5-DACH1, PAX5-DACH2, PAX5-ETV6, PAX5-HIPK1, and PAX5-POM121.
Results: Ectopic expression of these fusion proteins showed a predominant nuclear localization, which may be explained by the presence of the paired domain and at least one nuclear localization signal provided by PAX5 itself or the respective partner protein. Oligomerization was only observed for those fusion proteins that contain a known self-interaction motif like the sterile alpha motif of ETV6 or the coiled-coil domains of DACH1 and DACH2. In chromatin immunoprecipitation experiments all PAX5 fusion proteins exhibited binding to endogenous PAX5 target sequences. Notably, reporter gene assays showed that some fusions are capable of activating the *CD79A* promoter whereas others are not. However, none of the chimeras activated *Cd79a* and surface IgM expression in murine 558LμM plasmacytoma cells.
Summary / Conclusion: Our data show that PAX5 fusion proteins exhibit shared as well as distinct features, which may modulate their function and thus the development of the respective leukemia.
This project is funded by the Austrian Science Fund FWF (P21554-B19).

P012

ANALYSIS OF CRLF2 EXPRESSION IN A COHORT OF 91 NEWLY DIAGNOSED ADULT PATIENTS WITH B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA: CORRELATION WITH CLINICO-BIOLOGICAL FEATURES AND OUTCOME
F Brugnoletti[1,*] S Chiaretti[1], K Bontempi[2], L Elia[1], A Negulici[1], M Vignetti[1,2], A Vitale[1], A Guarini[1], R Foà[1]
[1]Division of Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, [2]GIMEMA Data Center, GIMEMA Foundation, Rome, Italy

Background: A deregulated expression of the cytokine receptor-like factor 2

(d-*CRLF2*) has been described in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) lacking recurrent chromosomal aberrations. An increased *CRLF2* expression is associated with activating *JAK1/JAK2* mutations and *IKZF1* lesions, seems to correlate with a "Ph-like" genomic profile and a poor outcome in high-risk patients. While the frequency and prognostic relevance of a *CRLF2* abnormal expression has been extensively investigated in pediatric cases, little is known about its role in adult ALL.

Aims: In order to evaluate the clinical relevance of *CRLF2* expression levels in adult ALL, we analyzed 91 newly diagnosed adult BCP-ALL cases (median age 44 years, range 19-81) negative for recurrent fusion genes, and correlated d-*CRLF2* with the clinico-biological characteristics and outcome. In addition, we assessed the incidence of the *P2RY8/CRLF2* transcript and its clinical impact on the same cohort of patients.

Methods: Total RNA was extracted from mononuclear cells of patients enrolled in different GIMEMA protocols. All samples were collected at diagnosis and contained at least 70% of leukemic blasts. Ninety-one BCP-ALL adult patients were studied: molecular screening, performed on all cases, proved negative for the recurrent fusion genes (*BCR/ABL1*, *ETV6/RUNX1*, *E2A/PXB1*, *MLL/AFF1*). To evaluate the expression of *CRLF2,* we performed quantitative PCR (Q-PCR) and the results were normalized on the housekeeping gene *GAPDH* ($\Delta Ct = Ct_{CRLF2} - Ct_{GAPDH}$). ΔCt values are inversely correlated to the expression levels of the gene. RT-PCR was carried-out to identify the presence of the *P2RY8/CRLF2* transcript.

Results: In our cohort, *CRLF2* showed an extremely heterogeneous expression (ΔCt range: 1.5-17.3). Correlation between *CRLF2* expression levels and the clinico-biological characteristics - i.e. age, white blood cell (WBC) and platelet (Plts) counts, and hemoglobin (Hgb) levels - showed a statistically significant association with hyperleukocytosis (P=0.0014) and thrombocytopenia (P=0.037), but not with age and Hgb levels. Next, by using a ΔCt ≤8 cut-off, based on martingale residuals, a statistically significant correlation was found with disease-free survival (DFS) and overall survival (OS) (P=0.004 and P=0.044, respectively); no association with response to induction chemotherapy was found. In addition, we evaluated the incidence of the *P2RY8/CRLF2* transcript: the fusion gene was identified in 7/91 patients (7.7%), with 3 cases showing a concomitant *CRLF2* overexpression. The correlation with outcome showed that of the 7 *P2RY8/CRLF2*+ cases, 2 experienced a relapse at 3 and 6 months, respectively, and 2 died during treatment.

Summary / Conclusion: These results indicate that *CRLF2* expression is highly heterogeneous in adult BCP-ALL cases and highlight a correlation with an increased WBC count and a decreased PLT count, as well as with a poor outcome. Furthermore, our study demonstrates that the incidence of the *P2RY8/CRLF2* transcript in adult BCP-ALL is similar to that reported in pediatric cohorts and confirms the lack of an absolute concordance between its presence and high *CRLF2* levels. Despite the small number of *P2RY8/CRLF2*+ cases, a negative role of this transcript on the outcome of adult patients is suggested.

P013

A CLINICALLY RELEVANT POPULATION OF LEUKEMIC CD34+CD19+ CD58- CELLS IN PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

Y Kong[1,*] Y Liu[1], Y Wang[1], Q Jiang[1], H Jiang[1], Y Qin[1], Y Lai[1], K Liu[1], X Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of HSCT, Beijing, China

Background: Xenotransplantation studies indicate that leukemia selectively develop from a faction of leukemia-initiating cells (LIC). Current therapies, despite actively targeting leukemic bulk blasts, often spare the quiescent and resistant LIC responsible for relapse. If clinically relevant, it is expected that LIC would be enriched in minimal residual disease (MRD) and predictive of relapse. Despite the considerable research on LIC over the past 2 decades, its clinical significance remains uncertain.

Aims: To investigate the leukemia-initiating capacity of CD34+CD19+CD58- cells and determine the prognostic significance of CD58 (lymphocyte function–associated antigen 3) expression by CD34+CD19+ cells in patients with *de novo* Philadelphia chromosome-positive acute lymphoblastic leukemia(Ph+ALL) treated in Peking University Institute of Hematology.

Methods: First, the leukemia-initiating potential of sorted $CD34^+CD19^+CD58^+$ and $CD34^+CD19^+CD58^-$ compartments was investigated *in vivo* using anti-mouse CD122 monoclonal antibody conditioned NOD/SCID mice by intra-bone marrow–injection. Second, we prospectively analyzed whether the $CD34^+CD19^+CD58^-$ compartment at diagnosis correlates with MRD frequency after therapy and clinical outcome in 49 adult patients (18-60 years) with *de novo* Ph^+ALL. According to ROC analysis, more than 20% of $CD34^+CD19^+$ cells with CD58 expression analyzed by flow cytometry at diagnosis were defined as $CD34^+CD19^+CD58^+$, all other cases were defined as $CD34^+CD19^+CD58^-$.

Results: Xenotransplantation of the sorted $CD34^+CD19^+CD58^-$ cells led to a repopulation of human B-ALL in recipient mice, which were phenotypically and clonally derived from the original Ph^+ALL patients analyzed by flow cytometry, as well as fluorescence in situ hybridization and quantitative reverse transcription-PCR for leukemia-specific cytogenetic abnormalities. In patients with Ph^+ALL, a $CD34^+CD19^+CD58^-$ phenotype at diagnosis significantly correlated with a lower complete remission rate and high MRD frequency. Additionally, it directly correlated with higher cumulative incidence of relapse(CIR, 51.79%±2.16% vs. 16.43%±0.49%, P=0.02) and unfavorable disease-free survival (DFS,40.18%±13.61% vs. 66.20%±12.17%, P=0.04) at 30-month. A good correlation between the MRD results detected by $CD34^+CD19^+$cells with aberrant CD58/CD123 expression and the BCR-ABL transcript levels was observed during the follow-up (n=360 pairs, Spearman r=0.88, P<0.0001). The $CD34^+CD19^+CD58^-$ group exhibited a higher rate of BCR-ABL mutations conferring higher level imatinib resistance than the $CD34^+CD19^+CD58^+$ group (42.86% *vs.* 5.71%, P=0.005). Multivariate analyses revealed that $CD34^+CD19^+CD58^-$ phenotype at diagnosis was an independent risk factor for relapse (HR=4.85, P=0.01) and DFS (HR=0.32, P=0.04) in Ph^+ALL.

Summary / Conclusion: Both the xenotransplantation data, as well as the clinical correlation studies, show that $CD34^+CD19^+CD58^-$ compartment enrich for leukemia-initiating cells in Ph^+ALL. $CD34^+CD19^+CD58^-$ phenotype at diagnosis independently correlates with an adverse prognosis, which promises to be an efficient tool for relapse prediction in Ph^+ALL patients.

TUMOR HETEROGENEITY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: IMMUNOPHENOTYPE-DEFINED CELL SUBPOPULATIONS AND TCR GENE CLONALITY

N Øbro[1,*] L Ryder[1], H Madsen[1], T Frandsen[2], H Hasle[3], P Wehner[4], S Rosthøj[5], K Schmiegelow[2], H Marquart[1]

[1]Dept. of Clinical Immunology, section 7631, [2]Dept. of Pediatric and Adolescent Medicine, University Hospital Rigshospitalet, Copenhagen, [3]Dept. of Pediatrics, Aarhus University Hospital Skejby, Aarhus, [4]Dept.of Pediatric Hematology and Oncology, Odense University Hospital, Odense, [5]Pediatric Department, Aalborg University Hospital, Aalborg, Denmark

Background: The ability to distinguish leukemic cells based on their immunophenotype or on DNA sequences of rearranged clonal T-cell receptor (TCR) loci is a prerequisite for minimal residual disease (MRD) monitoring in T-cell acute lymphoblastic leukemia (T-ALL). A problem in T-ALL is discrepancies between flow cytometry (FC)- and PCR-based MRD results. Occurrence of blast subpopulations/subclones is a potential pitfall of MRD monitoring. Subpopulations might harbor different rearranged TCR DNA sequences leading to risk of underestimated PCR-MRD results which are based on sequence information from the main population at diagnosis.

Aims: The aim of this study is to characterize T-ALL leukemic blast immunophenotypic heterogeneity and the TCR gene rearrangement profiles for distinct cell subpopulations, and thereby evaluate whether PCR-based MRD monitoring detects these subpopulations.

Methods: We analyzed the leukemia-associated immunophenotype (LAIP) by multicolor FC in diagnostic bone marrow/peripheral blood samples from 41 consecutive Danish T-ALL patients treated according to the NOPHO ALL-2008 protocol. The analysis focused on characterization of heterogeneous FC expression patterns (bimodal defined as distinct populations in contour-plot, and broad). 24 patients, having leukemic cell subpopulations with heterogeneous expression of one/more markers, are currently being investigated by flow-sorting and screening of TCR clonality patterns (IdentiClone Clonality assay).

Results: 83% of the T-ALL patients had leukemic cell subpopulations (comprising <2% of total blast count) characterized by bimodal marker expression, most often of TdT, CD1a and CD4 (27-34% of patients), as well as cytCD3 and CD34 (15-17%). A common heterogeneity comprised of bimodal CD1a with ~2/3 of the blasts being negative and ~1/3 positive. Markers that often showed broad expression pattern were: TdT, CD34, CD4, cytCD3 and CD1a.

Results from TCR clonality testing in flow-sorted subpopulations in 24 patients will be presented. Preliminary data from 9 patients showed that the majority of patients (8 out of 9) have identical TCR gene rearrangements in flow-sorted individual leukemic cell subpopulations. But one patient had a CD1a-bright subpopulation negative for a TCRD and TCRB V-J gene rearrangement found in the bulk CD1a-neg. leukemic population. The TCRD and TCRB markers had been used for PCR-MRD, but FC revealed that the CD1a-pos. cell population had disappeared at treatment day 29. (The LAIP and gene rearrangement profile of the CD1a-pos. subpopulation showed to be identical to that of the leukemic cell population detected in the lymph node biopsy).

Summary / Conclusion: Our data show that the majority of T-ALLs have leukemic cell subpopulations by FC analysis, often characterized by heterogeneous expression of markers used for flow-MRD monitoring (eg. TdT, CD1a, CD34). Our preliminary data show that cell subpopulations may be negative for TCR clonal markers identified in the bulk cell population, thus leading to a risk of MRD underestimation. Using both FC and PCR-based monitoring could minimize this risk, which is important for correct treatment stratification.

P015

IMMUNOPHENOTYPE AND PROLIFERATION PROFILE OF NORMAL B CELL PRECURSORS IN REGENERATING BONE MARROW FROM PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

P Theunissen[1,*] E Mejstrikova[2], L Sedek[3], T Szczepanski[3], A van der Sluijs[4], A Orfao[5], J van Dongen[1], V van der Velden[1]
[1]Department of Immunology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [2]Department of Pediatric Hematology and Oncology, 2nd Faculty of Medicine, Charles University (DPH/O), Prague, Czech Republic, [3]Department of Pediatric Hematology and Oncology, Medical University of Silesia (SUM), Zabrze, Poland, [4]Dutch Childhood Oncology Group, The Hague, Netherlands, [5]Cancer Research Center (IBMCC-CSIC), Department of Medicine and Cytometry Service, University of Salamanca (USAL) and Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain

Background: During follow up of B cell precursor (BCP) acute lymphoblastic leukemia (ALL) patients, the detection of minimal residual disease is the most important prognostic factor for relapse. The regeneration pattern of normal BCPs in bone marrow (BM) forms the background to which these remaining malignant blasts should be detected. During the treatment course of BCP-ALL, BCP numbers decrease dramatically. However, in between treatment blocks and after stop of treatment, massive regeneration of BCPs occurs in the BM.
Aims: BCP regeneration may hamper sensitive detection of MRD. In order to get more insight in the characteristics of regenerating BCPs in the BM of BCP-ALL patients, we compared the immunophenotype and proliferation profile of BCPs in regenerating BM and BM from healthy controls.
Methods: BM samples of healthy individuals (normal BM), patients with BCP-ALL after induction therapy (day 79) and patients with BCP-ALL one year after stop of therapy (month 36) were analyzed.For immunophenotypic analysis, 8 color flow cytometry was performed. Newly designed Infinicyt Software was used to define multiple maturation stages in the BCP population. For each individual marker, the expression pattern during these maturation stages was compared between regenerating BM and normal BM. To assess proliferation, four BCP subsets were sorted from each BM sample: pre-B-I, pre-B-II-large, pre-B-II-small and immature B cells. To determine the percentage of proliferating cells, propidium iodide (PI) was added and PI expression was measured using flow cytometry. The proliferation history of BCPs in the pre-B-II-small en immature subsets was assessed by performing a K-rearrangement excision circle (KREC)-assay. The ratio between the KREC and the rearranged *IGK*-gene represented the average amount of replication cycles the BCPs had undergone since *IGK*-rearrangement.
Results: The BCP expression patterns of CD19, CD10, CD34, CD58, CD66c, CD38, CD123, CD9, CD81, CD24, TdT, Igκ and Igλ of regenerating BM at day 79 and month 36 were similar to the expression patterns of BM from healthy individuals. As expected, most proliferation in normal and regenerating BM occurred in the pre-B-II-large subset. The average percentages of proliferation in respectively the pre-B-I and pre-B-II-large subsets were 13%±2% and 29%±3% at day 79 and 9%±2% and 30%±3% at month 36. This was comparable to the percentages of proliferating cells in the pre-B-I and pre-B-II-large subsets of normal BM. Regenerating BM at month 36 and normal BM showed no significant proliferation in the pre-B-II-small and immature BCP subsets. In regenerating BM at day 79, these two subsets were hardly present. KREC-analysis of the pre-B-II-small and immature subsets confirmed that no cell divisions had occurred after *IGK*-rearrangement in both normal BM and regenerating BM at month 36.
Summary / Conclusion: Regenerating BM in BCP-ALL patients seems immunophenotypically similar to normal BM. Proliferation in regenerating BM takes mainly place in the pre-B-II-large subset, like in normal BM. The percentage of proliferating cells and the number of cell divisions after *IGK*-rearrangement in the BCP subsets of regenerating BM are comparable to normal BM. Therefore, the regeneration of BCPs during and after therapy is unlikely the result of enhanced proliferation in the pre-B-I, pre-B-II-large, pre-B-II-small or immature subset, but might be due to a larger influx of non-committed stem cells into the B cell lineage. Knowledge on regenerating BCPs may support the design of sensitive flow cytometric MRD assays.

P016

INHIBITION OF S100A6 INDUCES GRAFT VERSUS LEUKEMIA EFFECTS IN MLL/AF4-POSITIVE ALL IN HUMAN-PBMC-SCID-MICE MODEL

H Tamai[1,*] H Yamaguchi[1], K Dan[1], K Inokuchi[1]
[1]Hematology, Nippon Medical School, Tokyo, Japan

Background: *Mixed-lineage leukemia (MLL)/AF4*-positive acute lymphoblastic leukemia (ALL) is associated with poor prognosis even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). The resistance to graft-*versus*-leukemia (GVL) effects may be responsible for the poor effect of allo-HSCT on *MLL-AF4*-positive ALL. Cytotoxic effector mechanisms mediated by tumor necrosis factor-alpha (TNF-α) was reported to contribute to the GVL effect. We have previously shown that *MLL-AF4*-positive ALL escapes from TNF-a-mediated apoptosis by up-regulation of S100A6 expression followed by interfering with p53-caspase 8-caspase 3 pathway *in vitro*.
Aims: We examined whether inhibition of S100A6 can induce effective GVL effect in a mice model.
Methods: To examine the long-term effects of inhibition of S100A6, we produced *MLL/AF4*- positive ALL cell lines (SEM) transduced with lentiviral vectors expresses both S100A6 siRNA and luciferase (SEM-Luc-S100A6siRNA). As a control SEM transduced with lentiviral vectors expresses both control siRNA and luciferase were produced (SEM-Luc-controlsiRNA). *In vitro* analysis, the growth of each cells were assessed with or without of TNF-α (1 and10 ng/mL). *In vivo* analysis,$1x10^7$/Body of SEM-Luc-S100A6siRNA cells were injected into five SCID mice and $1x10^7$/Body of SEM-Luc- control siRNA cells were injected into five SCID mice. After confirmation of engraftment of SEM cells by *in vivo* imaging system (IVIS), each groups of mice were injected $4.8x10^7$ of human- peripheral blood mononuclear cells (PBMCs). The serum concentrations of human-TNF-a three weeks after injection of human PBMCs were measured by ELISA (enzyme-linked immunosorbent assay) in each five mice.In addition to overall survival (OS) rate and tumor growth were assessed byIVIS.
Results: *In vitro* analysis, there were no significant differences between the growth of SEM-Luc-S100A6siRNA and those of SEM-Luc-control siRNA without TNF-a (P=0.890). However, the growth of SEM-Luc-S100A6siRNAwere significantly inhibited by TNF-α in comparison with the growth of SEM-Luc-control siRNA (P=0.012 for 1 ng/mL of TNF-α and P=0.005 for 10 ng/mL of TNF-α). *In vivo* analysis, although there were no significant differences between the serum concentrations of human-TNF-α after injection of human PBMCs of SEM-Luc-S100A6siRNA injected mice and those of SEM-Luc-control siRNA injected mice (145.0±5.0 pg/mL VS 150.0±40.0 pg/mL, P=0.95), significant differences were observed between OS of each mice (median >100 days VS median 54 days, P=0.002). As for tumor growth of 6 weeks after SEM cells engraftment, significant differences were observed between SEM-Luc-S100A6siRNA injected mice and SEM-Luc-control siRNA injected mice ($2.95±0.10x10^5$ p/s VS $1.42±0.05x10^7$p/s, P=0.001)
Summary / Conclusion: Our results showed thatinhibition of S100A6 can induce effective GVL effect in a mice model.These results suggest that inhibition of S100A6 may be a promising therapeutic target for *MLL/AF4*-positive ALL in combination with allo-HSCT because it induce effective GVL effectson *MLL/AF4*-positive ALL which is resistant to GVL effects.

P017

ETV6/RUNX1 TRANSCRIPT IS A POTENTIAL TARGET OF RNA-BINDING PROTEIN IGF2BP1

M Stoskus[1,2,*] A Eidukaite[2,3], L Griskevicius[1,4]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Clinics, [2]State Research Institute Centre for Innovative Medicine, [3]Children's Hospital, Vilnius University Hospital Santariskiu Clinics, [4]Clinics of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: In our previously published study (Stoskus *et al*. Blood Cell Mol Dis 2011) we have determined that IGF2 mRNA binding protein 1 (IGF2BP1) is significantly overexpressed in t(12;21)(p13;q22)-positive leukemia compared to other acute lymphoblastic leukemia (ALL) subtypes and healthy controls. These findings prompted us to hypothesize about the interaction and potential functional relationship between RNA-binding protein IGF2BP1 and leukemia fusion gene *ETV6/RUNX1* (*TEL-AML1*) transcript.
Methods: To test the possible interaction between IGF2BP1 protein and *ETV6/RUNX1* mRNA, we employed RNA immunoprecipation (RIP) approach using cytoplasmic extracts form *ETV6/RUNX1*-positive leukemia cell line REH and clinical samples of t(12;21)-positive ALL. Cytoplasmic extracts from clinical samples were prepared using -80°C frozen WBC pellets. IGF2BP1/mRNA complexes were precipitated using RIP-grade rabbit anti-IGF2BP1 antibody (MBL International) and isolated with ProtA Dynabeads (Life Technologies) as described by Jain R. *et al* (Methods Mol Biol. 2011). Normal rabbit IgG was used as a negative control for RNA immunoprecipitation (isotype control). Enrichment of control transcripts – *ACTB*, *CTNNB1*, *MYC* – and a potential target - *ETV6/RUNX1* – was assayed by RT-qPCR method. The level of *IGF2BP1* expression in the RNA input aliquot was used as a reference for normalization in delta Cq calculation.
Results: By using RIP approach we have identified *ETV6/RUNX1* leukemia fusion gene transcript in the anti-IGF2BP1 immunoprecipitate of t(12;21)(p13;q22)-positive cell line REH cytoplasmic extracts (Figure 1). Quantitative analysis indicates that the enrichment of *ETV6/RUNX1* mRNA is comparable to the values obtained for the known targets of IGF2BP1 – *ACTB*, *CTNNB1*, and *MYC* (Figure 1). Furthermore, we have validated these results in t(12;21)(p13;q22)-positive ALL using frozen WBC pellets prepared from five different diagnostic samples of this leukemia type (Figure 1). Note, that a "title" target of IGF2BP1 protein – IGF2 mRNA – is not expressed in REH cell line and diagnostic samples of t(12;21)(p13;q22)-positive ALL (data not shown) indicating that other pathways might be modulated by this evolutionary highly-conserved protein in ETV6/RUNX1-positive leukemia.
Summary / Conclusion: Taken together, these data indicate that

ETV6/RUNX1 transcript is a potential target of RNA-binding protein IGF2BP1 and warrant further research of IGF2BP1's role in *ETV6/RUNX1*-mediated leukemogenesis.

SNP ARRAY ANALYSIS OF ADULT ALL: A POPULATION BASED STUDY OF LITHUANIAN PATIENTS

V Dirse[1,*] T Zvirblis[1], L Griskevicius[1,2]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, [2]Clinics of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background: The frequency of abnormal karyotypes in adult acute lymphoblastic leukemia (ALL) is 64-85%. The different outcomes of adult compared to children ALL may be related to different frequencies of specific abnormalities (Mrozek *et al*., 2004). There is a need for novel markers in adult and adolescent ALL to allow a better risk stratification of these patients and to identify new treatment targets (Paulsson *et al*., 2008). Considering high resolution and sensitivity of SNP array (SNP-A), it is possible to detect not only established but also new submicroscopic aberrations. The application of SNP-A method on a population level may give new information on distribution of known genomic aberrations and help to identify new candidate genes and loss of heterozygosity (LOH) related to the pathogenesis of ALL as well as their phenotypic and clinical relevance.
Aims: To characterize genomic aberrations of adult ALL on a population scale using SNP-A and identify new candidate genes relevant to the pathogenesis of ALL.
Methods: We assumed 70% (+/-8%) incidence of chromosomal abnormalities in a sample of ALL cases. A minimum sample size for the Lithuanian population was calculated to be 55. Adult ALL bone marrow samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChip (Illumina Inc., San Diego, CA, USA). Genotypes were called by GenomeStudio GT module version 1.7 (Illumina Inc.). QuantiSNP version 1.1 software was used for detailed analysis of structural and numerical chromosomal aberrations and loss of heterozygosity. All detected genomic lesions were checked and filtered using Database of Genomic Variants database.
Results: Bone marrow samples of 57 adult ALL cases diagnosed between 2007 and 2012 were analyzed. SNP-A analysis detected 694 genetic abnormalities not corresponding to known copy number polymorphisms (96% of all the patients, 55/57). These comprised 160 (23%) hemizygous and 34 (5%) homozygous deletions, 363 (52%) duplications and 137 (20%) amplifications (copy number >3). The most aberrations we detected in 1q21-q41 region. Most hemezygous and homozygous deletions were detected in chromosomes 5q and 9p respectively, whereas most duplications and amplifications were detected in 1q and 4p (Figure 1). The majority of aberrations was <5 Mb and hence expected to be cytogenetically cryptic. The median size of all aberrations was 75.2 Kb. The median size (Kb) of hemizygous deletions, homozygous deletions, duplications and amplifications was 113.9, 50.1, 97.3 and 41.9. Loss of heterozygosity (LOH) (>10 Mb) was detected in 27 genomic regions. The analysis revealed 170 recurrent copy-number changes. These copy number abnormalities encompassed several leukemia-related genes – *CDKN2A* (16 cases, 28%), *CDKN2B* (4 cases, 7%), *MLL* (7 cases, 12%), *IKZF1* (3 cases, 5%), *PAX5* (4 cases, 7%). We identified several new recurrent aberrations which included possible new target genes *TACC3* (22 cases, 38%), *FGFR3* (16 cases, 28%), *LRP1B* (10 cases, 17%), *FAM5C* (10 cases, 17%), *RAD51B* (7 cases, 12%).
Summary / Conclusion: SNP-A analysis provides the landscape of genomic lesions on population level of adult ALL. New candidate genes of adult ALL were identified.

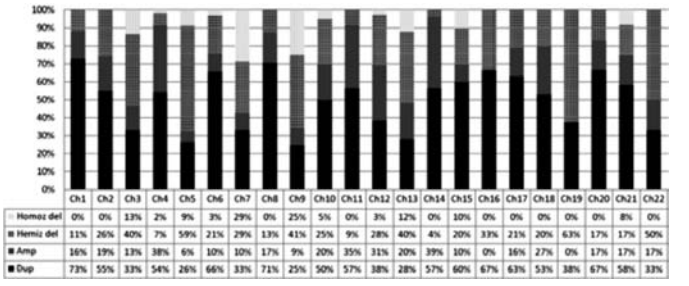

Figure 1.

P019

***IN VIVO* DUAL LUCIFERASE IMAGING ON PATIENTS' ACUTE LEUKEMIA CELLS GROWING IN MICE**

M Carlet[1], I Jeremias[1,*]
[1]Gene Vectors, Helmholtz Center Munich, Munich, Germany

Background: Acute lymphoblastic leukemia (ALL) is a frequent disease in children and adults which remains difficult to treat in a major part of patients. Novel therapeutic options are intensively desired.
Aims: The aim was to establish dual luciferase *in vivo* imaging in patient-derived xenograft ALL cells growing in mice for use in decisive preclinical treatment trials.
Methods: We transplanted primary tumor cells from patients with ALL into immuno-compromised mice as establisehd in the known individualized xenograft mouse model of ALL. We established lentiviral transduction of individual xenograft ALL cells for expression of transgenes. In patient-derived ALL cells, either Gaussia luciferase or an codon-optimized version of firefly luciferase was expressed.
Results: Using either Coelenterazine or Luciferine as a substrate in mice, patient-derived ALL cells could be easily monitored by *in vivo* imaging with either of both luciferases. Both luciferases enabled reliable and continuous follow up leukemic growth in mice. Sensitivity of both luciferases was high and allowed monitoring of minimal residual disease in mice as well as distinct disease phases and classical treatment outcome parameters. Most importantly, two distinct classes of leukemia cells could be monitored in parallel in a single mouse by use of the two different luciferases.
Summary / Conclusion: Taken together, dual luciferase imaging allows evaluating two different cell subpopulations in parallel in a single mouse in real time on patients' ALL cells *in vivo*. The method allows comparing, e.g., the therapeutic effect on genetically altered versus control cells in future preclinical treatment trials in mice.

Acute myeloid leukemia - Biology 1

P020

OVEREXPRESSION OF INTRONIC MIR-3151 AND ITS HOST GENE BAALC INCREASES LEUKEMOGENESIS IN ACUTE MYELOID LEUKEMIA (AML) BY DIRECT DEREGULATION OF TP53 AND MAY BE TARGETED BY BORTEZOMIB

A Eisfeld[1],* S Schwind[1], R Patel[1], X Huang[1], R Santhanam[1], C Walker[1], T Jarvinen[1], B Leffel[1], D Perrotti[1], G Marcucci[1], C Bloomfield[1], A de la Chapelle[1]
[1]Comprehensive Cancer Center, The Ohio State University, Columbus, United States

Background: High expression of both intronic *miR-3151* & its host gene *BAALC* associate with poor prognosis in cytogenetically normal (CN)-AML patients (Eisfeld *et al.* Blood 2012). The underlying mechanisms are unknown.are unknown.
Aims: To elucidate how the *miR-3151* & *BAALC* interplay contributes to aggressive AML.
Results: Pathway analysis of a previously derived gene expression profile that associates with *miR-3151*-expression in CN-AML patients (n=179; Eisfeld *et al.* Blood 2012) revealed TP53 signaling as the top canonical pathway. *TP53* is an *in silico* predicted direct *miR-3151* target. Luciferase assays proved a direct downregulating effect on the transcript from the *TP53*-3'-UTR by *miR-3151* (-40% mean [±1.6 standard deviation] *miR-3151* vs. scramble control, P<.001). Forced *miR-3151* expression reduced TP53 mRNA and protein compared to scramble in AML cells (KG1 cells: -70%, P=.007; MV4-11 cells: -86%, P=.002). Thus *miR-3151* directly deregulates TP53. We hypothesized that its host, *BAALC*, impacts the same pathway and tested the effects of *miR-3151* & *BAALC* overexpression on 30 TP53-pathway associated genes in primary AML blasts (n=4). *miR-3151* overexpression downregulated 15/30 genes compared to scramble. Overexpression of *BAALC* in comparison with scramble upregulated 8 genes, including the oncogene *JUN* (5.5 [±2.2]-fold). Thus, both *miR-3151* & *BAALC* deregulated the TP53-pathway. Caspase assays confirmed a decrease of apoptosis following *miR-3151* or *BAALC* overexpression, likely due to TP53 impairment, after 72h in KG1 (*miR-3151* vs. scramble: .44-fold [±.02], P=.002; *BAALC* vs. scramble: .36-fold [±.004], P<.001) and in MV4-11 (*miR-3151* vs. scramble: .70-fold [±.009], P<.001; BAALC vs. scramble: .80-fold [±.002], P<.001) cells. Next, we analyzed the impact of *miR-3151* & *BAALC* on AML leukemogenesis *in vivo* using a NOD scid gamma knock-out (NSG) mouse model, by injecting MV4-11 cells overexpressing *miR-3151*, *BAALC*, *miR-3151/BAALC*, or scramble (n=6 mice/group). Mice injected with *miR-3151* or *miR-3151*/*BAALC* had a significantly shorter survival compared to the scramble mice (*miR-3151*/*BAALC:* P=.006; *miR-3151*: P=.008; Figure 1). Survival of the mice injected with *BAALC* overexpressing cells did not differ from the scramble group (P=.4). Next, we sought to identify the causes of *miR-3151* & *BAALC* overexpression. We identified 2 possible transcription start sites (TSS-3151, -362 bp upstream of the stemloop; TSS-BAALC, -2038 bp upstream of the BAALC ATG). SP1 & NF-κB were *in silico* predicted to target both TSSs. Luciferase assays showed increased luciferase activity for both TSSs after addition of SP1 & NF-κB-constructs (TSS-3151: SP1: 4.9-fold [±.2], NF-κB: 2-fold [±.15]; TSS-BAALC: SP1: 5-fold [±.44], NF-κB: 1.8-fold [±.13]). Electromobility shift assays (EMSAs) confirmed SP1 & NF-κB binding. The proteasome inhibitor bortezomib abrogates SP1/NF-κB binding (Liu *et al.* Cancer Cell 2010). A decrease of *miR-3151* & *BAALC* expression was observed as early as 3 hours after bortezomib (100µg/ml) treatment compared to vehicle treated control cells (KG1a cells: *miR-3151* expression: -70%, P=.002; *BAALC* expression: -62%, P=.001).
Summary / Conclusion: We identify an interplay of an oncomiR, *miR-3151*, with its host gene, *BAALC,* that leads to deregulation of the TP53-pathway & thus promotes aggressive disease in AML. Overexpression of both *miR-3151* & *BAALC* may be targeted by bortezomib treatment in these high risk patients.

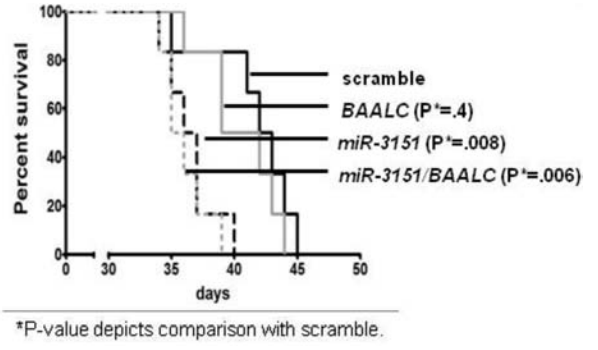

Figure 1. Survival of NSG mice after *miR-3151* and/or BAALC overespression.

SP1 STABILIZATION IS REQUIRED FOR AML1-ETO LEUKEMOGENESIS

A Maiques[1],* M Hernando[1], M Martín[1], M Wunderlich[2], J Mulloy[2], J Cigudosa[1], S Alvarez[1]
[1]Molecular Cytogenetics Group, Spanish National Cancer Research Centre (CNIO), Madrid, Spain, [2]Division of Experimental Hematology, Cincinnati Children's Hospital Medical Center, Cincinnati, United States

Background: The AML1-ETO (AE) fusion protein generated by the t(8;21), present in 10% of Acute Myeloid Leukemias (AMLs), has been shown to alter the transcriptional pattern of leukemic cells trough chromatin modifications and interaction with transcriptional factors. In murine and human hematopoietic stem and progenitor cells (HSPCs) AE promotes self-renewal and blocks lineage differentiation, but does not by itself cause leukemic transformation. Recently, genome-wide analyses have demonstrated the importance of several transcription factors recruiting AE promoter binding to non-AML1 binding sites. We have identified the transcriptional factor Sp1, an essential transcription factor for haematopoiesis development, as a crucial element driving AE DNA binding pattern and thus supporting the role of Sp1-targeted therapy [1].
Aims: Determine the mechanism of Sp1 accumulation upon AE expression and the role of Sp1 protein in the leukemic transformation of HSPC-AE to study Sp1 targeting as a possible therapeutic strategy.
Methods: We made use of human hematopoietic stem cells retrovirally transduced with AE (HSPC-AE)[2] and the t(8;21) SKNO1 cell line. Several compounds were used: Mithramicyn A and a proteasome inhibitor (MG-132) from Sigma-Aldrich, JNK inhibitor II (SP600125) from Calbiochem. Lentiviral vector MISSION pLKO.1shRNA-puro constructs targeting human Sp1 were obtained from Sigma-Aldrich.
Results: Upon AE expression high Sp1 protein levels on the presence of low Sp1 mRNA levels were observed, pointing to Sp1 protein stabilization and accumulation. To elucidate the mechanism under Sp1 accumulation, JNK1 mRNA and protein levels were investigated, as JNK1 kinase has been shown to phoshporylate Sp1 inhibiting its degradation via proteasome. High levels of JNK1 mRNA and protein in HSPC-AE relative to HSPC controls and a positive correlation between JNK1 and Sp1 protein levels were observed. Indeed, pharmacological inhibition of JNK1 kinase activity on SKNO1 cell line abrogated Sp1 protein phosphorylation and accumulation. The exposure of SKNO1 to the proteasome inhibitor MG132, known to activate JNK1, leaded to Sp1 protein accumulation. These data further support JNK1 activation as a mechanism of Sp1 protein stabilization on AE expressing cells.The biological importance of Sp1 on t(8;21) leukemia was further studied by lentiviral shRNA knockdown system. A complete abrogation of self-renewal of two independent HSPC-AE clones and a total impairment of proliferation in SKNO- Sp1 knockdown cells were observed. Interestingly, on THP1 cell line, harbouring the MLL-AF9 fusion protein, little effect upon Sp1 knockdown was observed. Furthermore, we evaluate the sensitivity of inhibiting Sp1 DNA binding using Mytramicin A. Higher sensitivity to this drug in the presence of the AE fusion protein compared to cells harbouring other fusion proteins was also confirmed. Finally, genome-wide expression profiling has been performed upon pharmacological Sp1 binding inhibition to determine the role of Sp1. A complete analysis of the changes induced by this pharmacological inhibition is warranted.
Summary / Conclusion: We have shown that, through JNK1 phosphorylation, Sp1 is stabilized in AE expressing leukemia cells, leading to a Sp1 accumulation that is required for AE leukemogenesis. These results further support Sp1 as a potential drugable target

P022

PML/RAR-ALPHA INHIBITS PTEN EXPRESSION IN HEMATOPOIETIC CELLS BY COMPETING WITH PU.1 TRANSCRIPTIONAL ACTIVITY

N Noguera[1,2,3],* G Angelini[2], G Gaur[2], G Catalano[3], S Amadori[3], F Lo Coco[2,3]
[1]Department of Chemical Biochemistry, Rosario National University, Rosario, Argentina, [2]Santa Lucia Foundation, [3]Department of Biomedicine and Prevention, Tor Vergata, University, Rome, Italy

Background: The chimeric PML/RARA protein contributes to the pathogenesis of APL by impairing the formation of functional PML nuclear bodies (PML NBs), downregulation and displacing of tumor suppressors and by deregulating genes that are critical to myeloid differentiation. All-trans retinoic acid (ATRA) treatment antagonizes PML/RAR effects, reverts the leukemic phenotype and enables leukemic cells to undergo terminal differentiation. Inactivating mutations of p53 and PTEN (phosphatase and tensin homologue deleted in chromosome 10) are uncommon in patients with APL and AML. Instability and downregulation caused by PML/RARA have been demonstrated for p53, while displacement to cytoplasm with loss of its nuclear function has been shown for PTEN in APL. The anti-oncogenic activity of PTEN is dose-dependent and down-regulation of the protein may be an additional relevant mechanism contributing to its impaired function. We found that primary blasts from patients with APL have significantly lower PTEN expression than blasts from other AML subtypes. To determine whether PML/RARA could directly down-regulate PTEN expression, we performed computational analysis of its promoter region and

found two RARE plus PU.1 and one RARE half plus PU.1 motifs. Ets transcription factor PU.1 is essential for myeloid development, and its silencing produces dysfunction and maturation arrest of hematopoietic stem cells.
Aims: The aim of this work is to asses PTEN expression in patients with APL and its modululation by PML-RARA protein.
Methods: Twenty eight APL and 28 unselected AML patients were analyzed by quantitative PCR using Taqman Probes to measure mRNA PTEN level expression. PTEN protein levels were also analysed in 15 AML and 12 APL cases using Western Blot. In addition, PTEN mRNA and protein levels were studied in: i) PR9 cells, a Zn inducible PML/RARA cell line; ii) APL patient primary blasts and NB4 cells after treatment with ATRA and ATO. ChIP-qPCR was used to analyse the regulatory PTEN sequence for the presence of PU.1 protein.
Results: PTEN mRNA and protein levels were significantly lower in APL as compared to AML samples (P=0.036 and P<0.0001, respectively). PTEN protein expression increased in primary patient blasts and in NB4 cells after *in vitro* treatment with ATRA. By analyzing the PR9 cell line transfected with a zinc inducible PML-RARA construct, we detected a decrease of PTEN mRNA at 2 and 4 hours, simultaneously with PML-RARA maximal expression. Treatment with arsenic trioxide (ATO) also enhanced PTEN expression for the first 1-2 hours, corresponding with degradation of PML/RARA protein. The upstream promoter sequence of PTEN gene locus contained several RARE and one RARE half plus PU.1 motifs. Treatment of NB4 cells with ATRA resulted in increased binding of PU.1 to PU.1-RARE half site as demonstrated by ChIP-qPCR analysis.
Summary / Conclusion: This is the first report showing that PTEN expression is suppressed in APL, and restored upon treatment with ATRA. In leukemic cells PU.1 enhances PTEN expression via binding to two specific motifs on the PTEN promoter sequence. We show that PML/RARA inhibits PTEN expression by directly binding to the protein promoter and displacing a pro-expression PU.1-RARA complex. The binding causes a major decrease of PTEN production thus contributing to compromise its antioncogenic activity.

P023

ACUTE MYELOID LEUKEMIA WITH T(8;21)/RUNX1-RUNX1T1 DEMONSTRATE A HIGH NUMBER OF SECONDARY GENETIC LESIONS: FREQUENCY AND IMPACT ON CLINICAL OUTCOME
M Krauth[1,2,*] C Eder[1], T Alpermann[1], W Kern[1], C Haferlach[1], T Haferlach[1], S Schnittger[1]
[1]MLL Munich Leukemia Laboratory, Munich, Germany, [2]Department of Medicine I, Division of Hematology & Hemostaseology, Medical University Vienna, Vienna, Austria

Background: The translocation t(8;21) with the resulting *RUNX1-RUNX1T1* rearrangement is one of the most common chromosomal abnormalities in acute myeloid leukemia (AML). Although it is generally associated with a favourable prognosis, impact of additional mutations is poorly understood.
Aims: In the present study, we aimed to assess the frequency and clinical impact of secondary mutations in AML patients (pts) harbouring t(8;21)/*RUNX1-RUNX1T1*.
Methods: We analyzed 139 pts which were referred to our laboratory for first diagnosis of AML between 2005 and 2012 (65 females, 74 males; median age 53.3 years, range 18.6 - 83.8 years) and were proven to have t(8;21)/*RUNX1-RUNX1T1*. Diagnosis was established using cytomorphology and multiparameter flow cytometry according to FAB and WHO classifications. Chromosome banding analysis and fluorescence in situ hybridisation were performed for detection of t(8;21) and/or *RUNX1-RUNX1T1*. Mutation analysis of *ASXL1, FLT3*-ITD, *FLT3*-TKD, *KIT (*D816V, exon8 and 9-11*), NPM1, MLL*-PTD, *IDH1* and *IDH2, KRAS, NRAS, CBL,* and *JAK2* was performed in all pts.
Results: 107/139 were classified according to FAB criteria (77.0%). 34/107 had AML M1 (31.8%) and 73/107 AML M2 (68.2%). 117/139 had *de novo* AML (84.2%), 22/139 therapy-related AML (t-AML) (15.8%). 69/139 (49.6%) had at least one molecular alteration in addition to *RUNX1-RUNX1T1*, 23/139 (16.5%) had two or more additional mutations. Most common were *KIT* mutations (23/139; 16.5%), followed by *NRAS* (18/139; 12.9%) and *ASXL1* (16/139; 11.5%). *FLT3*-ITD, *FLT3*-TKD*, CBL,* and *KRAS* were found in 4.3% - 5.0% of all pts, whereas *IDH2* and *JAK2* were detectable in 3.6% and 2.9%, respectively. *IDH1* mutations were found in only 0.7% (1/139), and, notably, *NPM1 and MLL*-PTD were never found in *RUNX1-RUNX1T1*. *FLT3*-ITD as well as *FLT3*-TKD were exclusive of *ASXL1*. Although not significant, *KIT* mutations were frequently associated with *NRAS* and *FLT3*-ITD, when compared to wildtype (*NRAS*: 21.7% vs. 11.2%; *FLT*-ITD 28.6% vs. 15.9%). With exception of *FLT3*-ITD, which was only present in *de novo* AML, there was no difference in mutation frequencies between *de novo* AML and t-AML. Cytogenetic data were available in all pts. 69.8% (97/139) had at least one chromosomal aberration in addition to t(8;21)(q22q22). Most frequent was the loss of either X- or Y- chromosome (together 46.8%), followed by del(9q) (15.1%), and trisomy 8 (5.8%). *FLT3*-ITD*, FLT3*-TKD and trisomy 8 were found to be mutually exclusive. The number of secondary chromosomal aberrations did not differ between pts with *de novo* AML or t-AML, showing a trend towards higher frequency of -Y, del(9q), and trisomy 8 in pts with t-AML. Survival was calculated in pts with intensive treatment (n=111/139, 79.9%; median follow-up 26.9 months; 2-year survival rate 73.4%). With exception of *KIT*D816V, which had a negative impact on survival in *de novo* AML (2-year survival rate 64.2% vs. 82.3%, P=0.05; pts censored on the day of transplantation), we found, that none of the above mentioned mutations influenced outcome. This also holds true for pts with 2 or more coexistent secondary molecular lesions. Moreover, no influence of secondary chromosomal aberrations on survival was found.
Summary / Conclusion: We analysed a sizeable cohort of pts with AML t(8;21)/*RUNX1-RUNX1T1* and screened for a broad panel of mutations as well as chromosomal aberrations. With exception of *KIT*D816V, which negatively influenced survival, our results emphasize the impact of the prognostic favourable t(8;21) status, which was not altered by secondary molecular or chromosomal lesions.

P024

CELLULAR AND MOLECULAR TARGETS OF MLL-AF9 IN A NOVEL CONDITIONAL MOUSE MODEL
V Stavropoulou[1,*] S Kaspar[2], L Brault[1], S Juge[1], S Morettini[2], A Tzankov[3], M Kyba[4], A Peters[2], J Schwaller[1]
[1]Dept. of Biomedicine, University Hospital Basel, [2]Friedrich Miescher Institute for Biomedical Research, [3]Department of Pathology, University Hospital Basel, Basel, Switzerland, [4]Department of Pediatrics, Lillehei Heart Institute, University of Minnesota, Minneapolis, United States

Background: Gene fusions involving the mixed lineage leukemia 1 (MLL1) gene on the long arm of chromosome 11 are associated with infant, pediatric and adult *de novo* and therapy related leukemia that are often linked to poor prognosis. Expression of several leukemia-associated mixed lineage leukemia (MLL) fusion genes transform human and mouse bone marrow cells *in vitro* and *in vivo*.
Aims: To dissect the molecular and cellular targets of the MLL-AF9 fusion using a novel inducible doxycycline (DOX)-regulated transgenic mouse model.
Results: Conditional *ex vivo* activation of MLL-AF9 induced aberrant self-renewal and impaired differentiation capacity of long-term hematopoietic stem (LT-HSC) and various progenitors including granulocyte-macrophage progenitor (GMP) cells. MLL-AF9 expression in LT-HSC or GMP cells caused accumulation of immature blast-like cells that displayed distinct origin-associated properties in colony formation, differentiation capacity and resistance to chemotherapeutic drugs. Turning-off of fusion expression resulted in multi-lineage differentiation of LT-HSC-derived cells, whereas differentiation of GMP-derived cells was restricted to mature macrophages and granulocytes suggesting maintenance of origin identity during MLL-AF9-mediated transformation. *In vivo*, conditional MLL-AF9 expression induced an aggressive and transplantable disease characterized as acute myelo-monocytic leukemia closely mimicking the human MLL-AF9 expressing disease. Fusion gene expression and leukemia induction was DOX dosage dependent and reversible upon DOX removal. LT-HSCs induced a more aggressive leukemia than GMPs. Notably, 10% of LT-HSC derived leukemia had a 50% shorter median latency (LT-"Early") as compared to other LT-HSC-, or GMP-derived leukemias. Cytarabine (Ara-C) treatment significantly delayed leukemia induction by GMP- but not LT-HSC-derived blasts. Gene expression profiling in immortalized pre-leukemic cells revealed MLL-AF9-dependent expression of over 300 genes, including well-known MLL targets such as *Meis1*, *HoxA5*, *HoxA9* and *HoxA10*. LT-HSC-derived blasts displayed distinct gene signatures that clearly separated them from the GMP-derived blasts. *Evi-1* and *Erg*, two known prognostic markers in patient-derived leukemia gene signatures where expressed differentially in LT- and GMP-derived disease. The aggressive "early" LT-derived murine leukemia displayed high *Evi-1* and *Erg* expression levels (*Evi-1* high, *Erg* high) as compared to the "late" LT-derived (*Evi-1* low, *Erg* high) or the GMP-derived leukemias (*Evi-1* low, *Erg* low).
Summary / Conclusion: These observations suggest that the previously reported poor prognosis associated with elevated *EVI-1* and/or *ERG* expression might directly reflect the cellular origin of the disease. We are currently exploiting this highly informative MLL-AF9 disease model to evaluate the functional relevance of novel MLL-AF9 origin-dependent genes and to identify novel prognostic markers and potential therapeutic targets.

P025

STAT3 AND 5 ARE CONSTITUTIVELY ACTIVATED IN T(6;9)(DEK/CAN)-POSITIVE ACUTE MYELOID LEUKEMIA MODELS AND EFFICIENTLY INHIBITED BY EXPOSURE TO ARSENIC TRIOXIDE
C Oancea[1,*] H Held[1], M Heinssmann[1], B Brill[2], Hubert Serve[1], M Ruthardt[1]
[1]Hematology, Goethe University Clinic, [2]Georg Speyer Haus, Frankfurt, Germany

Background: Acute myeloid leukemia (AML) is characterized by an abnormal accumulation of hematopoietic progenitors in the bone marrow (BM). The AML phenotype is maintained by an accelerated proliferation of blast cells and is supported by the aberrant stem cell capacity of poorly defined leukemic stem cells (LSC) along with a block in differentiation. AMLs are frequently associated with specific chromosomal translocations, such as t(15;17), t(8;21) or t(6;9) which

encode aberrant fusion proteins (FPs). These Fps, i.e. PML/RARα (PR), AML-1/ETO (AE) or DEK/CAN (DC), recapitulate the leukemic phenotype in the mouse. Constitutive STAT activation is frequently found in AML and it is postulated that the aberrant stem cell capacity in leukemia is correlated to the activation of STATs. A relationship between STAT-activation and response to arsenic trioxide (ATO) has been documented in models of t(15;17)(PR)-positive AML. The t(6;9)(DC)-positive AML represents a separate entity with a young age of onset and poor prognosis. The leukemogenic mechanisms of DC-induced AML are poorly understood.

Aims: Here we analyzed the activation status of STAT3 and 5 in models of DEK/CAN-positive leukemia and investigated whether the STAT-activation plays a role for the pathogenesis of t(6;9)-positive AML.

Methods: The expression and activation status of STAT3 and 5 was investigated by western blotting and intracellular flow cytometry with antibodies against the phosphorylated and total form of STATs. Apoptosis was measured by 7-AAD staining of U937 cells retrovirally transduced to express DC or PR and treated for 5 days with 1 μM ATO. As models of DC-induced AML we used primary Sca1+Lin- murine hematopoietic stem and progenitor cells (HSPCs) which were retrovirally transduced to express DC or PR as control. For the *in vivo* studies, we used DC-positive primary as well as 2° leukemic cells from established DC-induced AML. The effect of constitutively active STAT3 (STAT3*) on the stem cell capacity was investigated in serial replating and CFU-S12 assays using transduced mHSPCs. ATO treatment of the mice inoculated with DC-positive primary leukemic cells started at day 5 after transplantation and was performed for a period of two weeks. The leukemia development and the response to ATO treatment was assessed 30 days post-transplantation by spleen size and the effect on STATs activation was analyzed in BM and spleen.

Results: Here we show that i) in the pre-leukemic state of DC-positive AML the activation of the STATs was hardly detectable; ii) both STAT3 and 5 were strongly activated in primary blasts of DC and PR from mouse leukemia as well as in retrovirally transduced primary HSCPs; iii) the expression of STAT3* in HSPCs led to an increased replating efficiency in the presence of cytokines and slightly increased the CFU-S12 colony number as a read out for short-term stem cell and early progenitor potential; iv) similar to PML/RARα, DEK/CAN also sensitized the U937 cells to arsenic-induced apoptosis *in vitro*; v) ATO treatment led to a significantly decreased spleen size as compared to solvent treated controls; vi) exposure to ATO abolished the phosphorylation of STAT5 *in vivo.*

Summary / Conclusion: Our results indicate a direct relationship between the expression of the leukemogenic fusion proteins DC or PR and the activation of STATs which seem to play an important role for the maintenance of the leukemic stem cell. The STAT5 activation was efficiently targeted by ATO. Consequently, ATO treatment represent a novel therapeutic concept for the t(6;9)-positive AML.

P026

THE GENE SIGNATURE IN C/EBPA DYSFUNCTIONAL AML PREDICTS RESPONSIVENESS TO HDAC INHIBITORS

M Alberich Jorda[1,2,*] A Liss[3], C Ooi[3], P Zjablovskaja[2], T Benoukraf[3], H Radomska[1], C Ju[3], M Wu[3], M Balastik[2], R Delwel[4], T Brdicka[2], P Tan[3], D Tenen[1,3]
[1]Harvard Medical School, Boston, United States, [2]Institute of Molecular Genetics of the ASCR, Prague, Czech Republic, [3]Cancer Science Institute, National University of Singapore, Singapore, Singapore, [4]ErasmusMC, Rotterdam, Netherlands

Background: C/EBPa plays a crucial role in granulocytic development, and defects in this transcription factor have been reported in acute myeloid leukemia (AML). K562 cells stably transfected with an inducible C/EBPa-estrogen receptor fusion protein (C/EBPa-ER) have been used as a model for human granulocytic differentiation. When stimulated with b-estradiol (E_2) to induce nuclear translocation of C/EBPa, these cells differentiate towards neutrophils.

Aims: The aims of this project are: 1. To identify genes upregulated upon C/EBPa activation, and therefore involved in granulocytic development. 2. To determine whether this set of genes, referred as the C/EBPa signature, is downregulated in AML patient samples. 3. To identify small compounds that could reactivate the C/EBPa signature, and promote granulocytic differentiation.

Results: K562 C/EBPa-ER expressing cells were stimulated with 1 uM E_2 or EtOH vehicle control, and gene expression profiles were determined by microarrays. By using prediction analysis of microarrays (PAM), we identified the C/EBPa signature, characterized by a set of 33 genes which are upregulated upon C/EBPa activation. We analyzed the expression of the C/EBPa signature in a cohort of 525 *de novo* AML patients, and identified a subset of 110 patient samples characterized by low expression of this signature. We referred to this group of patients as the C/EBPa dysfunctional subset. Remarkably, a large percentage of samples harboring C/EBPa biallelic mutations clustered inside this subset. We hypothesize that re-activation of the C/EBPa signature in the C/EBPa dysfunctional subset could have therapeutic potential. In search for small molecules able to reverse the low gene expression of the C/EBPa signature we applied the Connectivity Map. This analysis predicted a positive connectivity between the C/EBPa activation signature and histone deacetylase (HDAC) inhibitors. We showed that HDAC inhibitors (trichostatin A and vorinostat) reactivate expression of the C/EBPa signature in K562 cells. Next, we determined that patient samples with biallelic mutations in C/EBPa from inside the dysfunctional group cultured in the presence of HDAC inhibitors showed upregulation of cell surface granulocytic markers such as CD15 and CD11b. On the contrary, patient samples with biallelic mutations in C/EBPa, but clustering outside the dysfunctional group, had no significant changes in the same conditions. In addition, quantitative RT-PCR showed upregulation of granulocyte specific genes such as G-CSF-R (*CSF3R*), Gelatinase A (*MMP2*), C/EBPe (*CEBPE*), and lysozyme (*LYZ*) in HDAC inhibitor treated cells compared to vehicle control (EtOH) in samples from inside, but not from outside, the C/EBPa dysfunctional group.

Summary / Conclusion: Altogether, our data identify HDAC inhibitors as potential candidates in the treatment of certain AMLs characterized by the downregulation of the C/EBPa signature.

AXL, A THERAPEUTIC TARGET IN AML MEDIATES STROMA-INDUCED CHEMORESISTANCE

I Batalla[1], A Schultze [1], M Wroblewski[1], R Erdmann[1], M Heuser[2], K Weber[3], M Binder[4], M Cuvas-Cordova[1], M Janning[1], J Wellbrock[4], B Fehse[5], C Hagel[6], J Krauter[2], A Ganser[2], J Lorens[7], W Fiedler[4], P Carmeliet[8], K Pantel[9], C Bokemeyer[4], S Loges[1,*]
[1]II. Medical Clinic & Institute of Tumor Biology, Campus Forschung, University Hospital Hamburg-Eppendorf, Hamburg, [2]Department of Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, Hannover Medical School , Hannover, [3] Research Dept. Cell and Gene Therapy, [4]II. Medical Clinic , [5]Research Dept. Cell and Gene Therapy, Campus Forschung, University Hospital Hamburg-Eppendorf, [6]Department of Neuropathology, University Hospital Hamburg-Eppendorf, Hamburg, Germany, [7]The Department of Biomedicine, University of Bergen, Bergen, Norway, [8]Dept. of Transgene Technology and Gene Therapy, VIB Vesalius Research Center, University of Leuven, Leuven, Belgium, [9]Institute of Tumor Biology, Campus Forschung, University Hospital Hamburg-Eppendorf, Hamburg, Germany

Background: Novel targets with potential to improve treatment of AML are urgently needed. Members of the Tyro3, Axl, Mer receptor (TAMR) tyrosine kinase family are abundantly expressed in physiological and malignant hematopoiesis and circumstantial evidence in literature links Axl expression to AML pathobiology. We discovered that Axl, the receptor for Growth Arrest-specific protein 6 (Gas6), represents a novel prognostic marker and potential therapeutic target in AML (Blood (ASH Annual Meeting Abstracts), Nov 2011; 118: 940).

Aims: Validate Axl as a new therapeutic target in AML and investigate its involvement in chemoresistance.

Methods: Gas6 levels were measured by ELISA and immunohistochemistry. Axl expression was detected by flow cytometry. Co-cultures of (murine) BM stroma cells (primary, OP9, S17) with Mv4-11 and OCI-AML5 cell lines were performed.

Results: By investigating primary AML and healthy BM (BM)(i) higher expression of Axl in AML BM compared to healthy BM donors (66.20±10.87 vs. 0.65±0.10%; n=8/6; P<0.05); (ii) Axl expression by 68±31% of AML blasts and (iv) higher expression of Axl by $CD34^+CD38^-$ AML stem cells compared to healthy $CD34^+CD38^-$ BM stem cells (58.43±4.63% vs. 6.00±2.01%; n=7/6; P<0.05). Thus, Axl blockade might be useful to inhibit AML stem cells. Subsequently we determined therapeutic efficacy of BGB324 on primary human AML cells. We incubated AML cells from patients at primary diagnosis with different concentrations of BGB324 and found a dose dependent inhibition of proliferation with a mean IC50 of 1.8 μM (range 0.2341-3.711 μM). Interestingly, sensitivity towards BGB324 (i.e. a lower IC_{50}) correlated with Axl expression on leukemia cells (Pearson's r = -0.9656, P<0.05). To investigate effect of BGB324 treatment on chemosensitivity of human AML cells we incubated primary AML cells with BGB324 in combination with cytarabine and found additive therapeutic effects of both treatments. Notably, BGB324 was also effective in cytarabine-refractory primary AML cells and could sensitize them for chemotherapy. Thus, Axl might be implicated in development of chemoresistance in AML. Analyses of BM sections revealed that expression of Axl`s ligand Gas6 was low in AML cells, similar to healthy hematopoietic cells while it was abundantly expressed in AML BM stromal cells with fibroblastic/mesenchymal morphology (referred to as BMDSCs). Gas6 expression was considerably lower in control BMDSCs (86±14% vs. 20±20%; n=5/7; P<0.05) thus suggesting a possible paracrine interaction between AML cells and BMDSCs leading to Gas6 upregulation in the stroma compartment. In order to test this hypothesis we utilized co-cultures of (murine) BM stroma cells (primary, OP9, S17) with Mv4-11 and OCI-AML5 leukemia cell lines. These experiments revealed specific upregulation of murine (m)Gas6 in BMDSCs mediated by leukemia-cell derived IL-10 and M-CSF. Co-cultures with antibodies blocking hIL-10 and hM-CSF could abrogate stromal Gas6 upregulation. Protective effect of stroma cells towards cytarabine-induced cytotoxicity could be eliminated by shAxl, sAxl or by BGB324. Thus, interaction between stroma-derived Gas6 and Axl^+ leukemia cells forms a chemoprotective niche for leukemia cells. In line with these findings Axl blockade

chemosensitizes Mv4-11 cells for treatment with doxorubicine *in vivo.*
Summary / Conclusion: Axl represents a therapeutic target in AML and Axl inhibition by BGB324 holds potential to treat chemosensitive and –resistant AML.

P028

RECURRING FLT3 N676K MUTATIONS IN CORE BINDING FACTOR LEUKEMIA ACTIVATE MAPK-SIGNALING AND CONFER FACTOR INDEPENDENT GROWTH OF BA/F3 CELLS

H Polzer[1,*] S Opatz[1], T Herold[1], N Konstandin[1], B Ksienzyk[1], E Zellmeier[1], S Vosberg[1], A Graf[2], S Krebs[2], H Blum[2], K Hopfner[3], P Kakadia[1], S Schneider[1], A Dufour[1], J Braess[4], M Sauerland[5], W Berdel[6], T Büchner[6], B Woermann[7], W Hiddemann[1], K Spiekermann[1], S Bohlander[8], P Greif[1]
[1]Department of Internal Medicine III, [2]Laboratory for Functional Genome Analysis at the Gene Center, [3]Department of Biochemistry at the Gene Center, Ludwig-Maximilians-Universität, Munich, [4]Oncology and Hematology, St. John-of-God Hospital, Regensburg, [5]Institute of Biostatistics and Clinical Research, [6]Department of Medicine A, Universität Münster, Münster, [7]German Society of Hematology and Oncology, Berlin, [8]Center of Human Genetics, Philipps University Marburg, Marburg, Germany

Background: The t(8;21) and inv(16)/t(16;16) rearrangements affecting the core-binding factors, RUNX1 and CBFB, respectively, are found in 15-20% of adult *de novo* AML cases and are associated with a favourable prognosis. Since expression of CBFB/MYH11 or RUNX1/RUNX1T1 on their own is not sufficient to cause leukemia it is likely that additional mutations are required for malignant transformation.
Aims: Identification of mutations which may collaborate with CBFB/MYH11 during leukemogenesis.
Methods: We performed exome sequencing of an AML sample with an inv(16). The sample was selected based on availability and absence of known additional genetic alterations. By comparing the AML exome sequence with the exome sequence of a remission sample from the same patient we were able to identify leukemia-specific sequence variants as described previously (Greif *et al*., 2012, Blood).
Results: By exome sequencing of a an AML patient with inv(16) we found an N676K mutation in the ATP-binding domain (TKD1) of the *fms-related tyrosine kinase 3* (*FLT*3) gene. Mutations affecting N676 resulting in variable amino acid changes (N676D or N676S) were initially discovered in a screen for resistance to tyrosine kinase inhibitors (TKI) in *FLT3* internal tandem duplication (ITD) expressing Ba/F3 cells (Cools *et al*., 2004, Cancer Res). An N676K point mutation has been reported in a cytogenetically normal (CN) AML patient with *FLT3*-ITD and TKI-resistance (Heidel *et al*., 2006, Blood). In contrast, our patient with inv(16) and the *FLT3* N676K did not carry an additional *FLT3*-ITD. In a cohort of 84 *de novo* AML patients with a CBFB/MYH11 rearrangement and in 36 patients with a RUNX1/RUNX1T1 rearrangement, the FLT3 N676K mutation was identified in 5 and 1 patients, respectively (5/84, 6%; 1/36, 3%). None of the CBF AML patients with *FLT3* N676K mutation had an additional *FLT3*-ITD. In 90 CN-AML patients we detected only a single *FLT3* N676K mutation and the affected patient had a concurrent *FLT3*-ITD. In addition we analyzed mutational hotspots of several commonly mutated genes in our CBFB/MYH11 positive cohort: FLT3, KRAS, NRAS, KIT, WT1, MLL and NPM1 (Figure 1).

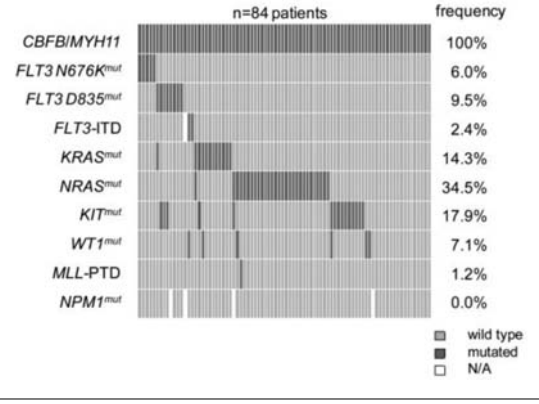

Figure 1. Frequency of additional mutations in CBFB/MYH11 positive AML.

Clinical parameters of 56 CBFB/MYH11 rearranged patients enrolled in the AMLCG-99 trial were correlated with FLT3 N676 status: The *FLT3* N676K mutation was significantly associated with higher leukocyte counts (P=.02), elevated LDH (P=.02) and male sex (P=.02). There was no significant difference in survival of patients with a FLT3 N676K (n=4) compared to patients with FLT3 N676 wild type (n=47). However, there was a trend towards reduced complete remission rates associated with FLT3 N676K mutations.

To test the transforming potential we expressed the FLT3 N676K mutant in Ba/F3 cells. As controls we expressed FLT3 wild type (WT), FLT3 mutants D835Y or ITD in parallel. Cell surface expression of N676K was similar to WT, but increased compared to D835Y and ITD. Cell proliferation assays were done in presence and absence of IL-3 or FLT3 ligand (FL). FLT3 N676K leads to IL-3 and FL independent cell growth reaching 25% of IL-3 mediated growth. FLT3 inhibition by AC220 or PKC412 abrogates this proliferation, but N676K is slightly more resistant to inhibition than ITD. In contrast to ITD expression that results in STAT5 phosphorylation, N676K expression leads to phosphorylation of MAPK and AKT.
Summary / Conclusion: Our findings point towards a specific association of activating *FLT3* N676K mutations with CBF leukemia. Although *FLT3* is a well known mutational target in AML, it appears that the spectrum of *FLT3* mutations is still not fully understood. Unbiased mutation screening by exome sequencing allows the detection of novel sequence variations even in extensively studied genes.

P029

THE EFFECT OF ARA-C TREATMENT ON HEMATOPOIETIC STEM CELL EXPANSION AND LEUKEMOGENESIS IN A MOUSE MODEL OF CEBPA MUTANT ACUTE MYELOID LEUKEMIA

M Cimino[1], A Venanzi[1], T Frammartino[1], D Sorcini[1], S Bruscoli[1], C Nerlov[2], C Riccardi[1], O Bereshchenko[1,3,*]
[1]Department of Clinical and Experimental Medicine, Sec of Pharmacology, University of Perugia, Perugia, Italy, [2]MRC Molecular Hematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [3]Josè Carreras Young Investigator, EHA, Perugia, Italy

Background: Acute myeloid leukemia (AML) is the most common acute leukemia in adults. Acquired mutations in the *CEBPA* gene are found in 11-12% of all AML cases and include N- and C-terminal mutations that are frequently found within the same patient on separate alleles. We have recently demonstrated that combining N- and C-mutations in mice resulted in loss of hematopoietic stem cells (HSC) quiescence and expansion of premalignant pool of cells, associated with accelerated AML. Therefore, pharmacologic targeting of the pre-leukemic HSCs has emerged as another critical step to combat tumor progression particularly relevant to prevent tumor relapse. Increased cycling of mutant pre-leukemic HSCs suggests that they could be susceptible to the action of anti-proliferative agents used in chemotherapy.
Aims: We will address the impact of cytosine arabinoside (Ara-C) treatment on proliferating mutant HSCs survival, as well long-term tumor development in a mouse model of *CEBPA* mutant AML. We will evaluate whether 1) Ara-C treatment leads to a selective mutant HSCs apoptosis and a consequent drop in mutant HCS number; 2) reduction in mutant HSC number affects tumor development.
Methods: We performed Ara-C treatment experiments in radiation chimeras generated by transplanting E14.5 fetal liver cells (CD45.2 allotype) of wild type or *CEBPA* N/C combined mutant genotype along with wild type competitor bone marrow cells (CD45.1 allotype). Apoptosis in wild type (CD45.1+) and mutant (CD45.2+) long term-HSCs (defined as Lin-c-kit+Sca1+CD150+) was measured by flow cytometry method using Annexin V/SytoxBlue staining. Frequency and total number of wild type and *CEBPA* mutant HSCs was calculated at 24 and 72 hours after a single injection of 150 mg/kg of Ara-C. In addition, cohorts of mice treated or not with Ara-C for 1 week were monitored overtime for: i) CD45.2/CD45.1 ratio, ii) percentange of Mac1+ cells, iii) white and red blood cells counts in the peripheral blood and mice survival.
Results: Here we demonstrate that Ara-C efficiently and selectively induced apoptosis in mutant HSCs and downregulated their frequency and total number. However it did not lead to their complete elimination. Interestingly, we found that mice treated with Ara-C at early stages of AML progression showed a greater accumulation of Mac-1+ cells and a reduction in the frequency of B and T cells in the peripheral blood at 4 and 6 months after treatment, as compared to untreated mice. Moreover mice treated with Ara-C showed a statistically significant increase in the number of white blood cells, a reduction in the number of red blood cells, hemoglobin and hematocrit at 6 months following the Ara-C treatment, suggesting an earlier onset of leukemic blasts accumulation and leukemia-associated anemia in these mice.
Summary / Conclusion: These data demonstrate that Ara-C treatment induces preleukemic HSC apoptosis, but does not lead to complete mutant cell clearance, revealing that Ara-C resistant mutant HSC population exists and initiates leukemia. Moreover, our results demonstrate that Ara-C-mediated HSC reduction does not lead to delay in leukemia progression. To the contrary, several parameters show even negative long-term effects of Ara-C treatment on AML progression, suggesting that either Ara-C directly modifies HSCs or post-treatment bone marrow provides environmental cues favoring further HSC expansion and leukemia progression. Caution therefore has to be taken in evaluating of the presence of residual mutant HSC in patients' bone marrow after chemotherapy. This study points to a critical role of therapy-resistant HSCs in leukemia progression or relapse and warrants further studies on their better characterization.

P030

COMBINED ANALYSES OF ROS, CELL CYCLE AND IMMUNOPHENOTYPE SHOWS THAT NORMAL HEMATOPOIETIC PROGENITOR SUBSETS HAVE A DIFFERENTIAL ROS PROFILE THAT IS LOST IN ACUTE MYELOID LEUKEMIA

N Khan[1],* P Vyas[2], C Bradbury[3], P Richardson[1], M Raghavan[4], C Craddock[3], D Grimwade[5], S Freeman[1]
[1]Clinical Immunology, University of Biirmingham, [2]Weatherall Institute of Molecular Medicine, University of Oxford, [3]Centre for Clinical Haematology, Queen Elizabeth Hospital, [4]School of Cancer Sciences, University of Biirmingham, Birmingham, [5]Medical and Molecular Genetics, King's College, London, United Kingdom

Background: There has been recent interest in the role of reactive oxygen species (ROS) in myeloid malignancies, driving efforts to target redox state as a therapeutic strategy. Leukemia stem cells (LSC) in acute myeloid leukemia (AML) appear to maintain low levels of ROS, which confers drug-resistance. However certain AML genetic abnormalities such as FLT-3/ITD are associated with increased ROS. Redox state may vary in the heterogenous leukemic subpopulations that are enriched for LSC. This may impact on redox-targeting drug sensitivities. It is thus important to understand if ROS are differentially modulated in normal CD34+ hematopoietic stem cells (HSC) and downstream progenitor subsets and how this may be altered in AML.
Aims: To compare ROS/cell cycle profile of normal CD34+ stem/progenitor with immunophenotypically equivalent AML subsets.
Methods: We performed 8-colour flow cytometric analysis of normal bone marrow (BM) and AML presentation BM and peripheral blood (PB) samples. This combined the ROS indicator dye, dichloro-dihydro-fluorescin diacetate (DCF), with monoclonal antibodies (mAb) specific for human stem/progenitor cell markers. Intracellular ki67 staining of DCF/mAb labelled cells allowed cell cycle analysis. Colony Forming Unit (CFU) assays were performed on purified cells to verify lineage potential of selected cell subsets.

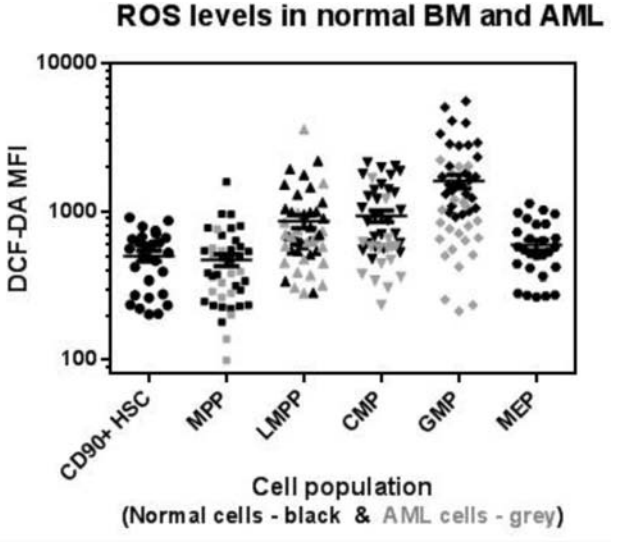

Figure 1.

Results: Total CD34+38hi cells had higher DCF staining than total CD34+38lo cells in normal BM (n=27) but within these two immunophenotypic compartments there was differential DCF staining (Figure 1). In CD38lo cells, lymphoid-primed multi-potent progenitors (LMPP; CD90-CD45RA+) had the highest DCF staining (mean 877 arbitrary units - calculated from MFI of 27 samples) while both HSC (CD90+CD45RA-) and multipotent progenitor cells (MPP; CD90-CD45RA-) were DCF-low (means 501 and 516 respectively). In the CD38hi subset, common myeloid progenitors (CMP; CD123+CD45RA-) were DCF-int (mean 1131), with ROS levels upregulated further (DCF-high - mean 2179) in granulocyte-macrophage progenitors (GMP; CD123+CD45RA+). However megakaryocyte-erythrocyte progenitors (MEP; CD123-CD45RA-) were mainly DCF-low (mean 596), akin to HSC and MPP. Purified CD34+38hi ROS-hi cells exclusively generated granulocyte (CFU-G) and macrophage (CFU-M) or mixed GM colonies (CFU-GM) in CFU assays, and had lost CFU-E potential. Sorting of CD45RA- cells into ROSlo/ROS-int/ROShi fractions revealed that CFU-E potential was limited to the ROS-low fraction and that increasing ROS correlated with higher CFU-M potential. CD38hi cells were also more actively cycling (40-90% ki67+) than CD38low cells (5-23% ki67+) consistent with an association between quiescence and low ROS. However since GMP (ROS-hi), CMP (ROS-int) and MEP (ROS-lo) were all mainly ki67+ (means 57.5%, 60%, 65% respectively), lower ROS could not be correlated with quiescence in CD34+CD38hi cells. CD34+ AML presentation samples (n=29) were most frequently composed of abnormally expanded GMP-/LMPP-like populations, although MPP-/CMP-like populations were also observed. ROS levels varied but were significantly lower in both immunophenotypically immature (MPP- and LMPP-like) and mature (CMP- and GMP-like) subsets (Figure 1 grey symbols) compared to normal subsets, with no difference between BM and PB blasts. Blasts with lowest ROS were enriched for quiescent cells.
Summary / Conclusion: ROS levels are maintained at different levels in normal stem/progenitor subsets; GMP cells are ROS-hi, while MEP cells are ROS-low similar to HSC. However both immature and more mature CD34+AML blasts appear to have downregulated ROS levels, suggesting a shared redox adaptation in different types of AML cells. These results provide a platform to investigate whether leukemic progenitor ROS levels correlate with treatment resistance and can be used to detect residual LSC.

Background: The prognostic impact of immunophenotypic markers in AML has been long controversial. Few studies have analyzed the prognostic value of the intensity of surface membrane antigen expression commonly expressed on AML blasts.
Aims: The prognostic impact of CD34, CD117, CD7, and CD123 levels of expression was analyzed on AML blasts and normal hematopoietic precursors by Multiparameter Flow Cytometry (MPFC) in *de novo* AML patients (pts). We also determined the correlation with disease characteristics and clinical outcome.
Methods: Five hundred ninety-two bone marrow samples from adult *de novo* AML pts excluding APL and diagnosed between 12/2003 to 08/2011 were included. All cases were diagnosed according to the WHO criteria and they were immunophenotyped using an extensive 4-color panel of monoclonal antibodies by MPFC. Patients were treated according to the multicenter CETLAM AML-03 protocol. Blast cells were gated after excluding all other cell populations, as well-delineated clusters of $SSC^{low/int}/CD45^{dim}$ events ("blast gate") using the merge function of the Infinicyt software (Cytognos SL, Salamanca, Spain). For each case, the reactivity for the following markers was evaluated in terms of mean fluorescence intensity (MFI; arbitrary units): CD123, CD117, CD34 and CD7. Normal residual bone marrow lymphocytes were used as reference for internal quality control purposes. Cytogenetic and molecular risk stratifications were based on the European LeukemiaNet (ELN) criteria. Overall survival (OS), leukemia-free survival (LFS) and relapse incidence (CIR) were measured by the Kaplan–Meier method and curves were compared with the log-rank test. Multivariate analysis was performed using the Cox regression model. P-value ≤0.05 was considered to be statistically significant.
Results: Median age was 52 years (range: 16-70) and M/F ratio was 324/268. Seventy-two pts (12%) had favourable cytogenetics, 380 (64%) intermediate, and 90 (15%) adverse according to MRC classification; 29 (5%) pts had no metaphases and 21 (4%) were unknown. NPM1mut was detected in 152 pts (34%), 136 pts (23%) harboured a FLT3-ITDmut, 23 (5%) pts carried CEBPA-mut, and 29 (5%) had MLL-PTD. In the overall series, the median follow-up of survivors was 17 months (range 3-100) and the OS, LFS and RI at 5 years were 39±2%, 42±3% and 47±7%, respectively. Independent prognostic variables were, age (P<.001), cytogenetics (P<.001), NPM1/FLT3-ITD status (P=.001),

molecular category (NPM1mut or CEBPAmut/FLT3-ITD neg vs. other; P<.001) and MLL-PTD rearrangement (P=.05) for OS. Univariate analysis of prognostic factors showed an association between higher MFI CD117 expression (>284.01; P=.019) and a higher MFI CD34 (>143.39; P=.004) expression with both a shorter OS and DFS and a higher RI. In addition, higher MFI CD7 expression (>15.61; P=.017) was associated with a shorter DFS and a higher RI. In multivariate analysis, a higher CD34 MFI retained its value as an independent predictor of a shorter OS (P=.005; HR=1.51, 95% CI=1.13-2.01) and DFS (P=.002; HR=1.66, 95% CI=1.20-2.29), and a higher RI (P=.016; HR=1.62, 95% CI=1.09-2.41). High MFI CD117 levels were an independent predictor of shorter DFS (P=.019; HR=1.52, 95% CI=1.07–2.16). Moreover, higher levels of MFI CD7 expression were an independent risk factor for RI (P=.017; HR=1.63, 95% CI=1.09–2.43).
Summary / Conclusion: In this study we show that high expression levels of immunophenotypic markers associated with immature myeloid precursors (CD34, CD117, and CD7) as assessed by MPFC, may have some prognostic value in *de novo* AML.

P032

C/EBPA REGULATES CXCR4 EXPRESSION IN ACUTE MYELOID LEUKEMIA

Y Kuo[1],* H Hou[2], Y Chen [2], Li Li[1], W Chou[3], H Tien[2]
[1]Graduate Institute of Oncology, National Taiwan University College of Medicine, [2]Division of Hematology , Department of Internal Medicine, National Taiwan University Hospital, [3]Departments of Laboratory Medicine, National Taiwan University Hospital, Taipei, Taiwan

Background: CCAAT/enhancer binding protein α (C/EBPα) is a transcription factor, whose expression plays an essential role in granulopoiesis. It blocks cell cycle progression and induce terminal maturation of hematopoietic cells. Mutations in one or both alleles of *CEBPA* are reported in about 7% to 15% of patients with acute myeloid leukemia (AML). These mutations can be divided into two types: the N-terminal mutations that result in the expression of the p30 isoform and the C-terminal mutations that disrupt the bZip region, which is responsible for DNA binding. Retrospective studies showed that patients with *CEBPA* mutant AML have an improved prognosis. SDF-1/CXCR4 signaling is involved in tumor progression, metastasis, and cell survival. In mouse models, the expression of CXCR4 in AML cells induces leukemia cell chemotaxis and migration beneath marrow stromal cells. Those leukemic cells show cell cycle arrest and reduced numbers of cell divisions, providing a potential mechanism of leukemia cell evasion from chemotherapy. AML patients with higher expression of CXCR4 have poorer prognosis than those with lower expression.
Aims: By searching the publicly available microarray database, we found that *CXCR4* transcription can be induced by CEBPα activation in murine 32D-CEBPα-ER cells. In addition, AML patients with *CEBPA* mutations showed lower *CXCR4* mRNA expression when compared to those with wild type *CEBPA*. Sequence analysis also revealed that the *CXCR4* promoter contains several conserved C/EBPα binding motifs. These clues compelled us to investigate the role of C/EBPα in the regulation of CXCR4-mediated chemotaxis in AML cells and evaluate whether *CEBPA* mutation would influence this effect.
Methods: C/EBPα wild type (p42) or mutants were ectopically expressed in 293T and K562 cells, which do not express C/EBPα. The RNA and protein levels of CXCR4 were measured by using quantitative RT-PCR and Western blot analysis. C/EBPα-mediated transcriptional activation of *CXCR4* was studied using luciferase reporter, gel-shift and chromatin-immunoprecipitation (ChIP) assays. Finally, RNA interference methods in combination with *in vitro* cell migration assays were used to assess the role of C/EBPα in regulation of CXCR4-mediated chemotaxis.
Results: Wild-type C/EBPα overexpression both in 293T or K562 cells increased endogenous *CXCR4* expression. In contrast, the expression of p30 diminished *CXCR4* transcription. Similarly, p42 but not p30 increased the *CXCR4* promoter activity. Furthermore, p42 no longer activated the truncated *CXCR4* promoter which does not contain any C/EBPα binding site. These data showed C/EBPα as an activator of *CXCR4*. Next, we defined the site at -231 to -246 on the *CXCR4* promoter that can be occupied by C/EBPα using the gel-shift assay and detected the binding of p42 to the *CXCR4* promoter *in vivo* by the ChIP assay. Finally, we demonstrated that the induction of p42 in the inducible K562-CEBPα cell lines increased the chemotactic migration, whereas the expression of mutants did not. Moreover, decreased expression of C/EBPα by RNA interference decreased levels of CXCR4 protein expression in U937 cells, thereby abrogating CXCR4-mediated chemotaxis.
Summary / Conclusion: Our results provide the first evidence that C/EBPα indeed regulates the activation of *CXCR4*, which is critical for the homing and engraftment of AML cells. Thus, CXCR4 blockage in AML cells may disrupt their interaction with the BM niche and sensitize them to chemotherapy.

P033

COMBINED INHIBITION OF C-KIT AND PI3K/MTOR SIGNALLING HAS SYNERGISTIC ACTIVITY IN C-KIT MUTANT AML

S Tinsley [1],* R Gale [1], A Khwaja[1]
[1]HAEMATOLOGY, Cancer Institute, University College London, London, United Kingdom

Background: Activating mutations of the c-KIT tyrosine kinase (TK) receptor are found in AML and mast cell leukaemias. In AML c-KIT is frequently mutated (~28%) in core binding factor leukaemias (CBFLs). CBFL are defined by the presence of t(8;21)(q22;q22) or inv(16)(p13;q22) which generate the fusion proteins RUNX1-RUNX1T1 and CBFβ-MYH11 respectively. This subset of patients have a favourable outcome although ~40% will relapse with current therapy. c-KIT is highly expressed in most CBFLs and is mutated via point mutations in exon 17 or insertion/deletions in exon 8. The presence of c-KIT mutations is associated with an increased risk of relapse. Dasatinib, an inhibitor of wild-type and mutant c-KIT isoforms, has been shown to inhibit c-KIT phosphorylation and induce apoptosis in cell lines expressing c-KIT mutations. Mutant c-KIT can activate downstream proteins including PI3K, mTOR, MEK and AKT. However, therapy with single agents targeting individual cell signalling molecules has had only modest activity in early clinical trials in AML and other malignancies.
Aims: Therefore this study examined the effect of combining Dasatinib with selective inhibitors of AKT (AZD5363), MEK (PD184352), mTOR (WYE-354), PI3K (ZSTK-474) and PI3K + mTOR (BEZ-235) on cell survival and signalling. Model cell lines including the CBFL Kasumi-1 (c-KIT N822K) and the mast cell leukaemia HMC1.2 (V560G/D816V c-KIT) were used to evaluate drug combination efficacy.
Results: In both Kasumi-1 and HMC1.2 cells combined inhibition of c-KIT (Dasatinib) and PI3K (ZSTK-474), mTOR (WYE354) or PI3K + mTOR (BEZ-235) led to strong synergistic cell killing (<0.3 Combination Index (CI) by Chou-Talalay). The most potent effects were seen combining Dasatinib with the dual PI3K/mTOR inhibitor BEZ-235 (e.g. Kasumi-1 cell line: average live cell fraction±SEM as % control; Dasatinib alone (20 nM) 69%±1.25, BEZ-235 alone (0.25 μM) 66.2%±4.4, Dasatinib (20 nM) + BEZ-235 (0.25 μm) 38%±4.6) No significant effect was seen when combining Dasatinib with MEK (PD184352) blockade in either cell line. In HMC1.2 cells Dasatinib inhibited c-KIT autophosphorylation fully at 313nM. However, there was still residual MEK, AKT, PI3K and mTOR signalling as shown by western blotting. In Kasumi-1 cells 40nM of Dasatinib inhibited c-KIT autophosphorylation and MEK fully but there was residual PI3K/mTOR signalling. Combining Dasatinib and BEZ-235 eliminated c-KIT auto-phosphorylation and markedly reduced residual MEK, AKT, PI3K and mTOR signalling compared with just Dasatinib treatment in both cell lines. Cell death was apoptotic shown by an increase in PARP cleavage and a reduction in pro-caspases 3 and 9. Screening of the Bcl-2 family of apoptosis regulators showed combined c-KIT and PI3K/mTOR inhibition led to a decrease in Mcl-1, Bcl-2 and Bcl-x. As a control for Dasatinib specificity, MV4-11 & MOLM-13 (FLT3-ITD AML cell lines) showed no synergistic effect when treated with a combination of Dasatinib and BEZ-235. However, combined FLT3 inhibition (AC220) and BEZ-235 demonstrated synergistic cell killing suggesting a broader application for combining TK inhibition with PI3K/mTOR blockade.
Summary / Conclusion: The combination of Dasatinib and PI3K/mTOR inhibition was synergistic at cell killing in CBFLs. Similar results were observed with AC220 + PI3K/mTOR inhibition in FLT3-ITD AML cell lines suggesting that a combination of TK and PI3K/mTOR blockade may provide a novel approach to treating c-KIT mutant CBFLs as well as FLT3 mutant AML.

P034

THE FUSION GENE NUP98-HOXA9 AS A MODEL FOR LEUKEMOGENESIS: EXPLORING ITS MOLECULAR MECHANISMS AND FUNCTIONAL EFFECTS

A Rio-Machin[1],* S Rodriguez-Perales[1], J Ramírez[2], R Torres[2], S Alvarez[1], J Cigudosa[1]
[1]Molecular Cytogenetics Group, Spanish National Cancer Research Centre (CNIO), [2]Unidad Vectores Virales, Centro Nacional de Investigaciones Cardiovasculares (CNIC), MADRID, Spain

Background: The chromosomal translocation t(7; 11)(p15, p15), that results in the oncogenic fusion protein *Nup98-Hoxa9*, appears in 1% of patients with Acute Myeloid Leukemia and it is associated with poor prognosis and low degree of overall survival. *Nup98-Hoxa9* seems to regulate the transcription of target genes involved in leukemogenesis and it appears that not only the homeodomain of the partner gene *HOXA9* is necessary in gene regulation, but also the region of *NUP98* present in the fusion could play a role in its oncogenic effect. Still, there is a long way to have a good understanding of the molecular mechanisms supporting the malignancy of this fusion protein. In fact, recent studies in mouse models have suggested a possible interaction between *Nup98* and *p300*, a molecular relationship that remains to be explored in the context of our fusion gene model.
Aims: We are aimed to investigate the molecular mechanisms by which the fusion protein *Nup98-Hoxa9* may be responsible of the leukemic transforma-

tion; mostly studying its binding sites in the DNA and its interactions with other transcription factors.
Methods: - Development of human cellular models that constitutively expresses *Nup98-Hoxa9* (human hematopoietic precursors (hHSC) and HEK293FT cells).
- Chromatin Immunoprecipitation Sequencing (*ChIP-Seq*), which will offer insight into the genomic binding regions of *Nup98-Hoxa9*.
- Validation of target gene regions by *qRT-PCR* and *luciferase assays*.
- Co-Immunoprecipitation assays for knowing which proteins interact with each other in the activator complex.
Results: We have cloned the cDNA of *NUP98-HOXA9* fused to FLAG-tag into a lentiviral vector and we have efficiently transduced hHSC and HEK293FT cells. Transcription of the fusion mRNA and the expression of the fusion protein have been demonstrated by conventional methods. Preliminary functional studies included the analysis of long-term cultures of hHSC and shown that the expression of *NUP98-HOXA9* conferred an advantage in proliferation, supporting so far the fitness of the model for further studies. We have optimized the *ChIP-seq* protocol in *NUP98-HOXA9* transduced human cells, customizing the *qRT-PCR* design to analyze the enrichment in some of the target genes of the fusion previously described. This is relevant since no previous data of the binding DNA sequences within the target genes of *NUP98-HOXA9* has been documented. Our data showed, for the analyzed genes, an enrichment of the binding sites of the fusion protein that was evenly scattered along the 15 Kb region upstream of the transcription start site.
Summary / Conclusion: Our results provided the first evidence of the specific binding of *Nup98-Hoxa9* to the DNA, describing its topography, and clarifying the role of this fusion protein as a transcription factor. This work provides a general methodology for the establishment of hHSC models that will allow the analysis of the effect of this and other leukemic fusion genes. Although the preliminary results are very promising, it is necessary to complete the planned experiments to fully understand the molecular mechanisms of *Nup98-Hoxa9*. Finally, the importance of this project lies in two major areas. By one hand, it will provide a better knowledge about the role of this fusion protein in the development of such as an aggressive leukemia. Secondly, it has an intrinsic biological interest since it will allow to study how a structural protein, such as the nucleoporin *Nup98*, upon a chromosome rearrangement, is able to function as a transcription factor, merely by changing its subcellular localization.

P035

ACID CERAMIDASE PROMOTES ACUTE MYELOID LEUKEMIA SURVIVAL THROUGH MCL-1 UPREGULATION

S Tan[1,*] X Liu[1], T Fox[2], B Barth[1], A Awwad[1], G Fabrias[3], D Feith[4], T Loughran[5]
[1]Experimental Therapeutics, Penn State Hershey Cancer Institute, [2]Pharmacology, Pennsylvania State College of Medicine, Hershey, United States, [3]Biomedicinal Chemistry, Institut de Química Avançada de Catalunya, Barcelona, Spain, [4]Cellular and Molecular Physiology, Pennsylvania State College of Medicine, [5]Medicine, Penn State Hershey Cancer Institute, Hershey, United States

Background: Acute Myeloid Leukemia (AML) is a heterogeneous disease affecting the differentiation and survival of myeloid precursors characterized by the CD34+ marker. As a result, patients have elevated immature leukemic cells known as blasts. Current therapeutics in AML exhibit limited success, and only approximately 25% of patients will remain disease free after achieving complete remission. Sphingolipids have recently emerged as a class of bioactive molecules, where the balance between pro-apoptotic ceramide and pro-survival sphingosine-1-phosphate (S1P) has been shown to play an important role in cancer cell fate. Ceramidases are hydrolases acting within the sphingolipid pathway that metabolize ceramide into sphingosine and free fatty acid. Sphingosine can then undergo sphingosine kinase-mediated phosphorylation to form S1P. Hence, elevated ceramidase activity increases S1P levels while reducing ceramide levels, thereby shifting the sphingolipid balance to a pro-survival state. Lysosomal acid ceramidase (AC) is highly expressed in solid tumors isolated from prostate, melanoma and breast cancers, as well as T-cell large granular lymphocyte (T-LGL) leukemia. Moreover, targeting AC induces programmed cell death and increases sensitivity to cytotoxic agents.
Aims: Our aims were to determine whether AC is elevated in AML, is essential in AML survival, and to identify the mechanism through which AC maintains blast survival in AML.
Methods: We used microarray and fluorogenic AC substrate to quantify AC expression and activity levels in primary cells. AC inhibitor LCL 204 and AC shRNA were used to assess AC's role in survival of patient samples and cell lines. We created a stably-overexpressing AC cell line for functional studies into AC-mediated survival. We used ESI-MS/MS to perform lipidomics analysis with AC inhibition and overexpression. For *in vivo* studies, we used a murine model to determine efficacy of AC inhibition to increase overall survival of mice engrafted with leukemic cells.
Results: Here, we report that AC is an important enzyme in AML blast survival. Our microarray data showed that AC, but not neutral or alkaline ceramidases, exhibited significantly elevated expression in AML patient mRNA samples compared to normal donor CD34+ cells. We confirmed this finding with an AC activity screen of 66 AML patients' samples and 12 normal donor CD34+ cells. These results showed elevated AC activity in each prognostic group (good, intermediate and poor) compared to normal controls. Treatment of patient samples and seven human AML cell lines with LCL 204 reduced viability and induced apoptosis in a dose-dependent manner through caspase-3 activation. Furthermore, AC overexpression in HL-60 cell line increased proliferation rate and expression of pro-survival Mcl-1. This is of significance as Mcl-1 has been identified as the predominant Bcl-2 family member responsible for survival in AML. Conversely, AC knockdown or inhibition reduced Mcl-1 levels. AC overexpression also induced a pro-survival lipid profile, with S1P levels significantly increased while ceramide species C_{16}, C_{24} and total ceramide decreased. Interestingly, AC overexpression was shown to induce NF- κB activation, possibly through the increase of endogenous S1P. Our *in vivo* study using murine AML cell line (C1498) engraftment model showed AC inhibition significantly increased overall survival.
Summary / Conclusion: Collectively, these studies demonstrate that AC is important in AML survival through its regulation of Mcl-1 and should be further explored as a potential therapeutic target in AML.

P036

ANTILEUKEMIC EFFECT OF PI3K-MTOR INHIBITORS IN ACUTE MYELOID LEUKEMIA- GENE EXPRESSION PROFILES REVEAL CDC25B EXPRESSION AS DETERMINATE OF PHARMACOLOGICAL EFFECT

H Reikvam[1,*] K Hatfield[1], S Skrede[2], R Holdhus[2], J Tamburini[3], L Poulain[3], E Ersvær[1], Ø Bruserud[1]
[1]INSTITUTE OF MEDICINE, UNIVERSITY OF BERGEN, [2]Institute of Clinical Medicine, Bergen, Norway, [3]Institut Cochin, Université Paris Descartes, Paris, France

Background: Acute myeloid leukemia (AML) is a heterogeneous malignancy with an overall leukemia-free survival of only 40-50% even after intensive therapy. Intracellular signaling through the phosphatidylinositol 3-kinase (PI3K)-Akt-mammalian target of rapamycin (mTOR) pathway is important for regulation of cellular growth and metabolism and aberrant signaling through this pathway has been implicated in AML. PI3K and mTOR inhibitors have currently entered clinical trials for AML, however despite their theoretical potential as antileukemic agents, they effects seem limited with potential effect in only subset of patients. The reasons of their lack of affectivity remain elusive.
Aims: The aims of the present study were to further analyze effects of different inhibitors of the PI3K-Akt-mTOR pathway in primary human AML cells, and especially to search for differences in gene expression which can define differences in pharmacological effect among AML patients.
Methods: The study included consecutive adult patients with a diagnosis of AML and with high peripheral blood blast counts. Cells were isolated from peripheral blood by density gradient separation. AML cells were cultured under highly standardized *in vitro* conditions, and pharmacological effects of two mTOR inhibitors (rapamycin and temsirolimus), and two PI3K inhibitors (GDC-0941 and 3-methyladenin (3-MA)) were evaluated. We analyzed cytokine dependent proliferation by seven days culturing (^{3}H-thymidine incorporation). Results were compared with microarray experiments performed using the Illumina iScan Reader. Real time polymerase chain reaction (rt-PCR) for control was performed.
Results: A larger experiment of antiproliferative effect of the four PI3K-mTOR inhibitors at four different concentrations including 56 consecutive AML patients using the ^{3}H-thymidine incorporation assay was performed. Heterogeneous effects among patients were observed, with patients usually responding similar to the different agents. The results were used to perform an unsupervised hierarchical clustering analysis base on differences in pharmacological responses, dividing patients in two major patient subset, were then identified; one group with a minimal effect of the pharmacological intervention (23 of 56 patients, 41%), and a second group with a relatively strong antiproliferative effect for all drugs and drug concentrations (36 of 56 patients, 59 %). The differences observed in antiproliferative effects had no correlation to cytogenetic, *FLT-3* or *NPM-1* mutation status. For 48 of the 56 patients described for antiproliferative effect of mTOR-PI3K inhibitors gene expression data were obtained. By dividing the patient population in sensitive and resistant cases we used the significance analysis of microarrays (SAM) algorithm to detect differently expressed genes between the two groups. Only five genes were found highly different expressed between the two subset (false discovery rate (FDR)<0.01). The only gene detected know to be involved in cell proliferation was *CDC25B*, encoding the protein cell division cycle 25B, a phosphatase which are a key regulator of the cell cycle. The finding was confirmed by correlation to RT-PCR for CDC25B.
Summary / Conclusion: Their lack of antileukemic effect of mTOR-PI3K inhibitors has been elusive. Here we demonstrate a distinct gene profile associated with resistance to these agents, special characterized with high expression of *CDC25B*. Further targeting of this pathway remains potential in AML.

P037

L-ASPARAGINASE ALTERS TRANSCRIPTION AND TRANSLATION OF GENES INVOLVED IN METABOLISM IN MYELOID LEUKEMIA

S Jun[1,*] I Dzneladze[1], Rob Laister[2], M Koritzinsky[2], B Wouters[2], M Minden[2]
[1]University of Toronto, [2]Ontario Cancer Institute, Toronto, Canada

Background: L-asparaginase is an enzyme that has been a part of the standard components of acute lymphocytic leukemia therapy for decades. The enzyme catalyzes the degradation of extracellular asparagine and glutamine. Cancer cells are vulnerable to the amino acid depletion as cells need excess amino acids for rapid biomass and protein synthesis for proliferation and cell survival. Amino acid degradation, in particular glutamine, may be useful in targeting cancer cell metabolism in addition to inhibiting protein synthesis.
Aims: To characterize the cellular response to L-asparaginase in myeloid leukemic cells and identify biological pathways affected by L-asparaginase treatment, and to assess the potential use of L-asparaginase in acute myeloid leukemia (AML) treatment.
Methods: To see the effect of amino acid depletion by L-asparaginase, we assayed proliferation and colony forming ability in a panel of myeloid leukemia cell lines and primary AML cells. Primary AML cells were transplanted in mice to study CD45+ cell engraftment *in vivo*. We selected two cell lines - K562 and HL60 – as representative resistant and sensitive lines respectively, to compare responses to L-asparaginase treatment by polysome profile analysis. Total RNA and efficiently translated RNA from polysomal fractions were isolated to evaluate and compare changes in gene transcription and translation. Geneset enrichment analysis of microarray data was utilized to identify enriched biological pathways in differentially expressed genes after L-asparaginase treatment.
Results: We observed inhibition of cell growth in cell lines treated with L-asparaginase. L-asparaginase also inhibited clonogenic survival of cell lines and primary AML cells. Results from the *in vivo* experiment demonstrate the average levels of CD45+ cell engraftment in the bone marrow was markedly decreased in treated mice.
Polysome profile analysis revealed a decrease in the amount of polysome-bound ribosomal RNA in both cell lines after treatment, indicating global RNA translation inhibition. Microarray analysis of total and polysomal mRNA provided information on enriched biological pathways altered by L-asparaginase treatment in K562 and HL60. As predicted, metabolic pathways were identified in addition to other cellular processes. In the resistant cell line K562, metabolic pathways such as aminoacyl-tRNA biosynthesis, amino acid metabolism, TCA cycle, pyruvate metabolism, and nucleotide metabolism were identified. Interestingly, it appears that K562 is capable of down-regulating TCA cycle. In HL60, amino acid metabolism pathways were also enriched as well as other carbohydrate metabolism pathways. For most genes, changes in total RNA levels (transcription) correlated with changes in polysomal mRNA (efficiently translated). However, we identified a short list of genes that are predicted to be translated differently through post-transcription regulation as a response to compensate for nutrient starvation.
Summary / Conclusion: L-asparaginase has cytotoxic and cytostatic effects in myeloid leukemia and inhibits global mRNA translation. It also induces a metabolic response in cell lines, demonstrating the potential of L-aspraginase as an effective drug with multiple targets including cancer metabolism, a role that was not previously recognized. This study discusses the off-label use of L-asparaginase for acute myeloid leukemia.

THE TYROSINE KINASE CSK ASSOCIATES WITH FLT3 AND KIT RECEPTORS AND REGULATES DOWNSTREAM SIGNALING IN ACUTE MYELOID LEUKEMIA

J Kazi[1,*] M Vaapil[2], S Agarwal[1], E Bracco[3], S Påhlman[2], L Rönnstrand[1]
[1]Experimental Clinical Chemistry, Department of Laboratory Medicine, [2]Center for Molecular Pathology, Department of Laboratory Medicine, Lund University, Malmö, Sweden, [3]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy

Background: The type III receptor tyrosine kinases (RTKs), FLT3 and KIT are widely expressed in acute myeloid leukemia (AML) and a number of AML patients carry an oncogenic mutant of FLT3 or KIT. In normal cells these receptors play important roles in a variety of cellular processes. A number of SH2-domain containing proteins interact with FLT3 and KIT regulating downstream signaling. The tyrosine kinase Csk is mainly studied in context of regulating Src family kinases. Here we present an additional role of this SH2-domain containing non-receptor protein tyrosine kinase in RTK signaling.
Aims: We aimed to identify the role of Csk in type III RTKs, FLT3 and KIT signaling in the context of AML.
Methods: We used Ba/F3 cells as a model system to analyze downstream signaling of FLT3 and KIT. Different Csk mutants were used to detect binding sites and localization patterns. Csk mRNA expression data from patient samples and corresponding healthy donors were used to compare Csk expression in AML. Both selective Csk inhibitor and Csk siRNA were used to study downstream signaling and biological events.
Results: We show that Csk interacts with FLT3 and KIT in a phosphorylation dependent manner. This interaction is facilitated through the SH2-domain of Csk. Under basal condition Csk is mainly localized throughout the cytosolic compartment but upon ligand stimulation it is recruited to the inner side of cell membrane. Csk association did not alter receptor ubiquitination or phosphorylation but disrupted downstream signaling. Selective depletion of Csk using siRNA, or inhibition with the Csk inhibitor, led to an increased phosphorylation of Akt and Erk but not of p38 upon FLT3-ligand stimulation. KIT-ligand-mediated Akt and Erk phosphorylation was also elevated by Csk inhibition. However, siRNA mediated Csk knockdown increased KIT-ligand stimulated Akt phosphorylation but decreased Erk phosphorylation. Akt activation was mediated through phosphorylation of SHC, Gab2 and SHP2. Furthermore, Csk depletion contributed to oncogenic FLT3- and KIT-mediated cell proliferation, but not to survival. A significant decrease in Csk expression was also detected in AML patients.
Summary / Conclusion: The results indicate that Csk association with type III RTKs, FLT3 and KIT can have differential impact in receptor downstream signaling in AML.

P039

WHOLE GENOME AND TARGETED BISULFITE SEQUENCING REVEALS 3 DNA METHYLATION CLUSTERS AND NEW BIOLOGICALLY RELEVANT HYPERMETHYLATED GENES IN AML PATIENTS

H Hajkova[1,*] M Fritz[2], Z Krejcik[1], M Belickova[1], M Merkerova[1], C Salek[3], R Petrbokova[1], J Markova[1], J Schwarz[3], O Fuchs[1], P Cetkovsky[3], V Benes[2], C Haskovec[1]
[1]Molecular Genetics, Institute of Hematology and Blood Transfusion, Prague, Czech Republic, [2]European Molecular Biology Laboratory, Heidelberg, Germany, [3]Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: In acute myeloid leukemia (AML), aberrant DNA methylation has been linked to the pathogenesis and progression of the disease. Changes in DNA methylation of promoters, or other regions, are studied primarily with respect to which pathways are involved in tumor transformation and their impact on prognosis.
Aims: The aim was to profile DNA methylation changes in AML patients using methods of next-generation sequencing and to correlate these changes with gene expression for discovering biologically relevant genes affected by hypermethylation.
Methods: Whole genome (3 AML, 2 controls) and targeted (14 AML, 1 control) bisulfite libraries were run on a HiSeqTM2000 sequencer (Illumina) using 105 bp paired-end sequencing reads. Validation of acquired methylation data was performed using 454 pyrosequencing and HumanMethylation27 Infinium arrays (Illumina). HumanHT-12 v4 Expression BeadChip (Illumina) was utilized for whole genome expression profiling. Expression data of selected genes were validated and extended to a larger number of examined patients by TaqMan real-time PCR.
Results: Unsupervised hierarchical clustering of CpG methylation outside and/or inside CpG islands revealed three DNA methylation clusters. From the clinical and molecular characteristics, only *CBF*/*MYH11*+ patients clustered together. None of the other molecular abnormalities (i.e. *DNMT3A* mutations, *MLL* translocation, *NPM1* mutations *FTL3*/ITD and *CEPBα* mutation) formed clusters and we did not observe an effect of clinical status of AML (*de novo*, secondary, AML with dysplastic changes or relapsed AML). A correlation between methylation and expression data enabled us to distinguish between aberrant DNA methylation with no effect on expression of downstream located genes (probably tissue-specific methylation) and biologically relevant DNA methylation (accompanied with changes of gene expression). *ELAVL2* and *CACNA1E* had enormous differences in DNA methylation between AML samples and controls; however they are very probably genes displaying tissue-specific methylation changes, because we did not detect their expression even in healthy precursor cells. On the other hand, there were genes - most notably *CHFR* and *PBX3*, where DNA methylation changes were accompanied with a change in their expression. We measured expression of *CHRF* and *PBX3* genes in 123 AML samples at diagnosis. 20% of AML had down- and 22% up-regulated *PBX3* expression, 5% of AML down- and 7% up-regulated *CHFR* expression. 454 pyrosequencing confirmed the role of DNA methylation in down- and up-regulation of PBX3 gene, hypomethylation (median methylation level 0.25, range 0.15 – 0.36) of a regulatory region located downstream of an annotated CpG island were connected with elevated levels of *PBX3*, whereas hypermethylation (median methylation level 0.51, range 0.31 – 0.98) with decreased levels of expression. Control samples displayed intermediate levels of methylation (median 0.35, range 0.19 – 0.51). Furthermore we observed correlation between *PBX3* and *HOXA9* expression, which is consistent with recently published data that *PBX3* is an important cofactor of *HOXA9* in leukemogenesis.
Summary / Conclusion: In summary, we found new and biologically important genes that are influenced by differential DNA methylation and were able to distinguish 3 major DNA methylation clusters in AML patients.
This study was a part of the COST Action BM0801 (EuGESMA) and was supported by the Czech Ministry of Education, Youth and Sports OC10042 grant and institutional funding grant IHBT00023736.

EXPRESSION OF THE SPLICE VARIANT NPM1-R2 HAS STRONGER PROGNOSTIC VALUE THAN NPM1 MUTATIONAL STATUS IN ACUTE MYELOID LEUKEMIA

M Zajac[1,*] A Dolnik[2], S Correa[3,4], K Dohner[2], R Schlenk[2], L Bullinger[2], K Giannopoulos[1,5]
[1]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, Poland, [2]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [3]Stem-cell Laboratory, Bone Marrow Transplantation Unit, National Cancer Institute (INCA), [4]Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil, [5]Department of Hematooncology and Bone Marrow Transplantation Unit, Medical University of Lublin, Lublin, Poland

Background: Recently, next generation sequencing technology has identified many new gene mutations in acute myeloid leukemia (AML) that provide novel insights into the mechanisms of leukemogenesis and that further unravel the molecular heterogeneity, in particular within the group of cytogenetically normal (CN) AML. In addition to genomic aberrations, aberrant expression levels of several genes have been identified as prognostic markers and deregulated gene expression is also involved in the pathogenesis of CN-AML. In this group of patients mutations of the nucleophosmin-1 (*NPM1*) gene identify a group with favorable prognosis in the absence of a FMS-like tyrosine kinase 3 internal tandem duplication(*FLT3*-ITD). Notably, wildtype *NPM1* encodes for three alternatively spliced isoforms R1 (B23.1), R2 (B23.2), and R3 (B23.3) that might also impact cellular function.
Aims: Since splicing variants play an important role in cellular functioning and splicing factor mutations have been reported in myeloid tumors including AML, the current study focuses on the characterization of *NPM1*-R2 splicing variant expression as well as its impact in AML patients.
Methods: For 201 samples (105 CN-AML and 96 samples with cytogenetic aberrations) qRT-PCR was performed. Expression level of *NPM1*-R2 was assessed. The existence of *NPM1*-R2 at the protein level was evaluated with the use of Western Blot technique.
Results: We found that the expression of R2 splicing variant was significantly higher in all AML patients compared to HVs with a median expression of 1.64 vs 0.33 (P=0.009). We have found no differences between groups of AML patients with and without *NPM1* mutations (1.21 vs 0.82, P=0.13). Based on the high coincidence of high expression R2 levels and *FLT3*-ITD mutations we analyzed the relevance of R2 high expression and *FLT3*-ITD mutations by comparing R2high/no*FLT3*-ITD, R2low/no*FLT3*-ITD, R2low/*FLT3*-ITD, R2high/*FLT3*-ITD. As shown in Figure1, overall survival (OS) was longer in R2high/no*FLT3*-ITD than in the rest of groups (P<0.001).
Summary / Conclusion: In our study we found that the expression level of *NPM1*-R2 was elevated compared to HVs suggesting that not only *NPM1* mutation but also its splice variant expression might play some role in the process of the tumorigenesis. As the R2 splicing variant represents a truncated form of *NPM1* gene due to the of the lack of exons 11 and 12 (coding for the domain responsible for nucleolar localization of the protein), this isoform mostly localizes in the nucleoplasm, and thus might also have a biological impact in the malignant cells. Most importantly, in our cohort of cases survival differences seen between the established ELN groups according to a *NPM1*/*FLT3*-ITD stratification were less impressive than between groups stratified according to R2 expression combined with *FLT3*-ITD mutational status. In summary, the expression of *NPM1*-R2 might be of biological importance for CN-AML patients. Moreover, R2 splice variant provides prognostic value for CN-AML patients and might information in addition the *NPM1* mutational status.

LEUKEMOGENIC FUNCTION OF TIM-3, A LEUKEMIA STEM CELL MARKER, IN ACUTE MYELOGENOUS LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

Y Kikushige[1,2,*] J Yuda[2], T Shima[1], T Miyamoto[2], K Akashi[1,2]
[1]Center for Cellular and Molecular Medicine, [2]Medicine and Biosystemic Sciences, Kyushu University, Fukuoka, Japan

Background: Acute myeloid leukemia (AML) originates from self-renewing leukemic stem cells (LSCs), an ultimate therapeutic target for AML. We have reported that the T-cell immunoglobulin mucin-3 (TIM-3) is expressed on LSCs in most types of AML but not on normal hematopoietic stem cells (HSCs). TIM-3$^+$ AML cells reconstituted human AML in immunodeficient mice, whereas TIM3$^-$ AML cells did not, suggesting that the TIM-3$^+$ population contains all functional LSCs. We established an anti-human TIM-3 mouse IgG2a antibody having complement-dependent and antibody-dependent cellular cytotoxic activities. This antibody did not harm reconstitution of normal human HSCs, but blocked engraftment of AML after xenotransplantation. Furthermore, when it is administered into mice grafted with human AML, this treatment dramatically diminished their leukemic burden, and eliminated LSCs capable of reconstituting human AML in secondary recipients (Kikushige *et al*, Cell Stem Cell, 2010).
Aims: The aim of this study is to clarify the expression and function of TIM-3 in various types of human hematological malignancies.
Methods: We analyzed bone marrow samples from primary MDS patients by multicolor FACS, and also performed the gene expression analysis of primary AML samples as we previously reported(Kikushige *et al*, Cell Stem Cell, 2010).
Results: We extended the analysis of TIM-3 expression into various types of human hematological malignancies, and found that human TIM-3 is expressed in the vast majority of CD34$^+$CD38$^-$ LSCs of human myeloid malignancies including chronic myeloid leukemia, chronic myelomonocytic leukemia and myelodysplastic syndromes (MDS). Although TIM-3 was not expressed in CD34$^+$CD38$^-$ stem cell fraction in normal bone marrow cells, TIM-3 was progressively up-regulated in this population of MDS, along with disease progression into leukemia: The average percentages of TIM-3$^+$ cells in the CD34$^+$CD38$^-$ population was 7.8% in RCMD (n=10), 19.2% in RAEB-1 (n=10), 84.0% in RAEB-2 (n=10) and 92.2% in overt AML (n=10). Thus, TIM-3 might be useful to isolate malignant stem cells responsible for progression into AML in MDS patients. The close association of TIM-3 expression with transformation into AML led us to hypothesize that TIM-3 itself has a function in AML stem cell development. TIM-3 is type 1 cell-surface glycoprotein and has a structure that includes an N-terminal immunoglobulin variable domain followed by a mucin domain, a transmembrane domain and a cytoplasmic tail. Tyrosine residues are clustered in the cytoplasmic tail, suggesting that TIM-3 can induce signal transduction in TIM-3$^+$ AML cells. Previous reports have shown that galectin-9 and HMGB-1 are the ligand of TIM-3 in lymphocytes and dendritic cells. TIM-3 is reported to signal differently in lymphocytes and myeloid cells, because TIM-3 ligation results in different patterns of tyrosine phosphorylation in these cell types, suggesting that TIM-3 has lineage- or cellular context-dependent signal transduction pathways or functions. Therefore, we considered that it should be critical to identify the function of TIM-3 in primary AML cells. We cultured TIM-3$^+$ AML cells in the presence or absence of galectin-9 or HMGB-1, and performed cDNA microarray analysis to find genes activated in response to TIM-3 ligation. Interestingly, pro-apoptotic genes such as BAX and SIVA were significantly down-regulated in the presence of ligands, suggesting that TIM-3 signaling could promote survival of TIM-3-expressing LSCs.
Summary / Conclusion: These data suggest that TIM-3 is a surface marker useful to track malignant LSCs in progression from MDS to AML, and TIM-3 may function for maintenance of LSC through inducing survival-promoting signaling.

P042

LARGE SCALE ANTIBODY ARRAY ANALYSIS OF PROTEIN MACHINERIES IN LEUKAEMIA

H Slåstad[1,*] W Wu[2], K Flatmoen[3], G Tjønnfjord[1], S Lehmann[4], F Lund-Johansen[2]
[1]Department of Haematology, [2]Department of Immunology, [3]Department of immunology and transfusion medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway, [4]Department of Haematology, Karolinska Institutet, Stockholm, Sweden

Background: Leukaemia classification is currently based on morphology, surface markers, cytogenetics and molecular genetics. Cellular behaviour is regulated by proteins that act in networks. Knowledge of these networks is relevant to understand intracellular pathways involved in leukemogenesis.
In this study, we applied a bead-based antibody array to detect up to 1725 proteins in each sample of mononuclear cells (MNC). MNC's were procured before treatment from 34 leukaemia patients. (23 AML, 6 ALL, 4 CLL and 1 T-PLL). Informed consent was obtained.
Aims: The overall aim of the study was to determine whether our bead based antibody array could be applied to study protein expression in leukaemic cells.

Subsequently, we wanted to investigate lineage-specific protein expression in subgroups of leukaemias.
Methods: *Sample preparation:* Proteins from cytosol, organelles, membranes and nuclei were extracted using a newly developed chemical method (Figure ure 1A). Proteins were biotinylated and separated by size exclusion chromatography (SEC) (Figure 1B and Figure 1C). A total of 96 sample fractions were incubated with arrays of antibodies bound to colour-coded latex beads. (Figure 1D). Captured proteins were labelled with fluorochrome-conjugated streptavidin and detected by flow cytometry. (Figure 1E and Figure1 F). *Data Analysis:* Flow cytometry files were processed using a custom-made software that automatically identifies populations of colour-coded beads and exports data for the median streptavidin fluorescence for each subsets. (Figure 1F). The output text files were imported into excel spreadsheets. Excel was used to generate line plots and calculate peak integrals.
Results: Many antibodies captured more than one target. Knowledge of the subcellular distribution of the intended target was highly useful to discriminate specific binding from cross-reactivity. Antibodies to nuclear proteins including RUNX1, PARP, DNMT1 and RB were found to capture well defined targets from the nuclear fraction. Cell surface proteins (CD antigens) were detected as reactivity peaks in the membrane fraction with elution profiles typical for micelle-associated proteins. Caspases, CDK`s and STAT`s were expressed in the cytosolic fraction. Markers of cytoplasmic organelles were found in a separate fraction obtained by treatment of digitonin-permeabilized cells with the detergent Tween 20. The size distribution profiles showed that several of the proteins occur in multi-molecular complexes. Results obtained with antibodies against hematopoietic lineage markers were in good accordance with immunophenotypes obtained by diagnostic flow cytometry. CD33 was consistently found in AML and CD14 was expressed in acute monocytic leukaemia. CD10 was recognized in ALL patients. (Figure 2).Lineage-specific markers included CD2, CD3E, CD4 and CD8 in T-ALL and CD40 and CD 72 in B-ALL. PAX5 was regularly expressed in CLL and B-ALL patients. (Figure 2)
Summary / Conclusion: The results show that it is feasible to perform parallel detection with thousands of antibodies. Combination of subcellular fractionation and SEC provides the resolution needed to ensure specificity. The ability to classify leukaemias on the basis of lineage-restricted surface proteins demonstrates that the technology has diagnostic potential. Compared to standard flow cytometry, antibody array analysis allows detection of more intracellular proteins.

HIGH RESPONSE RATE AND BRIDGING TO HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH QUIZARTINIB (AC220) IN PATIENTS WITH FLT3-ITD–POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

M Levis[1,*] J Cortes[2], A Perl[3], H Döhner[4], B Steffen[5], P Rousselot[6], G Martinelli[7], E Estey[8], A Burnett[9], G Gammon[10], D Trone[10], H Dombret[11]
[1]Department of Oncology, Division of Hematologic Malignancies, Johns Hopkins University School of Medicine, Baltimore, [2]Department of Leukemia, The University of Texas M.D. Anderson Cancer Center, Houston , [3]Division of Hematology/Oncology, University of Pennsylvania, Philadelphia, United States, [4]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [5]Department of Medicine, Hematology/Oncology, Goethe University of Frankfurt, Frankfurt, Germany, [6]Service d'Hématologie et Oncologie, Hôpital de Versailles, Université Versailles Saint Quentin en Yvelines, Le Chesnay, France, [7]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [8]Division of Hematology, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, United States, [9]Department of Medical Genetics, Cardiff University School of Medicine, Cardiff, United Kingdom, [10]Ambit Biosciences Corporation, San Diego, United States, [11]Hématologie Adultes, Hôpital Saint-Louis, AP-HP, Université Paris, Paris, France

Background: FMS-like tyrosine kinase 3 internal tandem duplications (FLT3-ITD) in acute myeloid leukemia (AML) are associated with early relapse after standard chemotherapy and poor survival. Quizartinib (AC220) is an oral FLT3 receptor tyrosine kinase inhibitor that is active against both ITD mutant and wild type FLT3.
Aims: To assess the efficacy of quizartinib monotherapy in FLT3-ITD–positive patients with AML relapsed or refractory to second-line, salvage chemotherapy or relapsed after hematopoietic stem cell transplantation (HSCT).
Methods: A phase 2 study was conducted to assess the efficacy and safety of quizartinib monotherapy in FLT3-ITD–positive and FLT3-ITD–negative patients (N=333 in 2 cohorts). We present here final data on the 136 FLT3-ITD–positive patients, comprising patients aged ≥18 years with AML relapsed or refractory to second-line, salvage chemotherapy or relapsed after HSCT. Patients were tested by a central laboratory for the FLT3-ITD mutation with a >10% ratio of ITD to total FLT3 defined as positive. Quizartinib was administered once daily as an oral solution during 28-day treatment cycles. The initial starting dose administered to the first 17 patients was 200 mg/day, but because of the occurrence of QT interval prolongation, the dose was reduced to 135 mg/day for men and 90 mg/day for women. Composite complete remission (CRc) consisted of complete remission (CR) plus CR with incomplete platelet recovery (CRp) plus CR with incomplete hematologic recovery (Cri).
Results: The CRc rate was 46% (5 CR, 2 CRp, and 55 CRi), with a median duration of CRc of 10.6 weeks and median overall survival of 24.0 weeks. Of those refractory to their last AML therapy, 47% achieved a CRc with quizartinib. Quizartinib was discontinued for HSCT in 47 of 136 patients (35%); 44 of the 47 patients (94%) had at least a partial response (PR) with 2 CRp, 24 CRi, and 18 PR on quizartinib. 8 of 47 patients (17%) had received previous HSCT and 32 of 39 patients (82%) who did not receive previous HSCT were refractory to second line therapy. Median overall survival (OS) was 41.5 weeks for patients who achieved a CRc (n=26) prior to HSCT and 29 weeks for patients with PR (n=18). The 1 year survival rate was 39% for both response groups. Patients with a CRc (n=36) or PR (n=20), but no HSCT, had a median OS of 24.5 weeks and 20.9 weeks, respectively, and 1-year survival rates of 25% and 5%, respectively. Of 27 patients with OS >52 weeks, 17 (63%) had HSCT. The group comprising responders going to HSCT compared to responders not receiving HSCT, were similar with median age of 44.5 vs. 47 years, 70% vs. 54% refractory to last chemotherapy and 5% and 4% prior MDS. Responders receiving HSCT were less likely to have had a prior transplant (25% vs. 46% previous HSCT).
Summary / Conclusion: The prognosis of relapsed/refractory FLT3-ITD–positive patients, including those relapsing after HSCT, is remarkably poor. In this context, our results demonstrate notable activity of quizartinib therapy and very promising survival, particularly for responding patients who subsequently received HSCT.

P044

PROGNOSTIC IMPACT OF THE FERRITIN LEVEL AT DIAGNOSIS IN ACUTE MYELOID LEUKEMIA PATIENTS WITH INTERMEDIATE CYTOGENETIC RISK

D Lebon[1,*] F Vergez[2], S Bertoli[3], V Harrivel[4], S De Botton[5], J Marolleau[6], C Recher[3]
[1]Service d'Hématologie Clinique, CHU AMIENS, AMIENS CEDEX1, [2]Laboratoire d'Immunologie, Centre de Recherche en Cancérologie de Toulouse, Université Paul Sabatier, [3]Service d'Hématologie, Centre de Recherche en Cancérologie de Toulouse, Université Paul Sabatier, CHU de Toulouse, TOULOU-

SE, [4]Laboratoire d'Hématologie, CHU Amiens, AMIENS CEDEX1, [5]Service d'Hématologie Clinique, Institut Gustave Roussy, VILLEJUIF, [6]Service d'Hématologie Clinique, Université de Picardie Jules Verne, CHU Amiens, AMIENS CEDEX[1], France

Background: Elevated ferritin level (FL) has been described as an unfavorable prognostic factor in myelodysplastic syndromes. Little is known in acute myeloid leukemia (AML) although the pre-allogeneic stem cell transplantation (alloSCT) high FL has been shown to influence outcome.
Aims: In this study, we evaluated the prognostic impact of the FL at diagnosis in *de novo* AML patients with intermediate cytogenetic risk treated by intensive chemotherapy.
Methods: Since 2007, quantification of the FL performed by spectrophotometry is included in the initial workup of AML. Between May 2007 and December 2011, 164 patients with *de novo* WHO defined-AML were treated by 3+7-like chemotherapy in Toulouse University Hospital Center. The relevant ferritin threshold was calculated using ROC curves analysis. Briefly, median age of these patients was 59 years (16-81y); complete remission (CR) was achieved in 85% (140/164); 5-years disease free (DFS) and overall survival (OS) were 35% and 38%. Median follow-up for patients alive at the date of last contact was 30 months. 43 patients (26%) had a FL at diagnosis superior to 4N. Those patients had a higher white blood cell (WBC) count (P=0.003) and a higher rate of good mutational profile (NPM1c^{pos}FLT3-ITD^{neg}, P=0.04). Then, results were validated in an independent cohort of 66 patients treated between 2007 and 2011 in Amiens University Hospital Center.
Results: FL, WBC count and NPM1c^{pos}FLT3-ITD^{neg} had no impact on achievement of CR whereas age had a significant impact. By logistic regression, age lower than 60 years and WBC count retained significance for CR achievement. For the 140 complete responders, WBC count had no impact on disease-free survival (DFS). Interestingly, patients with FL<4N and FL>4N had median DFS of 26.9 and 9.2 months, respectively (P=0.033, Figure 1A). NPM1c^{pos}FLT3-ITD^{neg}, age and alloSCT were also significantly associated with DFS. In multivariate analysis, FL>4N was significantly associated with shorter DFS (P=0.001, HR: 2.39, 95%CI 1.4-4.0). FL, age, WBC count, NPM1c^{pos}FLT3-ITD^{neg} and alloSCT significantly influenced OS. Median OS was 39 and 11.6 months for patients respectively with FL<4N and those with FL>4N (P=0.0015, Figure 1B). Multivariate analysis for OS retains 4 significant factors: WBC count (HR: 1.01, 95%CI, 1.00-1.01, P=0.004), alloSCT (HR: 0.36, 95%CI, 0.2-0.7, P=0.0009), NPM1c^{pos}FLT3-ITD^{neg} (HR: 0.24, 95%CI, 0.12-0.47, P<0.0001), and FL>4N (HR: 2.64, 95%CI, 1.6-4.4, P=0.0002). Among the 35 patients with NPM1c^{pos}FLT3-ITD^{neg}, FL>4N was predictive of shorter DFS (median: 10.5 months vs not reached, P=0.005) and OS (median: 21.4 months vs not reached, P=0.01). The impact of the FL at the threshold of 4N, was also significantly correlated with OS in an independent cohort of *de novo* AML patients with intermediate cytogenetic-risk (n=66). Median OS was 27.6 and 7.7 months for patients with FL<4N and with FL>4N, respectively (P=0.01).
Summary / Conclusion: This study emphasizes the prognosis impact of the FL at diagnosis in AML patients. If validated on a larger prospective cohort of patients enrolled in multicenter clinical trials, the FL could represent a new prognosis marker easily translated into the clinical practice. Furthermore, the heterogeneity of FL at diagnosis in a "non-iron overload" setting and its impact on leukemic relapse suggest a link between inflammatory response, oxidative stress, metabolic syndrome and chemoresistance.

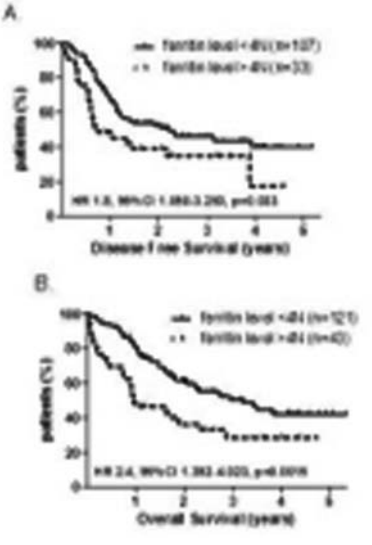

Figure 1. Impact of FL on outcome of patients with *de novo* AML. A. DFS of 140/164 complete responder patients. B. OS of 164 patients treated by 3+7 chemotherapy.

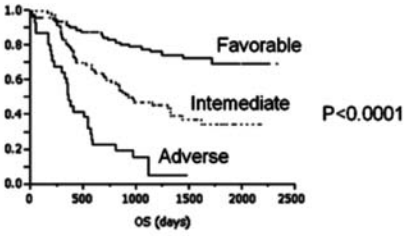
Background: Several genetic alterations, which are involved in the development and progression of acute myeloid leukemia (AML), have been identified. Although their prognostic relevance are not fully clarified, the European LeukemiaNet (ELN) recently recommended a novel risk classification system based on the genetic status in addition to the cytogenetic risk. However, several groups suggested that the combination with another genetic status would stratify each ELN risk group into further risk groups.
Aims: To establish more precise risk classification system, we comprehensively analyzed mutations in 51 genes as well as the karyotype, and evaluated their prognostic impacts in AML.
Methods: The study population included 197 *de novo* adult AML patients who were registered to the Japan Adult Leukemia Study Group (JALSG) AML201 study. Bone marrow samples were collected from them at initial diagnosis. Informed consent was obtained from all patients to use their samples for banking and molecular analysis, and approval was obtained from the ethics committee of all participating institutes. We screened mutations in 51 genes using the high throughput sequencing system, and confirmed each mutation by the Sanger sequence method.
Results: Mutations were identified in 44 genes. We identified mutations of Class I in 117 patients (59%), those of Class II in 84 (42%), those of epigenetic regulators in 91 (46%), those of BCOR family in 17 (9%), those of NCOR family in 18 (9%), those of NOTCH1/2 in 19 (10%), those of the cohesion complex in 22 (11%), and those of splicing factors in 9 (5%). *FLT3*, *NPM1*, *CEBPA*, *DNMT3A* and *IDH2* mutations were predominantly identified in cytogenetically normal (CN)-AML, while *KIT* and *TP53* mutations were frequent in core binding factor (CBF)-AML and AML with complex karyotype, respectively. A multivariate logistic-regression analysis showed that *TP53* mutation, wild-type *NPM1* and cytogenetic findings other than good risk were independent unfavorable factors for achieving complete remission (CR). Univariate analysis showed that *FLT3*-ITD, *DNMT3A*, *TP53*, *RUNX1*, and *MLL*-PTD mutations were the poor prognostic factors for overall survival (OS). When patients were stratified into the ELN risk groups, their prognoses were clearly distinguished. However, *DNMT3A*, *GATA2*, *MLL*-PTD and *TP53* mutations were identified to be further poor prognostic factors in the favorable genetic risk, intermediate risk I, intermediate risk II and adverse risk groups of the ELN classification, respectively. Based on these findings, we could stratify AML patients into 3 risk groups; Favorable: CBF-AML or CN-AML harboring *CEBPA* or *NPM1* mutation without *FLT3*-ITD and *DNMT3A* mutation (n=83, OS at 4 year: 73%, event free survival (EFS) at 4 year: 48%, CR rate: 93%), Intermediate: *DNMT3A* mutation, *FLT3*-ITD, adverse-risk karyotype and none of the mutation or cytogenetic abnormality leading to assignment into Favorable and Adverse groups (n=83, OS at 4 year: 37%, EFS at 4 year: 21%, CR rate: 80%), Adverse: *RUNX1*, *MLL*-PTD, *GATA2* or *TP53* mutations (n=31, OS at 4 year: 5%, EFS at 4 year: 0, CR rate: 58%).
Summary / Conclusion: We demonstrated a modified risk classification system for adult AML patients based on the genetic and cytogenetic status by the

comprehensive mutation analysis. However, the frequencies of most mutations were less than 5%. Further large-scale studies are required to confirm the prognostic impact of each mutation.



Risk group	Subsets	4yr OS
Favorable (n=83)	CBF-AML Normal karyotype CEPBA Mt. or NPM1 Mt. without FLT3-ITD and DNMT3A Mt.	73%
Intermediate (n=64)	FLT3-ITD or DNMT3A Mt. Adverse karyotype not classified to favorable or adverse	37%
Adverse (n=50)	TP53 Mt., MLL-PTD, RUNX1 Mt. or GATA2 Mt.	5%

Figure 1. Overall survival according to risk groups.

P046

LYSYLOXIDASE IS ASSOCIATED WITH INFERIOR OUTCOME AND EXTRAMEDULLARY DISEASE IN ACUTE MYELOID LEUKEMIA

F Stölzel[1,*] M Kramer[1], T Illmer[1], C Dill[1], M Bornhäuser[1], G Ehninger[1], M Schaich[1]
[1]Medizinische Klinik und Poliklinik I, University Hospital Carl Gustav Carus Dresden, Dresden, Germany

Background: Lysyloxidase (LOX) has been described as necessary for premetastatic niche formation in epithelium-derived malignancies and its expression level correlates with distant metastasis free- and overall survival (OS).
Aims: We were interested to investigate whether the LOX-concentration in AML plasma samples is of prognostic relevance and whether it is associated with certain characteristics such as extramedullary disease.
Methods: Plasma samples of 683 patients with AML (age 17 – 60 years) who were treated within the prospective AML2003 trial (NCT00180102) of the SAL study group were analyzed for LOX concentration using the Amplite Fluorimetric LOX Assay Kit (AAT Bioquest, Sunnyvale, CA, USA). All fluorescence reads were performed in triplicate with recombinant human LOXL2 (R&D Systems, Minneapolis, MN, USA) for standard curve estimation. Signals were read by a fluorescence microplate reader at Ex/Em 540/590 nm. Supernatant of the *NPM1* mutated AML cell line OCI/AML3 served as internal control. The method of Kaplan-Meier was used to estimate OS and event-free survival (EFS). Survival distributions were compared using the log-rank test. Prognostic parameters were tested in a Cox regression model for OS and event-free survival (EFS).
Results: The range of LOX concentration for all patients was 0 – 2184 ng/mL. Inspection of the Martingale residuals of a Cox model testing the influence of LOX on OS revealed that a cut-off model is the most appropriate. The optimal cut-off LOX value was determined using a minimal-p-value method resulting in a logarithmic logLOX = 2.0403 (109 ng/mL) which identified dichotomizing all patients into a LOX-high group (>109 ng/mL, n=272, 40%) and a LOX-low group (≤109 ng/mL, n=411, 60%). Comparing LOX-high and LOX-low patients revealed a 3-year OS of 47% (95% CI: 40 – 53%) and 53% (95% CI: 48 – 58%, P=.022), and 3-year EFS of 27% (95% CI: 21 – 32%) and 35% (95% CI: 31 – 40%, P=.005), respectively. In the Lox-high group significantly more patients had reported extramedullary AML compared to the Lox-low group, P=0.037. Indeed in the multivariate analysis the LOX-extramedullary interaction term for OS and EFS was significant (P=.025 and P=.006, respectively). Therefore, in patients with extramedullary disease the LOX level predicted survival. Patients within the LOX-low group had an OS of 43% (95% CI: 23 – 63%) and EFS of 36% (95% CI: 17 – 54%) as compared to the LOX-high group with an OS of 13% (95% CI: 1 – 25%) and EFS of 6% (95% CI: 0 – 15%), P=.002 and P=.008, respectively.
Summary / Conclusion: High LOX levels are associated with statistically significant worse OS and EFS in AML patients. The positive correlation between high LOX levels and extramedullary AML suggests a potentially pathophysiological relevant mechanism involved in extramedullary homing and growth of AML and may offer further insights into AML biology. Furthermore, the prognostic heterogeneous group of AML patients with extramedullary disease can be separated in those with superior and those with inferior survival by applying the plasma LOX level at diagnosis. Future prospective clinical trials will have to confirm these data and experimental studies will need to address the functional modalities of how LOX is regulated and how it contributes to migratory and adhesion properties in AML.

P047

REAL-WORLD OUTCOMES AMONG AML PATIENTS TREATED WITH DECITABINE OR AZACITIDINE

B Smith[1,*] C Beach[2], D Mahmoud[3], L Weber[3], H Henk[4]
[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins, Baltimore, [2]Hematology/Oncology Clinical Reserch and Development, [3]Global Pricing & Market Access,, Celgene, Summitt, [4]Optum, Eden Prairie, United States

Background: Both decitabine (DEC) and azacitidine (AZA) are indicated for treatment of elderly AML patients with 20%>30% BM blasts in the EU.
Both agents have shown an improvement in survival, however these studies were limited: DEC demonstrated an OS benefit (2.1 month gain; P=0.5735) in an unplanned statistical analysis (DACO-016 clinical study) and AZA demonstrated a 9 months (P=0.001) survival benefit (the AZA-001 trial) in a study of high grade MDS patients that also included elderly AML patients with 20-30% blasts.
Aims: The purpose of this study is to compare overall survival (OS) and other clinical benefits of DEC and AZA using real world data.
Methods: US health plan data were assessed between 01 January 2006 and 31 April 2012 to identify enrollees initiating DEC or AZA for treatment of AML (ICD-9-CM: 205.0x). Comparisons between DEC and AZA patients made via survival models to account for variable length of follow up. Similarly, the number of hospitalizations was measured and calculated as 'hospitalizations per person-year.' A Cox proportional hazards model was used to examine the relationship between choice of demethylating agent and OS, controlling for age, gender, comorbidity score, prior MDS diagnosis, prior red blood cell transfusion, prior hospitalizations, and insurance type.
Results: 487 AML patients were identified as initiating therapy during the study period (n=199 DEC and n=288 AZA). The two cohorts were similar in terms of age, gender, prior MDS diagnosis, prior red blood cell transfusion needs, and insurance coverage, but patients receiving DEC were more likely to have had a hospitalization in the prior six months (70% vs 62%; P=0.032) and more likely to have Charlson comorbidity score of 3 or greater (59% vs 50%; P=0.036). Median OS (6.9 vs. 10.1 mos.; P=0.007) and time to hospitalization (3.9 vs. 6.6 mos.; P=0.015) were significantly longer among AZA treated patients. After controlling for demographic and clinical characteristics, AZA treated patients continue to show better OS (hazard ratio=0.721; P=0.008) and a greater time to hospitalization (hazard ratio=0.787; P=0.020). DEC patients averaged more hospitalization (3.15 per person-year) than AZA patients (2.72 per person-year).
Summary / Conclusion: Although AZA and DEC have not been formally compared head to head in elderly patients with AML, it is generally accepted that both agents have clinical activity in such patients. This analysis suggests that AML patients treated with AZA do better clinically than those patients who physicians elect to treat with DEC based on statistically significant longer OS and fewer hospitalizations.

P048

OUTCOME OF PERSONALIZED THERAPY BASED ON HIGH-THROUGHPUT *EX VIVO* DRUG SCREENING IN PATIENTS WITH RELAPSED, CHEMOREFRACTORY ACUTE MYELOID LEUKEMIA (AML)

M Kontro[1,*] Tea Pemovska[2], E Kulesskiy[2], H Edgren[2], S Eldfors[2], E Elonen[1], R Karjalainen[2], M Majumder[2], A Murumägi[2], A Parsons[2], T Aittokallio[2], K Wennerberg[2], O Kallioniemi[2], K Porkka[1]
[1]Hematology Research Unit, Helsinki University Central Hospital, [2]Institute for Molecular Medicine Finland, FIMM, University of Helsinki, Helsinki, Finland

Background: Recent genomic studies have provided new insight on mutations contributing to AML onset and progression. However, the aberrations observed are often complex and rarely directly actionable in selecting patient therapies. To rapidly identify novel patient-specific therapies, we developed a high-throughput drug sensitivity and resistance testing (DSRT) platform. This assay allows us to determine the sensitivity of patient AML cells *ex vivo* against a pharmacopeia-wide panel of oncology drugs, as well as emerging inhibitors to discover novel therapeutic options for individual patients.
Aims: Here we present drug screening results for the first 16 AML patients tested, and report the clinical outcome of DSRT-guided therapies.
Methods: Fresh mononuclear cells from bone marrow aspirates of 16 relapsed or refractory AML patients (>50% blast count) and 5 healthy donors were screened against a collection of all clinically available cytotoxic chemotherapy agents (n=103) and targeted preclinical and clinical drugs (n=100-170). The drugs were tested over a 10,000-fold concentration range for constructing dose-response curves for each compound and sample. A leukemia-specific drug sensitivity score (sDSS) was derived from the area under each dose response curve in relation to the total area, and relating results from leukemia samples to normal bone marrow. The turnaround time for the DSRT assay was 4 days. When enough cells were available, the samples also underwent exome and transcriptome sequencing to define clonal evolution and mechanisms of

response and drug resistance from consecutive sampling of the patients.
Results: DSRT-profiles were unique to each AML patient and sample (Figure 1 for an example). Drugs which commonly showed selective responses *ex vivo* were dasatinib, temsirolimus, MEK-inhibitors and sunitinib. DSRT results were considered clinically implementable in a patient if a distinct leukemia-selective response pattern was observed and drugs with the most leukemic-selective responses were clinically available (as compassionate or on/off-label use). DSRT-guided therapy was possible in 13/16 (81%) of the patients. Non-guided chemotherapy was chosen for 6 patients (treatment protocol). Of the remaining 7 patients, 2 patients received 2 courses of DSRT-guided personalized treatment based on two separate DSRTs from different relapse time points. Of the 9 therapies, 3 patients had a response to therapy (ELN criteria, table): 1 complete response (CRi), 2 with a morphologic leukemia free state. Three remaining patients showed meaningful clinical responses not meeting the ELN criteria. Patient 560 showed a rapid clearance of blasts in peripheral blood after five days of treatment (dasatinib, sunitinib) after which therapy was discontinued due to gastrointestinal toxicity. Patient 252 had an 8 week progression-free period during dasatinib monotherapy (bone marrow blasts 65-40-70%). Patient 784 achieved a transient response with bone marrow blasts decreasing from 70 to 35%. Analysis of exome/transcriptome indicated mechanistic clues to patient responses/relapses and suggested individual biomarkers for response.
Summary / Conclusion: Our drug-response phenotype-based assay provided actionable drug candidates for most patients with relapsed, chemorefractory AML. Promising clinical responses suggest good predictive power of the *ex vivo* testing platform. DSRT is a powerful tool for drug repurpositioning and devising personalized therapies. When combined with next-gen sequencing, DSRT will provide unique insight into the pathogenesis of relapsed AML and may facilitate introduction of new treatments to otherwise refractory patients.
Off-label use: Many of the drugs used in DSRT-guided therapies are not indicated for AML.

Pt #	DSRT-guided treatment	Disease state at treatment start	Treatment response (ELN)
252	DAS	Relapsed, resistant	SD 8 weeks
393	DAS	Relapsed, PR	Not evaluable
560_1	DAS, TEM	Relapsed, CR	RD
560_2	DAS, SUN	Relapsed	Clearance of blasts (blood)
600	DAS, TEM, SUN	Relapsed, resistant	CRi
718	CLO, SOR	Relapsed, resistant	Morphologic leukemia-free state
784_1	DAS, SUN, TEM	Resistant	RD, transient response
784_2	CYT, ETO, SUN, VBL	Resistant	RD, transient response
800	CLO, DAS, VBL	Resistant	Morphologic leukemia-free state

DAS=Dasatinib, SUN=Sunitinib, TEM=temsirolimus, SOR=sorafenib, CLO=clofarabine, CYT=Cytarabine, ETO=etoposide

Background: To aid in the identification of effective treatments for individual patients, *ex vivo* assays for detecting cell death inducible by drugs for hematological malignancies have been in development for over 20 years. We have developed a novel automated flow cytometry-based platform (ExviTech).
Aims: The purpose of this study is to examine the *ex vivo* pharmacology of single drugs used to treat AML against the malignant cell population in bone marrow samples from 80 AML patients.
Methods: Bone-marrow samples from patients diagnosed with AML were sent to Vivia from 24 hospitals across Spain within 24 hrs, in collaboration with PETHEMA. The whole sample was plated into 96-well assay plates containing 8 concentrations of each drug. The plates were incubated for 48-hours, and then prepared for analysis by our flow cytometry-based ExviTech© platform. All processes have been automated and multiple controls are used that greatly increase the accuracy of the analysis. The percentage of leukemic cell death was determined via labeling with monoclonal antibodies and AnnexinV-FITC. A survival index is computed for each drug, the lower the survival index, the more effective the drug. Dose-response curves of cytarabine, idarubicin, daunorubicine, etoposide, mitoxantrone, fludarabine, decitabine, 5-azacitidine, clofarabine, panobinostat, sorafenib, melphalan, cyclophosphamide, lenalidomide, busulfan and 6-thioguanine were measured in 64-99 patient samples.
Results: There is a large range of interpatient variability in the response to a single drug. These two results are depicted in Figure 1. The red line is the average patient response to fludarabine, while the light grey lines are the individual results from 94 patients, representing wide interpatient variability. The dark blue lines are average dose response curves for the other 15 drugs referenced above, demonstrating the range of effect of these drugs *ex vivo*. Interestingly, panobinostat (far left blue line), was the most potent and effective drug tested, suggesting that for a subset of patients it could potentially be a useful treatment. The anthracyclines, idarubicin, daunorubicin and mitoxantrone show a similar average response. Although anthracyclines are stronger drugs than fludarabine *on average*, certain fludarabine patient curves actually overlap with Dauno and Mito average curves. This means personalizing treatment may be as important as average drug strength. Clofarabine presented the widest variability of all of the drugs tested, with some patients responding very well while others were totally resistant. Epigenetic drug 5-azacytidine, which clinically requires several cycles to work at low doses, shows depletion dose responses at 48 h similar to Cytarabine. This likely reflects its cytotoxic mechanism at high doses, but still most sensitive patients identified here may also be sensitive for the hypomethylation mechanism. Interestingly, the related epigenetic drug Decitabine acting on the same target is very inefficient in this assay.
Summary / Conclusion: By testing the drugs used in the treatment protocols for AML directly on patient samples, a pharmacological based model could be developed to infer drug resistance or sensitivity, patient by patient. Idarubicin, daunorubicin and mitoxantrone are commonly used in combination with cytarabine, and testing may be able to determine which would be better for each individual patient. Similarity, testing could be used as a companion diagnostic to identify subsets of patients for which treatments such as clofarabine or panobinostat would be effective.

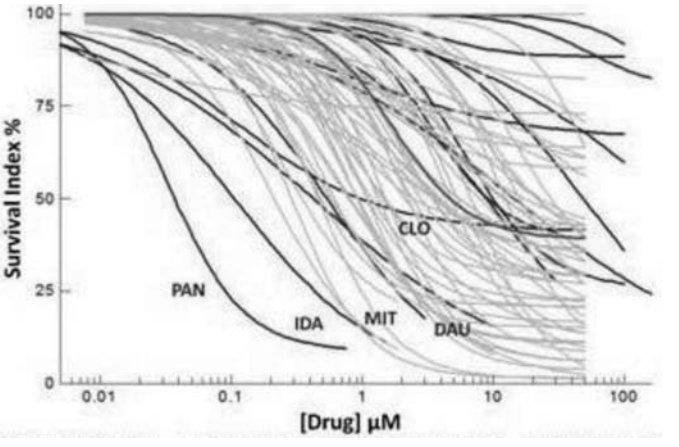

Figure 1. Red line, average curve of fludarabine; gray lines, individial curves of fludarabine; black lines, average curves of other drugs tested with panobinostat (PAN), idarabucin (IDA), mitoxantrone (MIT), daunorubicin (SDAU) and clofarabine (CLO) identified.

P050

SYSTEMATIC REVIEW AND META-ANALYSIS OF ANTI-CD33 ANTIBODY TREATMENT IN AML – GEMTUZUMAB OZOGAMACIN HAS ANTI-LEUKAEMIC EFFICACY

J Loke[1,*] J Khan[2], J Wilson[2], C Craddock[1], K Wheatley[2]
[1]Centre for Clinical Haematology, Queen Elizabeth Hospital, [2]Cancer Research UK Clinical Trials Unit (CRCTU), University of Birmingham, Birmingham, United Kingdom

Background: Immunotherapeutic strategies represent a major advance in the treatment of haematological malignancies. Conventional chemotherapy is ineffective in the majority of patients with Acute Myeloid Leukaemia (AML). Monoclonal antibodies (gemtuzumab ozogamacin (GO) and lintuzumab) which recognise the CD33 antigen expressed on myeloid progenitors) have been reported to improve outcome in some randomised controlled trials (RCTs). However, reports of associated excess toxicity have resulted in GO's licence being withdrawn. As a result, the role of these agents in the management of AML remains unclear.
Aims: Our aim was to assess the effectiveness and safety of anti-CD33 antibody treatment in patients with AML.
Methods: Standard systematic review methods were employed. We searched Medline (1946-2012), Embase (1974-2012), Cochrane Library (up-to 2012) and major conference proceedings for RCTs, where one arm included anti-CD33 antibody therapy. Fixed effects meta-analysis methods were used, involving calculation of observed minus expected number of events, and variance for each endpoint in each trial, with the overall treatment effect expressed as Petos' odds ratio with 95% confidence interval.
Results: Fourteen RCTs met the inclusion criteria, 12 with GO, 2 lintuzumab. Meta-analysis of 12 RCTs with 14 randomisations involving GO was undertaken. GO did not improve complete remission (CR) rates (OR=1.03, 95% CI=0.77-1.37, P=0.9). In the setting of induction treatment (total 1961 patients), 13 cases of VOD were reported, but there was no significant adverse impact of GO on induction death. However, a clear reduction in resistant disease (P=0.02) can be seen. There was an impact of GO on cumulative incidence of relapse (CIR) (HR=0.88, 95% CI=0.79-0.97, P=0.01), largely related to the use of GO in induction (HR=0.83, 95% CI=0.73-0.93, P=0.002). There was no effect of GO on death in CR (P=0.7). The reduction in CIR resulted in an improvement in relapse-free survival (RFS) with GO (HR=0.88, 95% CI=0.81-0.96, P=0.003). Subgroup analyses investigated the optimal delivery of GO and whether some types of patient may benefit more. A benefit on RFS was clearly seen when GO was used as part of induction therapy (HR=0.85, 95%CI=0.77-0.94, P=0.001). There was no evidence that the effect size for RFS differed depending on the dose of GO (less than or more than 9 mg/m^2) or with patient age (less than or greater than 60). Based on data from a limited number of trials, the benefit of GO appears greatest in patients with favourable genetics, with no evidence of benefit in patients with adverse genetics, for overall survival (test for trend: P=0.009).
Summary / Conclusion: GO has a clinically important anti-leukaemic effect, as demonstrated by reductions in relapse and resistant disease. The suggestion of increased toxicity of GO is not confirmed by this meta-analysis. Further trials are needed to clarify whether certain types of patients benefit more than others and what is the optimal dose and schedule of GO.

P051

RISK-ADAPTED TRANSPLANT SELECTION ATTENUATES THE NEGATIVE PROGNOSTIC ROLE OF MINIMAL RESIDUAL DISEASE AND GENETIC HIGH RISK FEATURES

F Buccisano[1,*] L Maurillo[1], M Del Principe[1], C Sarlo[1], R Cerretti[1,2], A Picardi[1,2], L Cudillo[1,2], B Mariotti[1,2], C Ditto[1], M Refrigeri[1], M Cefalo[1], F Giannotti[1], G Del Poeta[1], F Lo Coco[1], S Amadori[1], W Arcese[1,2], A Venditti[1]
[1]Hematology, Tor Vergata University, [2]Rome Transplant Network, Policlinico Tor Vergata, Rome, Italy

Background: The outcome of adult AML still remains unsatisfactory due to two main reasons: 1) the risk-category allocation based on the sole definition of pre-treatment biological features may fail to distinguish some high-risk patients who, therefore, might necessitate to be timely addressed to allogeneic SCT (ASCT); 2) the delivery of ASCT is often hampered by the paucity of candidates (25-30%) with a full matched family donor. We have reported (Buccisano *et al*, Blood, 116:2295-303, 2010) that a proper combination of upfront genetics/cytogenetics and minimal residual disease (MRD) represents a powerful tool to predict the risk of relapse on an individual basis.
Aims: We have designed a risk-adapted strategy in which high-risk patients (those with an adverse karyotype, FLT3-ITD mutations, or MRD positivity after consolidation therapy) should receive ASCT.
Methods: Definition of MRD positivity required ≥ 3.5x10^{-4} residual leukemic to be counted in the bone marrow and once a given patients was declared to be at high-risk, he received ASCT whatever the source. For comparison, we analyzed the outcome of a matched historical cohort of high-risk patients who were submitted to ASCT only in the case a full matched family donor was available or, alternatively, to autologous stem cell transplantation (AuSCT).
Results: The prospective and retrospective cohort included 34 (1 MRD+, 3 favorable-K/MRD+, 16 intermediate-K/MRD+, 7 adverse-K and 7 FLT3-ITD) and 77 patients (2 MRD+, 9 favorable-K/MRD+, 50 intermediate-K/MRD+, 3 adverse-K and 13 FLT3-ITD), respectively. Sixteen of 77 (21%) in the retrospective cohort received ASCT whereas in the prospective cohort 25 of 34 (74%) did the same (8 from a matched family donor, 17 from alternative sources) (P<0.001). After a median follow-up of 33 and 50 months, respectively, survival of high risk patients in the prospective cohort was significantly longer than the one of high risk patients in the retrospective one (61% vs 21%) and similar to that of a historical group of patients categorized as low risk (58%) (P=0.006) (Figure n.1). Relapse rate before transplant was similar in the 2 cohorts (26% vs 22%, respectively, P=NS).
Summary / Conclusion: We conclude that in adult patients with AML, a therapeutic approach based on the risk-driven "transplant *versus* no transplant" rather than "donor *versus* no donor" strategy is feasible and may favorably impacts on the negative prognostic role of MRD positivity and adverse genetics/cytogenetics.

CHARACTERISTICS AND PROGNOSIS OF ACUTE ERYTHROLEUKEMIA (AEL) - RESULTS OF A SUBGROUP ANALYSIS OF THE STUDY ALLIANCE LEUKEMIA (SAL) AML TRIALS

S Parmentier[1,1,*] M Kramer[1], K Koch[1], B Mohr[1], C Thiede[1], C Röllig[1], M Hänel[1], N Schmitz[2], K Schäfer-Eckart[3], W Aulitzky[4], W Berdel[5], H Serve[6], S Krause[7], J Mayer[8], M Bornhäuser[1], G Ehninger[1], M Schaich[1]
[1]Medical Department I, University Hospital Dresden , Dresden, [2]Abteilung f. Hämatologie, Onkologie und Stammzelltransplantation, Asklepios Klinik St. Georg , Hamburg, [3]5. Medizinische Klinik, Klinikum Nord , Nürnberg, [4]Innere Klinik II, Robert-Bosch-Krankenhaus, Stuttgart, [5]Medizinische Klinik A, Universitätsklinikum Münster, Münster, [6]Medizinische Klinik II, Universitätsklinikum Frankfurt am Main, Frankfurt, [7]Medizinische Klinik5, Universitätsklinikum Erlangen, Erlangen, Germany, [8]Department of Haematol-oncology, University Hospital Brno, Brno, Czech Republic

Background: Acute erythroleukemia (AEL) represents a rare type of acute myeloid leukemia accounting for less than 5% of all cases. So far, according to WHO classification this AML entity is thought to have a poor prognosis in itself.
Aims: We assessed the influence of relevant clinical and demographic parameters, FLT3-ITD, NPM1 status and cytogenetics on complete remission rates (CR), overall survival (OS) and event free survival (EFS) separately in AEL and non-AEL patients.
Methods: 3267 patients with newly diagnosed AML were treated according to the protocols of the AML96, AML2003 or AML60+ studies of the Study Alliance Leukemia (SAL). Informed consent was obtained by all patients. 116 of these patients had acute erythroleukemia (AEL). In only 78 of these cases slides for systematic morphologic review were available. Only cases with morphological review were included into subgroup analysis.
Results: After morphological review, three diagnostic groups could be separated according to WHO 2008: acute erythroid/myeloid leukemia (n=54; AML M6a according to FAB), pure erythroid leukemia (n=4; AML M6b according to FAB) and acute myeloid leukemia with multilineage dysplasia (n=20). No significant differences between these distinct groups could be elucidated, but all BM harborded severe dysplastic features and mostly multilineage dysplasia. Compared to non-AEL AML, NPM1 and FLT3-ITD mutations were found in 13.3% and 6.3% of the patients with AEL and in 32.1% and 20.7% of the patients with non-AEL AML (P=0.002, P=0.008), respectively. All patients with AEL and NPM1 mutations were *de novo* AMLs and had normal cytogenetics. Several cytogenetic aberrations, most of them associated with poor prognosis, are found more often in the AEL cohort than in the non-AEL AML cohort (Trisomie 8: 16.3% vs.

9%, P=0.026; del(5q): 12.5% vs. 6.6%, P=0.038; -7: 12.5% vs. 5%, P=0.003; complex aberrant: 27.5% vs. 13.3%, P<0.001; abnl 17p: 11.3% vs. 4.2%, P=0.003; other monosomies: 16.3% vs. 5%, P<0.001). Despite these differences, no significant differences in CR rates, OS and EFS were found between both groups. This finding was confirmed in a multivariate analysis including cytogenetics, molecular markers and clinical parameters (LDH, WBC, blast count, platelet count and ECOG). According to the analysis, AEL morphology was not an independent prognostic factor for OS and EFS. Within the AEL group, patients with monosomy 7 (n=10), complex aberrant karyotype (n=22) and abnl 17p had a shorter median OS (5.7, 5.2, 4.3 months) compared to patients with AEL and not such aberrancies (20.4, 22.3, 18.9 months) (P=0.001, <0.001, 0.015), respectively. A complex aberrant karyotype was found more often in patients with secondary AEL than in patients with *de novo* AEL (P=0.024).
Summary / Conclusion: According to our data, the characteristic morphological features of acute erythroleukemia do not confer an unfavorable prognosis in itself. Compared to non-AEL AML, cytogenetic aberrations associated with poor prognosis are found more often in patients with AEL, but it confers only within the AEL group to a significant worse OS. NPM1 and FLT3-ITD mutations were much less common in patients with AEL.

P053

ELACYTARABINE / IDARUBICIN IN PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO FAILED CYTARABINE BASED INDUCTION, AND EVALUATION OF THE IMPACT OF THE TRANSPORTER HENT1 ON RESPONSE; RESULTS OF A PHASE II STUDY
D Rizzieri[1], N Vey[2,*] X Thomas[3], F Huguet-Rigal[4], R Schlenk[5], J Krauter[6], T Kindler[7], B Gjertsen[8], I Blau[9], M Johansen[10], T Bergeland[10], Athos Gianella-Borradori[10], T Jacobsen[10], U Krug[11]
[1]Duke University Medical Center, Durham, United States, [2]Institut J. Paoli and I. Calmettes, Marseille, [3]Hospital Edouard Herriot, Lyon, [4]Hospital Purpan, Toulouse, France, [5]Universitätsklinikum Ulm, Ulm, [6]Medizinischen Hochschule Hannover, Hannover, [7]Johannes-Gutenberg-Universität, Mainz, Germany, [8]Haukeland University Hospital, Bergen, Norway, [9]Charite University Hospital Benjamin Franklin, Berlin, Germany, [10]Clavis Pharma, Oslo, Norway, [11]Universitätsklinikum Münster, Münster, Germany

Background: Elacytarabine is a novel, patented anti-cancer drug in development (phase III) for treatment of acute myeloid leukemia (AML). Elacytarabine has demonstrated longer plasma elimination half-life, prolonged intracellular retention compared to cytarabine and activity independence of membrane nucleoside transporters. The human equilibrative nucleoside transporter 1 (hENT1) in particular has been reported as an important modulator of resistance to cytarabine (Hubeek *et al*., 2005). A phase I study established elacytarabine 1000 mg/m^2/d continuous infusion (CIV) d 1 – 5 as the recommended dose given in combination with idarubicin 12 mg/m^2/d IV d 1-3 (Giles *et al*, 2012).
Aims: To determine the efficacy and safety of elacytarabine in combination with idarubicin in adult patients with AML who did not respond to a first cytarabine-anthracycline remission induction course. To explore the relationship between the hENT1 status in AML cells and response to elacytarabine and to cytarabine.
Methods: A bone marrow (BM) sample was collected at diagnosis and analysed by immunocytochemistry (ICC) for hENT1 protein expression. Patients who had not attained blast clearance after the first remission induction course, entered the study and received elacytarabine + idarubicin at doses/schedules as described above. The hENT1 expression level in BM was again analysed before elacytarabine+idarubicin treatment. Safety and efficacy were assessed. Patients are followed for duration of response and survival for at least 12 months.
Results: The study recruited 51 patients [28 male, 23 female, median age 61 years (range 18-78), ECOG PS 0-2]. 35% of the patients were diagnosed with secondary leukaemia. The median time from start of cytarabine induction to study entry was 37 days (range 18-78). After treatment with elacytarabine and idarubicin the overall response rate (ORR) is 45%, with 21 out of 47 evaluable patients in CR or CRi. Median time to remission was 41.5 days (range 21 to 169). The incidence of low-level hENT1 protein expression both at time of initial AML diagnosis as well as at study entry was approximately 45%. The response to elacytarabine was similar in both groups with 10 out of 23 patients responding in the hENT1 high expression group and 8 out of 19 patients in the hENT1 low expression group. The response to cytarabine was lower for the hENT1 low expression group (9 out of 18 patients) compared to the hENT1 high expression group (15 out of 22 patients). The most frequently reported non haematological adverse events, CTCAE grade ≥3, were infections/sepsis, hypokalemia, hypoalbuminaemia, fatigue and hypoxia. Five patients died within 30 days after start of treatment, all due to sepsis/infections. Four patients died within 60 days after start of treatment either due to progressive disease (three patients) or complications after stem cell transplantation (one patient). Seven of nine patients who died early were initially diagnosed with secondary leukaemia.
Summary / Conclusion: Elacytarabine in combination with idarubicin shows promising clinical activity with a CR/CRi rate of approximately 45% in patients in whom an initial and single cytarabine based induction course has failed. As hypothesized, the hENT1 expression level demonstrated no impact on the efficacy of elacytarabine while it influenced response to cytarabine. The safety profile is manageable and is as expected for a combination cytotoxic therapy. Updated event free survival and survival data will be presented.

P054

RISK STRATIFICATION OF 444 PATIENTS WITH DE NOVO NON-M3 ACUTE MYELOID LEUKEMIA BY INTEGRATING MOLECULAR GENE MUTATIONS WITH CYTOGENETICS
H Hou[1,*] C Lin[1], W Chou[1], Y Lai[1], C Chen[1], J Tang[1], M Yao[1], S Huang[1], Bo Ko[1], S Hsu[1], S Wu[1], W Tsay[1], H Tien[1]
[1]National Taiwan University Hsopital, Taipei, Taiwan

Background: Acute myeloid leukemia (AML) is a heterogeneous hematologic malignancy with great variability in the pathogenesis, clinical features and treatment outcomes. The goal of risk stratification is to explore personalized therapy, thereby reduce the risk of relapse and treatment-related side effects.
Aims: Extensive mutational analysis can better discriminate AML patients into various prognostic groups.
Methods: We investigated a comprehensive analysis of cytogenetic change and 17 molecular alterations, includingClass I mutations, such as *FLT3*-ITD and *FLT3*-TKD*, N-RAS, K-RAS, JAK2, KIT and PTPN11* mutations and Class II mutations, such as *MLL*-PTD*, CEBPA* and *AML1/RUNX1* mutations, as well as *NPM1, WT1,* and epigenetic alterations, such as *ASXL1, IDH1, IDH2,TET2* and *DNMT3A* mutationsin a large cohort of 444 *de novo* non-M3 AML patients in Taiwan.
Results: Genetic alterationsoccurred more frequently in patients with intermediate-risk cytogenetics (92.1%) than in those withfavorablekaryotype (68.9%) or unfavorable cytogenetics (50.8%, P<0.0001).We found that mutations of *AML1/RUNX1, WT1, ASXL1* and *DNMT3A* were associated with poorer overall survival (OS) while *NPM1*$^+$/*FLT3*-ITD$^-$, *CEBPA*$^{double\text{-}mutation}$ and *IDH2* mutation predicted better survival. Further refinement of intermediate-risk cytogenetic group can be achieved through molecular screening of these eight relevant genes. Patients with mutant *NPM1, IDH2* and *CEBPA*$^{double\text{-}mutation}$ in absence of *FLT3*-ITD belong to a favorable molecular genotype, an unfavorable molecular genotype including mutant *AML1/RUNX1, WT1, ASXL1*, and *DNMT3A* while the remaining genotypes was part of intermediate genotype. The probability of achieving a CR for favorable-risk, intermediate-risk and unfavorable-risk profile was 90.2%, 76.9% and 64.1%, respectively (P<0.001). The relapse rate for the three risk groups was 40.6%, 63.3% and 67.1%, respectively (P=0.0006). The median OS for favorable-risk, intermediate-risk and unfavorable-risk profile was not reached, 25 months and 12.3 months, respectively and five-year survival rate was 59.6%, 38.6% and 18.2% in these three risk groups (both P<0.001). Intriguingly, allogeneic HSCT may improve OS among patients with unfavorable molecular genotype.
Summary / Conclusion: These findings suggest the proposed risk stratification using integration of both cytogenetic and mutational profiles can further discriminate patients into different prognostic groups, especially in those with intermediate-risk cytogenetics. Further, allogeneic HSCT may provide survival benefits for patients with unfavourable mutational profile.

P055

ACUTE MYELOID LEUKEMIA (AML) PATIENTS HARBOURING BOTH, FLT3-ITD AND NPM1 MUTATION, MAY BENEFIT FROM A MINIMAL RESIDUAL DISEASES (MRD) GUIDED TRANSPLANT DECISION
J Schiller[1,*] I Praulich[1], M Hallek[1], K Kreuzer[1]
[1]Department I of Internal Medicine | University at Cologne, 50937 Cologne, Germany

Background: Minimal residual disease (MRD) monitoring in patients with acute myeloid leukemia (AML) can predict relapse clearly in advance and therefore allows early therapeutic intervention. Moreover, recent studies have highlighted the significance of personalized treatment on the basis of MRD status for improving outcome in AML.
Aims: The *FLT3* internal tandem duplication (*FLT3*-ITD) occures in 15-35% of all AML. Clinically, *FLT3*-ITDs have been strongly associated with poor outcome. However, due to the high sequence variability of individual *FLT3*-ITD commonly a universal PCR approach is applied which has a low sensitivity (approx. 1: 5x10^2).
Methods: To develop a novel cDNA-based, highly sensitive quantitative real-time reverse transcription polymerase chain reaction (qRT-PCR) assay for the detection of the *FLT3*-ITD mutation level. On the basis of invidual *FLT3*-ITD, mutation-specific primers were designed. The expression of *FLT3*-ITD was determined using complementary DNA samples at different points in time diagnosis and subsequent treatment.
Results: From a total of 394 newly diagnosed AML patients 55 (14%) were *FLT3*/ITD positive. Retrospectively we analyzed ITD mutation of *FLT3* in 39 available cases. The length of ITD ranged from 3 to 144 base pairs (median

46). Nine patients had extra insertions of 2-38 base pairs between two repeats. For the *FLT3*-ITD quantification we developed patient-specific qRT-PCR for 29 individuals with mutation-specific forward primers and studied 83 peripheral blood and 61 bone marrow samples. Three cases with *WT1*, fifteen with *NPM1*, three with *MLL*-PTD and five with *PML*/*RARα* fusion genes expression levels were compared with *FLT3*-ITD expression levels. 26 of 29 assays (90%) were highly specific ($1:10^4$ - $1:10^5$) and yielded similar results when compared to other high sensitive assays for molecular markers like *NPM1* or *PML*/*RARα*. In three cases (10%) a co-amplification of the wild-type could not be avoided resulting in lower sensitivity ($1:10^3$). We could show that *FLT3*-ITD positivity reliably predicted relapse up to 10 months in advance. 92% patients, who achieved *FLT3*-ITD negativity with our assay, did not relapse. Furthermore we compared paired PB and BM samples at diagnosis and after induction therapy in 5 cases. The difference in *FLT3*-ITD expression were not statistically significant (P=0.8) which is in line with recent studies.

Summary / Conclusion: We conclude that highly sensitive detection of individual *FLT3*-ITD posses equal prognostic power in AML like established molecular MRD markers. Using this approach MRD guided treatment decisions appear to be justified and should be incorporated in future studies.

P056

PATTERNS OF RELAPSE IN 169 PATIENTS TREATED WITH ORAL ARSENIC TRIOXIDE DURING INDUCTION AND/OR MAINTENANCE: A 12-YEAR EXPERIENCE

H Gill[1,*] A Leung[1], E Tse[1], Y Kwong[1]
[1]Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China

Background: Despite excellent response rates and long-term survivals with current treatment strategies, multiple relapses and central nervous system (CNS) disease remain major causes of treatment failure and mortality in patients with acute promyelocytic leukaemia (APL).

Aims: In this study, 169 patients with APL treated with oral arsenic trioxide (As_2O_3) during maintenance at first complete remission (CR1), or as re-induction and subsequent maintenance, were prospectively investigated. We aimed at describing different patterns of relapse, identifying risk factors for relapse and CNS disease, and prognostic factors for survival.

Methods: This was a 12-year prospective follow-up study of 169 patients treated with oral arsenic trioxide during induction and/or maintenance. Clinicopathologic features, treatment characteristics and outcome of relapsed APL were reviewed. Prognostic factors for relapse and CNS involvement were analyzed using logistic regression. Survivals were analyzed using Kaplan-Meier method and Cox-proportional hazard regression.

Results: ***Risk factors for relapse***. A total of 79 patients had one or more relapses, including 14 patients with CNS involvement. Maintenance regimens without arsenic trioxide at CR1 and high peak white blood cell (WBC) count were independently associated with increased risk of relapse (P<0.001 and P=0.008 respectively). By Cox-proportional hazard regression, patients who received maintenance regimens without arsenic trioxide had significantly inferior relapse-free survival (hazard ratio=12.97, P<0.001, 95% confidence interval:6.61-12.05).

Patterns of relapse. Three different patterns of relapse were compared. There were 65 patients with isolated medullary relapse, 8 patients with concurrent bone marrow and CNS involvement at relapse, and 6 patients with isolated CNS relapse. Risk factors associated with isolated CNS relapses included high WBC count on presentation (P=0.007); relapses beyond second complete remission (P=0.003); and relapse while on maintenance regimens containing oral arsenic trioxide (P=0.001). Risk factor for concurrent medullary and CNS relapse was relapses beyond second complete remission (P=0.003). Patients relapsing while on oral arsenic trioxide maintenance have more frequent Fms-like tyrosine kinase 3-internal tandem duplication (FLT3-ITD) at the time of relapse (odds ratio=4.61, P=0.03, 95% confidence interval:1.13-18.92). Isolated positive molecular testing for *PML-RARA* fusion gene during oral arsenic trioxide maintenance predicted a subsequent morphologic relapse (odds ratio=6.18, P=0.024, 95% confidence interval:1.27-29.94).

Survivals. The 5-year overall survival of our cohort of patients was 85.9%. Three factors were associated with significantly inferior survivals: relapse while on oral arsenic trioxide (hazard ratio=9.43, P<0.001, 95% confidence interval:4.01-21.32); relapses beyond third complete remission (hazard ratio=16.45, P<0.001, 95% confidence interval:4.49-60.34); and concurrent bone marrow and CNS relapse (hazard ratio= 22.84, P<0.001, 95% confidence interval:5.88 - 88.74).

Summary / Conclusion: Advanced relapses, high WBC count and relapse while on oral arsenic trioxide were associated with a higher risk of CNS involvement and in turn inferior overall survivals. Identification of such risk factors is important in formulating effective treatment and prophylactic protocols for high-risk APL patients.

P057

SURVIVAL IMPACT OF COMPLEX AND MONOSOMAL KARYOTYPE AND LOSS OF CHROMOSOMES5, 7 AND 17 IN OLDER PATIENTS WITH AML. FIRST EVALUATION OF CYTOGENETIC DATA FROM THE POPULATION BASED SWEDISH AML REGISTRY

V Lazarevic[1,2,*] A Hörstedt[3], B Johansson[4], P Antunovic[5], R Billström[6], M Brune[7], Å Derolf[8], E Hullegårdh[7], L Möllgård[9], C Nilsson[8], D Stockelberg[7], B Uggla[10], L Vennström[7], A Wahlin[11], M Höglund[12], G Juliusson[2,13]
[1]Hematology and Coagulation clinic, Skåne University Hospital, Lund, [2]Stem Cell Center, Lund University, [3]Regional Tumor Registry in South Sweden, [4]Department of Clinical Genetics, Skåne University Hospital, Lund, Lund, [5]Hematology, Linköping University Hospital, Linköping, [6]Hematology, Sahlgrenska University Hospital, Skövde/Göteborg, [7]Hematology, Sahlgrenska University Hospital, Göteborg, [8]Hematology, Karolinska University Hospital, Stockholm, [9]Hematology, Karolinska University Hospital, Göteborg, [10]Hematology, Örebro University Hospital, Örebro, [11]Hematology, University Hospital of Northern Sweden, Umeå, [12]Hematology, Academic Hospital, Uppsala, [13]Hematologi and Coagulation, Skåne University Hospital, Lund, Lund, Sweden

Background: The incidence and impact of chromosomal abnormalities (abns) in AML have mostly been evaluated in younger and/or highly selected patients (pts) treated within clinical trials, whereas data from large population-based studies are lacking. The Swedish National Acute Leukemia Registry contains data on 98% of all Swedish AML pts diagnosed 1997-2006 (Blood 2009;113:4179). During this period, karyotyping was recommended at diagnosis for all pts eligible for intensive treatment, but molecular analyses were not routinely performed. We have now retrospectively added cytogenetic data from the original medical reports to the database.

Aims: We analyzed the impact on survival of the number of chromosomal abns, those involving 5q-/-5, 7q-/-7, and/or 17p-/-17, and monosomal karyotype in pts treated with intensive chemotherapy. Pts with APL were excluded in this analysis. Survival was updated in May 2012. Data was analyzed by the R-program software (http://www.r-project.org), and p-values were computed from a Cox proportional hazards model.

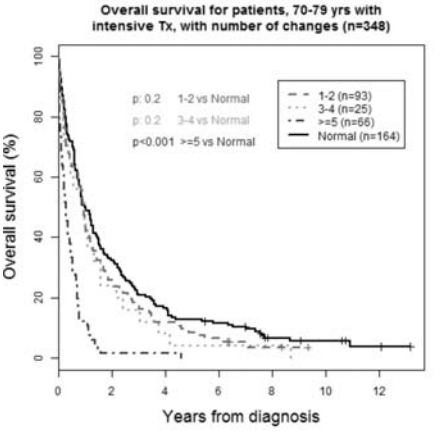

Figure 1.

Results: Evaluable karyotypes were found in 1904/3293 registered patients, i.e., in 150 (78%) of patients <40 years, 492 (78%) in ages 40-60 yrs, 467 (71%) between 60-69 yrs, 591 (58%) in patients 70-79 yrs, and 199 (25%) of patients over the age of 80. Karyotypes were missing due to several reasons, e.g., not performed, not indicated, report not available. Pats with ≥5 chromosomal abns had significantly worse overall survival than those with 3-4 vs 1-2 abns or normal karyotype in all age groups (Figure 1), whereas the difference between 3-4 vs fewer abns were less. Monosomal karyotype did not separate survival curves within the groups with 3-4 vs≥5 abns in any age group; e.g., 2 yrs OS with 3-4 abn:s: MK+ 48% vs MK- 44%; and with ≥5 abn:s MK+15% vs MK-, 16%, (P=NS). Abns involving 5/7/17 were strongly correlated and often occurred together in monosomal karyotypes; pats with all three of those abns had very poor outcome.

Summary / Conclusion: We now have population-based data on cytogenetics in the largest age cohort of AML, i.e., 60-79 years. There is a significant overlap between complex karyotypes, and abns involving chromosomes 5/7/17, and monosomal karyotype, in all age cohorts. Five or more chromosomal abns were clearly worse than 3-4 abns, especially with combined chromosome abns involving 5/7/17.

P058

PATIENTS WITH LATE RELAPSE OF ACUTE MYELOID LEUKEMIA HAVE A HIGH RATE OF DURABLE SECOND COMPLETE REMISSIONS WHEN TREATED WITH CHEMOTHERAPY ONLY

Å Derolf[1,*] M Hultcrantz[1], M Björkholm[1]
[1]Division of Hematology, Department of Medicine, Karolinska University Hospital, Solna and Karolinska Institutet, Stockholm, Sweden

Background: Complete remission (CR) rates are high among patient with acute myeloid leukemia (AML) but long-term survivors are few, because eventually more than half of the patients relapse. A relapse usually occurs within two years of achieving CR, while late relapses, defined as a recurrence of AML after more than five years from achieving CR, are considered rare events. The prognosis is generally poor when there is a relapse. However, the remission rate is higher among patients with a long duration of the first complete remission (>18 months) and with favorable cytogenetics at diagnosis. Allogeneic stem cell transplantation (SCT) is often recommended to sustain the second CR although a number of patients, particularly those with favorable cytogenetics, can achieve durable second remissions when treated with chemotherapy alone.
Aims: The aim was to assess the number of patients with late relapse in a population-based cohort of long term AML survivors and to collect detailed information on clinical and laboratory features.
Methods: All patients diagnosed with AML in the Stockholm, Uppsala, and Örebro regions between January 1st 1973 and December 31st 2003 were identified in the Swedish Cancer Registry. Patients who died within five years of their AML diagnosis were identified through the Cause of Death Registry and excluded from the study. Thus, only patients surviving five years or more were included. In 228 long-term survivors clinical information was available. Detailed information on laboratory variables including cytogenetics and immunophenotype at diagnosis and relapse, treatment (type of chemotherapy regimen, number of courses, SCT), myelodysplastic syndrome (MDS) preceding the relapse and cause of death was collected from medical records.
Results: Among 228 patients surviving for at least 5 years after their AML diagnosis, 33 patients had a recurrence of their disease 36 months or more after first CR. Results of cytogenetic analysis at diagnosis were available in 23 patients (70%); thirteen had a normal karyotype, three patients had unfavorable karyotypes while there were no patients with core binding factor (CBF) leukemia. Cytogenetic analyses were available in 13 patients (39%) at relapse; five patients had a normal karyotype. In 11 patients cytogenetic information was available at both diagnosis and relapse, with a change in karyotype occurring in four patients. Seven patients were diagnosed with MDS (n=6) or chronic myelomonocytic leukemi (CMML; n=1) preceding their AML relapse. In two of these patients, MDS related karyotypes were identified at relapse but not at diagnosis. Results of treatment will be presented here in detail only for the group of patients who relapsed five years or more after AML diagnosis because the inclusion criteria excluded patients relapsing prior to this date if they did not survive at least two years from their relapse. There were 23 patients (10%) out of 228 patients with a relapse after more than five years of achieving first CR (median age at relapse 66 years; range 32-88). Seventeen were treated with intensive chemotherapy and 12 (71%) achieved a second CR. Intensively treated patients had a median survival of 3.8 years (Figure 1). Six patients are alive (one underwent allogeneic SCT) with a median follow-up time after relapse of 7 years. The cause of death was AML in 18 patients, one patient died from graft versus host disease, and one patient died of pneumonia while in MDS phase. In three patients the cause of death was not associated with AML and in the remaining the cause was unknown.
Summary / Conclusion: Late relapse of AML is probably more common than we like to think. However, in the event of a late relapse the outcome of treatment is favorable, also among elderly patients, unless MDS features are present. Therefore, this group of patients may not necessarily need SCT to remain in a second CR.

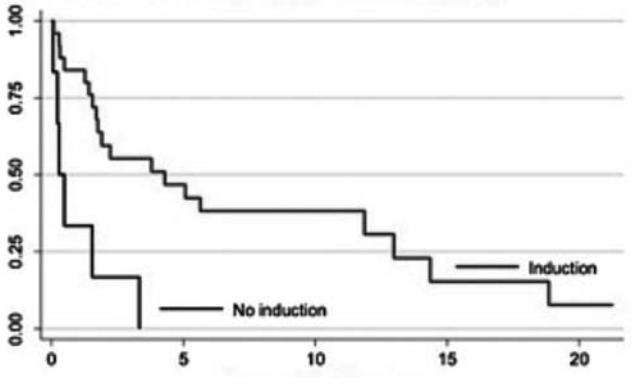

Figure 1. Overall survival (years) among patients with first five or more years after diagnosis, stratified by treatment.

Acute myeloid leukemia - Clinical 2

P059

SURVIVAL IN PATIENTS WITH ACUTE MYELOBLASTIC LEUKEMIA IN GERMANY AND THE UNITED STATES: UNEXPLAINED DIFFERENCES IN SURVIVAL IN YOUNG ADULTS

D Pulte[1,2,*] L Jansen[1], A Gondos[1], A Katalinic[3], B Barnes[4], M Ressing[5], B Holleczek[6], S Luttmann[7], H Brenner[1]
[1]German Cancer Research Center, Heidelberg, Germany, [2]Medicine, Thomas Jefferson University, Philadelphia, United States, [3]Cancer Registry of Schleswig-Holstein, Luebeck, [4]Robert Koch Institute, Berlin, [5]Cancer Registry of Rhineland-Paltz, Mainz, [6]Saarland Cancer Registry, Saarbruecken, [7]Cancer Registry of Bremen, Bremen, Germany

Background: The prognosis for patients with acute myeloblastic leukemia (AML) varies by age, with older patients usually showing poorer prognosis. However, previous population based studies in the United States (US), found lower survival in young adults compared to middle-aged adults, with adults age 15-24 having a lower survival than adults age 25-34 at 47.2% and 53.5%, respectively, in 2001-2005 (Pulte D, Gondos A, Brenner H. Expected long-term survival of patients diagnosed with acute myeloblastic leukemia during 2006-2010. Ann Oncol. 2010;21(2):335-4). Here, we compared survival for patients with AML in the US with patients in Germany. If the unexpectedly low survival in young adults in the US is due to biological factors, a similar pattern is likely to be observed in Germany. If, however, the pattern is due to socioeconomic issues such as poverty, compliance, or insurance a consistent decrease with age, rather than a deep decrease in early adulthood with a better survival in middle age, is more likely to be observed in Germany.
Aims: To determine survival of patients with AML diagnosed in Germany in the early 21st century and compare these results to patients diagnosed in the same time period in the US
Methods: Data were extracted from the Surveillance, Epidemiology, and End Results database in the US and 11 cancer registries in Germany. Patients diagnosed with AML and age <65 were included in the analysis. Cases reported to the cancer registry by death certificate only were excluded. Period analysis was used to estimate 5-year relative survival (RS) for the period 2002-06. Because acute promyelocytic leukemia (APL) has a better prognosis and different treatment options compared with other forms of AML, an analysis excluding APL was also performed, to rule out the possibility that differences observed were due to differences in the frequency of APL.
Results: Overall, age-adjusted RS for patients age 15-64 was higher in Germany at 40.4% than in the US at 32.8% (Table 1). Estimates of 5-year RS in Germany were higher than in the US for each age group, with differences ranging from +16.3 percentage points (age 18-24) to +5.4 percentage points (ages 35-44 and 60-64). In Germany, survival decreased with age, with the highest RS observed for patients age 18-24 at 60.2%, compared with 43.9% for patients of the same age in the US. In contrast, in the US the highest survival was seen in patients aged 35-44 at 50.4%. When APL was excluded from the analysis, survival decreased for both countries, but the differential in survival increased, with overall RS for Germany and the US being 39.0% and 27.9%, respectively.
Summary / Conclusion: Five year relative survival for younger and middle-aged patients with AML is higher in Germany than in the US. Survival for patients with AML in the US is lower in young adults than in middle-aged adults. This pattern is not observed in Germany such that there is an especially large disparity for ages 18-24.

Table 1.

	Germany			US				
Age	N	5-year RS	SE	N	5-year RS	SE	Diff	P-value (Model)

Background: Patients with acute myeloid leukemia (AML) who fail to achieve a complete remission (CR) after the first cycle of induction therapy and those with relapsed disease have a bleak prognosis. The FLAG-IDA regimen (fludarabine plus idarubicine and cytarabine) has been frequently used to achieve a second CR in refractory/relapsed patients and may be a bridge towards stem cell transplant (SCT). In an attempt to improve the CR rates in relapsed/refractory patients, the Programa Español de Tratamientos en Hematología (PETHEMA) group recommended between 2007 and 2010 the addition of gentuzumab ozogamizin (GO) to the FLAG-IDA regimen (FLAGO-IDA).
Aims: To analyse the results (short- and long-term outcomes) of salvage therapy with FLAG-IDA or FLAGO-IDA regimen in a large series of patients with relapsed/refractory AML treated with first-line PETHEMA LMA protocols.
Methods: This retrospective and multicenter study was performed in patients treated with first-line PETHEMA LMA protocols (LMA99, LMA2007, and LMA2010) consisting of 3+7 regimens (daunorubicin or idarubicin plus cytarabine) followed by consolidation with anthracycline/cytarabine combination with or without SCT in first CR. In patients who achieved a partial remission (PR) after first induction cycle an identical second cycle of 3+7 was recommended in the PETHEMA LMA99 and LMA2010 protocols, while FLAG-IDA or FLAGO-IDA administration was recommended in the LMA2007 protocol. In all protocols, FLAG-IDA or FLAGO-IDA was routinely administered in patients showing absolute resistance after first cycle or relapse. The inclusion of GO to second-line induction therapy depended on the resources of each centre. We perform a univariate analysis to establish the factors associated to CR rates and overall survival (OS) estimates using the Kaplan-Meir method. A multivariate analysis for OS risk factors is also reported.
Results: Between May 1999 and January 2012, 157 patients with refractory/relapsed AML who received second line therapy with FLAG-IDA or FLAGO-IDA were identified in the PETHEMA AML registry (82 males, 75 females, median age 50 years [range 14-76], 40 patients older than 60 years). Study protocol distribution was: 48 patients in the LMA99, 89 in the LMA2007, 20 in the LMA2010. FLAGO-IDA/FLAG-IDA was administered in 85 refractory patients and in 72 relapsed patients; 122 patients received FLAG-IDA and 35 patients received FLAGO-IDA. FLT3-ITD was present in 21% of patients, favourable karyotype in 12 patients (9%), intermediate in 86 (62%), unfavourable in 40 (29%), and no available results in 19 patients (12%). The median follow-up of the patients still alive was 25 months. The median OS was 16.5 months (21% OS at 5 years). The CR rate was 46% in relapsed patients (33 out 72) and 34% in refractory/PR patients (30 out 85). Stem-cell transplantation (SCT) was performed in 43 patients (39 allogenic, 4 autologous). The univariate analyses showe significant differences between patients relapsed after 12 months, before 12 months, and primary refractory patients (median OS: 104, 13.8, and 9.3 months, respectively; P<0.0001), cytogenetic risk (median OS: favourable 34.7, intermediate 19.2, and unfavourable 7.8 months; P=0.0002), FLT3-ITD vs. no FLT3-ITD (median OS: 9 vs. 22.3; P=0.004), and SCT vs. no SCT (median OS: 45.8 vs. 11.4 months; P<0.0001). No significant differences were observed between FLAGO-IDA and FLAG-IDA (median survival 11.3 vs. 18.7 months; P=0.26). Age >60 years was almost significant associated with lower OS (median 10 vs. 19, P=0.052). In multivariate analyses unfavourable karyotype, no SCT, FLT3-ITD and primary refractory/early relapse were associated with lower OS.
Summary / Conclusion: FLAG-IDA or FLAGO-IDA may induce a CR2 in an acceptable percentage of patients with relapsed/refractory AML We could identify several risk factors predicting worse OS after second-line therapy (unfavourable karyotype, FLT3-ITD, refractory disease/early relapse). Patients with favourable genetic and molecular characteristics presenting late relapse (>12 months after CR1) have a good prognosis after salvage therapy with FLAGO-IDA or FLAG-IDA, especially when CR is followed by an allo-SCT. Alternative salvage strategies to improve outcomes could be recommended in the remaining subsets.

P061

LOW- DOSE CHEMOTHERAPY AND DIFFERENTIATING AGENTS AS POST- REMISSION MAINTENANCE PROLONGED DISEASE- FREE AND OVERALL SURVIVAL IN A CASE-CONTROL RETROSPECTIVE STUDY ON POOR PROGNOSIS AML/MDS PATIENTS

D Ferrero[1,*] E Crisà[1], T Gatti[1], V Giai[1], C Aguzzi[1], F Marmont[2], E Audisio[2], S D'Ardia[2], C Frairia[1], B Bruno[1], M Festuccia[1], R Passera[3], M Boccadoro[1]
[1]Haematology, University of Turin, Torino, [2]Haematology, A.O. Città della Salute e della Scienza, torino, [3]Nuclear Medicine, A.O. Città della Salute e della Scienza, Torino, Italy

Background: Patients aged over 60 or with poor prognosis AML or MDS have an unfavourable outcome despite of the achievement of a complete response (CR) with aggressive treatments. In fact, only about 10% of these patients become long-term survivors. It is therefore evident that standard post-remission chemotherapy should be integrated by somewhat different strategies to improve the outcome of this group of patients. Indeed, some studies have already shown an advantage in relapse free survival with low dose cytarabine based maintenance treatment (Büchner *et al* 2003, Krug *et al* 2010).
Aims: To evaluate the impact of a maintenance therapy with low-dose chemotherapy plus differentiating agents on survival and remission duration in a cohort of poor prognosis AML/MDS patients in CR after standard induction chemotherapy.
Methods: We included 92 patients treated from 1997 to 2012. AML patients (82) had poor prognosis for either age over 60, and/or therapy-related AML, AML secondary to MDS, or second CR. MDS patients (10) were at intermediate 2/high risk according to the IPSS.
All patients have been in stable CR for at least 2 months after induction +/- consolidation therapy and were ineligible to allogeneic stem cell transplantation at CR achieving. Forty-two patients received a maintenance therapy and were compared to a matched historic population of 51 patients that had not received further therapy after consolidation. Maintenance treatment consisted on two alternated schedules: the first one included 6-thioguanine 40 mg daily for 3 weeks and 13-cis retinoic acid 40 mg daily + (OH)2 vitamin D3 (D3) 1 ug daily for 5 weeks; the second one contained cytarabine 8 mg/mq bis daily by subcutaneous injection for 2 weeks and all-trans retinoic acid 30 mg bis daily + D3 0,5 ug bis daily for 5 weeks. This therapy was started after a median time of 3 months from CR achievement and was continued for 4 years or until relapse.

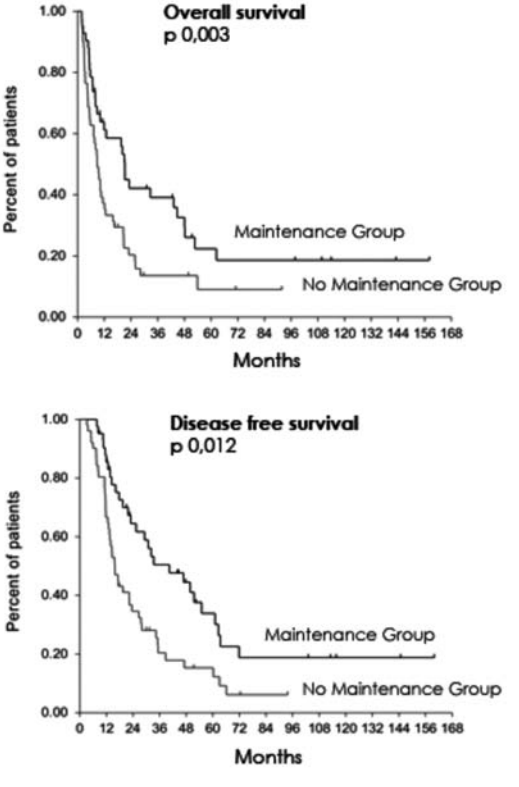

Figure 1.

Results: The two groups of patients were balanced with regard to both patient and disease characteristics, in particular median age (63 years) and prevalence of unfavourable karyotype (24% versus 28%). Relapse incidence (RI) was significantly lower in the maintenance group than in the control group: 53,6% versus 83,3% at 3 years and 67,5% versus 88,5% at 5 years, respectively (P

0,004). Disease free survival (DFS) too was better in the maintenance group with a median of 21 months (ms) vs 9 ms in the control group (P 0,012). The reduction in the relapse rate led to an overall survival (OS) advantage too, with a median OS of 40 ms and survival rates at 3 and 5 years of 51.4% and 34.5%, respectively, in the maintenance group compared to a median OS of 16 ms and 21.4% and 12.8% survival at 3 and 5 years, respectively, in the control group (P 0,003). The presence of unfavourable karyotype negatively affected OS, but in multivariate analysis maintenance therapy remained an independent outcome predictor.

Summary / Conclusion: Our maintenance therapy significantly prolonged patients survival by reducing the relapse incidence. The treatment schedule was safe and well tolerated. Therefore, our results suggest that a different strategy of post-remission therapy based on the association of differentiating agents and low dose chemotherapy might improve the outcome of poor risk AML/MDS patients. These data, however, need to be confirmed in a larger prospective study.

P062

A STUDY OF ELACYTARABINE IN RELAPSED OR REFRACTORY AML EVALUATING CARDIAC SAFETY AND PHARMACOKINETIC PROPERTIES

S Knapper[1],* T Chevassut[2], R Duarte[3], J Bergua[4], O Salamero[5], M Johansen[6], P Hals[6], S Hagen[6], T Bergeland[6], T Jacobsen[6], A Gianella-Borradori[6], P Voiriot[7], M Smith[8]

[1]University Hospital of Wales, Cardiff, [2]Royal Sussex County Hospital, Brighton, United Kingdom, [3]Department of Haematology, L'Hospitalet de Llobregat, Barcelona, [4]Hospital San Pedro de Alcántara, Cáceres, [5]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [6]Clavis Pharma, Oslo, Norway, [7]CardiaBase, Nancy, France, [8]St Bartholomews Hospital, London, United Kingdom

Background: Elacytarabine, an elaidic acid ester derivative of cytarabine, has pharmacokinetic (PK) and pharmacodynamic properties that may lead to improved clinical outcome (Adema *et al* 2011) compared to cytarabine (ara-C). Elacytarabine is metabolized to active cytosine arabinoside 5`-triphosphate (ara-CTP) and inactive ara-U. The compound has reached phase III of clinical development for the treatment of patients with relapsed or refractory acute myeloid leukaemia (AML).

Aims: The on-going study was designed to evaluate the cardiac safety and PK of elacytarabine. In addition the clinical efficacy and safety were evaluated.

Methods: Elacytarabine for infusion 7.5 mg/mL was administered at 2000 mg/m^2/day as a continuous intravenous infusion (CIV) for 120h to adult patients with relapsed or refractory AML. Blood samples for PK analyses were collected and electrocardiography (ECG) was assessed pre-treatment, during treatment and after treatment at specified time-points. The PK was characterised by compartmental as well as non-compartmental analyses. The ECG was centrally monitored. Safety and efficacy were assessed. Patients are followed for relapse and survival for at least six months.

Results: Forty-three patients [26 males, 17 females, median age 64 years (range 18-77), ECOG PS 0-1] were treated with elacytarabine. All patients had previously been treated with ara-C, and had relapsed or were refractory following previous treatment. Of these 43, 23 had blood sampled using a rich-sampling protocol for PK characterization and 30 had ECGs taken with matching blood sample collection for determination of plasma concentration of elacytarabine and its metabolites. Thirty-six patients were evaluated for response and the overall response rate was 42% with nine patients achieving a complete remission (CR) and six patients a complete remission but with incomplete blood count recovery (CRi) following study treatment. The most frequently reported non-haematological adverse events (CTCAE grade ≥3) were infections, febrile neutropenia, hyponatremia, hypokalaemia and increased alanine aminotransferase. The ECG assessments showed that 12 of 30 patients had a change in the QTcF interval from baseline to peak by >30 msec, in addition three patients had a change in the QTcF interval from baseline to peak by >60 msec. This increase seemed to be unrelated to the plasma concentrations of elacytarabine, ara-C and ara-U and there were no concomitant torsades de pointes. No patient had a peak QTcF above 500 msec. The most frequently reported cardiac adverse events was tachycardia (six patients). One patient experienced a grade 3event of; all others were grade 1 or 2. The plasma concentrations of elacytarabine and ara-C declined rapidly once the infusion was stopped. Using non-compartmental analysis, the median terminal half-life and total clearance for elacytarabine were 12.8 h and 4.6 L/h/m^2. For ara-C and ara-U the median terminal half-lives were 2.6 and 8.9 h, respectively.

Summary / Conclusion: Elacytarabine is a novel anti-leukemic agent in development for treatment of patients with advanced AML. Its efficacy, tolerability, safety and PK characteristics make it a promising single agent treatment for patients with relapsed or refractory AML. Finale results will be presented at the meeting.

P063

MULTI-LINEAGE DYSPLASIA AS ASSESSED BY IMMUNO-PHENOTYPE HAS NO IMPACT ON OUTCOME OF ACUTE MYELOID LEUKEMIA WITH MUTATED NUCLEOPHOSMIN (NPM1)

F Mannelli[1],* S Bencini[1], G Gianfaldoni[1], V Ponziani[1], I Cutini[1], B Scappini[1], F Pancani[1], C Biagiotti[1], M Bonetti[1], G Longo[1], A Bosi[1]

[1]Hematology, University of Florence, Florence, Italy

Background: World Health Organization (WHO) classification of myeloid neoplasms considers AML with multi-lineage dysplasia (MLD) as a separate subset. Morphologic assessment of residual hemopoiesis at AML diagnosis is the standard criteria for defining MLD. The prognostic value of MLD is still under debate due to technical and biologic reasons. Technical reasons include: i) residual non-blast cells are few at AML diagnosis; ii) morphology is an operator-dependant technique. Moreover, MLD-related poor prognosis is supposed to rely on neoplastic progression: MLD would imply a pre-existing myelodysplastic syndrome (MDS). On the other hand, MLD might merely be the result of pathologic differentiation/maturation by the leukemic clone. A major controversy concerns the significance of MLD in NPM1-mutated (NPM1+) AML. This issue has major implications since NPM1+ status correlates with a relatively good prognosis (especially when FLT3-wt). Falini *et al* (Blood 2010) showed that morphologic MLD has no impact on biologic and prognostic features of NPM1+ AML.

Aims: To investigate the prognostic significance of MLD in NPM1+ AML by a technique alternative to morphology. Flow cytometry (FC) is emerging as a useful method to study dysplasia, mainly by investigating the expression of key antigens along with maturation. The application of FC to maturing cell compartments at AML diagnosis can provide some advantages compared to morphology: i) the amount of studied cells is much larger; ii) phenotypic parameters can be quantified and referred to controls and thus reliably standardized.

Methods: Patients: 70 pts with NPM1+ AML were included and characterized according to standard criteria (morphology, karyotype, molecular genetics). Flow cytometry: FACSCanto II (BD) and Infinicyt software (Cytognos) were used for data acquisition and analysis, respectively. Some major bone marrow compartments (blast cells; maturing granulocytic, monocytic and erythroid compartments) were identified on the basis of light scatter and reactivity for CD45 and CD34. We adapted to AML an approach previously described for MDS (Matarraz *et al*, Leukemia 2008): MLD was appraised through an immuno-phenotypic score (IPS) including 18 parameters (14 for granulocytic and 4 for erythroid lines).

Results: MLD was analyzed in 70 intensively treated NPM1+ AML cases. Median age was 57 (24-70). Median white blood count (WBC) was 48.0 x 10^9/L (1.2-260.0). Karyotype was normal in 62 (88.6%) pts. FLT3-ITD occurred in 27 pts (38.6%). MLD was assessable by morphology in 66 cases; according to WHO criteria, 24 (36.4%) showed MLD. IPS was calculated in all 70 pts. Median IPS value was 6.25 (range 0.5-18.5). Pts were categorised according to IPS higher (IPS+) or lower-equal (IPS-) than the median. Age, WBC and incidence of morphologic MLD were not different in IPS groups. IPS+ group showed lower incidence of FLT3-ITD (25.7% vs 51.4%; P=0.048); interestingly, Falini *et al* (Blood 2010) have reported analogue results with morphologic analysis. CR rate was not different in IPS- (82.9%) and IPS+ (74.3%; P=0.56) groups. IPS did not affect disease-free survival and overall survival, as displayed in Figure 1 A-B. FLT3 status confirmed its prognostic value in our cohort (Figure 1 C-D).

Summary / Conclusion: This study provides evidence that MLD, as assessed by flow cytometry, does not influence clinical characteristics and outcome of NPM1+ AML. These findings further support NPM1+ AML to be considered as a separate entity and its prognostic assessment should not be based upon MLD.

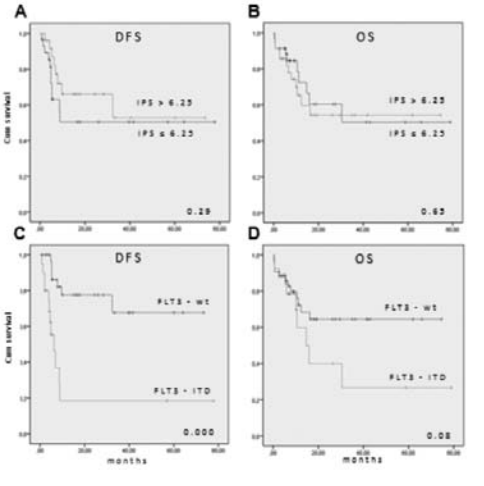

Figure 1.

P064

COMPREHENSIVE GENE MUTATION ANALYSES IN ACUTE MYELOID LEUKEMIA: OVERLAP OF THE GENE MUTATIONS ARE IMPORTANT FOR THE PROGNOSIS OF THE INTERMEDIATE RISK KARYOTYPE GROUP

S Wakita[1,*] H Yamaguchi[1], T Ryotokuji[1], T Hirakawa[1], I Omori[1], T Kitano[1], K Arai[1], F Kosaka[1], K Dan[1], K Inokuchi[1]
[1]Division of Hematology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background: Molecular abnormalities in acute myeloid leukemia (AML) have been revealed to be important.
Aims: To clarify their importance, we analyzed *de novo* AML patients with the intermediate risk karyotype for molecular abnormalities in *C/EBPα, NPM1, MLL-PTD, FLT3, N/K-RAS, DNMT3a, IDH1/2* and *TET2* genes.
Methods: We analyzed samples from 142 AML patients with the intermediate risk karyotype diagnosed at Nippon Medical School Hospital from 2000 to 2012. Bone marrow or peripheral blood samples containing 20% or more blast cells were used for analyses. Mutation analyses were performed using PCR amplification for *FLT3*-ITD and *MLL*-PTD, and direct sequence for *NPM1*, *C/EBPα*, *DNMT3a*, *IDH1/2*, *TET2 and N/K-RAS*.
Results: The *NPM1, DNMT3a, FLT3*-ITD*, IDH1/2, TET2, C/EBPα, N/K-RAS* and *MLL*-PTD mutations were detected in 40.1%, 26.8%, 24.6%, 18.3%, 17.6%, 14.8%, 13.4% and 6.3% of our cohort, respectively. Many gene mutations were found to be overlapped, but mutations of *TET2* and *IDH1/2*, *FLT3*-ITD and *N/K-RAS* mutation were mutually exclusive. When we performed prognostic analyses for mutations of these genes, *DNMT3* mutation and *FLT3*-ITD were isolated as a poor prognostic factor in overall survival (OS) as previously reported (*DNMT3a* mutation: P=0.0056) (*FLT3*-ITD: P=0.0077). Moreover, in the *FLT3*-ITD positive cases, OS of patients with *DNMT3a* R882 mutation was significantly shorter than those without R882 mutation (P=0.0256). On the other hand, *NPM1* and *C/EBPα* mutation known as a favorable prognostic factor in the *FLT3*-ITD negative cases did not affect the prognosis. Patients with *DNMT3a, FLT3*-ITD*, NPM1, IDH1/2, TET2* and *C/EBPα*, mutations frequently had overlapping gene mutations in 92.1%, 82.9%, 77.2%, 76.9%, 72.0% and 38.1%, respectively. Furthermore, the prognosis of these AML patients could be classified by the number of overlapping mutations of these genes except no mutation group (Figure 1, P<0.0001), and their prognostic importance was also shown after excluding *FLT3*-ITD positive cases (P=0.0034). Additionally, in patients with multiple gene mutations, *DNMT3a* mutations, especially of R882 mutations, were found highly frequently (*DNMT3a*: P<0.0001) (*DNMT3a* R882: P<0.0001).
Summary / Conclusion: Our study revealed that the gene mutations appeared to be overlapped, and the number of these gene mutations significantly affected the prognosis. Intriguingly the *DNMT3a* mutation may contribute to an occurrence of other gene mutation by giving genetic instability to acute myeloid leukemia cells.

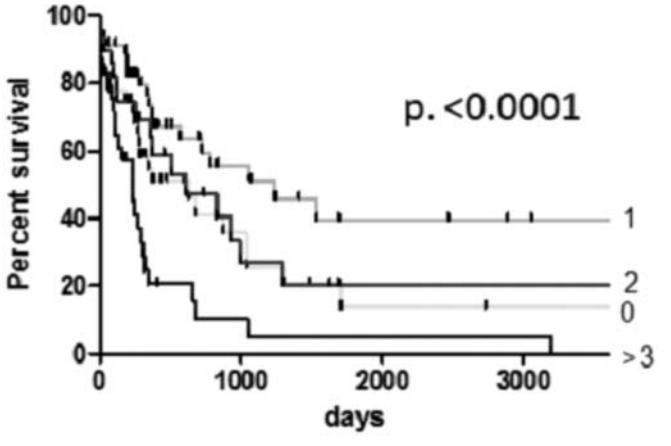

Figure 1.

P065

MEDIUM-SIZED FLT3 INTERNAL TANDEM DUPLICATIONS CONFER WORSE PROGNOSIS, THAN SHORT AND LONG DUPLICATIONS

M Koszarska[1,*] B Andras[1], N Papp[2], D Czifra[2], O Csacsovszki[2], A Batai[2], E Adam[2], A Kozma[2], N Lovas[2], A Sipos[2], J Dolgos[2], S Fekete[2], P Remenyi[2], T Masszi[2], A Tordai[2], H Andrikovics[2]
[1]Hungarian National Blood Transfusion Cervice, [2]Department of Hematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, Budapest, Hungary

Background: The internal tandem duplication (ITD) of the fms-like tyrosine kinase 3 (FLT3) gene occurs in about 25% of adult acute myeloid leukemia (AML) patients. Several previous studies attempted to characterize the impact of the size and the load of FLT3-ITD. While high mutant-to-wild type ratio was repeatedly shown to be associated with adverse prognosis, different conclusions emerged about how the length of the duplication may influence the outcome.
Aims: To investigate the frequency of FLT3-ITD mutations and the possible correlation between FLT3-ITD insertion size and clinical associations and prognosis in AML patients.
Methods: 388 AML patients (184 males/204 females; median age: 51; range: 16-93 years) diagnosed and followed between 2001-2009 were enrolled in the study. Remission and relapse rates and survival were analyzed for 324 patients younger than 60 years and treated with curative intention. FLT3-ITD mutations were studied using PCR followed by capillary electrophoresis.
Results: FLT3-ITD mutations were detected in 82/388 (21.1%) cases. The presence of ITD was related to *de novo* AML etiology (P<0.001). It associated more frequently with M5 [34% (25/74) ITD+ vs. 15% (40/273) ITD-; P=0.0004]. ITD+ patients presented with significantly higher WBC counts and LDH at diagnosis (both P<0.001). ITD+ associated with intermediate risk cytogenetics [86% (65/76) ITD+ vs. 50% (147/292) ITD-; P<0.001] and NPM1 mutation [59% (47/80) ITD+ vs. 16% (50/304) ITD-; P<0.001]. In our entire patient cohort, ITD+ itself did not associate with adverse prognosis, only relapse rate seemed to be increased [65% (33/51) in ITD+ vs. 51% (88/174) ITD-; P=0.08]. The FLT3 ITD- and NPM+ subgroup showed better overall and disease free survival (OS and DFS) in the intermediate and normal karyotype subgroups. In contrast, FLT3-ITD mutants with insertion length shorter or longer than 48bp, showed similar clinical characteristics at diagnosis, but profoundly different treatment outcome in the entire AML group. Longer ITDs were associated with higher early death ratio [17% (5/30) ITD>48bp vs. 0% (0/38) ITD<48bp; P=0.01]; a tendency toward higher relapse rate [84% (16/19) ITD>48bp vs. 55% (17/31) ITD<48bp; P=0.06]; resulting in worse OS (P=0.02) and DFS (P=0.005). Patients with ITD>48bp had worse OS and DFS compared to ITD negative patients (n=255; P=0.04; P=0.013 respectively). Interestingly individuals with longer than 60bp insertions (ITD>60bp; n=15) showed better OS and DFS compared to patients with insertion between 48 and 60bp (ITD48-60bp; n=15, P=0.014; P=0.019 respectively). Median survival at 24 months was 0% in ITD48-60bp, 40±3% in ITD negative, 45±8% in ITD<48bp and 33%±12% in ITD>60bp AML groups.
Summary / Conclusion: Our results suggest that the length of ITD mutations may influence disease outcome, in a way that medium-sized FLT3 ITDs (48-60 bp) may confer worse prognosis than shorter or longer mutations. As a possible explanation, ITD was reported to lead to the constitutive activation of the kinase domain by disrupting the autoinhibitory interaction between the juxtamembrane domain and activation loop. In line with this hypothesis, longer ITDs could lead to more profound destabilization of the inactive kinase. On the other hand, longer ITDs were reported to be inserted more C-terminally in the FLT3 protein, which may cause increased interference with the kinase activity, leading to a reduced transforming capacity.

P066

CHARACTERIZATION OF FLT3 AND NPM1 MUTATIONS IN 17,783 AML PATIENTS

N Adams[1,*] T Fodrie[2], F Neff[1], A Cubbon[1,2]
[1]LABPMM GMBH, Martinsried, Germany, [2]LabPMM LLC, San Diego, United States

Background: A recent series of publications confirms that *FLT3* internal tandem duplications (ITD) mutations are driver mutations for acute myeloid leukemia (e.g., Smith *et al.*, *Nature*. 2012. 485:260-3). From 2008 through February 2013 our laboratories assayed bone marrow specimens and peripheral blood 17,783 AML patients to identify and characterize ITD, *FLT3* tyrosine kinase domain (TKD) and *NPM1* mutations.
Aims: A systematic review of the data derived from testing 17,783 patient samples for ITD, TKD, and 2743 patients for *NPM1* mutations.
Methods: The ITD and TKD containing regions of the *FLT3* gene, and exon 12 of *NPM1* gene were amplified using PCR. The size of the ITD and *NPM1* amplicon products were determined by capillary electrophoresis. The TKD amplicon product was first digested with the EcoRV restriction enzyme and presence of the mutation was determined by capillary electrophoresis. We determined the rates of mutation for age/gender groups, and probed the dataset for trends for co-incident evidence of mutations. Patients older than 100 were allocated to the 90-100 years age group. The mutations in ITD positive patients (n=3,240) were assessed and characterized by ITD insertion size, number of insertions and the presence of a concurrent TKD or *NPM1* exon 12 mutation.
Results: For all mutations, the highest mutation rates were found in samples in the middle age range and were lower in younger and older patients (e.g. 10-20 years ITD 19.4%, TKD 4.1%, *NPM1* 22.1%; cf 30-40 years ITD 21.9%, TKD 7.6%, *NPM1* 22.1%; cf 80-90 years ITD 12.7%, TKD 4.5%, *NPM1* 5.1%). The positive rate in females was higher compared to male subjects (14% higher for all ages, but 48% higher in the 50-60 years age group). For all patients who tested positive for an ITD mutation, there is an increased chance that they will test positive for the TKD mutation. In the 20-50 years age group, this rate is 15%;

between 80-90 years the co-mutation rate is 55% increased in a TKD positive result compared to the chances of being positive over all. Similar trends are seen when comparing other combinations. ITD insertions varied from 3bp to 382bp with over 50% of insertions less that 57bp. Approximately 9% harbour the TKD mutation and >29% contained more than one ITD insertion. Of patients (n=304) also tested for NPM1 48% had a detectable exon 12 mutation. Although the majority of AML patients harbouring ITD mutations have a single mutation and an ITD that is <57bp, more than 9% of patients had ITD mutations that were more than 100bp in size.
Summary / Conclusion: The rate of *FLT3* ITD and TKD mutations seen in this patient population (22.5%, n=17783) is similar to the 23% (n~53000) reported by the Wellcome Trust Sanger COSMIC DB (www.sanger.ac.uk/genetics/CGP/cosmic/) for all mutations in *FLT3*. Forty eight percent of FLT3 ITD positive patients also had a NPM1 mutation.

P067

THERAPY-RELATED MYELOID NEOPLASMS: REPORT OF THE ITALIAN NETWORK ON SECONDARY LEUKEMIAS

Camillo, Roma, [21]Hematology Division, Ospedale Niguarda, Milano, Italy

Background: In 2001, the World Health Organization (WHO) recognized therapy-related myeloid neoplasms (t-MN) as a distinct entity including acute myeloid leukemia (AML) and myelodisplastic syndromes (MDS). At present, about 10% of all AML patients have a previous history of exposure to chemotherapy and/or radiation for a primary malignancy or autoimmune disease.
Aims: In 2009, we initiated through a Web-database an epidemiological registry, with the purpose of collecting t-MN observed at Italian Hematological or Oncological Divisions. Demographic and clinical information on individuals with t-MN were included in the database whose access was restricted to selected users and was password-protected.
Methods: Between May 2009 and December 2012 a total of 275 patients observed at 21 Italian Centers [119 males and 154 females; median age 64 years (range 24-88 years)] with secondary leukemia were registered in the web-database. Patients were diagnosed with a t-MN between 1999 and 2012, with 246 cases arising after chemo or radiotherapy for a primary malignancy or immunosuppressive therapy for an autoimmune disease, while in 29 cases leukemia represented a second cancer in patients treated for a primary malignancy with surgery alone.
Results: The primary malignancy (PM) was a hematological neoplasm in 115 cases (42%), a solid tumor in 152 cases (55%), an autoimmune disease in 8 patients (3%). Thirteen patients (5%) had a history of two or more previous cancers. Among hematological malignancies, the most frequent PM were lymphoproliferative diseases (83/115 cases), while breast cancer (62/152 cases) was the most frequent primary solid tumor. In particular, hematological PM were: 83 lymphoprolipherative diseases (62 Non Hodgkin and 17 Hodgkin lymphoma, 4 chronic lymphocytic leukemia); 12 Multiple myeloma; 1 Acute lymphoblastic leukemia; 4 Acute myeloid leukemia (acute promielocytic leukemia in 2 cases). There were also 15 patients with a previous history of myeloproliferative neoplasms (10 Myelofibrosis; 3 polycitemia vera; 2 essential thrombocythemia). Sites of primary solid tumors were: 62 Breast; 37 Urogenital (17 prostate; 7 bladder; 1 kidney; 7 uterus; 5 ovarium) ; 17 Colon-rectal; 11 Lung; 7 Thyroid; 6 CNS; PM were localized at sites uncommon for t-MN in 11 patients (1 stomach, 4 skin, 4 oropharynx; 2 sarcoma); 1 unknown. Eigth patients had previously received immunosuppressive therapy for a rheumatologic disease (5 with mitoxantrone and 3 with methotrexate). Two-hundred-eight patients had previously received chemotherapy for their primary malignancy, associated to radiotherapy in 79 cases. RT represented the only primary treatment in 38 cases. Median latency between PM and t-MN was 6.6 years (range 0.2-48). No differences were observed in age of patients (P=0.09) or in the median latency (P=0.20) between t-MN after lymphoprolipherative diseases or after breast cancer. According to morphology, t-MN were classified as 172 AML, 97 MDS and 6 ALL. Kariotype was available for 188 patients only and was unfavorable in 65 patients (complex in 51 patients including del(7) in 36 cases; 14 cases with isolated del(7)]. A recurrent chromosomal translocation was present in 12 patients only [3 t(8;21), 8 t(15;17) and 1 inv(16)]. One-hundred-forty-eight patients received chemotherapy for t-MN, while the hypomethylating drug Azacitidine was administered to 54 patients. Fifty-four patients underwent bone marrow transplantation (39 allogeneic and 15 autologous). Median OS from the t-MN diagnosis was 9.4 months (range 0.2-128+).
Summary / Conclusion: The incidence of t-MN is rising as a result of the increasing number of cancer survivors. Lymphoprolipherative diseases and breast cancer result as the most common primary malignancies at risk of developing this disorder.

P068

AZACITIDINE FOR RELAPSE TREATMENT IN MYELOID MALIGNANCIES FOLLOWING ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

B Tessoulin[1,*] P Chevallier[1], S LeGouill[1], P Moreau[1], P Peterlin[1], A LeBourgeois[1], M Mohty[2], T Guillaume[1]
[1]Clinic of Hematology, University Hospital, Nantes, [2]Clinic of Hematology, University Hospital-Saint Antoine, Paris, France

Background: Relapse after allo-HSCT for acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) remains the main cause of treatment failure and is associated with poor prognosis and short survival. Pharmacological immune-modulatio, chemotherapy with or without DLI(Donor Lymphocyte Infusion) or second allo-HSCT are classically used as slavage therapy, but usually yield disappointing results with a relatively high toxicity, highlighting the need for novel salvage therapies in this situation.
Aims: We aimed to assert the safety and efficacy of the hypomethylating agent 5-Aza with a standard dosing (75 mg/m^2/d for 7 days) as a salvage regimen at relapse after Allo-SCT for myeloid malignancy, associated or not with DLI.
Methods: Between Sept. 2006 and Sept. 2012, thirty-one pts (median age, 57 y (range, 14-69) with *de novo* AML, n=13; secondary AML, n=6; MDS, n=11; MPN, n=1, were treated in our institution with AZA for relapse occurring at a median of 3.7 months (range, 1.7-37.6) after allo-HSCT.
Results: AZA was given SC at 75 mg/m^2/d for 7 days per cylce. Grade III-IV toxicities were observed in 32% of cases. AZA had to be discontinued due to toxicity in 8 pts. 35% of the pts had to be readmitted to hospital due to complications of AZA. No *de novo* GVHD was reported during AZA therapy. Eleven pts achieved a response: 7 partial responses, 4 complete responses, with a median time to best response of 92 d (range, 35-247). The median overall survival (OS) time from treatment with AZA for the whole group was 153 days (range, 39-928) without any difference in survival between patients receiving or not subsequent DLI or other additional treatments. In univariate analysis, achieving a response to 5-Aza improved the OS (308d vs 108d) whereas having a monosomic or complex caryotype impaired the OS (118 vs 188, 105 vs 198, respectively), there was no interaction between rate of response to 5-aza and caryotype characteristics, except for a trend between having a complex caryotype and non-response to 5-Aza (OR=0,16 [P=0,11]). With multivariate analysis, only the response to 5-Aza and the monosomic caryotype did still have a significant level to impact the OS. Of note, the DLI had no significative benefit, even for people obtaining a response (31months with DLI vs 13m without) in our small cohort.
Summary / Conclusion: These findings suggest that AZA might be a potentially effective strategy for relapse of high risk myeloid malignancies post allo-HSCT, without unexpected toxicities or *de novo* GVHD. Prospective studies, but also preemptive strategies using AZA are needed in such high risk diseases.

MONITORING MINIMAL RESIDUAL DISEASE IN NPM-1 MUTATED ACUTE MYELOID LEUKEMIA. PRELIMINARY RESULTS AT A SINGLE INSTITUTION

C Pagani[1,*] E Borlenghi[1], E Cerqui[1], G Ruggeri[2], F Antoniazzi[1], F Schieppati[1], C Lamorgese[1], C Cattaneo[1], M Chiarini[3], G Rossi[1]
[1]UO EMATOLOGIA, [2]III Laboratorio, [3]Laboratorio Biotecnologie, Spedali Civili, Brescia, Italy

Background: The measure of minimal residual disease (MRD) can be a reliable prognostic tool in patients (pts) with acute myeloid leukemia (AML), even in those with better prognosis because of NPM-1 mutation.
Aims: To identify pts at higher risk of relapse westudied MRD by real-time quantitative PCR of NPM-1 (Gorello, 2006) at different time points, compared with WT-1 expression quantification (Cilloni, JCO 2009) and with identification of aberrant leukemia-associatedimmunophenothypes (LAIPs) by six-color multiparametric flow cytometry (MFC).
Methods: From June 2010 to January 2013, we observed 31 *de novo*, consecutive NPM-1 mutated pts (1 B-type, 30 A-type) [M/F 15/16; median age 60y (range 30-75y)], treated according to GIMEMA AML17 and NILG AML00 protocols. At diagnosis, 26/31(83.8%) had normal karyotype and 5 had chromosomal abnormalities; FLT3-ITD was detected in 10/30 (33,3%) cases. Peripheral blood (PB) and bone marrow (BM) samples were collected at diagnosis, after induction, consolidation and at the end of therapy. The cut-off value used for MFC detection of MRD was 0.1% after induction (Al-Mawali, 2009) and 0.035% after consolidation (Buccisano, 2010).
Results: Complete remission (CR) was achieved in all pts after one course of chemotherapy (ICE or MICE or FLAG). Relapse occurred in 6 (19.3%) at a median of 12 months (range 6-17) from the achievement CR and 1,5 months (range 1-7) from the end of therapy. Median follow-up was 12 months (1-41). MRD data at different time points were evaluated as predictors of relapse risk. There weren't differences in the pretreatment parameters of CCR vs relapsed pts, particularly median age (60 vs 63 y), FLT3-ITD mutation (36% vs 20%) and chromosomal aberrations (19% vs 20%), respectively. The median level of NPM-1/ABL x 10^4 was significantly lower in CCR then in the relapsed pts [50054 (range 380-97280) vs 96175 (range 843-132390), (P 0.039 Student's T test)]. At CR achievement and after consolidation, the negativity of NPM-1, considering all the series, was achieved in 4/29 (13,8%) and in 10/27 (37%) respectively, without difference between the 2 groups of pts. The decrease of NPM-1 level compared to pretreatment levels was greater in CCR then in relapsed pts (40,6% vs 20%>P 0.3 Fisher's test). At the end of therapy NPM-1 was undetectable in 11/19 pts (57,9%), with significant difference between CCR and relapsed pts (11/13 vs 0/6: p0.001 Fisher's exact test). The WT-1 was overexpressed in PB and in BM in all pts, without differences between PB vs BM and CCR vs relapsed pts. Significantly more pts who obtained the WT-1 normalization levels (<213/abl x10^4) in BM after CR did not relpase(P 0,009-Fisher's test). LAIPs were identified in 21/25 (84%) at diagnosis; 9/19 (47.3%) and 4/18 (22,2%) had MRD negative in MFC in the post induction and after consolidation, respectively, without differences in 2 groups. The overall survival between 2 groups was significantly different (P 0.017).
Summary / Conclusion: In AML patients with NPM-1 mutation, only NPM median levels among pretreatment parameters including FLT3-ITD status, age and additional chromosomal aberrations, significantly influenced prognosis. Achieving WT-1 negativity post induction and, more strongly, NPM-1's negativity at the end of therapy, as reported also by Kronke (JCO, 2011), significantly predicted continuous CR. The role of NPM-1 clearance during treatment and of LAIPs MRD levels need further studies.

P070

THE PROGNOSTIC IMPACT OF ADDITIONAL KARYOTYPIC ABNORMALITIES IN T(8;21) ACUTE MYELOID LEUKEMIA

L Zhentang[1,*] H Fung[1], N Hin[2], L Zi Yi[2], C Xin[1], C Charles[1], H Aloysius[1]
[1]Haematology, Singapore General Hospital, [2]Haematology-Oncology, National University Cancer Institute, Singapore, Singapore

Background: Acute myeloid leukemia (AML) with translocation (8;21)(q22;q22) is associated with a favourable prognosis with standard treatment for AML with an overall survival of 50-60% based on large databases. However, significant heterogeneity appears to exist amongst the patients diagnosed with t(8;21) AML, with some patients experiencing early relapse and subsequently refractory disease. In addition, a few Asian studies also showed that t(8;21) was not found to be associated with a better survival compared with normal risk AML, suggesting that unidentified genetic polymorphism might be at play.
Aims: We aim to perform a retrospective analysis of patients with t(8;21) AML from registry databases in the National University Hospital (NUH) and the Singapore General Hospital (SGH) looking at prognostic factors that may influence outcomes of these patients.
Methods: Patients diagnosed with t(8;21) AML identified from the registry were included in the review. Those who did not receive induction chemotherapy were excluded. Univariate survival and outcomes data were analysed according to demographic and cytogenetic subgroups using the Kaplan Meier method. Multivariate analysis of the different subgroups was performed using cox-regression.
Results: 61 patients were available for analysis. The median age was 38 years old (interquartile range (IQR): 25-51 years), 31.1% of patients were younger than the age of 30. 47.5% of the patients were female. The median total white count was 11.65x10^9/L (IQR: 5.75-25.68) and median bone marrow blast was 60% (IQR: 40-77%).
5 patients were excluded from analysis of overall survival and progression survival as they did not receive intensive chemotherapy with curative intent. The median follow up time was 81.3 months (range: 1.4 to 178 months). 3 patients (5.4%) of the patients did not attain a complete remission after induction and required a second induction. Overall survival at 8 years was 61.9% and relapse free survival was 50.6% Most of the patients relapsed within 15 months after initiation of induction treatment. In univariate analysis, the age of > 30, > 1 additional structural cytogenetic abnormality and the presence of additional chromosomal abnormalities other than sex chromosome or 9q deletion appears to be associated with a worse overall survival. In particular, t(8;21) AML associated with additional chromosomal abnormalities other than sex chromosome or 9q deletion is associated with only 22.7% 8 year survival compared with 82.2% 8 year survival in those with an additional sex chromosome or 9q deletion (P=0.001). This remained significant after multivariate analysis, HR 4.14 (95% CI: 1.02-16.95). C-Kit mutation analysis was performed on 42(68%) patients, D816 mutation was found in 8 (19%) of the patients. The presence of D816 mutation showed a trend towards worse relapse free survival (P=0.059) but not overall survival (P=0.32).
Summary / Conclusion: There is significant heterogeneity amongst the t(8;21) AML cohort, those with complex cytogenetics or additional chromosomal abnormalities other than sex chromosome or 9q deletion appear to be associated with a worse prognosis. Further analysis using whole exome sequencing is underway to further identify partner mutations that may affect the prognosis of this cohort of patients.

P071

BAALC GENE EXPRESSION REDUCTION DURING INDUCTION PREDICTS OUTCOME IN ACUTE MYELOID LEUKEMIA

V Ponziani[1,*] F Mannelli[1], G Gianfaldoni[1], B Scappini[1], I Cutini[1], G Longo[1], C Biagiotti[1], F Pancani[1], M Bonetti[1], S Bencini[1], A Bosi[1]
[1]Hematology, Careggi Hospital, Florence, Italy

Background: Age, cytogenetics and secondary *versus de novo* disease are the most important factors predicting CR in AML patients. These factors provide a pre-treatment stratification in risk groups with different probabilities to obtain CR but they are not sufficient to predict the individual response to induction treatment that is variable. Moreover, to collect the necessary information in time to allow stratification at diagnosis is not generally possible. Recently, a variety of novel molecular markers have refined the risk stratification of intermediate-risk AML; in addition altered genes expression have been proposed as important prognostic marker. BAALC (Brain And Acute Leukemia, Cytoplasmic) is a gene located on chromosome 8q22.3, it encodes a protein with unknown function. BAALC expression was found mainly in CD34+ cells but is restricted to the compartment of progenitor cells, while no expression was detected in mature bone marrow or circulating white blood cells. High BAALC expression levels were shown to be associated with treatment outcome in AML.
Aims: In our previous studies we displayed that early peripheral blast clearance (PBC), as assessed by flow cytometry and by WT1 copy reduction, well correlates with first course response and CR attainment in AML. We investigated whether assessment of BAALC transcript levels in peripheral blood the first days during standard induction therapy could provide information on the chemosensitivity of leukemic blasts and predict for clinically relevant end points.
Methods: We explored the kinetics of BAALC transcript to estimate PBC in peripheral blood samples collected on day 1 (immediately before starting therapy) and on day 5 (the fifth day after start of treatment, immediately before cytarabine infusion) in 57 adult patients with AML. Written informed consent was obtained in accordance with the Declaration of Helsinki. Quantification of BAALC gene expression was carried out by real time quantitative PCR using BAALC ProfileQuant Kit from Ipsogen. We calculated BAALC ratio as the ratio of copy number measured on day 1 and on day 5. We used median BAALC ratio as the cut-off to divide the patients into two groups.
Results: Main characteristics of 57 examined patients were: median age 48 years (18-65), median WBC count/microL 13400 (1240-286000), low intermediate and high cytogenetic risk group patients number was7, 32, 15 respectively, FLT-3-ITD occurred in 14 patients (24%). The median BAALC ratio in overall cohort was 5.82 (range 0.83-373.11). The median BAALC ratio was greater in patients attaining CR as compared to non responders (10.7 vs 2.04; P=0.0006). Of 29 patients with a BAALC ratio >5.82, 24 (82%) achieved CR compared to 11 of 28 patients (41.4%) with a ratio ≤5.82 (P=0.002). We found that among the 35 patients attaining CR after the "3+7" course, the DFS (Figure 1A) and OS (Figure 1B) were significantly longer in those patients displaying a BAALC ratio >5.82 compared to patients with a BAALC ratio ≤5.82 (P=0.024 and P<0.001, respectively).
Summary / Conclusion: These data confirmed that PBC assessment by

BAALC kinetics is an early predictor of disease outcome and it allows accurate stratification of patients since the very first days of therapy; as such, it entails potential implications for the management of AML, specifically in order to customize treatment since the outset.

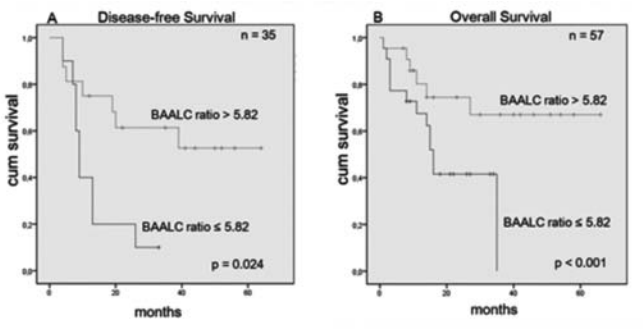

Figure 1.

P072

MIDOSTAURIN (MIDO) DEMONSTRATES A FAVORABLE SAFETY PROFILE IN OLDER PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML) OR MYELODYSPLASTIC SYNDROME (MDS)

T Fischer[1,*] H Kantarjian[2], E Feldman[3], G Ehninger[4], P Larson[5], M Khan[5], J Virkus[5], R Stone[6]
[1]Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany, [2]The University of Texas MD Anderson Cancer Center, Houston, [3]Weill Cornell Medical College, New York, United States, [4]Technische Universität, Dresden, Germany, [5]Novartis Pharmaceuticals Corporation, East Hanover, [6]Dana-Farber Cancer Institute, Boston, United States

Background: The majority of pts with AML are aged ≥ 60 years (y) and have therapeutic challenges related to host factors (such as age or comorbidities) and to intrinsic resistance to available therapies. Fms-like tyrosine kinase receptor 3 internal tandem duplications (FLT3-ITD) are observed in 25-30% of older pts with AML and correlate with poor prognosis. The multitargeted FLT3 tyrosine kinase inhibitor (TKI) mido (PKC412) has demonstrated activity and tolerable safety as a single agent in pts with systemic mastocytosis (Gotlib *et al. Blood*. 2012) as well as in a phase 2 study in AML or high-risk MDS (Fischer *et al. J Clin Oncol*. 2010). The current subset analysis represents full safety data from the latter study to better define the safety of mido in older (60-74 y and ≥ 75 y) pts with AML or MDS.
Methods: Pts with relapsed/refractory (r/r) AML or *de novo* AML not on standard chemotherapy (n=85) or MDS (n=10) were included. Pts received mido 50 mg (n=51) or 100 mg (n=44) twice daily (BID) in 28-d cycles. All pts received at least 1 dose of study drug and were evaluable for safety.

Table 1. Most frequent studydrug related-AEs (≥10% of pts unless otherwise indicated).

	All Pts ≥ 60 y, n (%) (N = 80)		Group A: Pts 60-74 y, n (%) (n = 58)		Group B: Pts ≥ 75 y, n (%) (n = 22)		Group C: Pts < 60 y, n (%) (n = 15)

[a] Occurring in ≥ 5% of pts.
[b] Includes the terms "abdominal pain" and "abdominal pain upper."
ALT, alanine aminotransferase; AST, aspartate aminotransferase.

Results: Of 95 enrolled pts, 58 were aged 60-74 y (Group A; median 67 y) and 22 were ≥75 y (Group B; median 77 y). Fifteen pts were aged <60 y (Group C). More pts in Group A vs Group B had r/r disease at baseline (48% vs 14%, respectively). Pts aged 60-74 y were also more likely to have AML than MDS (91% vs 82% with AML in Group A and B, respectively), a recurrence within 3 mo of study entry (40% vs 9%), and poorer performance status (WHO ≥2: 12% vs 5%). The median duration of exposure to mido was shorter in Group A vs B (44 d [range, 1-332] vs 62 d [range, 12-187]). All pts experienced at least 1 adverse event (AE). The first onset of most AEs occurred by cycle 2. Pyrexia was the only AE with first onset occurring during or after cycle 3 in ≥ 10% of pts (n=9, 11%). Study drug–related AEs were experienced by 70% of pts (69% and 73% of pts in Group A and B, respectively) and were mainly grade 1/2, with gastrointestinal (GI) toxicity occurring most frequently (Table 1). Rates of drug-related AEs of any grade were slightly higher in pts aged 60-74 y than in pts ≥ 75 y, with the exception of thrombocytopenia, nausea, diarrhea, and anorexia. Drug-related grade 3/4 AEs were less frequent in pts aged 60-74 y (17% vs 36% in Group A vs B) and most commonly included hematologic AEs and laboratory abnormalities. No drug–related grade 4 GI AEs were reported. Drug-related AEs (any-grade and grade 3/4) were more frequent with 100 mg BID vs 50 mg BID in pts aged ≥75 y, but this dose effect was not observed in pts 60-74 y. Serious AEs occurred in 58 pts (73%; 42 and 16 pts in Groups A and B, respectively) and most commonly included febrile neutropenia (n=18), pneumonia (n=18), and pyrexia (n=12). Twelve (21%) and 4 (18%) pts in Groups A and B, respectively, discontinued study treatment due to AEs, most commonly due to infections or respiratory, thoracic, and mediastinal disorders. Of the 27 pts who died on study, more deaths occurred in pts aged 60-74 y (36% and 27% of pts in Groups A and B), a higher proportion of whom had r/r disease.
Summary / Conclusion: Overall, AEs occurring on mido monotherapy were less frequent in pts aged 60-74 y than in the small group of pts ≥ 75 y. The most common AEs were low-grade GI events that resolved with dose modification or interruption. There were only slight differences in the rates of GI AEs (nausea, diarrhea) between pts aged 60-74 and ≥ 75 y, and fewer AEs, including GI AEs, were observed in pts aged ≥ 60 than pts < 60 y.

P073

HAEMOSTATIC PARAMETERS AS PROGNOSTIC FACTORS IN ACUTE MYELOID LEUKEMIA

I Djunic[1,*] N Suvajdzic-Vukovic[1,2], M Virijevic[1], A Novkovic[3], M Mitrovic[1], N Colovic[1,2], A Vidovic[1,2], D Tomin[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Clinical Hospital Center Zemun, Belgrade, Serbia

Background: Haemostatic abnormalities are apparent at presentation in a subset of patients with nonpromyelocytic acute myeloid leukemia (AML). Recent studies indicated that a high level of fibrinogen at presentation is correlated with a poor outcome for patients with AML (Lancet. 2010;376(9757):2000-8; ASH abstract 2011: No 3593).
Aims: The aim of this study was to determine the role of haemostatic parameters as prognostic factors for overall survival (OS), complete remission (CR) rate, disease-free survival (DFS) and early death (ED) in patients with AML.
Methods: This single-center study involved 302 adult patients with nonpromyelocytic *de novo* AML during follow-up of 48 months. At presentation of disease the following haemostatic parameters were evaluated at diagnosis as risk factors for OS, CR, DFS and ED: fibrinogen level > 4 g/L, prothrombin time (PT) <60%, activated partial prothrombin time (aPTT) > 35s, D-dimer level >250 ng/mL and International Society for Thrombosis and Haemostasis Scoring System for disseminated intravascular coagulation (ISTH DIC score) ≥ 5. Patients were treated according to Medical Research Council (MRC) 12 protocol, with 50% reduction of the anthracycline dose for subjects aged > 60 years. Patients aged >75 years received hydroxyurea per os. Risk factors were identified using univariate and multivariate analysis.
Results: The mean patients' age was 57 years (range 19-79 years). Multivariate logistic regression analysis indicated that a high fibrinogen level was the most significant factor for poor OS (P<0.001, relative risk (RR) = 2.168; 95% CI 1.574-2.986). In addition, multivariate analysis identified a high fibrinogen level as the most significant factor for both - lower CR rate (P=0.001, RR = 0.378; 95% CI 0.203-0.706) and shorter DFS (P=0.016, RR = 1.971; 95 % CI 1.135-3.423). In contrast, multivariate analysis identified an ISTH DIC score ≥ 5 to be the most important haemostatic parameter for ED (P=0.006, RR 2.371; 95 %CI 1.282-4.385).
Summary / Conclusion: This study has shown that a high fibrinogen level at presentation of nonpromyelocytic AML is significantly correlated with poor OS, CR rate and DFS, while ISTH DIC score ≥ 5 is associated with a higher ED rate. According to data in the literature high fibrinogen levels in AML have a potential role in resistance to chemotherapy. A high concentration of fibrinogen may also be a marker of increased inflammation in AML patients, which needs to be confirmed in further investigations.

P074

SUCCESSFUL SALVAGE TREATMENT WITH CLOFARABINE AND CYTARABINE (ARA-C) IN RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

A Malato[1],* A Santoro[1], R Felice[1], S Magrin[1], D Turri[1], R Di Bella[1], D Salemi[1], F Acquaviva[1], R Scimè[1], F Fabbiano[1]
[1]UOC Ematologia con UTMO, Ospedali Riuniti Villa Sofia-Cervello, Palermo, Palermo, Italy

Background: Relapsed/refractory AML patients have a poor prognosis, with CR rates of 1%>30%, unless allogeneic hematopoietic stem cell transplantation (HSCT) is an available option. Although retrospective modeling studies have demonstrated the prognostic value of selected parameters, responses with salvage therapies remain still poor. It was previously established the activity of clofarabine plus cytarabine in AML relapse (clofarabine dosed once daily for 5 days with 40 mg/m^2 followed 4 hours later by ara-C at 1 g/m^2 per day). However, modifications of this combination in AML therapy of relapsed/refractory patients warrant further evaluation.
Aims: To determine the efficacy and safety of clofarabine and cytarabine (Ara-C) in adult patients with relapsed or refractory acute myeloid leukemia (AML).
Methods: Twenty-five patients aged (30-67) years with refractory/relapsed AML were treated at the dose of clofarabine 30 mg/mq on days 1-5 + cytarabine 1000 mg/mq gg on days 1-5. We evaluated the complete remission rate (CRR), duration of remission (DOR) and overall survival (OS). Minimal residual disease (MRD) by molecular targeting was considered in all patients.
Results: Twenty-five patients received clofarabine 30 mg/mq on days 1-5 + cytarabine 1000 mg/mq gg on days 1-5, (followed by gentuzumab therapy in only three patients). All patients had relapsed/refractory myeloid leukemia and had received multiple priors therapies. Six pts had received a prior hematopoietic stem cell transplant (HSCT). Fourteen patients achieved a complete remission (CR); nine patients went on to receive allogeneic transplants after clofarabine/ARA-C salvage. The complete remission rate (CRR) was (56,00 %) The Median of Overall survival for all patients was (149) days (range 12-1152), while the media of Overall survival (OS) was (221.52) days, and we estimated a duration of remission (DOR) as (195.00) days in median (range 41-1131), and (311.36) days in media (we calculated from the first day of remission). Treatment was complicated by neutropenic fever (n=16), grade III-IV mucositis (n=2), skin rush (n=1) grade II- III, hepatic transaminase elevations (n=2). Two (n=5) patient died before their disease status could be evaluated
Summary / Conclusion: Combination treatment with clofarabine 30 mg/mq and ARA-C 1000 mg/mq in adults pts with refractory or relapsed AML resulted in an ORR of (56,00 %) and of the (14) patients who achieved a CR, nine (64.29%) proceeded to HSCT (Five are still alive). The safety profile is acceptable in this relapsed/refractory population, and our results are very similar to previous regimes using higher clofarabine dosages. More studies with this combination in adults are warranted

Chronic lymphocytic leukemia: Translational Research

P075

ACHIEVING BONE MARROW CLL MINIMAL RESIDUAL DISEASE-FREE STATUS WITH FIRST-LINE FCR IS ASSOCIATED WITH IMPROVED PFS AND CAN BE CONSIDERED A PRIMARY TREATMENT OBJECTIVE

P Strati[1],* M KEATING[1], S O'Brien[1], A Ferrajoli[1], J Burger[1], N Jain[1], Z Estrov[1], J Jorgensen[1], S Faderl[1], W Wierda[1]
[1]MD Anderson Cancer Center, Houston, United States

Background: MRD-Free Status After 3 courses of First-Line FCR Achieves Comparable PFS to 4-6 Courses
Aims: To prospectively investigate clinical and biological factors associated with bone marrow MRD status and outcomes in first-line FCR. To determine the prognostic and therapeutic implications of bone marrow MRD in CLL.
Methods: Two-hundred thirty-seven pts with CLL and standard NCI/IWCLL indication for treatment were evaluated for pretreatmet characteristics, including prognostic factors. They received up to 6 courses of standard first-line fludarabine, cyclophosphamide, and rituximab (FCR) between 09/2008 and 09/2012. MRD was prospectively assessed in bone marrow by 4 or 6-color flow cytometry after course 3 and 2 months after 6th or last course of treatment. Categorical and continuous variables were compared using χ^2 and Mann-Whitney tests. Kaplan-Meier estimates were compared using the log-rank test. Cox regression was used for multivariate analyses (MVA).
Results: All 237 pts completed treatment and were evaluable for response assessment by NCI/IWCLL criteria; 61% were male, 21% were older than 65 years, 40% had Rai stage III-IV CLL, 41% had beta2-microglobulin (B2M) ³ 4 mg/L, 61% had unmutated *IGHV* gene, and 18% had FISH analysis positive for trisomy 12 (+12), 21% for deletion 11q and 7% for deletion 17p (del17p). Seventy-five percent of pts received more than 3 total courses of FCR. The complete remission (CR) and overall response (OR) rate was 65 and 97%, respectively. MRD negativity was achieved in 59% of pts at response assessment. Baseline characteristics independently associated with MRD negative status in MVA were Rai stage 0-II (P=0.04), mutated *IGHV* gene (P=0.002), +12 (P=0.02) and lack of del17p (P=0.02). After a median follow-up of 28 months (range 4-53), median progression-free survival (PFS) and overall survival (OS) were not reached. Baseline characteristic associated with a shorter PFS in MVA were unmutated *IGHV* gene (P=0.03) and presence of del17p (P<0.001). When evaluating response variables in MVA, partial remission (P=0.01), non-response (P=0.03) and MRD positivity (P=0.002) were independently associated with shorter PFS. Five groups were defined according to number of FCR courses and MRD status (Figure 1): pts receiving 3 or fewer total courses, MRD positive (MRD3+) and MRD negative (MRD3-); pts receiving more than 3 total courses, negative both after 3 courses and at response assessment (MRD3-/EOT-), positive at both time points (MRD3+/EOT+), or positive after 3 courses, but negative at response assessment (MRD3+/EOT-). PFS was significantly shorter for MRD3+ (median 30 months, P<0.001) and for MRD3+/EOT+(median not reached, P<0.001). No differences in PFS were observed between MRD3-, MRD3-/EOT- and MRD+/EOT- with current follow up. When comparing MRD3+/EOT- and MRD3+/EOT+ according to baseline and treatment characteristics, only a high CR rate was associated with MRD3+/EOT- (P<0.001).
Summary / Conclusion: CLL pts with early stage disease, mutated *IGHV* gene, +12 positive and lack of del17p are more likely to achieve MRD negativity with frontline FCR therapy, which is independently associated with improved PFS. With this early follow up, it appears that if MRD free status is achieved after 3 courses, FCR can be safely stopped without compromising PFS outcome.

Background: Until now, the prognosis and indication for treatment in chronic lymphocytic leukemia (CLL) are guided by the staging systems of Binet and Rai. During the last decade, however, a number of robust predictors of overall survival (OS) have been identified. The multiplicity of new markers, limited information on their independent prognostic value, and a lack of understanding of how to interpret discordant markers have been major barriers to application of these prognostic tools in routine clinical practice.
Aims: We therefore performed a pooled analysis using the database of the German CLL Study Group (GCLLSG) to develop an integrated prognostic index. This index was subsequently validated in an independent cohort of untreated CLL patients (pts) from the Mayo Clinic CLL Database.
Methods: The development of the index was based on data collected between 1997 & 2006 in three GCLLSG phase III trials: 710 in CLL1 ("watch and wait" versus fludarabine (F)), 362 in CLL4 (F versus F and cyclophosphamide (FC)) and 817 pts in the CLL8 trial (FC versus FC and rituximab (FCR)). The external validation was performed on a series of 676 pts with newly diagnosed CLL followed and managed at Mayo Clinic.

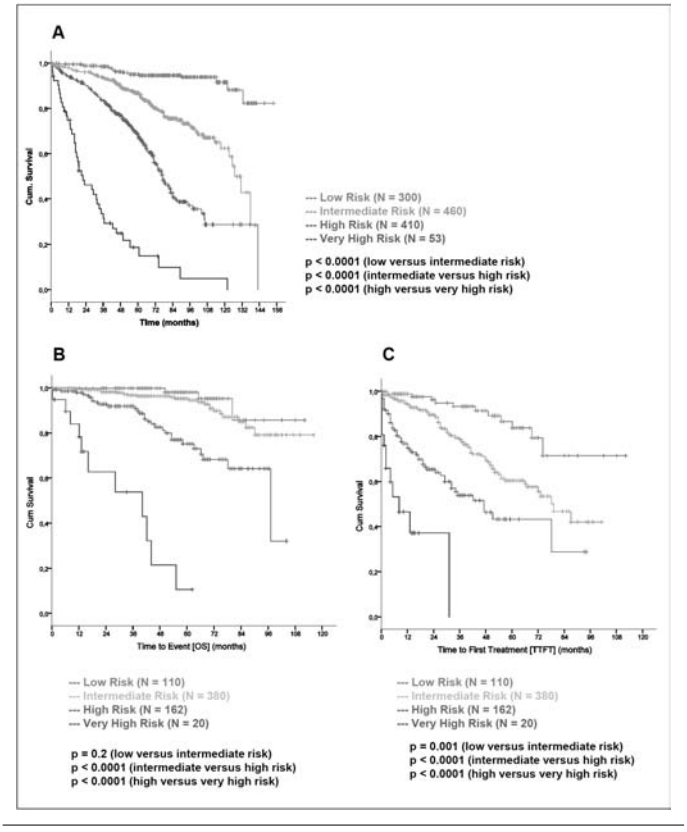

Figure 1.

Results: The GCLLSG data set, a total of 1948 pts (median age of 60 years (range, 30 to 81 years)), was used for the pooled analysis. The study population consisted of physically fit patients at all stages of disease (799 (42.4%) Binet stage A, 717 (38.0%) Binet stage B and 370 (19.6%) Binet stage C patients). After a median observation time of 63.4 months 485 deaths were reported. Multivariate analyses of 23 prognostic factors including baseline characteristics, laboratory results, molecular cytogenetic, mutational status and serum parameters were performed. Eight parameters were identified as independent predictors for OS: sex, age, ECOG status, genetic aberrations del(17p) and del(11q), *IGHV* mutation status, s-TK, and s-β_2m. By using a weighted grading of independent factors, a prognostic index was derived separating four different pts groups: low risk (score 0 - 2), intermediate risk (score 3 - 5), high risk (score 6 - 10) and very high risk (score 11 - 14) (Figure 1A) with significant different OS rates (95.2%, 86.9%, 67.7% and 18.7% survival after 5 years for the low, intermediate, high and very high risk group (P<0.001, respectively)). This prognostic index was then validated in a cohort of 676 pts from the Mayo Clinic. At last follow-up, 163 (24.1%) patients have been treated and 66 (9.8%) have died. At presentation, 396 (57.1%) patients were Rai stage 0, 270 (39.9%) Rai stages I-II and 20 (3.0%) Rai stages III-IV. The four risk groups of the prognostic index for OS were reproduced with 98.3%, 95.4%, 75.4% and 10.8% survival after 5 years (Figure 1B). Slight differences in survival rates by risk category between the two cohorts are likely explained bya shorter observation time (median, 63.4 versus 47.0 months, P<0.001) and high proportion of censored data. The prognostic index predicted survival independent of disease stage for all Rai risk categories (not shown). Furthermore the index score provides accurate estimations regarding the time to first treatment for newly diagnosed CLL patients (Figure 1C).
Summary / Conclusion: Using a multi-step process including an independent external validation cohort, we developed a comprehensive prognostic index for pts with CLL. The prognostic index provides more accurate prediction of both treatment-free and overall survival for CLL patients and appears generally applicable.

P077

THE EXPRESSION OF A SINGLE MICRORNA - MIR-34A – IS A RELIABLE MARKER FOR IMPAIRMENT OF P53-PATHWAY IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Mraz[1,*] K Cerna[1], K Musilova[1], J Malcikova[1], K Plevova[1], S Pavlova[1], B Tichy[1], Y Brychtova[1], M Doubek[1], J Mayer[1], M Trbusek[1], S Pospisilova[1]

[1]CEITEC MU, Brno, Czech Republic; Dept. of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, Brno, Czech Republic

Background: We and others have shown that miR-34a is down-regulated in the aggressive CLL subtype harbouring p53 aberration (Mraz, 2009; Zenz, 2009; Asslaber, 2010). However, these studies only specifically studied the expression of miR-34a or few other selected miRNAs that were previously shown to be associated with cancer biology.
Aims: Here we performed an unbiased search for miRNAs that are involved in fludarabine-induced cell death in CLL cells *in vitro* and *in vivo* to investigate the relevance of miR-34a as a marker for impairment of p53 pathway and resistance of CLL to therapy.
Results: To test for miRNAs that are involved in apoptotic pathways in CLL cells we treated *in vitro* ten purified primary CLL B-cell samples with fludarabine (IC50 dose of 3.5 ug/mL, 48hrs), and profiled the expression of 750 miRNAs (TaqMan miRNA Cards, ABI). This identified induction of 15 miRNAs (fold induction [FI] >1.5) with miR-34a being the most prominently up-regulated miRNA (FI 3.7). To verify this observation *in vivo* we obtained peripheral blood from CLL patients treated with a FCR regimen that includes administration of rituximab (R) on day1, followed by fludarabine (F) and cyclophosphamide (C) on day2, 3 and 4. The samples were obtained from patients before administration of therapy, 24hrs after administration of R and 48hrs after FC. The administration of R did not induce miR-34a expression, which was however clearly induced in most samples (96%) after FC administration (FI 2.2, P<0.0001). Additionally, the levels of miR-34a before or after FCR administration were strongly correlated with P53-aberration present in 5 out of 52 FCR-treated patients; with patients harbouring P53-aberration having the lowest miR-34a levels from the whole cohort. Interestingly, CLL cases with deletion of ATM (del11q23, N=19), an up-stream regulator of p53, had similar basal and induced levels of miR-34a compared to cases without del11q23 (N=28). Importantly, when the FCR-treated patients were divided into terciles based on the level of miR-34a after FC, those with the lowest levels of miR-34a experienced significantly shorter time to treatment failure (1.1 years vs. 2.2 years; P=0.037; HR 3.01). These data and the broad screening of fludarabine-induced miRNAs confirmed that miR-34a is the preferential miRNA activated with apoptosis and DNA damage pathway in CLL. This prompted us to develop an assay for absolute quantification of miR-34a that allowed us to determine the copy numbers of miR-34a and to define the precise cut-offs(similarly to assays for bcr-abl quantification in CML). Using this assay, we profiled the expression of miR-34a in 200 CLL patients (miR-34a expression ranged from 1 to 81820 copies/10e6 copies of internal standard). Significantly, miR-34a levels below 2500 copies (N=47) were corre-

lated with shorter overall survival (9.6 years vs. not-reached, HR 2.2 [CI 1.1-4.5], P=0.03). The low miR-34a levels were also apparently associated with the deletion & p53 mutation of 17p13 (N=18) or sole p53 mutation (N=13) in this second CLL cohort (P<0.005).
Summary / Conclusion: Our data provide evidence and novel tool for the use of miR-34a as a marker of p53-aberration, which can be especially useful in cases with sole p53 mutation not accompanied by 17p13 deletion that cannot be discriminated by routine FISH. Patients with sole p53 mutation represents approx. 1/3 of p53 aberrant cases with inferior prognosis similar to cases with del17p13.
IGA MZCR NT11218-6/2010, FR-TI2/254.

P078

CHRONIC LYMPHOCYTIC LEUKEMIA CELLS FROM PAIRED LYMPH NODE AND PERIPHERAL BLOOD SHOW A DIFFERENT PATTERN OF COPY NUMBER ABERRATIONS
S Bonina[1,*] I Giudice[1], S Chiaretti[1], M Marinelli[1], M Messina[1], F Mauro[1], V Maio[1], M Propris[1], S Raponi[1], M Nanni[1], D Rossi[2], G Gaidano[2], A Guarini[1], R Foà[1]
[1]Division of Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, [2]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of neoplastic B cells in peripheral blood (PB), bone marrow (BM), lymph nodes (LN) and hepatosplenic tissue. BM and LN are most likely the sites of disease maintenance and progression, where the crosstalk with accessory stromal cells prevents CLL cells from apoptosis and enhances their proliferation. Recent data indicate that CLL cells obtained from PB exert a different gene expression profile compared to LN cells.
Aims: Aim of the study was to assess if CLL shows a distinctive qualitative and quantitative pattern of chromosomal alterations in different disease compartments by analyzing copy number aberrations (CNAs) by single nucleotide polymorphism (SNP) arrays in tumor cells extracted concurrently from the PB and LN of each patient.
Methods: Genomic DNA was extracted from paired PB, LN and saliva samples of 10 CLL patients. Cases were selected on the basis of: *i)* availability of CLL cells simultaneously extracted from PB and LN biopsies; *ii)* $CD5^+/CD19^+$ cells in PB and LN >70%; iii) absence of Richter syndrome and *iv)* availability of germline material (saliva). CNA analysis was performed by genomic hybridization using the CytoScan HD array (Affymetrix), according to manufacturer's instruction. The array contains more than $2.6x10^6$ copy number markers, including 750.000 SNPs. Data were analyzed using the Chromosome Analysis Suite (ChAS) Software (Affymetrix). Germline DNA was used to exclude non tumor-related aberrations.
Results: LN samples showed CNAs in all cases, with an average of 4.8 CNAs/case (range1-16). LN CNAs were mainly represented by losses (81%), of which 38% were focal (≤10 genes) and 62% non-focal. The other 19% of CNAs were non-focal gains. PB samples showed CNAs in 9/10 cases, with a mean of 4.4 CNAs/case (range 0-16). A similar pattern to that of LN was found in PB, with 79% of losses and 21% of gains, with a slight increase of focal lesions (45% losses and 17% gains). Overall, a total of 26 CNAs were shared by paired LN and PB samples, while 6 CNAs specific of the LN compartment were not found in the corresponding PB; 2 lesions were specific of the PB compartment. An intra-patient analysis showed that in 3 cases (30%) LN revealed different CNAs compared with the corresponding PB: one exclusive LN lesion (del6q16.3-q26) in case #1, 4 in case #2 (del8p23.3-p11.11, del9p24.3-p13.1, del13q14.1-q31.1 and del13q31.1), while case #3 showed one CNAs exclusive of the LN (del5q14.3-q21.3) and 2 specific of the PB (del6q23.3-q24.1 and del13q14.11). In addition, two shared CNAs were much larger in the LN than PB in case #2 and case #3. The other 7 cases shared the same lesions in both compartments. Among them, it is interesting to note that 8 CNAs of 4 patients were represented at a higher percentage in the LN compared to the PB (mean: 81% in LN and 64% in PB).
Summary / Conclusion: This study shows that a subset of CLL patients with LN involvement reveals a specific pattern of CNAs in LN-derived tumor cells compared to the corresponding circulating counterpart. In fact, LN-derived cells can show either additional or larger CNAs than PB in at least one third of cases, with a greater clonal representation of the common lesions, corroborating the notion that the LN microenvironment contributes to CLL cell proliferation and possible clone selection. Further investigations on the genetic lesions are warranted.

P079

SF3B1 MUTATIONS IN CLL ARE FUNCTIONALLY EQUIVALENT TO ATM GENE ALTERATIONS AND CAUSE DEFECTIVE PUMA AND P21 UPREGULATION IN RESPONSE TO DNA DAMAGE
D Raa[1,*] I Derks[1], J van Laar[1], H Monsuur[1], D Luijks[1], V Navrkalova[2], J Malcikova[2], M Trbusek[2], A Jethwa[3], J Hüllein[3], C Geisler[4], T Zenz[3], S Pospisilova[2], T Stankovic[5], M Van Oers[1], A Kater[1], E Eldering[1]
[1]Departments of Hematology and Experimental Immunology, Academic Medical Center Amsterdam , Amsterdam, Netherlands, [2]CEITEC - Center of Molecular Medicine, Masaryk University and University Hospital, Brno, Czech Republic, [3]Department of Translantional Oncology, National Center for Tumor Diseases (NCT), German Cancer Research Center (DFKZ) & Department of Medicine V, University Hospital Heidelberg, Heidelberg, Germany, [4]Department of Hematology, Rigshospitalet, Copenhagen, Denmark, [5]School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom

Background: Mutations or deletions of the tumor suppressor p53 or its upstream kinase ATM are well-known determinants of poor prognosis in chronic lymphocytic leukemia (CLL). In recent years, genome-wide sequencing has uncovered novel gene mutations that also correspond with poor prognosis. Specifically, recurrent mutations in the splicing factor *SF3B1* and the *Notch1* proto-oncogene have been found. These mutations were (in part) mutually exclusive with *TP53* aberrations, which suggested their overlap in biological function.
Aims: To investigate whether *SF3B1* and *Notch1* mutations affect the p53/ATM axis.
Results: Here, we report results of a comparative analysis of p53 target genes and *in vitro* responses to cytotoxic drugs in CLL samples with *TP53* (n=13), *ATM* (n=18), *SF3B1* (n=20) and *Notch1* (n=10) mutations. Upon irradiation, mRNA induction of p53 targets genes (*p21, Puma, CD95, Bax, PCNA, FXDR)* was decreased in *SF3B1* (overall P<0.01), but not in *Notch1* mutated CLL samples. *SF3B1* mutated samples resembled ATM mutated CLL in displaying a defective but not absent p53 response. At protein level, Puma and p21 induction were defective or absent. This corresponded with decreased apoptosis after *in vitro* treatment with fludarabine. Treatment with nutlin, either alone or in combination with fludarabine, restored cell death induction, again indicating an overlap with ATM dysfunction. Since it is emerging that *SF3B1* mutation correlates with 11q deletion we performed extensive analysis of the coding sequence of the *ATM* gene (exons 1-62) in all *SF3B1* mutated cases. In this cohort there was an overlap of *SF3B1* mutations with *ATM* mutations and/or 11qdeletions in 59% of *SF3B1* mutated cases (10/17; in 3 cases ATM analysis is ongoing), and of 18% (3/17) with *TP53* mutation. Importantly, 4 *SF3B1* mutated cases did not have an *ATM* mutation, 11q deletion or *TP53* mutation, but still these samples displayed an impaired response to irradiation and cytotoxic drugs, indicating that the functional defect can occur independently of *ATM* or *TP53* mutation/deletion.
Summary / Conclusion: In conclusion, the recently described mutations in a splicing factor *SF3B1* in CLL can be linked at the functional level to defective ATM and/or p53 target gene responses, providing an explanation for the poor clinical prognosis of CLL patients with *SF3B1* mutations.

Background: Genetic abnormalities in CLL define subgroups of patients with different survival. Recently, our group and others have reported that the number of losses in 13q or 17p is associated with the prognosis. CLL patients with 11q- have a bad prognosis, although the exact impact of 11q- in the outcome remains to be elucidated
Aims: To analyze in a multicentric study whether the number of losses in 11q in patients with CLL has an influence in OS and TFT.
Methods: A total of2,493 patients registered in DataBase of CLL of Spanish Group of Cytogenetics (GCECGH) and Spanish Group of CLL (GELLC) were included. Clinical data, FISH information (11q, 12, 13q, 14q and 17p probes) and molecular studies were recorded. Genome-wide expression analysis of clonal B-cell lymphocytes of 11q- patients was also performed using Human Gene 2.0 microarrays (Affymetrix).
Results: A total of 242 patients (10.3%) had 11q-. The final analysis was limited to 197 cases (151 male, median age 65 yr) after excluding cases with monoclonal B-cell lymphocytosis, lack of clinical data or inappropriate follow-up. Most of patients (61%) were in Binet's stage A. In 82 out of 197 patients (42%) 11q- was the sole cytogenetic aberration at diagnosis. Median OS of patients with 11q- was 106 months (CI95%, 97-128) and TFT was 25 months (CI95%, 31-44). Interestingly, in patients with loss of 11q ³40 % of cells (146 cases, 74%), the OS was 90 months (CI95%, 57-123), while in the group with <40 % of losses in 11q, the OS has not been reached (CI95%, 114-157) (P=0.008).In the univariate analysis, clinical stage (P=0.002), B-symptoms (P=0.041), hepatomegaly (P=0.025), splenomegaly (P<0.0001), lymphocyte count >20 x 10^9/L (P= 0.049), a high serum LDH (P<0.0001), β_2M levels (P<0.0001) and high number of cells 11q- (>40) (P< 0.0001) were associated with a short OS. In the Cox analysis for OS, variables included in the final model were serum LDH (P=0.035), β_2M serum (P=0.005) and del11q ≥40 (P=0.004).Regarding TFT, in patients with ≥40% of losses in 11q the median TFT was 18 months (CI95%, 12-24) vs. 44 months (CI95%, 33-55) (P<0.0001).In the univariate analysis, significant variables were clinical stage (P=0.004), serum LDH (P=0.045), serum β2M (P=0.012), high CD38 expression (P=0.022), high ZAP70 expression (P=0.025), unmutated IGVH (P<0.0001) and del11q ≥40 (P<0.0001). In the multivariate analysis, only unmutated IGVH status resulted significant in predicting TFT (P=0.014). No differences in OS or TFT were observed between patients with del11q as a sole cytogenetic aberration vs. del11q plus other cytogenetic aberration, although patients with 11q- and 13q- combination exhibited a trend for a better OS (P=0.06). Regarding gene expression analysis, patients with 11q- showed a distinctive gene expression profile characterized by an activation of NFkB signaling, due to the overexpression of genes such as BTRC and TLR. In addition, an overexpression of URB4, ILK, BSG, SHH, and downregulation of STC1 and CASR, leading to a decreased apoptosis (P=0.006), as well as upregulation of ILK, BTRC, RPL7A and FOXM1, involved in deregulation of the cell cycle (P=0.03) was observed in 11q- patients. Of note, overexpression of JUNB, described as a proto-oncogen was also observed in 11q-patients, which could lead to a higher cell proliferation (P=0.009).
Summary / Conclusion: In patients with CLL, a high number of losses in 11q is associated with a shorter TFT and OS. This group of patients is characterized by an activation of NFkB signaling leading to a decreased apoptosis and high proliferation

M. Misericordia, Udine, [5]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, [6]Division of Hematology, Ferrarotto General Hospital, Catania, [7]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Roma, Italy

Background: stabilizing mutations of *NOTCH1* have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated *IGHV* (*IGHV*-UM), immuno-chemorefractory or advanced disease phase CLL. In CLL, all *NOTCH1* mutations disrupt the C-terminal PEST domain (about 80% of which are a 7544-7545delCT frameshift deletion) and cause an accumulation of an active NOTCH1 isoform. Clinically, the presence of *NOTCH1* mutations is an independent predictor of overall survival in CLL and identifies a subset of patients with particularly unfavourable prognosis (Rossi *et al*, Blood, 119, 2012; Del Poeta *et al*, Br J Haematol, 160, 2013).
Aims: to identify molecular/biological features of *NOTCH1* mutated CLL.
Methods: the presence of the *NOTCH1* 7544-7545delCTwas investigated by ARMS-PCR.The percentage of *NOTCH1* DNA in the context of the CLL clone was determined by quantitative real-time PCR (QRT-PCR). Gene expression profile (GEP) was performed by a one-color labeling strategy using the 4x44K platform. Specific gene/protein validations were performed by QRT-PCR, western blotting, immunofluorescence for confocal microscopy and immunohistochemistry. Proliferation of CLL cells by CpG/IL2 stimulation was evaluated by a BrdU uptake assay.
Results: in a cohort of 431 *IGHV*-UM CLL, the *NOTCH1* 7544-7545delCT was found in 97/431 (22.5%) cases. QRT-PCR revealed a percentage of *NOTCH1* mutated DNA ranging from 1 to 37%. CLL carrying the *NOTCH1* 7544-7545delCT (*NOTCH1*-mut, 8 cases; from 11% to 37% of *NOTCH1* mutated DNA) showed higher NOTCH1 protein expression than cases lacking *NOTCH1*-mut (11 cases) employing monoclonal antibodies either recognizing the trans-membrane (mean fold increase=3.0) or the intra-citoplasmic (mean fold increase=2.1) NOTCH1 domain. A GEP comparing purified cells of 5 *IGHV*-UM *NOTCH1*-mut CLL (from 15% to 37% of *NOTCH1* mutated DNA) and 5 *IGHV*-UM CLL lacking *NOTCH1*-mut selected nucleophosmin-1 (*NPM1*) and genes codifying for several ribosomal proteins (*RPS6*, *RPS10*, *RPS17*, *RPS28*, *RPSA*, *RPL7A*, *RPL18*) as significantly up regulated in *NOTCH1*-mut CLL. QRT-PCR validations confirmed GEP results in a wider series of 34 cases (18 *NOTCH1*-mut cases). Western blot in 19 cases (8 *NOTCH1*-mut cases) confirmed a higher NPM1 protein expression in *NOTCH1*-mut cases (1.3-5.2 range of fold increase). Consistently, lymph nodes preparations from *NOTCH1*-mut cases revealed a strong NPM1 staining both in nucleoli and cytoplasms. When intracellular distribution and fluorescent intensity of *NPM1* immunostaining was evaluated, both *NOTCH1*-mut and *NOTCH1*-wt showed a visible nucleoplasmic staining; with an additional cytoplasmic staining visible in *NOTCH1*-mut cases. Finally, when stimulated in-vitro with the CpG/IL2 combination, *NOTCH1*-mut *IGHV*-UM CLL cells proliferated, as detected by a BrdU uptake assay (>10 fold increase over control), and up-regulated NPM1 both at transcript (mean fold increase=2.02 after 18 hours of CpG exposure, P=0.001) and protein (fold increase=1.34 after 6 hours of CpG exposure) levels.
Summary / Conclusion: NPM1 was constitutively overexpressed in *NOTCH1*-mut *IGHV*-UM CLL together with several ribosome-associated components. An increased activity of the ribosomal machinery/DNA-repair mechanisms (Lindstrom MS. Biochem. Res. Int. 2011, 2011) in *NOTCH1*-mut CLL may concur to explain immuno-chemorefractoriness of patients affected by CLL bearing this novel mutation.

Background: CLL is considered a disease of the elderly, however, 20-30% of patients referred to specialized hematological centers are aged 55 or younger. Limited information is available concerning possible distinctive features of younger patients, especially with respect to the immunoglobulin (IG) repertoire of the clonotypic antigen receptors, which is relevant in view of recent therapeutic developments.
Aims: We conducted a large, multicenter study aiming at obtaining insight into

the clinical and biological characteristics of patients in different age groups, with a special emphasis on immunogenetic profiles.
Methods: The cohort included 4615 patients with the following characteristics: males: 2953/4615 (64%); Binet stage A/B/C: 2154/624/346; mutated/unmutated (M/U) IGHV genes: 2472 (53.5%)/2143 (46.5%); CD38 expression: 905/3176 (28.5%); del(13q): 1383/2284 (61%), del(11q): 362/2248 (16%), del(17p): 258/2272 (11%), trisomy 12: 414/2090 (20%). Based on age distribution, patients were divided in four groups, each representing almost a quartile of the sampled population: A: 71+ years, n= 1048; B: 63-70 years, n=1158; C: 55-62 years, n=1218; and D: <55 years, n=1191.
Results: Advanced age (71+) was associated with Binet stage C (P=0.003), CD38 expression (P=0.015) and trisomy 12 (P<0.001); in contrast, del(11q), del(13q) and del(17p) were equally distributed among the four age groups. The mutational status of the clonotypic IGHV genes was overall similar in all age groups. Notably, however, the four age groups exhibited distinct IGHV gene repertoires: (i) lower frequency of the IGHV4-34 and IGHV1-69 genes in group A (71+) versus groups B-C-D (P=0.008); (ii) higher frequency of the IGHV4-39 and IGHV1-2 genes in group A (71+) versus groups B-C-D (P=0.032); (iii) predominance of the IGHV3-21 gene in groups A-B-C versus D (<55) (P<0.05). Extending the analysis to B cell receptor (BcR) stereotypy, the age distribution of major stereotyped subsets was distinctly different (P<0.001). In particular, patients in subsets #4 (M-CLL, IGHV4-34), #148 (M-CLL, IGHV2-5), #3, #5 and #7 (U-CLL, all IGHV1-69) had significantly younger ages at diagnosis compared to subsets #1 (U-CLL, Clan I genes), #2 (IGHV3-21), #6 (U-CLL, IGHV1-69) and #8 (U-CLL, IGHV4-39). Among 2952 cases with available data, disease progression requiring treatment was seen in 63% of Group A cases, 69% of Group B cases, 72.6% of Group C cases and 75.2% of Group D cases (P<0.001); admittedly, this could also be related to the fact that younger patients are allowed more time to progress before they die of comorbidity. In univariate analysis, advanced age had a significant negative impact on time-to-first-treatment (TTFT) (P=0.04) along with male gender, advanced clinical stage, unmutated IGHV genes, CD38 expression and del(17p). However, in multivariate analysis only advanced clinical stage, unmutated IGHV genes and del(17p) retained significance.
Summary / Conclusion: In conclusion, CLL patients in different age groups exhibit distinct features extending from clinical stage at diagnosis to immunogenetic profiles. The striking IG repertoire differences between younger versus older patients with CLL could reflect different rates of disease progression or different antigen exposure histories, including excessive production of apoptotic and oxidative products due to aging that could stimulate cells with distinctive antigen receptors. Alternatively, repertoire biases in older patients might also be a consequence of the physiological process of immune senescence.

P083

DETECTION OF TP53 DYSFUNCTION IN CHRONIC LYMPHOCYTIC LEUKEMIA BY AN IN VITRO FUNCTIONAL ASSAY BASED ON TP53 ACTIVATION BY THE NON-GENOTOXIC DRUG NUTLIN-3: A PROPOSAL FOR CLINICAL APPLICATION

F Pozzo[1,*] M Bo[1], N Peragine[2], R Bomben[1], M Degan[1], D Marconi[1], A Zucchetto[1], F Rossi[1], P Bulian[1], D Rossi[3], A Chiarenza[4], F Raimondo[4], F Zaja[5], G Pozzato[6], G Gaidano[3], G Poeta[7], R Foà[2], A Guarini[2], V Gattei[1]
[1]Clinical and Experimental Onco-Hematology Unit, Centro di Riferimento Oncologico, Aviano, [2]Division of Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, [3]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, [4]Division of Hematology, Ferrarotto Hospital, Catania, [5]Department of Hematology, DISM, Azienda Ospedaliero Universitaria S. M. Misericordia, Udine, [6]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, [7]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Impaired TP53 function through mutations and/or deletions is the most characterized factor associated with chemoresistance in chronic lymphocytic leukemia (CLL). Since direct sequencing, the standard technique for *TP53* mutation detection, does not evaluate TP53 function, a functional assessment of the TP53 pathway may be of interest to identify high risk CLL.
Aims: To develop a short-term functional assay evaluating TP53 and TP53 target gene modulation upon *in vitro* exposure of CLL cells to the non-genotoxic TP53 activator Nutlin-3.
Methods: The functional assay was set-up on cell lines recapitulating all *TP53* genotypes (EHEB, $TP53^{wt/wt}$; RAJI, $TP53^{mut/wt}$; MEC-1 and MAVER1, $TP53^{mut/del}$; HL-60, $TP53^{del/del}$) and evaluated in two multi-institutional cohorts, purposely enriched in CLL bearing *TP53* disruption: a training cohort (TC) of 100 cases and a validation cohort (VC) of 40 cases, characterized by FISH and *TP53* direct sequencing. Cells were exposed to 10μM of Nutlin-3 for 24 hours. TP53 accumulation was evaluated by Western blotting (WB) and TP53 transcriptional activity was determined by quantitative real time PCR (qRT-PCR) of the TP53-target genes *CDKN1A, BAX, PUMA*.
Results: By WB analysis on cell lines, we defined: i) a normal pattern (i.e. absence of basal TP53 and induction after treatment) in EHEB cells; ii) a mutant pattern (i.e. high basal TP53 without increase after treatment) in MEC-1, MAVER-1 and RAJI cells; iii) a null pattern (i.e. absence of TP53 before and after treatment) in HL-60 cells; iv) a detection sensitivity of 5% of TP53-expressing cells by dilution experiments. By WB analysis of the TC, we defined: i) 63 normal patterns (51 $TP53^{wt/wt}$, 12 $TP53^{del/wt}$); ii) 18 mutant patterns (3 $TP53^{mut/wt}$, 15 $TP53^{mut/del}$); iii) 19 intermediate patterns, i.e. an important basal accumulation of TP53 which increased upon Nutlin-3 exposure (11 $TP53^{wt/wt}$, 5 $TP53^{mut/wt}$; 3 $TP53^{mut/del}$). QRT-PCR of TC cases for expression of the TP53-target genes *CDKN1A*, *BAX*, *PUMA* revealed that all the 25 cases with a mutated *TP53* status ($TP53^{mut/wt}$ or $TP53^{mut/del}$) had negligible/no induction of all the three TP53-target genes upon Nutlin-3 exposure, while in the 75 cases with unmutated *TP53* status ($TP53^{wt/wt}$ or $TP53^{del/wt}$) a marked induction of all three genes (P<0.001) was observed. Of note, *CDKN1A* had the greatest amplitude of induction compared to *BAX* or *PUMA* (P<0.001 for both comparisons), suggesting the use of this target for the TP53 functional evaluation. In particular, a value of about 5-fold increase for *CDKN1A* was able to segregate: i) all the 18 mutant patterns from the majority (56/63) of normal pattern cases (including the 12 $TP53^{del/wt}$ cases); ii) in the context of cases with an intermediate pattern by WB, the 8 cases with a *TP53* mutated status from the 11 $TP53^{wt/wt}$ cases. In addition, this approach was able to identify 7 cases with a normal WB pattern which failed to up-regulate *CDKN1A*, i.e. putatively carrying defects on the DNA damage pathway other than TP53 defects. The proposed functional assay was separately validated "in blind" (5 independent data analysers) in a VC which included 13 $TP53^{wt/wt}$ cases, 3 $TP53^{del/wt}$ cases, 12 $TP53^{mut/wt}$ cases and 12 $TP53^{mut/del}$ cases (sensitivity 0.9, 95% CI 0.78-1; specificity 0.875, 95% CI 0.713-1).
Summary / Conclusion: The combined evaluation of TP53 and *CDKN1A* modulation upon Nutlin-3 exposure may represent a useful low-cost functional test to identify TP53 dysfunctional cases that escape FISH and direct sequencing. This approach may contribute to refine the prognostic assessment of high risk CLL.

P084

ATM INACTIVATION DISTURBS ATM-P53 PATHWAY IN RESPONSE TO DNA DAMAGE INDUCED BY DOXORUBICIN BUT NOT FLUDARABINE IN CLL CELLS

V Navrkalova[1,*] L Sebejova[1], B Kubesova[2], M Doubek[1], J Mayer[2], S Pospisilova[1], M Trbusek[1]
[1]Molecular medicine, CEITEC, MU, [2]Department of Internal Medicine-Hematooncology, University Hospital Brno , Brno, Czech Republic

Background: Abnormalities of *ATM* gene are frequent in chronic lymphocytic leukemia (CLL) patients and represent important prognostic factor. *ATM* defects are commonly assessed through 11q deletion (11q-) monitoring, nevertheless complete ATM inactivation stems from biallelic *ATM* defects (mutation/11q- or two mutations) or from sole *ATM* mutation manifesting dominant-negative effect. After DNA damage caused by ionizing radiation (IR), it is well established that ATM plays crucial role in response to dsDNA breaks (DSBs), especially through triggering the p53 pathway. The impact of ATM inactivation in response to conventionally used DNA damaging drugs is much less understood although this inactivation could have important predictive value.
Aims: Our aim was to assess ATM inactivation impact on *in vitro* CLL cells response to fludarabine and doxorubicin, with respect to the ATM-p53 pathway activation.
Methods: To assess p53 pathway activation after drug exposure we used: (a) Real-time PCR to analyze p53-downstream gene (*CDKN1A* (*p21), BBC3* (*PUMA), BAX,* and *GADD45*) induction after 24 h treatment of CLL cells with fludarabine and doxorubicin or after2, 10, 24 h IR exposure (5 Gy in total, 0.3 Gy/min), (b) Western blotting (WB) for total p53 and Ser15-p53 after 24 h fludarabine treatment; these experiments were performed on wt samples with artificially inactivated ATM (inhibitor KU55933) and on CLL samples harboring *ATM* mutation(s), and (c) WB for Ser1981-ATM and Ser15-p53 to evaluate immediate ATM activation in mutated samples after 1 h IR exposure.
Results: The samples with inactivated ATM exhibited clearly impaired induction of all four p53-downstream genes after doxorubicin, but not fludarabine treatment (3/3 artificially inactivated samples and 16/20 *ATM*-mutated samples from our previous study; 14 samples harbored biallelic defect and two harbored single mutation at hot-spot codon 3008). Since doxorubicin is supposedly radiomimetic drug, we verified the ATM-dependent response to DSBs using IR. We performed the same analysis on 8 *ATM*-mutated samples and 5 samples with preserved ATM function (i.e., wt or sole 11q-) and observed similarly impaired response in ATM-defective group, however with the exception of *BAX* gene that had preserved induction. The preserved p53-downstream pathway response after fludarabine prompted us to analyze p53 accumulation and activation. Firstly, we confirmed that fludarabine creates DSBs (gH2AX accumulation after 24 h exposure) and then showed that in relevant proportion of cases the p53 stabilization is present (2/4 artificially inactivated samples and 3/4 *ATM*-mutated samples; the last mutated sample demonstrated partial p53 stabilization). Our observations show subtle ATM impact on studied response to fludarabine suggesting the involvement of other signaling kinase(s) in the p53 pathway activation. To further analyze loss of ATM function within the DNA damage response cascade, we also monitored ATM autophosphorylation on Ser1981 and p53 phosphorylation on Ser-15 in two *ATM*-mutated samples after IR. One *ATM*-mutant showed obvious-

ly diminished autophosphorylation and both mutants completely lost any activity towards p53 activation and stabilization.
Summary / Conclusion: CLL cells lacking ATM activity manifest clearly impaired p53 pathway activation after doxorubicin, while this response appears to be normal after fludarabine. It seems that ATM inactivation is prominently manifested in the end of ATM-p53 pathway while initial processes are less influenced. The work was supported by grants FR-TI2/254, NT13519 and MUNI/A/0723/2012.

P085

SEQUENTIAL MRD ANALYSIS IN CLL DEMONSTRATES EXPONENTIAL EXPANSION WITH A PATTERN THAT CANNOT BE PREDICTED FROM PRE-TREATMENT DOUBLING TIME.

A Rawstron[1,*] R de Tute[1], T Munir[2], A Jack[1], P Hillmen[2]
[1]HMDS, [2]Haematology, St. James's Institute of Oncology, Leeds, United Kingdom

Background: Minimal residual disease (MRD) is an independent predictor of disease-free and overall survival in B-cell chronic lymphocytic leukaemia. There is a correlation between the levels of residual disease and the time to relapse which suggests that CLL cells probably undergo exponential expansion even at a very low level. However the kinetics of disease progression when CLL cells represent less than 1% of total leucocytes is not clearly defined.
Aims: To obtain pilot information on the pattern of relapse at low level which could be valuable for the design of clinical trails aimed at consolidation, maintenance and MRD eradication.
Methods: Peripheral blood samples from 30 individuals with CLL who achieved MRD-negative status after treatment were prospectively assessed for minimal residual disease using multi-parameter flow cytometry with a detection limit of 0.004% every 3-6 months. Inclusion criteria for this analysis were the availability of at least 4 sequential samples with detectable residual disease with no therapeutic intervention during the follow-up period and 18/30 patients were evaluable.
Results: CLL cells showed an exponential increase from the first point of detection in all evaluable cases. There was a median of 6 (range 4-19) informative time-points in the 18 cases. The Pearson correlation coefficient between log CLL cell level and time since first MRD-positive sample was a median 0.981, range 0.903-0.998. Doubling times after treatment were significantly lower than pre-treatment (pre-treatment median 6.3 months vs. post-treatment median 2.3 months, paired T-test P=0.03). Although the expansion was exponential it was noted that in many individuals there was an apparent pause in progression followed by a change in the expansion rate when the CLL cell level approach normal B-cell levels, i.e. approximately 500/µL. We further analysed 8 patients with sufficient data to evaluate expansion kinetics when the CLL cell levels were below 500/µL and compared to the rate of expansion when CLL cell levels were above 500/µL. The doubling time was on average twice as long when the CLL cell levels were above 500/µL compared to the initial rate (paired T-test P=0.049) although individuals with an initial doubling time less than 4 months typically maintained a rapid doubling time (n=5). Changes in the doubling time from less than 6 months to more than 12 months were seen in 2/8 cases.
Summary / Conclusion: The results from this pilot data support the hypothesis that expansion of CLL cells even at the lowest detectable levels follows an exponential pattern. Cases with a rapid doubling time before treatment also show rapid expansion after treatment but otherwise the post-treatment CLL doubling rate is not predictable from pre-treatment lymphocyte doubling time. In many cases the rate of expansion changes as CLL cell count approaches normal B-cell levels. Analysis of a larger series of cases is required to understand the pattern of expansion and identify optimal time-points to re-introduce treatment. The data provides biological support for the application of MRD as a surrogate end-point in CLL treatment.

Background: The deletion of the long arm of chromosome 14 (del14q) is a rare (<5%) but recurrent event in CLL. The size of the deletion is variable, and its molecular consequences are unknown.
Aims: The aim of our study is to characterize this abnormality in a large cohort of patients.
Methods: The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected data from 89 patients with CLL or LL, harboring a del14q. Morphological review was performed for 65 of them and immunological review for 48. All karyotypes were reviewed by members of the GFCH. Fluorescence in situ hybridization (FISH) analysis was performed with 5 probes (CEP12, 13q14, TP53, ATM, 6q21), an IGH probe, and BACs RP11-35D12 and RP11-226F19 covering the ZFP36L1 gene on 14q24.1. SNP-array analysis (illumina omni1, omin2.5) was performed for 37 patients. The *IGHV* status was analyzed locally, or in our laboratory. The mutation hotspots of *NOTCH1* (exon 34), *SF3B1* (exons 14-16), *XPO1* (exons 14-15), *MYD88* (exon 5) and *TP53* (exons 4-10) were analyzed by direct sequencing.
Results: Patients were classified as 49 CLL Matutes score 4-5, 5 atypical CLL score 3 (all CD5+, CD23+), and 27 LL. The sex ratio M/F was 1.02. Among CLL, there were 35 (66%) stages A and 18 (34%) stage B/C. The median time from diagnosis to first treatment was 17 months for CLL, 1 month for LL. Eight patients were excluded with a Matutes score<3 or not evaluable. The karyotype showed chromosomal translocation in 26/79 (33%) (10 balanced, 16 unbalanced) and was complex (> 3 abnormalities) in 26/79 (33%) cases. Using karyotype and FISH, we observed 28/79 (35%) trisomy 12, 12/79 (15%) 13q14 deletions, 11/80 (14%) *TP53* deletions, 5/79 (6%) *ATM* deletions, 3/76 (4%), 6q21 deletions. The whole CLL cohort showed 15/53 (28%) tri 12, 11/53 (21%) del13q, 8/54 (15%) del*TP53*, 4/53 (7%) del*ATM*, 2/50 (4%) del6q. There was no significant difference between CLL score 4-5 and CLL score 3. *IGHV* status was not mutated in 41/53 (77%) patients, and the gene *IGHV1-69* was rearranged in 21/52 (40%) cases. *NOTCH1* gene was mutated in 14/45 (31%) patients, *SF3B1* in 3/45 (7%), *XPO1* in 2/45 (4.5%), *MYD88* in *0/43*, *TP53* in 6/43 (14%) cases. Comparing LL to CLL, there was no significant difference regarding cytogenetic and molecular abnormalities except for trisomy 12, more frequent in LL (13/26 (50%) vs 15/53 (28%), P=0.08) and 13q14 deletion, less frequent in LL (1/26 (4%) vs 11/53 (21%), P=0.09). The 14q deletions appeared distributed along chromosome 14 from bands q11 to q32. The centromeric and telomeric breakpoints of the 14q deletion were investigated by FISH or SNP-array when material was available, and allowed us to categorize the patients in 4 groups: Group 1: 37/77 (48%) patients, with IGH and ZFP36L1 loci rearranged; Group 2: 17/77 (22%), with ZFP36L1 deleted and IGH not deleted; Group 3: 7/77 (9%), with ZFP36L1 and IGH not deleted; Group 4: 16/77 (21%), all the other combinations. Group 1 showed a deletion del14q24.1-14q32.3 of about 38 megabases, which broke in or near *ZFP36L1*, and in the *IGH* gene. It included 26 (70%) LLC score 4/5 and 11 (30%) LL. When compared to the other patients, patients in Group 1 showed significantly more trisomy 12 (18/36 (50%) vs 7/40 (17.5%), P=0.004), and *NOTCH1* mutations (9/18 (50%) vs 4/26 (15.5%), P=0.02). Of note *NOTCH1* mutation was not statistically correlated with trisomy 12. *IGHV* status was unmutated in 22/24 (92%) patients in Group1, 12/24 (50%) harboring the gene *V1-69*.
Summary / Conclusion: When compared to the literature, both CLL and LL with del14q are associated with higher tri12, lower 13q deletion, higher del*TP53*, higher unmutated *IGHV* status, with an over-representation of the *V1-69* repertoire, and higher *NOTCH1* mutated, some of them being poor prognostic factors. The size of the 14q deletion is variable, with in about half of the cases a recurrent interstitial deletion 14q24.1-14q32.3. Among all 14q deletions, patients with both IGH and ZFP36L1 loci rearranged are more specifically associated with trisomy 12, *NOTCH1* mutated, *IGHV* unmutated, and the *V1-69* gene.

UNRAVELING THE HETEROGENEITY OF T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL)

A Langerak[1,*] J Schilperoord-Vermeulen[1], D de Ridder[2], V van der Velden[1], M C Kappers-Klunne[3], K van Lom[3]
[1]Immunology, Erasmus MC, Rotterdam, [2]Delft Bioinformatics Laboratory, Delft University of Technology, Delft, [3]Hematology, Erasmus MC, Rotterdam, Netherlands

Background: T-cell prolymphocytic leukemia (T-PLL) is a proliferation of small to medium sized prolymphocytes with a mature post-thymic T-cell phenotype. T-PLL accounts for 2% of all mature lymphocytic leukemias in adults over the age of 30. T-PLL is a heterogeneous disease with a wide range of clinical, morphological and molecular features which occasionally impedes the diagnosis. Despite current knowledge of the biology, T-PLL patients remain to have a poor prognosis with a short median survival of 7.5 months due to an aggressive disease progression and limited therapeutic responses.
Aims: To further understand the biology of this disease and to identify possible subgroups we selected 27 T-PLL cases for a comprehensive analysis of phenotypic and genotypic features.
Methods: Multi-color flow cytometry, micro-array gene analysis, TCR rearrangement analysis.
Results: For all 27 T-PLL clonality was confirmed, but no stereotyped T-cell receptor beta (TRB) usage was observed. Cytogenetic analysis showed complex aberrations, including frequent occurrence of the inv(14)/t(14;14) aberration. In accordance with literature, our T-PLL cohort consists of 56% CD4+/CD8-, 33% CD4+/CD8+ and 11% CD4-/CD8+, whilst no other clear subgroups could be observed by extensive eight-color flowcytometry. Interestingly, when comparing the T-PLL phenotype to that of normal T-cell subsets, T-PLL mostly cluster with normal memory T-cells and less with naïve and effector T-cells, suggesting that memory T-cells might be the normal counterpart of T-PLL. Preliminary micro-array-based gene expression data on 23 T-PLL and these normal T-cell subsets confirms this suggestion. Furthermore, unsupervised analysis of the gene expression data is suggestive of at least 2 T-PLL subgroups, but these T-PLL subgroups do not seem to directly correlate with morphological variants of T-PLL (blastic vs. lymphocytic).
Summary / Conclusion: Overall, our findings seem to support the idea of subgroups within the T-PLL entity, and further investigations are required to establish the potential clinical implications of this heterogeneity.
This work was supported by an unrestricted grant from Genzyme and Sanofi.

EPIGENETIC INACTIVATION OF MIR-34B/C IN ADDITION TO MIR-34A AND DAPK1 IN CHRONIC LYMPHOCYTIC LEUKEMIA

L Wang[1,*] Y Lam Kwong[1], K Wong[2], C Kho[3], D Jin[4], E Tse[1], A Rosèn[5], C Chim[1]
[1]Department of Medicine, The Li Ka Shing Faculty of Medicine, The University of Hong Kong, [2]Queen Elizabeth Hospital, [3]Pamela Youde Nethersole Hospital, [4]Department of Biochemistry, The Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China, [5]Department of Clinical & Experimental Medicine, Linköping University, Linköping, Sweden

Background: *TP53* mutation or del(17p) is only found in only 5% to 10% of chronic lymphocytic leukemia (CLL) patients at diagnosis. The inactivation of other members in TP53-centered network, may also block TP53 downstream pathway. *DAPK1* gene, as the upstream gene of TP53, could trigger TP53 activation upon oncogenic cellular transformation and its methylation may contribute to CLL progression by blocking the apoptosis of leukemia cells. Moreover, since *miR-34* family is a transcriptional target of TP53, its methylation might also lead to the perturbation of the TP53 tumor suppression pathway.
Aims: We postulated that components of TP53-centered tumor suppressor network, *miR-34b/c*, in addition to *DAPK1* and *miR-34a* might be inactivated by DNA hypermethylation in CLL. Moreover, we tested if *miR-34b/c* methylation might correlate with *miR-203* or *miR-124-1* methylation.
Methods: *miR-34b/c*, *miR-34a* and *DAPK1* methylation was studied in 8 normal controls, 7 CLL cell lines, and 78 diagnostic CLL samples by methylation-specific polymerase chain reaction. MEC-1 cells were treated with 5-Aza-2'-deoxycytidine for reversal of methylation-associated miRNA silencing. Tumor suppressor function of *miR-34b* was illustrated upon over-expression of precursor *miR-34b* in MEC-1 cells.
Results: *miR-34b/c* promoter was unmethylated in normal controls, but completely methylated in 4 CLL cell lines. *miR-34b/c* expression was inversely correlated with *miR-34b/c* methylation. 5-Aza-2'-deoxycytidine treatment led to promoter demethylation and *miR-34b* re-expression in MEC1 cells. Moreover, over-expression of *miR-34b* resulted in enhanced cellular death and inhibition of cell proliferation. In 78 primary CLL samples, *miR-34a*, *miR-34b/c* and *DAPK1* methylation was detected in 2.6%, 17.9% and 34.6% of patients at diagnosis respectively. Furthermore, 39.7%, 3.8% and 2.6% patients had methylation of one, two or all three genes respectively. Overall, 46.2% patients had methylation of at least one of these three genes. Besides, *miR-34b/c* methylation was associated with methylation of *miR-34a* (P=0.03) and *miR-203* (P=0.012).
Summary / Conclusion: *miR-34b/c* is a tumor suppressor miRNA frequently methylated, and hence silenced in CLL. Together with *DAPK1* methylation, *miR-34b/c* methylation may contribute to the disruption of the TP53-centered tumor suppressor pathway. Moreover, the association of miRNA methylation in CLL warrants further study.

GENOMIC LANDSCAPE OF PRIMARY ULTRA-HIGH RISK AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS FROM THE CLL2O TRIAL

J Edelmann[1,*] C Haferlach[2], J Saub[1], V Teleanu[3], F Cymbalista[4], V Leblond[5], A Delmer[6], A Bühler[1], T Zenz[1], S Mack[1], S Ibach[7], M Hallek[8], H Döhner[1], S Stilgenbauer[1]
[1]Department of Internal Medicine III, Ulm University, Ulm, [2]MLL Munich Leukemia Laboratory, Munich, [3]Innere Medizin III, Universitätsklinikum Ulm, Ulm, Germany, [4]Department of Hematology, Hôpital Avicenne, Bobigny, [5]Service d'Hématologie, Hôpital de la Pitié-Salpêtrière, Paris, [6]Hematology Department, University Hospital, Reims, France, [7]Wissenschaftlicher Service Pharma GmbH, Langenfeld, [8]Department of Internal Medicine I, University of Cologne, Cologne, Germany

Background: Ultra-high risk chronic lymphocytic leukemia (CLL) can be defined by the presence of *TP53* loss and/or mutation, refractory disease or early relapse (<24-36 months) after treatment with purine analogue-based combinations. The underlying pathogenic mechanisms are yet only partly understood.
Aims: To obtain a comprehensive registry of the genome in primary ultra-high risk and refractory CLL, 83 samples obtained from the CLL2O trial were screened for copy number alterations (CNAs) and copy-neutral loss of heterozygosity (CN-LOH) by Affymetrix 6.0 single nucleotide polymorphism (SNP) arrays in parallel with chromosome banding analysis (CBA).
Methods: 52 cases were treatment-naïve, primary ultra high-risk cases carrying del(17p). The other 31 cases were refractory to fludarabine or bendamustine-based therapy. SNP-array analysis was performed on CD19 sorted CLL cells against intra-individual reference DNA (paired); data was analyzed using dChipSNP, reference alignment and circular binary segmentation. CBA was performed using the immunostimulatory CpG-oligonucleotide DSP30 and IL-2.

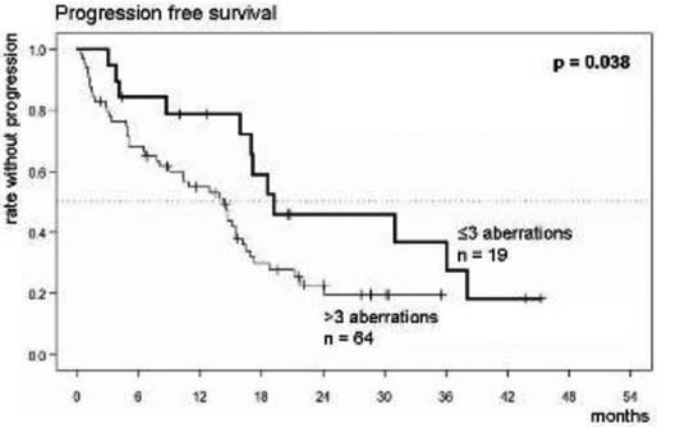

Figure 1. Kaplan-Meier estimates for progression free survival, according to the presence of a complex karyotype detected by combined SNP-array and chromosome banding analysis (defined by >3 aberrations per case).

Results: In total, 499 tumor-specific CNAs were discovered by SNP-array analysis leading to a mean number of 6.01 per case. Compared to data obtained from standard-risk patients at first treatment, this number was strikingly high (CLL8 trial; 1.8 CNAs per case). In contrast, tumor-specific CN-LOH was rare as it was found in only 10 cases. 122 (24%) CNAs detected by SNP-array could not be observed by CBA mostly due to their small size. Of note, 290 (77%) of the remaining 377 CNAs resulted from complex genomic rearrangements. Only 87 (23%) CNAs were described as simple loss or gain of genomic material by CBA. Altogether 280 translocations – mostly unbalanced – could be observed in CBA in 71 cases (range: 1 to 12/case). Translocation breakpoints in at least 5 cases were found in the following cytobands: 17p11 [n=15], 13q14 [n=12], 17p12 [n=9], 14q32 [*IGH*-locus, n=7], 12q24 [n=6], 3q21, 8p11, 13p11 and 19q13 [n=5 each]. Of note, 47 unbalanced translocations in 37 cases had their breakpoint in the centromere resulting in whole arm translocations. Whole arm translocations with concomitant loss of the short arm were the most frequent mechanism leading to del(17p) [n=35; 42% of all 17p deletions] with chromosomes 18 [n=7], 8 [n=5], 15 [n=5] and 17 [isochomosome 17q; n=5] being the most common translocation partners. Other mechanisms leading to del(17p) were complex genomic rearrangements resulting in derivative [n=30; 36%] or dicentric chromosomes [n=5; 6%]. Simple loss of the short arm was

the underlying mechanism in only 13 cases [16%]. Interestingly, up to three different mechanisms of acquiring del(17p) could be observed within one case. Despite the complex and heterogeneous genomic lesions, recurrent concomitant lesions could be identified. The most common ones were gain(8)(q24.21) [n=14; 17%]; del(15)(q15.1) [n=12; 14%], del(10)(q24.32) [n=12; 14%] and del(9)(p21.3) [n=10; 12%]. Cases with loss and/or mutation of *TP53* [n=70] had more genomic aberrations per case than those without [median 6 vs. 4; P=0.02]. Of note, prior therapy had no influence on genomic complexity: treatment-naïve cases had a mean of 6.7 aberrations per case versus 6.0 in cases with prior Fludarabine or Bendamustin-based therapy. In univariate analysis, patients with a complex karyotype defined by more than 3 aberrations had an inferior progression free survival (PFS) [P=0.04] and a trend towards inferior overall survival [P=0.11].

Summary / Conclusion: Primary ultra-high risk (17p- / *TP53* mutated) CLL is characterised by high genomic complexity, similar to refractory CLL. Whereas mutation or loss of *TP53* was associated with increased genomic aberrations, prior therapy did not appear to further increase this. The presence of a complex karyotype was associated with shorter PFS, though its prognostic value has to be further evaluated in multivariate analysis.

P090

CD49D HAS INDEPENDENT NEGATIVE PREDICTIVE POWER FOR OVERALL SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS FROM MULTI-CENTER POOLED ANALYSIS

P Bulian[1,*] T Shanafelt[2], C Fegan[3], A Zucchetto[1], L Cro[4], H Nuckel[5], L Baldini[4], A Kurtova[6], A Ferrajoli[6], J Burger[6], G Gaidano[7], G Del Poeta[8], C Pepper[3], D Rossi[7], V Gattei[1]

[1]IRCCS CRO, Aviano, Italy, [2]Mayo Research Center, Rochester, United States, [3]Institute of Cancer & genetics, Cardiff, United Kingdom, [4]Ospedale Maggiore Policlinico, Milano, Italy, [5]University of Duisburg-Essen, Duisburg-Essen, Germany, [6]MD Anderson Cancer Center, Houston, United States, [7]Amedeo Avogadro University of Eastern Piedmont, Novara, [8]Tor Vergata University, Roma, Italy

Background: A number of data support the value of CD49d expression as independent prognostic variable in chronic lymphocytic leukemia (CLL). However, the available studies differ for: i) clinical end points employed (overall survival, OS; treatment free survival, TFS); ii) factors included in multivariate analyses; iii) choice of cut-off to define CD49d positivity.

Aims: To perform a worldwide multi-center pooled analysis using individual patient data (IPD) from published as well as unpublished series to evaluate the ability of CD49d to predict OS in CLL.

Methods: Authors provided IPD from published cohorts identified by Medline search by 30 April 2011, as well as from unpublished series. The following variables were collected: date of diagnosis, OS, TFS, CD49d, CD38, ZAP-70, immunoglobulin mutational status (*IGHV*), del17p and del11q chromosomal aberrations, age, stage, absolute lymphocyte count (ALC), and β2 microglobulin concentration. We performed a pooled analysis with a fixed effect model, applied multivariate Cox proportional regression analysis, stratified for study site, and recursive partitioning to rank the relative importance of CD49d with respect to the other flow cytometry prognostic factors in CLL (CD38, ZAP-70). The optimal CD49d cut off to predict OS was chosen with a training/validation strategy.

Results: IPD from3,267 patients was initially available. After excluding 265 patients for missing data, the remaining2,972 CLL patients were included in final analysis (1,556 published; 1,416 unpublished). The optimal CD49d expression cut-off was investigated by applying both data-driven and outcome-driven methods. Although these methods failed to agree on a single cut-off, the value of 30% CD49d positive CLL cells was finally chosen because of its slightly higher outcome discrimination capacity, (C-index 0.61 vs 0.59 for 30% and 45% respectively; P<0.0001). By pooled analysis of the merged database CD49d expression ≥30% associated with a 2.5 increase in the hazard of death (HR=2.5; 95% CI, 2.1-3.0), resulting into an OS decrease of 7% at 5-years (94% in CD49d- CLL versus 87% in CD49d+ CLL) and 23% at 10-years (84% in CD49d- CLL versus 61% in CD49d+ CLL) for CD49d positive patients compared to CD49d negative cases. OS shortening was explained by the higher progression rate displayed by CD49d positive cases. Indeed, CD49d positive patients showed a significantly lower probability of remaining treatment free at both 5-years (68% in CD49d- CLL versus 42% in CD49d+ CLL), and 10-years (50% in CD49d- CLL versus 24% in CD49d+ CLL. In a multivariate Cox model for OS stratified for study site, CD49d, but not CD38 and ZAP-70 expression, remained an independent prognosticator (adjusted HR=2.0, 95% CI, 1.4-3.0) along with age, gender, *IGHV* mutational status, del17p and ALC. Consistently, a recursive partitioning hierarchical full-grown tree model which included the three flow cytometric prognosticators, selected CD49d at the first split indicating that no additional prognostic power was given by CD38 and ZAP-70 after CD49d was considered. CD49d was also at the first split in tree models developed for early stage and young (≤65 years) patients.

Summary / Conclusion: Our large, multi-center study preferentially selected CD49d ahead of CD38 and ZAP-70 as a powerful independent prognostic marker for OS in CLL; a 30% cut-off value provided optimal separation. These findings may have implication for patient stratification in future prospective studies and potential therapeutic efforts targeting CD49d or CD49d signaling.

P091

BIALLELIC LOSSES OF 13Q DO NOT CONFER A POORER OUTCOME IN CHRONIC LYMPHOCYTIC LEUKEMIA: ANALYSIS OF 627 PATIENTS WITH ISOLATED 13Q DELETION

Background: Losses in 13q as a sole abnormality by FISH confer a good prognosis in chronic lymphocytic leukemia (CLL). Nonetheless, patients with del(13q) are a heterogeneous group. Prognostic differences related to the percentage of altered cells or the size of the deletion have been proved. Regarding the number of deleted alleles, whereas about 70% of the 13q deletions are monoallelic (13qx1), some cases harbour biallelic (13qx2) or mosaic mono/biallelic (13qM) losses (about 15% each). IThe clinical significance of biallelic 13q deletions still remains controversial.

Aims: To describe and compare the characteristics and clinical course of patients harboring isolated monoallelic and biallelic 13q14 deletions by FISH.

Methods: Electronic database containing information from 2452 patients with CLL from 26 Spanish institutions was screened for CLL patients with del(13)(q14) at diagnosis or prior to treatment. Clinical and evolutive data, as well as cytogenetics and FISH for 11q23, CEP12, 13q14 and 17p13 results were analyzed.

Table 1. Baseline patients characteristics at diagnosis.

Patients characteristics	del(13qx1) (N=515)	del(13qx2) (N=54)	del(13M) (N=58)
Median age at diagnosis (range)	66 (28-92)	65 (43-90)	69 (44-88)
Male	314 (61%)	33 (61.1%)	30 (51.7%)
Binet stage (N=616)			
A	454 (89.4%)	43 (84.3%)	53 (93%)
B	38 (7.5%)	5 (9.8%)	3 (5.3%)
C	16 (3.1%)	3 (5.9%)	1 (3.2%)
Absolute white blood cell count ($x10^9$/L)	18.5 (2.9-357)	20.7 (3.8-150)	20 (6.4-63)
Absolut lymphocyte count ($x10^9$/L)	12.9 (1.9-287)	15.3 (1.8-114.9)	13,8 (1.7-60.1)
Hemoglobin (g/dL)	14 (6,4-18)	14 (11-17)	14 (6-18)
Platelets ($x10^9$/L)	196 (40-560)	194 (83-470)	200 (74-450)
Lactate dehydrogenase (IU/L)	314 (81-1420)	318 (103-575)	330 (151-658)
Beta-2 Microglobulin (mg/L)	2.0 (0.6-17.4)	1.9 (1-5.7)	2.3 (1-6.7)
Adenopathies (n=512)	124 (29.5%)	11 (31.4%)	12 (21.1%)
Splenomegaly (n=615)	43 (8.5%)	3 (5.8%)	3 (5.2%)
Hepatomegaly (n=425)	25 (4.9%)	2 (3.8%)	3 (5.2%)
ZAP-70 positive (n=278)	67/223 (30%)	7/19 (36.8%)	3/36 (8.3%)
CD38 positive (n=418)	57/345 (16.5%)	4/33 (12.1%)	6/40 (15%)
Unmutated *IGHV* (n=148)	29/124 (23.4%)	4/18 (22.2%)	1/6 (16.7%)
Abnormal G-banding karyotype	67/251 (26.7%)	5/19 (26.3%)	15/43 (34.9%)
Median follow-up (months)	52 (0-250)	53 (0-196)	39 (0-250)

Results: A total of 627 patients (377M/250F, median age 66) presented isolated del(13)(q14): 515 (82.1%) were monoallelic (13qx1), 54 (8.6%) were biallelic (13qx2), and 58 (9.3%) were considered as mosaics due to the coexistence of monoallelic and biallelic clones (13qM). No significant differences in the clinical characteristics among all three groups were found (Table 1). The median percentage of altered nuclei significantly differed across groups (55% in 13qx1, 72.5% in 13qx2 and 80% in 13qM groups; P<0.001). Focusing in the 13qM group, the median percentage of both monoallelic and biallelic clones found in each patient was not significantly different (35% and 27.5%, respectively; P=0.651). Moreover, no predominance of any of the clones was observed in the 13qM group. After a median follow-up of 50 months (0-250), 195 patients (31.1%) required treatment and 94 (15%) died. No significant differences in the

five-year cumulative incidence of treatment (TtFT) or overall survival (OS) were observed among different groups. The percentage of abnormal cells had a significant impact on the outcome of the studied patients, being 90% the highest predictive power cut-off for a worse TfFT (45% *vs* 28%;P<0.005) and the OS (148m *vs* not reached;P<0.005).
Summary / Conclusion: 1. Patients with biallelic 13q deletions do not show a poorer clinical outcome than those with monoallelic del(13)(q14). 2. Detection of 13q14 deletion in more than 90% of nuclei, is associated to a worse clinical outcome.

P092

A HIGH SENSITIVITY METHOD REVEALED A TWOFOLD-INCREASED INCIDENCE OF NOTCH1 MUTATION WITH ADVERSE PROGNOSTIC IMPACT IN CHRONIC LYMPHOCYTIC LEUKAEMIA

P Sportoletti[1,*] S Baldoni[1], B Del Papa[1], P Aureli[1], L Ruggeri[1], S Plebani[2], A Di Tommaso[2], M Cantelmi[1], M Di Ianni[2], F Falzetti[1]
[1]Haematology Section, University of Perugia, Perugia, [2]Department of Internal Medicine and Public Health, University of L'Aquila, L'Aquila, Italy

Background: Our understanding of the genetics of chronic lymphocytic leukaemia (CLL) has advanced significantly in the last few years. We were the first group to show the presence of activating mutations of *NOTCH1* in CLL patients at diagnosis (Di Ianni 2009) and correlate this genetic alteration with an unfavourable clinical outcome (Sportoletti 2010). Whole genome and exome sequencing studies confirmed that CLL genome harbours recurrent mutations of *NOTCH1* that impacted on overall survival (OS). About 80% of *NOTCH1* mutated CLL cases displayed a c.7544_7545delCT frame shift deletion. The currently available approaches for the detection of the *NOTCH1* mutations display a low sensitivity, thus hampering the diagnostic accuracy and increasing the risk of false negatives especially in patients with oligoclonal B cell mutated clones.
Aims: (1) Developing a sensitive, easy, and inexpensive test for the detection of the *NOTCH1* c.7544_7545delCT mutation in blood samples, (2) Assessing the accuracy of this test in a large cohort of CLL patients and correlate *NOTCH1* mutation with other clinical and biological prognostic factors. (3) Evaluating the impact of the *NOTCH1* c.7544_7545delCT mutation on the clinical outcome of CLL patients
Methods: We investigated 303 consecutive unselected CLL patients with median age 63 years (range 30-89). The *NOTCH1* c.7544_7545delCT mutation was screened by using a newly developed allele specific PCR (AS-PCR) and direct Sanger sequencing at CLL diagnosis.

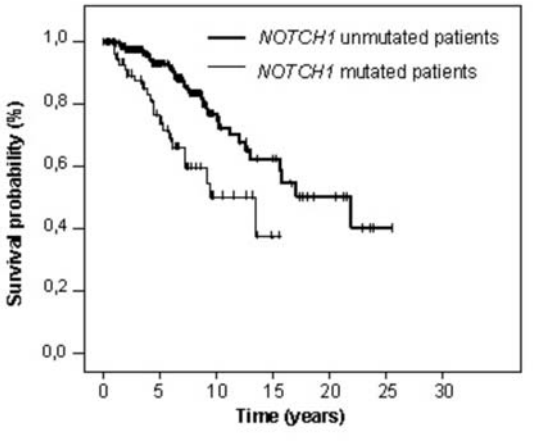

Figure 1.

Results: The analytical sensitivity of our new AS-PCR in serial dilutions of DNA established the lower detection limit to be the 0.1% of mutant alleles. Strikingly, the analysis of 303 CLL samples demonstrated an increased incidence of *NOTCH1* mutation detected by the AS-PCR, compared to Sanger sequencing (20.4% vs 10,5%). In our cohort of patients, *NOTCH1* mutation was associated with adverse prognostic markers such as unmutated IgVH status (280 total available cases, 42/57; P<0.0001) and ZAP-70>20% (189 total available cases 31/49; P=0.0034). In addition, *NOTCH1* mutated patients had more frequently trisomy 12 (132 total available cases 15/39; P=0.0006). To determine whether the AS-PCR detectable *NOTCH1* mutation maintained its prognostic impact in CLL, we estimated its influence on OS, in our cohort of patients.In univariate analysis, patients with *NOTCH1*-mutated CLL showed shorter median OS when compared with unmutated patients (13.46 vs 21.86 years; P<0.001; HR, 2.484; 95% CI, 2.14-6.66) (Figure 1).*NOTCH1* mutation was confirmed to be an independent prognostic factor for OS in a 6 variable model multivariate analysis that included age, sex, Rai Stage, IgVH and ZAP70 (P<0.05, HR 2.053; 95% CI 1.007-4.180).
Summary / Conclusion: The new PCR based approach, exploited in the current study, revealed a significant increased incidence of *NOTCH1* mutation in CLL. Univariate and multivariate statistical analysis proved that *NOTCH1* mutation is an independent prognostic factor retaining its predictive value in CLL. Our diagnostic test allowed us to identify patients with a low allelic burden in the blood demonstrating that the presence of small clonal *NOTCH1* mutated fractions impact on the clinical outcome of CLL patients. Therefore, the AS-PCR determination of *NOTCH1* mutation should be considered in drawing prognostic scores.

P093

PREDICTIVE CLINICAL MODEL FOR UNTREATED DEL(17P13.1) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

D Stephens[1,*] A Ruppert[1], J Jones[1], J Woyach[1], K Maddocks[1], S Jaglowski[1], L Andritsos[1], Joseph M Flynn[1], Michael R Grever[1], N Muthusamy[1], N Heerema[2], J Byrd[1]
[1]Hematology, [2]Cytogenetics, The Ohio State University, Columbus, Ohio, United States

Background: The subset 10% of CLL patients (pts) with del(17p13.1) (17p-) karyotype typically exhibit poor response to therapy. There are limited data on clinical outcomes of these pts and no publication of a large group of these patients treated at a single institution.
Aims: We aimed to report the characteristics and time to treatment of *de novo* 17p- CLL patients from initial visit at Ohio State University (OSU).
Methods: We retrospectively reviewed records of 115 CLL pts with 17p- with no prior therapy seen at OSU from 2002-2012. Treatment free survival (TFS) was calculated from date of 1st OSU visit until date of 1st treatment or death from any cause, censoring pts alive and treatment-free. Overall survival (OS) was calculated from date of 1st OSU visit until date of death or last follow-up. TFS/OS estimates were calculated using the Kaplan-Meier method. Proportional hazards models were fit using backwards selection to identify variables significantly associated with TFS & OS.
Results: Median time from CLL diagnosis (dx) to 1st OSU visit was 4.8mos (range: 0 days-19.7 yrs). Median age at 1st OSU visit was 62yrs (40-92), 70% were male, and 92% were Caucasian. At CLL dx, 55%, 35%, and 10% had Rai Stage (RS) 0, 1/2, and 3/4 respectively. Median WBC, hemoglobin, platelets, and LDH were 26.8K/uL (2.4-446.6), 13.5g/dL (5.9-16.8), 186.5K/uL (13-385), and 169U/L (99-1791) respectively. 39% (80 evaluable) had β2microglobulin≥3mg/L. In addition to 17p-, 14%, 55%, and 21% of patients harbored 11q-, 13q- and tri(12) aberrations respectively. Complex karyotype (CK; ≥3 abnormalities including 17p-) was identified in 37% (n=42), and 70% (n=38/54 evaluable patients) expressed un-mutated IgVH status.Of 105 pts followed for TFS, 57 have started treatment (54%) and 8 died prior to treatment, most within 2yrs of visit. Median TFS estimate was 16.2mos (95%CI=6.4-27.0) with a 2-yr TFS estimate of 42% (95%CI:0.31-0.52). At median follow-up of 3yrs, 47 pts have died. Estimated median OS was 4.2yrs (95%CI:3.4-7.8) with an OS estimate at 2yrs of 77% (95%CI:0.68-0.85). In multivariable analysis, the variables significantly associated with shorter TFS were older age (hazard ratio [HR] for 10yr increase:1.53 (95% CI:1.19-1.97 ;p50%. Age and RS remained in a multivariable model for OS (P≤0.0001), yet CK was included instead of 17p -% as an independent significant prognostic factor (P=0.009), and presence of 11q- was not significantly associated with OS.
Summary / Conclusion: Pretreatment characteristics of higher age at referral, higher RS at diagnosis, higher 17p -%, and presence of 11q- can identify pts who will progress quickly and require treatment sooner than those without these adverse risk factors in this population of *de novo* 17p- CLL. The role of 17p-% and CK warrants further study, considering the strong degree of association between the two variables.

NOVEL ASSAY FOR THE IDENTIFICATION OF NOTCH1 PEST DOMAIN MUTATIONS USING FRAGMENT ANALYSIS AND ALLELE SPECIFIC PCR

P Campregher[1],* R Petroni[1], N Muto[1], j Rodrigues[1], r santana[1], o Ramos[1], R Sitnik[1], N Bacal[1], E Velloso[1], g Oliveira[2], I Metze[2], N Hamerschlak[1]
[1]Albert Einstein Hospital, Sao Paulo, [2]UNICAMP, Campinas, Brazil

Background: NOTCH1 is a proto-oncogene with activating mutations described in a variety of malignancies, including acute lymphoblastic leukemia (ALL), mantle cell lymphoma (MCL) and chronic lymphocytic leukemia (CLL). While the prognostic significance of NOTCH1 mutations remains controversial in ALL, recent data suggest that NOTCH1 PEST domain mutations are associated with adverse prognosis in patients with CLL.
Aims: NOTCH1 mutations are found in around 10% of CLL patients at diagnosis, and since this disease has a heterogeneous clinical course and few prognostic markers, we aimed at designing a fast, cost effective and robust assay to detect NOTCH1 PEST domain mutations in patients with CLL.
Methods: While 92% of the mutations in NOTCH1 PEST domain found in CLL are insertions or deletions, only 8% are represented by point mutations. Therefore we decided to use a fragment analysis approach in our assay. Given that a single mutation (c.7544_7545delCT), represents roughly 75% of all PEST domain mutations in CLL we designed a test that can, at the same time, detect the presence of this mutation specifically and also any insertion or deletion in exon 34. We designed a PCR reaction using one FAM-labeled forward primer anchored at codon 2407 and two reverse primers. One specific for the c.7544_7545delCT mutation anchored at codon 2414 yielding a product of 356 base pairs (bp) and one anchored at codon 2425, yielding a product of 391 bp, comprising the hot spot for mutations in the NOTCH1 PEST domain. Primers were designed with Primer3 software (http://frodo.wi.mit.edu/) and the specificity of the reaction evaluated using the tool "PCR in silico" (http://genome.ucsc.edu/cgi-bin/hgPcr?command=start). The test yields three possible outputs: a) A single 391 bp peak: wild type samples; b) Three peaks (391 bp, 389 bp and 356 bp): heterozygous for c.7544_7545delCT; c) Two peaks (391 bp and another bigger or smaller, depending on the size of insertion / deletion): another insertion or deletion, but not c.7544_7545delCT.
Results: We have first studied 46 blood samples from unselected patients with CLL, in several disease stages. NOTCH1 wild type was detected in forty patients. Six patients had a pattern compatible with c.7544_7545delCT NOTCH1 mutation (Figure 1A), and no patient presented with another mutation. DNA sequencing was performed in selected samples, and the specificity of our assay was confirmed (Figure 1B). Recent studies have demonstrated that NOTCH1 mutation occur more frequently in CLL patients with trisomy 12 (2). In order to confirm these findings, we studied a second cohort of 14 CLL patients with trisomy 12. Of these, 7 patients presented with mutated NOTCH1 (50%). Overall the frequency of NOTCH1 mutations in our series was: 12% and 50% in patients without and with trisomy 12 respectively, in agreement with previous reports. All mutated cases (N=13) had c.7544_7545delCT. We were not able to study the correlation between NOTCH1 mutations and clinical features at this time, since clinical information was not available for most patients.
Summary / Conclusion: In conclusion, we have designed a robust, fast and cost effective assay for routine identification of NOTCH1 PEST domain mutations using fragment analysis and allele specific PCR that is suitable for implementation in the clinical setting for CLL patient evaluation.

Chronic lymphocytic leukemia: clinical studies

P095

LONG-LASTING RESPONSES TO LENALIDOMIDE AS INITIAL THERAPY OF ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

P Strati[1],* M KEATING[1], W Wierda[1], X Badoux[1], S Calin[1], J Reuben[1], S O'Brien[1], S Kornblau[1], H Kantarjian[1], B Lee[1], A Ferrajoli[1]
[1]MD Anderson Cancer Center, Houston, United States

Background: We conducted a phase II study evaluating the activity of lenalidomide as initial therapy for elderly pts with CLL. At the time of its initial report, this treatment was associated with an overall response rate of 65% and an overall survival of 88% at 2 years (Badoux, Blood 2011).
Aims: We analyzed outcome, toxicity, clinical and laboratory characteristics of long-term responders in this trial.
Methods: Pts with a response lasting 36 months or longer were defined as "long-term responders" (LTRs). Clinical characteristics, prognostic factors, serum immunoglobulin levels, circulating T cell numbers (up to 36 months) and plasma cytokine levels of LTRs were compared with the rest of the study population using non-parametric and Chi-square tests. Differences were considered to be significant if p was equal to or less than 0.05.
Results: Thirty-four of the 60 pts (57%) are LTRs. Best responses among LTRs consisted of 24 (71%) complete remissions (CR), including 5 pts with MRD-negative CR, and 10 (29%) partial remissions. Median time to failure (TTF) has not been reached for LTRs, after a median follow up of 47 (37-60) months. The median daily dose of lenalidomide at last follow-up in LTRs pts is 5 mg (2.5-10). Twenty-four LTRs are still on therapy and ten have discontinued lenalidomide. Reasons for treatment discontinuation were: progression after 43 months in 1 pt, toxicity in 6 pts (deep venous thrombosis after 41 months in 1 pt, moderate neuropathy after 30 and 39 months in 2 pts, persistent fatigue after 23 months in 1 pt, moderate weight loss after 5 months in 1 pt, immune thrombocytopenia after 11 months in1 pt), infectious complications in 1 pt (sepsis, after 12 months), second malignancy (new onset invasive squamous cell carcinoma of the skin after 26 months) in 1 pt and change of institution in 1 pt. Lenalidomide is often associated with myelosuppression in pts with CLL. Interestingly, LTRs experienced neutropenia during the first 12 months of therapy that later resolved in 83% of pts (Figure 1A); additionally a recovery in hemoglobin and platelets compared to baseline values was also seen in 100 and 77% of LTRs, respectively (Figure 1B-C). We also observed a recovery in the percentage of circulating T cells (CD3+) in 41% ofpts and a recovery in plasma levels of immunoglobulins A, G and M levels in 68, 58 and 52% ofpts, respectively (Figure 1D). As therapy continues until progression, we focused on lenalidomide-related late (defined as toxicities observed after 48 months of therapy) toxicities. Grade 1-2 diarrhea was observed in 2 pts and Grade 1 peripheral neuropathy in 3 pts. One patient developed skin lesions shown to be *in situ* squamous and basal cell carcinomas on biopsy. We compared pretreatment clinical characteristics of LTRs and the other pts on study. We observed that LTRs had lower baseline beta-2-microglobulin (median values: 4 vs 5 mg/L; P=0.005) and were less likely to have a deletion 17q (0 vs 6; P=0.005) but more likely to have trisomy 12 (11 vs 2; P=0.03). Furthermore, baseline plasma levels of IL8, IFNγ, sVEGFR2 and MIP1α were significantly lower in the LTRs (P=0.05, 0.06, 0.05 and 0.02, respectively).
Summary / Conclusion: Lenalidomide as initial therapy of elderly pts with CLL induced responses that are durable, with 57% of pts maintaining their response for more than 3 years. Myelosuppression is observed, but it is transient and resolves past the first year. Compared to the pts with shorter response duration, LTRs were more likely to have lower baseline levels of beta2-microglobulin, IL8, IFNγ, sVEGFR2 and MIP1α and intermediate or favorable cytogenetic abnormalities.

LOW-DOSE FCR IN ELDERLY/COMORBID PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA (CLL/SLL): UPDATED RESULTS OF PROJECT Q-LITE BY CZECH CLL STUDY GROUP

L Smolej[1,*] Y Brychtova[2], E Cmunt[3], M Doubek[2], M Spacek[3], D Belada[1], M Motyckova[1], I Zygulova[4], D Adamova[4], V Prochazka[5], M Simkovic[1], K Klaskova[6], T Kozak[6]
[1]4th Department of Internal Medicine - Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, [2]Department of Internal Medicine – Hematology and Oncology, University Hospital, Brno, [3]First Department of Medicine, Charles University General Hospital, Prague, [4]Hematology/Tranfusiology Department, Silesian Hospital, Opava, [5]Department of Hematology-Oncology, University Hospital, Olomouc, [6]Department of Internal Medicine - Hematology, University Hospital Královské Vinohrady, Prague, Czech Republic

Background: Combination of fludarabine, cyclophosphamide and rituximab (FCR) is currently considered the treatment of choice in physically fit patients (pts) with chronic lymphocytic leukemia (CLL). However, many patients cannot tolerate this aggresive regimen because of advanced age and/or serious comorbid conditions which may lead to unacceptable toxicity. Protocols based on low-dose fludarabine have recently demonstrated promising results in small studies.
Aims: Aims: to assess efficacy and safety of low-dose FCR regimen used in elderly/comorbid patients with CLL/SLL; updated results including first data on progression-free survival (PFS) and overall survival (OS) are presented.
Methods: Between March 2009 and July 2012, a total of 207 pts with active disease (CLL, n=196, SLL, n=11) were treated by low-dose FCR at 16 centers cooperating within Czech CLL Study Group. Dose reduction of chemotherapy in comparison to full-dose FCR was following: 50% of fludarabine dose (12 mg/m^2 i.v. or 20 mg/m^2 orally on days 1-3) and 60% of cyclophosphamide dose (150 mg/m^2 i.v./p.o. on days 1-3). Rituximab was administered in standard schedule (375 mg/m^2 i.v. day 1 in 1st cycle, 500 mg/m^2 i.v. day 1 from 2nd cycle). Treatment was repeated every 4 weeks; antimicrobial prophylaxis with sulfamethoxazol/trimethoprim and aciclovir or equivalents was recommended. Data regarding efficacy and safety are currently available in 199 pts; the descriptive characteristics are summarized in Table 1.
Results: Based on intention-to-treat principle, the overall response rate / complete responses (including clinical CR [without bone marrow biopsy] and CRi [with incomplete marrow recovery]) were 79/37% in first line and 64/29% in relapsed/refractory setting. Serious (CTCAE grade III/IV) neutropenia was frequent (57 and 49%) but did not translate into high occurrence of serious infections (14 and 18%, Table 1). The most common causes of death were CLL progression and infections. At the median follow-up of 19 months, median progression-free survival for previously untreated and relapsed/refractory patients was 20 and 15 months; median overall survival has not been reached in previously untreated pts (80% at 2 years) and was 31 months in relapsed/refractory pts. CIRS score and age did not significantly influence PFS or OS.
Summary / Conclusion: Our data show that treatment of elderly/comorbid patients with CLL/SLL using low-dose FCR has promising efficacy in first line as well as relapsed/refractory disease, including reasonable PFS and OS. Toxicity is acceptable and manageable.

Table 1. Basic charcateristics, therapeuic efficacy and severe (CTCAE grade III/IV) toxicity.

	1st line	Relapsed/refractory
Total number of patients	102	97
Age (median, range)	69 (54-83)	71 (58-87)
Males	64%	59%
Advanced Rai stages	56%	66%
Bulky lymphadenopathy	41%	37%
CIRS score (median, range)	5 (0-13)	6 (0-14)
Unmutated IgVH	75%	72%
Del 11q	32%	36%
Del 17p	8%	9%
Number of FCR cycles (median, range)	5 (1-7)	4 (1-6)
Overall response rate	79%	64%
CR + cCR + CRi	37%	29%
Stable disease	9%	21%
Progressive disease	8%	6%
Not evaluable	4%	9%
Neutropenia	57%	49%
Anemia	10%	13%
Thrombocytopenia	7%	19%
Infections	14%	18%

P097

PLATINUM AND HIGH-DOSE CYTARABINE-BASED CHEMOTHERAPY IN ULTRA HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA AND RICHTER'S SYNDROME: RESULTS OF A RETROSPECTIVE MULTICENTER STUDY

E Durot[1,*] V Leblond[2], S Leprêtre[3], A Michallet[4], Q Le[1], A Delmer[1]
[1]Hematology, Hôpital Robert Debré, Reims, [2]Hematology, Hôpital Pitié Salpêtrière, Paris, [3]Hematology, Centre Henri Becquerel, Rouen, [4]Hematology, Centre hospitalier Lyon-Sud, Pierre Bénite, France

Background: Ultra high-risk chronic lymphocytic leukemia (CLL) and Richter's syndrome (RS) usually display a poor prognosis. Although they are widely used as salvage therapy in many types of lymphomas, platinum and cytarabine (PI + AraC)-based regimens have not been evaluated in large cohorts of patients with CLL or RS.
Aims: The aim of this study was to assess the efficacy of PI + AraC-based regimens in patients with aggressive forms of CLL (high or ultra high-risk CLL or Richter's syndrome).
Methods: This French retrospective analysis included 75 patients with relapsed/refractory CLL or RS, who received at least one course of PI + AraC-based chemotherapy (DHAP±rituximab, ESHAP±rituximab or OFAR) in 4 centers between 2000 and 2012.
Results: Forty-seven patients with relapsed or refractory CLL (including 36 ultra high-risk CLL) and 28 with RS were included. Median age was 62 years (range, 18-79 years). The median number of previous therapies was 3 (range, 1-7), including fludarabine-based regimens (75%) and alemtuzumab (32%), and 61% of the patients were refractory to the last treatment. Tumor mass >5 cm and splenomegaly were present in 32% and 42% of patients respectively. LDH and β2-microglobulin were elevated in 75% of cases. The incidences of 17p and 11q deletions were 40% and 39% respectively. The overall response rate was 60% with 24% complete response (CR) in CLL, and 43% with 25% in RS. The median progression-free survival and overall survival were 11 and 14.6 months respectively. Fludarabine refractoriness and 17p deletion were not associated with a poorer outcome. In multivariate analysis, the only factors associated with a shorter survival were performance status ≥2 (P=0.04) and albumin level <35 g/L (P=0.0004). The main toxicities were myelosuppression (grade III-IV in 80% of cases) and infectious complications (toxic death 15%). Twenty-one patients underwent thereafter autologous or allogeneic stem cell transplantation (SCT).
Summary / Conclusion: Platinum and high-dose cytarabine-based regimens provide high response rate in high-risk CLL and RS. In ultra-high-risk CLL (17p deletion or fludarabine refractoriness), these regimens should be considered as an option for tumor control before allogeneic transplantation.

P098

DOSE-ESCALATION AND PHARMACOKINETICS (PK) OF DIFFERENT LENALIDOMIDE (LEN) STARTING DOSE REGIMENS IN PATIENTS WITH RELAPSED OR REFRACTORY (REL/REF) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) (CC-5013-CLL-009)

C Wendtner [1,*] M Hallek[2], G Fraser[3], A Michallet[4], P Hillmen[5], J Duerig[6], S Gregory[7], M Kalaycio[8], T Aurran-Schleinitz[9], L Trentin[10], S Stilgenbauer[11], T Kipps[12], B Purse[13], J Zhang[13], N Chen[13], J Mei [13], A Chanan-Khan[14]
[1]Klinikum Schwabing, Munich, Germany; Clinic I of Internal Medicine, University of Cologne, [2]Clinic I of Internal Medicine, University of Cologne, Cologne, Germany, [3]Juravinski Cancer Centre, Hamilton, ON, Canada, [4]Department of Hematology, Hospices Civils de Lyon, Pierre Bénite, France, [5]St James's Institute of Oncology, Leeds, United Kingdom, [6]Universitaetsklinikum Essen, Essen, Germany, [7]Rush University Medical Center, Chicago, IL, [8]Cleveland Clinic, Cleveland, OH, United States, [9]Institut Paoli Calmettes, Marseille, France, [10]Padua University School of Medicine, Padua, Italy, [11]Department of Internal Medicine III, Ulm University, Ulm, Germany, [12]UCSD Moores Cancer Center, San Diego, CA, [13]Celgene Corporation, Summit, NJ, [14]Mayo Clinic, Jacksonville, FL, United States

Background: CLL patients (pts) who relapse after purine-analog or bendamustine-based treatments have a poor prognosis. Lenalidomide is an immunomodulatory agent that has shown significant activity in rel/ref CLL. Various doses and schedules have been explored. Here we report the preliminary results on tolerability, efficacy, and PK from the CLL-009 study, in which different doses were investigated to determine the optimum starting dose regimen.
Aims: To investigate primarily the safety and secondarily the efficacy of LEN initiated at 3 starting doses (5, 10, and 15 mg/d) followed by a step-wise dose escalation as tolerated in rel/ref CLL. Exploratory endpoints included PK analyses.
Methods: In this phase2, randomized, double-blind, multicenter trial, rel/ref CLL pts (after ≥ 1 purine-analog or bendamustine-based regimen) were randomized 1:1:1 to receive a starting dose (5, 10, or 15 mg/d) of oral LEN on days 1–28 of each 28-day cycle. All doses were escalated by 5 mg increments every 28 days to reach a maximum dose of 25 mg/d, as tolerated. In case of poor tolerability, dose reductions occurred in 5 mg decrements.
Results: A total of 104 pts were enrolled; median age was 64.5 years (range 32-81). Pts were heavily pretreated-median number of 3 prior treatments-and

had poor prognostic features. The safety population consisted of 103 pts and PK data are available for 26 pts: 11/34 in the 5 mg, 6/34 in the 10 mg, and 9/35 in the 15 mg dose level. For the 103 evaluable pts, 51.4% did not escalate above their starting dose level (50.0%, 38.2%, and 65.7% for the5, 10, and 15 mg groups, respectively). Additionally, 56% of dose reductions occurred in the first 3 treatment cycles. In cycle1, 17.6% (5 mg), 29.4% (10 mg), and 22.9% (15 mg) of pts had dose reductions; in cycle2, dose reductions from the respective starting dose occurred in 20.6%, 11.8%, and 20.0%. Reductions in these 2 cycles were primarily due to hematologic events of neutropenia (41%) and thrombocytopenia (10.3%). 7 pts in cycle 1 and 1 pt in cycle 2 were dose reduced due to tumor flare; the average duration was 13.8 days and each of these patients continued study therapy. However, of the 39 responders (13 in each group) 7.7% (5 mg), 23.1% (10 mg), and 53.8% (15 mg) did not escalate to a higher dose level. 34 responders (87.2%) reached a dose ≥15 mg/d and 38.5% escalated to the maximum allowed dose of 25 mg/d. LEN was rapidly absorbed and eliminated. The maximum plasma concentration was observed 1 hour after dosing and the mean terminal half-life was approximately 3 hours in all starting dose levels (Table 1). The differences in plasma exposure in each group were approximately proportional to the starting doses from 5 to 15 mg/d. The PK pts had a median age of 64 years (range 54–78) and 46% were ≥ 65 years old. It is noted that the mean LEN clearance in pts ≥ 65 years and < 65 years was 184 and 212 mL/min, respectively ($p > 0.05$), consistent with the respective mean creatinine clearance of 78.7 and 89.3 mL/min. Cross-study comparisons suggested that LEN clearance in CLL pts is comparable to patients with multiple myeloma or myelodysplastic syndromes.

Summary / Conclusion: Efficacy data with a longer follow-up will be presented, but at a median treatment duration of 34.0 wks, ORR was 38.2% in this heavily pretreated population. The data suggest that titration of doses up to 15 mg/d or greater correlates with better responses, while starting dose of 15 mg/d appears to be too high. The PK of LEN in CLL pts is consistent with that observed in other disease populations studied.

Table 1. Pharmacokinetic parameters of lenalidomide in CLL patients.

Parameter	5 mg dose (n = 11)	10 mg dose (n = 6)	15 mg dose (n = 9)
T_{max} (h)	1 (0.5–2)	1 (0.5–3)	1 (0.5–4)
C_{max} (ng/mL)	85 (22.6)	220 (45.8)	263 (31.6)
AUC_{24} (ng*h/mL)	414 (21.0)	1,022 (22.7)	1,247 (43.3)
$t_{1/2}$ (h)	3.37 (23.5)	3.35 (43.3)	3.09 (38.2)
CL/F (mL/min)	201 (21.0)	163 (22.7)	201 (43.3)
V/F (L)	58.7 (24.7)	47.3 (31.8)	53.7 (20.5)

Data are expressed as median (range) for T_{max} and geometric mean (coefficient of variation) for other parameters.
Abbreviations: AUC_{24}, area under the curve at 24 hours; CL/F, total clearance; C_{max}, maximum plasma concentration; $t_{1/2}$, mean terminal half life; T_{max}, time to maximum plasma concentration; V/F, volume of distribution.

P099

TOXICITY AND RESPONSE BY COMORBIDITY AND AGE IN A RANDOMIZED STUDY OF ORAL FLUDARABINE AND CYCLOPHOSPHAMIDE WITH RITUXIMAB FIRST-LINE THERAPY OF FIT ELDERLY WITH CHRONIC LYMPHOCYTIC LEUKAEMIA

S Mulligan[1],* D Gill[2], P Turner[3], W Renwick[4], R Harrup[5], M Latimer[6], G Cull[7], L Berkahn[8], C Forsyth[9], N Mackinlay[1], D Simpson[10], P Campbell[11], C Tam[12], M Collins[13], M Sulda[14], G Best[1], B Kuss[14]

Background: Combination immunochemotherapy with fludarabine (F), cyclophosphamide (C) and rituximab (R) gave superior progression free and overall survival compared to FC in the CLL8 Study. The median age in CLL8 was 61 years compared to the median age of CLL overall at 72 years. There is debate regarding the tolerability of FCR based therapy in the elderly.
Aims: We aimed to assess the safety and tolerability of F(C)R based therapy in fit elderly patients with CLL requiring treatment in a dose de-escalation study. Fitness was assessed as a Cumulative Illness Rating Scale [CIRS] score ≤6. This analysis was performed on 12 February 2013, seven months after the last recruitment, when all patients should have completed therapy, and focused on toxicity and response by CIRS score and age. The study was supported by Roche Products Australia, and Genzyme (formerly Bayer Schering).
Methods: Previously untreated fit patients with progressive CLL aged ≥65 were randomized to one of three treatment regimens "FR5", "FCR3" and "FCR5" as follows: (i) Fludarabine 24 mg/m^2 orally for five days + Rituximab (375 mg/m^2 C1, 500 mg/m^2 C2-6) iv Day 1 (FR5), (ii) Fludarabine 24 mg/m^2 and Cyclophosphamide 150 mg/m^2 both orally for three days (D1-3) + Rituximab iv D1 (FCR3) or (iii) Fludarabine 24 mg/m^2 + Cyclophosphamide 150 mg/m^2 both orally for five days (D1-5) + Rituximab iv D1 (FCR5), all given at 4 weekly intervals for an intended 6 cycles. Patients were administered their therapy arm with no dose reduction. Therapy was delayed up to 2 weeks if there was grade 3 or 4 toxicity, and if unresolved after 2 weeks, patients were taken off study. If toxicity resolved to grade 2 or less, therapy proceeded.
Results: Recruitment of all 120 randomised patients was completed in July 2012. Median age was 71 (range 65-83) years. Binet stage at registration was progressive A – 20 (16.7%), B – 56 (46.7%) and C – 44 (36.7%). Haematological toxicity and overall response rates (ORR) are as follows for the total patient cohort by CIRS comorbidity score and age bracket but with no analysis by treatment arm. The overall grade 3/4 neutropenia rate was 39.8% and febrile neutropenia / infection was 15.9%. Grade 3/4 toxicity across the CIRS score brackets 0-2, 3-4 and 5-6 respectively was 56%, 39% and 56% for all haematological toxicity, 43%, 31% and 50% for neutropenia, and 15%, 19% and 13% for febrile neutropenia and/or infection. Grade 3/4 toxicity across the age brackets 65-69, 70-74, 75-79, and 80-84 respectively was 52%, 53%, 43% and 20% for all haematological toxicity, 45%, 38%, 43% and 0% for neutropenia, and 18%, 7%, 33% and 0% for febrile neutropenia and/or infection. The overall response rate (ORR) across the CIRS score brackets 0-2, 3-4 and 5-6 respectively was 94%, 87% and 100%, and across age brackets 65-69, 70-74, 75-79, and 80-84 respectively was 93%, 91%, 92% and 100%. Using stringent stopping criteria, 35% stop early due to toxicity, intercurrent illness or patient choice, and 61.9% have a delay during therapy.
Summary / Conclusion: Oral F(C)R therapy appears generally safe and well tolerated in CLL patients aged ≥65 years requiring first-line therapy according to incomplete data 7 months from end of recruitment. For fit elderly patients, neither a CIRS score between 0 and6, nor age bracket appear to be associated with toxicity. ORR is high at 92.4%, and complete remission in 40.5% at Final Staging 2 months after treatment. ORR was similar across all CIRS score and age brackets.

P100

PHASE 1B STUDY OF IDELALISIB (GS-1101) PLUS CHLORAMBUCIL±RITUXIMAB IN PATIENTS WITH RELAPSED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

J Barrientos[1],* J Leonard[2], R Furman[2], I Flinn[3], S Vos[4], S Coutre[5], M Schreeder[6], N Wagner-Johnston[7], J Sharman[8], T Boyd[9], N Fowler[10], Y Kim[11], L Holes[11], D Johnson[11], R Dansey[11], R Dubowy[11], K Rai[1]

D. Anderson Cancer Center, Houston, [11]Gilead Sciences, Seattle, United States

Background: PI3K-delta (δ) is critical for activation, proliferation and survival of B cells and plays a role in homing and retention in lymphoid tissues. PI3Kδ signaling is hyperactive in many B-cell malignancies. Idelalisib is a first-in-class, selective oral inhibitor of PI3Kδ. It has shown activity as a single agent and in combinations with bendamustine and anti-CD20 mAbs, in patients with relapsed or refractory (R/R) CLL.
Aims: The primary objective of this study is to evaluate the safety of the addition of idelalisib to chlorambucil (Chl) and chlorambucil plus rituximab (R) in pts with R/R CLL. The secondary objective is to evaluate the clinical activity of the combination. Preliminary results are presented.
Methods: Pts required therapy according to IWCLL 2008 guidelines. All pts received idelalisib 150 mg po bid continuously. Those on idelalisib+Chl received Chl 10 mg/m^2 po qd on days 1-7 every 28 days for a minimum of 3 and maximum of 12 cycles, based on achievement of optimal response. Those on idelalisib+Chl+R received, in addition, R 375 mg/m^2 on day 1 of the first 6 cycles. Response was assessed by the investigators based on scheduled CT evaluations and clinical criteria following IWCLL 2008.
Results: 29 subjects were enrolled from March 2011 through August 2012: median age 65 (range: 41-82); M/F 83/17 (%); WHO 0/1/2 79/21/0 (%); current Rai III/IV 3/48 (%). The median number of prior regimens was3, mean3, range 1-11. 48% of subjects were refractory to their last therapy (progressed within 6 months) and 48% had relapsed at >6 mo, 4% unknown. Of 13 subjects treated with idelalisib+Chl+R, 5 (39%) were refractory to rituximab. The ORR was

63% for idelalisib+Chl (1/16 CR, 9/16 PR) and 92% for idelalisib/Chl/R (1/13 CR, 11/13 PR). Median PFS has not been reached. As of 22 Feb 2013, 4 subjects have discontinued therapy (2 from each arm): 1 PD (idelalisib+Chl), 1 death, 1 withdrew consent and 1 other. The median time on idelalisib therapy is currently 8.1 mos (range: 0.9-10.2). The most frequently reported treatment-emergent AEs (≥20% of all subjects) and lab abnormalities are shown in Table 1.

Summary / Conclusion: Idelalisib, when combined with either chlorambucil or chlorambucil plus rituximab, is effective in inducing responses in the majority of relapsed and refractory patients with CLL. The safety profile is not different from what would be expected from the addition of each of the administered drugs. These results support further studies with these combinations in patients with CLL.

Table 1.

Adverse Event	Idelalisib / Chl (N=16)		Idelalisib / Chl/R (N=13)

PRELIMINARY RESULTS FROM A SURVEY OF 'REAL-LIFE' FIRST LINE THERAPY OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE UK

T Todd[1,*] A Forbes[2], M Ewings[3], M Dyer[4], L Sanders[4], W Thomas[1], S Hewamana[5], C Dearden[5], A Copplestone[2]

[1]Haematology, The Royal Devon and Exeter Hospital, Exeter, [2]Haematology, Derriford Hospital, Plymouth, [3]Haematology, Musgrove Park Hospital, Taunton, [4]Haematology, Leicester Royal Infirmary, Leicester, [5]Haematology, The Royal Marsden Hospital, London, United Kingdom

Background: FCR is widely regarded as standard 1st line therapy for chronic lymphocytic leukaemia. In October 2009 the UK National health Service made FCR freely available to all patients in England for this indication. However, the landmark studies establishing the role of this treatment had patient populations younger than the median age and in generally more robust health, e.g. median performance status in CLL8 is 1.

Aims: To determine the applicability and tolerance of trial derived standard treatment to the unselected CLL patient population To determine the degree to which patients entering trials were representative of the unselected patient population. To determine the range of non-FCR treatments in use. To determine the sequence of 1st and 2nd line treatments in current use and any impact on 2nd line treatment of toxicity from 1st line treatment

Methods: We initiated a prospective survey of 1st line treatment choices and outcomes in CLL from 1st October 2009 at 7 hospitals across England serving a combined population of approximately 3.3 million. The survey consists of short questionnaires at treatment initiation, 6 months post treatment completion and at relapse.

Results: To date 209 patients have received treatment, 6 month follow up is available for 151 of these and 12 month for 43. Median age at treatment initiation is 70, Binet stages are A 22%, B 28% and C 50%. *Treatment choice*:97 were scheduled for full dose FCR (88) or received non-FCR treatment in a trials with an FCR arm (9). The full range of treatments is shown in Table 1. For the 54% (112) of patients not considered suitable for full dose FCR the reasons not to use it were medically unfit 25%, known 17p 0%, patient choice 18%, patient age 33%, other 24%. (including previous non-haematological cancer, omission of Rituximab because of grossly elevated WCC, the perception of FCR as excessive for low disease burden and a desire to avoid marrow suppression). 8% (17) of all patients were treated within a trial. *Treatment completion:*Of patients planned for 6 cycles of full dose FCR only 41% receive this while 26% receive ≤5 cycles, 12% have dose reductions and a further 20% have both cycle number and dose reductions. Data from 6 months after completion of treatment is available for 54 of these and 51% have some cytopenia with 34% having severe cytopenia (neutrophil <1x10^9/L, Hb<100 g/L or platelets <100x10^9/L). Of patients planned to have dose reduced FCR from the outset 61% required further dose reduction and 33% have persisting cytopenia 6 months post treatment. At 12 months 30% of those exposed to FCR have persisting cytopenia and 5 have required second line therapy, in 2 cases choice or dose was altered by post=FCR cytopenia.

Summary / Conclusion: Our survey indicates that: 1. a wide range of 1st line treatment options remain in use. 2. fewer than 50% of patients are felt suitable for full dose FCR. 3. Patients planned for full or reduced dose FCR tolerate it poorly with 60% required unplanned dose reductions. 4. Long term cytopaenia, which could compromise future treatment choices, may be a significant problem following full dose FCR treatment. 5. Patients entering trials of 1st line treatment represent a very small percentage of the patient population

Table 1.

Initial Treatment choice	Number (Percentage)
Full dose FCR	96 (41%)
Reduced dose FCR	29 (14%)
FC	2 (1%)
Chlorambucil + Prednisolone*	15 (7%)
Chlorambucil alone	40 (19%)
Chlorambucil + splenectomy/ splenic irradiation	3 (1.5%)
R-CVP	2 (1%)
R-CHOP	1 (0.5%)
R-HDMP	1 (0.5%)
FC	2 (1%)
FCMR (trial)	6 (3%)
FCM-miniR (trial)	2 (1%)
Rituximab+oral prednisolone	2 (1%)
R-Chlorambucil	2 (1%)
Bendamustine	1 (0.5%)
HDMP	2 (1%)

P102

NOTCH1 MUTATIONS IDENTIFY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS THAT DO NOT BENEFIT OF AN INDUCTION AND CONSOLIDATION TREATMENT BASED ON RITUXIMAB

G Del Poeta[1,*] M Dal Bo[2], D Ragusa[1], M Del Principe[1], F Pozzo[2], D Rossi[3], F Buccisano[1], L Maurillo[1], P Niscola[1], P de Fabritiis[1], A Perrotti[1], A Venditti[1], S Amadori[1], G Gaidano[3], V Gattei[2]

[1]Hematology, University Tor Vergata, Roma, [2]Clinical and Experimental Onco-Hematology Unit, CRO, IRCCS, Aviano (PN), [3]Division of Hematology, Clinical and Experimental Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: Recent studies showed that stabilizing mutations of *NOTCH1* gene occur in about 10% CLL at diagnosis and are associated with advanced disease and unfavourable prognosis (Rossi *et al*, Blood, 2012; Del Poeta *et al*, Br J Haematol, 2013).

Aims: Here, we investigated whether: i) *NOTCH1* mutations (*NOTCH1*^{mut}) are confirmed to be an independent predictor of poor clinical outcome in a cohort of CLL patients (pts) all treated with the same therapeutic approach, and ii) *NOTCH1*^{mut} are able to identify a subset of CLL pts not benefiting from the use of rituximab (rtx).

Methods: We assessed the incidence and impact of *NOTCH1*^{mut} in 123 CLL symptomatic pts, median age 63 years (37-80), homogeneously treated in first line with six monthly courses of intravenous (25 mg/m^2) or oral fludarabine (30-40 mg/m^2) followed by four weekly doses (375 mg/m^2) of rtx. Out of 123 pts, 43 reached complete remission (CR); the remaining 80 pts either reached CR but remained positive for minimal residual disease detection by flow cytometry (CR/MRD+; n=46), or underwent partial remission/stable disease (PR/SD; n=34). Among them, 21 pts entered follow-up without further therapy (unconsolidated pts), while 59 underwent to a consolidation-maintenance phase (consolidated pts) with rtx (four monthly cycles of rtx at 375 mg/m^2 followed by twelve monthly doses of rtx at 150 mg/m^2; Del Poeta *et al*, Cancer, 2008). *NOTCH1* c.7544_7545delCT mutation was investigated by amplification refractory mutation system (ARMS) PCR using frozen samples collected at presentation.

Results: *NOTCH1*^{mut} were found in 20 of 123 pts (16.3%). Regarding baseline characteristics, there were significant associations of *NOTCH1*^{mut} with trisomy 12 (P=0.03), unmutated *IGHV* (P=0.0001), ZAP-70 >20% (P<0.0001) and CD49d >30% (P=0.0004). Regarding response to therapy, 12 out of 20 (60%) *NOTCH1*^{mut} pts showed only PR/SD vs 22/103 (22%) *NOTCH1* wild-type (*NOTCH1*^{wt}) pts (P=0.002). At extended follow-up (median 68 months), *NOTCH1*^{mut} was associated with significantly decreased response duration (RD), (13% vs 48% at 8 years, P=0.00004, Figure 1) and inferior overall survival (OS), (0% vs 57% at 15 years, P=0.00002). The 59/80 consolidated patients showed a longer RD vs the 21/80 unconsolidated pts [50% vs 0% at 5 years; P=0.001]. Equally, OS was longer in consolidated pts vs unconsolidated pts (81% 0% at 13 years; P=0.0008). Among consolidated pts, *NOTCH1*^{mut} cases (10/59) experienced significantly shorter RD and OS intervals than con-

solidated *NOTCH1*^{wt} pts (RD, 0% vs 61% at 5 years, P=0.004; Figure 2; OS, 38% vs 95%, at 10 years, P=0.004). Of note, RD and OS intervals of *NOTCH1*^{mut} consolidated pts was not dissimilar to that of the 21 unconsolidated CLL pts (p>0.05 in both cases), 8 of them bearing a *NOTCH1*^{mut} genotype. *NOTCH1*^{mut} maintained an independent prognostic impact in Cox regression multivariate analyses, by evaluating: i) RD (*NOTCH1*^{mut} HR 2.96, P=0.02) along with consolidation-maintenance (HR 0.38, P=0.005) and *IGHV* (HR 2.73, P=0.01); ii) OS (*NOTCH1*^{mut} HR 7.31, P=0.002) along with *IGHV* (HR 3.14, P=0.04), *TP53*$^{mut/del}$ (HR 4.18, P=0.02) and age >60 years (HR 4.14, P=0.03).
Summary / Conclusion: Our results confirm that *NOTCH1*^{mut} represent an independent clinical prognostic factor in homogeneously treated CLL pts and identify a subset of CLL pts that does not benefit from the addition of rtx to therapy.

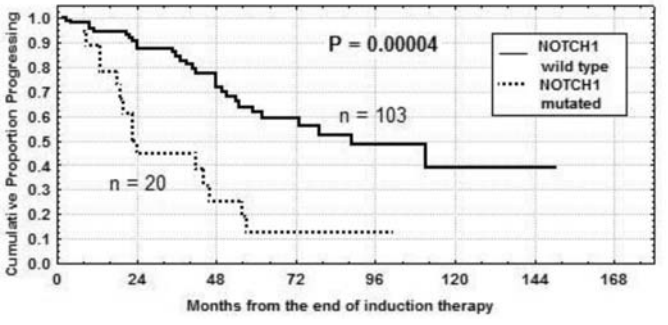

Figure 1. Response duration by NOTCH1 mutations.

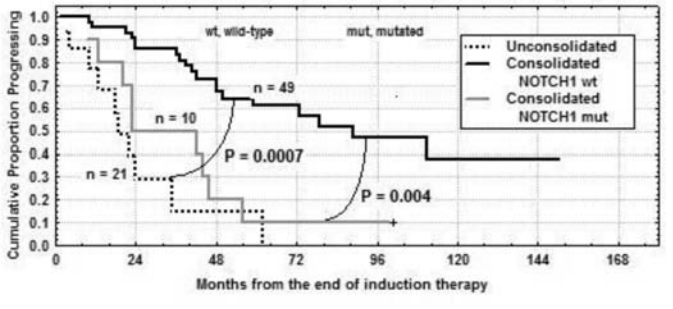

Figure 2. Response duration in unconsolidated vs NOTCH1 wt and NOTCH1 mut consolidated pts.

P103

INCREASED EXPRESSION OF THE EZH2 METHYLTRANSFERASE AND EVIDENCE OF FUNCTIONALITY IN CLL SUBGOUPS WITH AGGRESSIVE CLINICOBIOLOGICAL PROFILES

N Papakonstantinou[1,*] S Ntoufa[1], T Touloumenidou[1], A Anagnostopoulos[1], C Belessi[2], K Stamatopoulos[1,3]
[1]Hematology Department and HCT Unit, G. Papanicolaou Hospital, Thessaloniki, [2]Hematology Department, Nikea General Hospital, Piraeus, [3]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece

Background: EZH2 is the enzymatic subunit of the polycomb repressive complex 2 (PRC2), which induces gene repression through trimethylation of histone H3 at lysine 27 (H3K27). EZH2 over-expression has been reported in a broad range of both hematopoietic and solid malignancies and associated with poor prognosis. Furthermore, activating mutations of the EZH2 gene are recurrent in B cell lymphomas of germinal center origin. Recently, we demonstrated for the first time that EZH2 is expressed in CLL and, notably, that EZH2 mRNA and protein levels were up-regulated in the aggressive stereotyped subset #1 versus the indolent subset #4.
Aims: In order to obtain deeper insight into the role of EZH2 in CLL pathobiology, here we extended our studies by investigating EZH2 expression and function in a well-annotated cohort of 116 patients with CLL.
Methods: EZH2 mRNA levels were determined in negatively selected CD19+ cells from peripheral blood samples obtained at diagnosis or before any treatment by real-time quantitative PCR (RQ-PCR) using abl as the housekeeping gene. Using Western blotting, we also evaluated (i) EZH2 protein expression; and, (ii) its functional effects, by measuring H3K27me3 levels.
Results: A total of 116 cases were evaluated for EZH2 mRNA expression by RQ-PCR; of these, 55 (47.4%) carried unmutated IGHV genes (98-100% identity to the germline, U-CLL), whereas the remaining 61 cases (52.6%) carried mutated IGHV genes (<98% identity to the germline, M-CLL). Significantly higher EZH2 mRNA levels were identified in U-CLL vs. M-CLL (fold difference, FD, >2, P<0.00001). In accordance with this result, Western analyses of 59 cases (U-CLL, n=26; M-CLL, n=33) revealed significantly higher EZH2 protein expression in U-CLL vs M-CLL (FD=4.5, P<0.0001). Interestingly, we also observed higher levels of H3K27me3 in U-CLL vs M-CLL (FD=4.3, P<0.01), strongly supporting that EZH2 over-expression in U-CLL is functionally relevant. We next evaluated whether the clustering of CLL cases in subsets based on BcR stereotypy might be reflected in subset-biased differences in EZH2 expression, focusing on the largest subsets in the present cohort, namely: (i) subset #1 – IGHV1 clan genes, U-CLL, n=8; (ii) subset #4 – IGHV4-34, M-CLL, n=9; (iii) subset #6 – IGHV1-69, U-CLL, n=8; and, (iv) subset #8 – IGHV4-39, U-CLL, n=7. Significantly (FD>1.7-2.2, P<0.05) higher EZH2 mRNA levels were identified in (i) subset #1 versus subset #4, confirming our previous findings; (ii) subset #1 versus U-CLL subsets #6 and #8 as well as U-CLL in general. Finally, we investigated possible clinical implications and found significantly shorter time-to-first-treatment (P=0.04) in patients with increased EZH2 mRNA levels. However, likely due to relatively small numbers, EZH2 mRNA levels did not retain prognostic significance on multivariate analysis, where only advanced clinical stage and U-CLL status emerged as independent negative prognostic factors.
Summary / Conclusion: EZH2 is over-expressed in aggressive CLL subgroups and seems to have a functional impact as evidenced by distinctive histone marks. These results offer hints about the evolution of CLL through epigenetic activation of oncogenic signaling cascades and inhibition of pro-differentiation pathways. Better understanding of the molecular basis of such regulation in agressive CLL could help in establishing EZH2-mediated epigenetic silencing as a therapeutic target.

P104

OUTCOMES OF PATIENTS WITH FLUDARABINE-REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) – A POPULATION-BASED STUDY FROM A WELL-DEFINED GEOGRAPHIC REGION

S Sylvan[1,*] L Hansson[1], C Karlsson[1], S Norin[1], J Lundin[1], Anders Österborg[1]
[1]Departments of Hematology and Oncology, Karolinska University Hospital, Stockholm, Sweden

Background: Treatment of fludarabine-refractory (FR) chronic lymphocytic leukemia (CLL) remains unsatisfactory. Several new agents have been or are currently being tested in pivotal, non-controlled phase 2 trials. Knowledge on the natural history of similar groups of advanced-phase CLL and outcome of existing salvage regimens in routine health care is therefore mandatory.
Aims: To study the outcome of consecutive patients with FR CLL from a geographically well-defined area without external referrals. Such patients are likely to represent an important group of non-selected patients that can serve as comparators for data obtained with new orphan drugs in non-randomised phase II trials.
Methods: Patients with CLL (n=1479) were identified from the Cancer Registry in Stockholm (1991-2010). 1301 patient files (94%) were identified and reviewed to identify FR patients. Efficacy and toxicity of salvage therapies were recorded as well as long term follow-up. Patients were also subclassified as follows: FR with bulky lymph nodes (BFR group); double-refractory to both F and alemtuzumab (DR group), or being FR without fulfilling criteria for BFR or DR (group "Other").
Results: Chart review identified totally 92 consecutive, non-referred patients with FR CLL undergoing various types of salvage therapy. Median age was 69 years, most had Rai stage III/IV and had received a median of 3 prior therapies (range 1-9). The overall response rate (ORR) was 20% (all but 3were PR), which was significantly lower in the BFR subgroup (ORR 8%) and the DR group (ORR 20%) than in the group "Other" (ORR 31%) (P=0.01). Median time to treatment failure in all patients was 5 months. The ORR in patients who received antibody therapy was 35% with a median time to start of next therapy of 10 months. Early deaths (within 8 wk) occurred in 5% and ≥ grade 3 infections in 20% of patients which appeared lower than previously reported from other centers/series. Median overall survival (OS) was 18 months; it was significantly longer in BFR patients (median 29 months) than in the DR group (median 13 months) (P<0.05, log-rank test). There was no significant difference in OS between refractory patients treated in the first decade vs the second time period of this study. Among baseline prognostic factors on survival, only gender reached statistical significance (P=0.01, multivariate Cox regression analysis).
Summary / Conclusion: Our study describes the natural history of fludarabine-refractory CLL in consecutive patients in a region with almost complete follow-up and without influence on the results from external referrals. Such results may be used for comparison with data obtained in non-controlled phase 2 trials on new orphan drugs.

P105

PROLONGED CYTOPENIA RELATED TO FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Strati[1],[*] W Wierda[1], J Burger[1], A Ferrajoli[1], S Lerner[1], M Keating[1], S O'Brien[1]
[1]Leukemia, The University of Texas, M.D. Anderson Cancer Center, Houston, United States

Background: Fludarabine, Cyclophosphamide and Rituximab (FCR) is the most effective frontline treatment for Chronic Lymphocytic Leukemia (CLL). This regimen is often associated with transient cytopenia during administration that resolves after treatment. In a fraction of patients (pts), cytopenia persistence can raise concerns for CLL relapse, increased risk of infections, or development of secondary myeloid malignancies (SMM).
Aims: To define laboratory and clinical features associated with the development of cytopenia after frontline FCR in CLL pts. To investigate its association with survival and risk for SMM.
Methods: Cytopenia were graded according to CTCAE4 criterias and considered significant if grade 2-4. Only pts achieving complete remission (CR), CR with incomplete marrow recovery (CRi) and nodular partial remission were included. Categorical and continuous variables were compared using the χ^2 and Mann-Whitney test. Kaplan-Meier estimates were compared using the log-rank test.
Results: Three-hundred pts were treated with frontline FCR at our institution between 1999 and 2002. Two-hundred-seven pts met criteria for analysis. The incidence of cytopenia after treatment at3, 6 and 9 months is described in the Table 1. Baseline characteristics of cytopenic (CY)(72) and non-cytopenic (NCY)(132) pts, including prognostic factors, were compared. CY pts were significantly older (P=0.02), had more advanced Rai stage disease (P=0.01) and more profound baseline neutropenia (P=0.04), anemia (P=0.04) and thrombocytopenia (P=0.001). CY pts had a significantly lower likelihood of completing 6 cycles of FCR (67% vs 87%)(P=0.001). Progression Free Survival (PFS) for CY pts was 135 months and Overall Survival (OS) has not been reached, after a median follow up of 114 months (7-155). No differences in PFS (135 vs 95 months, P=0.31) and OS (both not reached, P=0.84) were observed in comparison to NCY pts, even for CY with persistence of cytopenia at 6 and 9 months. The incidence of SMM was comparable between the 2 groups (2 CY, 5 NCY)(P=NS).
Summary / Conclusion: Cytopenia commonly occurs during FCR. Our analysis indicates that cytopenia is a more frequent finding in older patients, and patients presenting with Rai stage IV disease. Response duration, OS, and the rate of SMM are identical to those seen in patients without cytopenia.

Table 1.

	CYTOPENIA	G2	G3-4
3 months	72/207 (35%)	32/72 (44%)	40/72 (56%)
6 months	45/191 (24%)	20/45 (44%)	25/45 (56%)

P106

FRONTLINE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA WITH DELETION 17P

P Strati[1],[*] M Keating[1], S O'Brien[1], A Ferrajoli[1], J Burger[1], S Faderl[1], N Jain[1], W Wierda[1]
[1]MD Anderson Cancer Center, Houston, United States

Background: Patients (pts) with relapsed Chronic Lymphocytic Leukemia (CLL) bearing deletion 17p (del17p) are very high-risk for poor clinical outcomes.
Aims: We summarize outcomes for first-line treatment of del17p CLL.
Methods: We identified 63 pts with CLL and del17p by FISH who received first-line treatment at MDACC between 1/04 and 12/12. Log-rank test and Cox regression were used for univariable and multivariable analyses.
Results: Baseline characteristics are shown (Table 1). Median time from diagnosis to first treatment (TTFT) was 15 (11-19) months (mos); no association between % del17p positive cells at diagnosis and TTFT was noted (P=.45). First-line therapy consisted of fludarabine, cyclophosphamide, rituximab (FCR) based regimen in 49 pts, rituximab-based in 6 pts, and lenalidomide-based in 8 pts. Ninety pts (30%) achieved complete remission (CR), 2 (3%) nodular partial remission (nPR), 18 (30%) PR, and 24 (37%) were non-responders. Fourteen CR pts (78%) were minimal residual disease free by 4-colour flow cytometry. The median time-to-treatment failure (TTF) was 14 (10-18) mos (43 events); the median follow-up was 33 (1-89) mos. Univariable analyses showed age >65 yrs (P=.04), complex karyotype (P=.02), lack of response to therapy (P<.001) and >50% cells positive for del17p by FISH (P=0.009) associated with shorter TTF. The multivariable model showed karyotype (P=.005) and quality of response (P<.001) independently associated with TTF. Median overall survival (OS) was 63 (43-83) mos (28 deaths). Fifteen pts (23%) developed Richter Syndrome (RS) after a median of 12 (1-27) mos; 8 deaths (29%) were related to RS. Univariable analyses showed that only lack of response was associated with a shorter OS (P=.001).
Summary / Conclusion: Del17p CLL is high-risk for first-line therapy; better response to therapy was observed in young patients with <50 % del17p positive cells by FISH who received FCR. New strategies and agents must aim at both improving response and maintaining remission, particularly in pts with complex karyotype.

Table 1.

P107

THE IMPACT OF NOVEL RECURRENT GENETIC MUTATIONS ON THE EFFICACY OF ALEMTUZUMAB CONTAINING TREATMENT IN HIGH RISK CLL PATIENTS: RESULTS FROM THE HOVON68 TRIAL

D Te Raa[1],[*] A Kater[1], W Ghidey Alemayehu[2], D Luijks[1], A Jethwa[3], J Hüllein[3], E Eldering[1], T Stankovic[4], T Zenz[3], C Geisler[5], M Van Oers[1]
[1]Departments of Hematology and Experimental Immunology, Academic Medical Center Amsterdam , Amsterdam, [2]HOVON Data Center, Erasmus MC, Rotterdam, Netherlands, [3]Department of Translational Oncology, National Center for Tumor Diseases (NCT), German Cancer Research Center (DFKZ) & Department of Medicine V, University Hospital Heidelberg, Heidelberg, Germany, [4]School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom, [5]Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background: Alemtuzumab treatment is effective in CLL patients with 17p deletion and with chemo refractory disease, indicating that alemtuzumab may act independently of the ATM/p53 axis. However, the impact of *ATM* mutations on alemtuzumab efficacy is less well defined. Moreover, it is currently not known whether alemtuzumab is also effective in patients with the recurrent somatic mutations, which were recently discovered in CLL by next generation sequencing. These include *SF3B1* and *NOTCH1* which have been shown to be associated with impaired prognosis.
Aims: To study the incidence and clinical impact of the novel recurrent genetic mutations in high risk CLL patients treated with alemtuzumab in combination with fludarabine and cyclophosphamide (FCA).
Methods: In the HOVON68 trial, treatment naïve CLL patients with a high risk profile defined as either 17p deletion, 11q deletion, trisomy 12, unmutated IGHV and/or VH3-21, were randomized between treatment with 6 cycles of FC (Oral fludarabine 40 mg/m^2 day1-3 and cyclophosphamide 250 mg/m^2 day1-3) and FC + alemtuzumb (30 mg sc, in cycle 1 day-1 to +1, in cycles 2-6 day1 only). We evaluated 119/272 (43.8%) trial patients based on availability of DNA. This cohort was representative for the complete trial population as there were no differences in main prognostic factors, including age, clinical stage, IGHV mutational status, ZAP-70 or cytogenetic aberrations (17p-, 11q-, trisomy 12, 13q-). Mutational analysis of *SF3B1* (ex14+15), *NOTCH1* (ex34), *TP53* (ex4-10), *BRAF* (ex11+15), *KRAS* (ex2+3), *NRAS* (ex2+3), *EZH2* (ex16), *MYD88* (ex3+5)

and *PIK3CA* (ex9+20) was performed by next generation sequencing. Extensive mutational analysis of *ATM* (ex1-62) is currently being performed (analyzed at present: n=19). Complete analysis will be reported at EHA.
Results: 19 (16%) *SF3B1*, 12 (10%) *NOTCH1*, 16 (13%) *TP53*, 5 (4%) *BRAF*, 5 (4%) *KRAS*, 2 (2%) *NRAS* and 1 (1%) *MYD88* mutations were found. Thus far *ATM* mutations were identified in 5 (out of 19) patients. Mutations in *TP53* correlated with 17p deletion (P<0.0001), *SF3B1* mutations with 11q deletion (P=0.008) and *NOTCH1* mutations with trisomy 12 (P=0.001). The overall response rate (ORR) and complete response (CR) were decreased in patients with *TP53* mutation (P=0.001 and P=0.01 respectively) but not in those with the other mutations. FCA improved ORR in patients with *TP53* mutations (14% vs 67%, borderline-significance P=0.06). However in patients with the other mutations there were no differences in ORR/CR between the two treatment arms.
The median follow-up was 42.5 months (range: 4-82 months). Progression free survival (PFS) was impaired in patients with *TP53* mutation (P<0.001) but not in patients with *NOTCH1* mutation (P=0.82). FCA improved PFS in patients with *TP53* mutation (median 3 vs 16 months, P=0.02), as well as in *SF3B1* mutated patients (median 33 vs 44 months, P=0.05). Overall survival (OS) was only decreased in *TP53* mutated (P=0.02) patients and there was a trend for improved OS due to FCA (median 24 vs 67 months, P=0.09).
Summary / Conclusion: Novel recurrent mutations were found in this high risk CLL treatment naïve patient group, in frequencies comparable to those reported in recent literature. As expected, *TP53* mutations had an adverse prognostic impact as to ORR, CR, PFS and OS, which was overcome by alemtuzumab. In addition, we found that patients with an *SF3B1* mutation might benefit from alemtuzumab. This latter finding is in line with our recent observation suggesting that *SF3B1* mutations affect the ATM/p53 axis.

P108

UPDATED RESULTS OF A PHASE II STUDY OF LENALIDOMIDE AND RITUXIMAB IN RELAPSED/REFRACTORY (R/R) CHRONIC LYMPHOCYTIC LEUKEMIA.

M Piris-Villaespesa[1,*] J Chavez[2], S Dalia[2], M Veliz[3], Jeffrey Lancet[2], C Bello[2], E Turba[2], B Shah[2], R Komrokji[2], L Sokol[2], F Locke[4], M Kharfan-Dabaja[4], E Sotomayor[2], J Pinilla-Ibarz[2]
[1]Hematology, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain, [2]Malignant Hematology, H. Lee Moffitt Cancer Center, [3]Hematology, Central Florida Hematology Onc, [4]Bone Marrow Transplant, H. Lee Moffitt Cancer Center, Tampa, FL, United States

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with variable clinical course. Patients with R/R disease have a very poor outcome. Response rates to salvage therapy are 20 to 40%; however they are short-lasting. Lenalidomide (L) has shown encouraging and significant response duration in phase II studies with acceptable toxicity. It is postulated that lenalidomide enhances the antibody dependent cytotoxicity (ADCC) of rituximab (R) by potentiating NK cell responses.
Aims: The primary endpoints included objective response rate (ORR) [complete (CR) and partial (PR) remission], clinical benefit [stable disease (SD) + ORR] and safety and tolerability of the combination regimen. Secondary endpoints were time to treatment failure (TTF), overall survival (OS) and assessment of adverse events (AEs).
Methods: This phase II study evaluated a combination of L+R in R/R CLL. The regimen consisted in dose-escalated L=2.5 mg (days 1-7), 5 mg (days 8-14) and 10 mg (days 15-21) followed by 7 days of rest in a 28-day cycle; for cycle 2 and beyond L=20 mg was given on days 1-21 on a 28 day cycle. R was dosed at 375 mg/m^2 IV weekly for 4 weeks starting on day 15 of cycle 1. In high tumor burden disease (lymphocytes count ≥25,000/μL) R was given prior to lenalidomide. Treatment was continued until disease progression or if unacceptable toxicity ensues. Responses were assessed according to IWCLL 2008 criteria.
Results: Twenty four patients were enrolled in the study. Median age was 62.5 years (41-79). Male/female ratio was 1.67. Patients characteristics included: Rai stage III-IV=13 (54%), bulky disease=11 (45.8%), median number of prior chemotherapy regimens=3 (range 1-5), fludarabine refractory=4 (16.7%), unmutated IgVH =13/19 (54.2%), CD38 ≥30%=9/23 (37.5%), ZAP-70=5/15 (20.9%). Cytogenetic abnormalities included trisomy 12 (10/24), del11q (9/24), del13q (9/24) and del17p (3/24). Five patients did not complete more than 3 cycles [hypercalcemia (1), seizures (1), ischemic stroke (1), severe hematological toxicity (1) and withdrawal of consent (1)] and one patient did not initiate L (due to infusion reaction to R). The ORR in 18 evaluable patients was 61.1% and on the intention to treat (ITT) analysis was 45.8%. The clinical benefit (ORR+SD) was 83.3% in evaluable patients. The median time-to-response and median duration of response were 4.1 and 22.5 months, respectively. The ORR was independent of age, gender, Rai Stage, bulky disease, hierarchical genetic abnormalities, IgVH mutational status or fludarabine refractoriness. The regimen was well tolerated. The most common grade 3/4 AEs were fatigue (33.3%), infections (25%) and diarrhea (12.5%). Most common causes of infections were pneumonia (20.8%) and sinusitis (8.3%). Hematological toxicity consisted of grade 3/4 neutropenia (50%) anemia (8%) and thrombocytopenia (4%). Tumor flare reaction was observed in eight cases (33.3%). The TTF in the evaluable patients was 17.7 months and in the ITT analysis was 14.3 months. After a median follow-up time of 31.2 months the OS was not reached. By univariate analysis, achieving a response predicted a better overall survival.
Summary / Conclusion: The combination of lenalidomide and rituximab is a feasible alternative for the treatment of R/R active CLL, including high risk and heavily pretreated patients, with significant and durable responses and an acceptable toxicity profile.

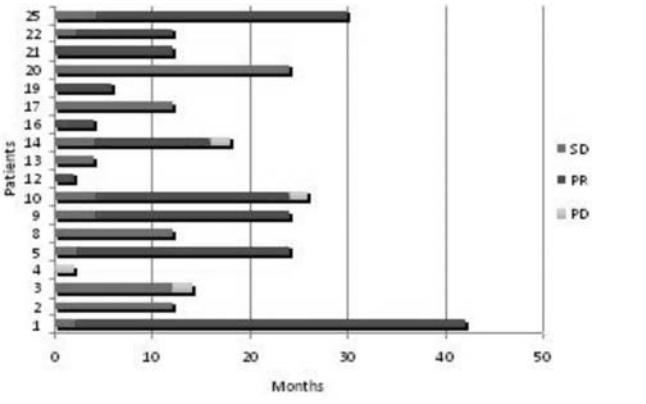

Figure 1.

Papanicolaou Hospital, Thessaloniki, Greece, [19]Hematology, Trafford General Hospital, Manchester, United Kingdom, [20]Hematology, Groupe Hospitalier Pitié Salpêtrière, Paris, France, [21]Hematology, Hospital General de Albacete, Albacete, Spain, [22]Hematology, Policlinico di Modena, Modena, [23]Hematology, IRST Meldola, Meldola, [24]Hematology, Azienda Ospedaliero Universitaria Careggi, Firenze, [25]Hematology, Fondazione IRCCS Istituto Nazionale Tumori, Milano, [26]Hematology, ULSS 18-Rovigo Ospedale "S.Maria della Misericordia', Rovigo, Italy

Background: Ofatumumab was given a conditional approval in the EU on April 2010 for the treatment of CLL refractory to fludarabine (F-ref) and alemtuzumab (A-ref), encouraging the retrieval of further data in patients treated in a "daily life" setting and to investigate treatment safety.
Aims: The main objective of the study was to obtain information on the safety profile of ofatumumab in patients with CLL treated outside clinical trials. The secondary endpoints were efficacy, progression free survival (PFS), and overall survival (OS).
Methods: This was an observational, retrospective study. Patients were eligible for the study regardless of prior treatments or disease status and provided they had not been included in phase II or phase III ofatumumab clinical trials. Data on patients' characteristics at diagnosis, prior treatment, toxicity to therapy, response rate, PFS and OS were recorded.
Results: One hundred and twenty patients were screened, of which 103 from 25 centers in 10 European countries were eligible for the study. There were 71 males; median age at initiation of ofatumumab was 64 years (range, 38-84); 66% patients were in advanced clinical stage;54% were F-ref, 70% A-ref and 41% were both. One hundred and sixty one toxic events were reported in 68 patients, with 28 (17%) of them being considered as ofatumumab-related. Infusion reactions occurred in 19 (30%) patients (grade III-IV: 21%). Neutropenia was reported in 26% patients (grade III-IV: 22%), thrombocytopenia in 15% (grade III-IV: 12%) and anemia in 15% (grade III-IV: 7%). The non-hematological adverse events were infection (29%), dyspnea (10%), fatigue (7%), fever (7%), rash (7%), cough (5%), diarrhea (4%) and nausea (1%). A correlation was observed between the number of prior lines of therapy and

hematologic toxicity. Autoimmune hemolytic anemia was recorded in one patient. One patient developed Richter's syndrome while receiving ofatumumab. Two heavily pre-treated patients presented progressive multifocal leukoencephalopathy.The overall response rate (ORR) was 23% and the median PFS and OS were 5 and 12 months, respectively. The main causes of death were disease progression (61%) and, infection (28%).
Summary / Conclusion: These results show that with the only exception of the ORR (lower in this study) all endpoints (PFS, OS) and safety profile in CLL patients treated with ofatumumab in daily practice are consistent with those observed in phase II and III clinical trials.

P110

THE PROGNOSTIC VALUE OF THE NUMBER OF CELLS WITH A DELETION OF 13Q14 IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
T Zagoskina[1,*] V Ovsepyan[1], E Zotina[1], S Baranchikova[1], E Krinitsyna[1]
[1]Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: The presence of isolated deletion 13q14 (del13q14) in patients with chronic lymphocytic leukemia (CLL) is a favourable prognostic factor of the disease. However, patients with CLL differ in the number of cells with del13q14, as well as in the degree of expression of Zap-70 and the level of thymidine kinase (TK). Zap-70 and TK are considered as the independent predictors of overall survival (OS) and the outcome of CLL.
Aims: Determine the prognostic value of the number of cells with del13q14 in association with Zap-70 and TK.
Methods: We identified 124 patients with CLL. The median age was 61 years. Twenty-five were in Binet stage A, 84 in stage B and 15 in stage C. Chromosomal abnormalities were determined by FISH. Moreover, the expression of Zap-70 and the contents of serum TK were determined by flow cytometry (cut-off value 20%) and a radioenzyme method accordingly (cut-off value 20 U/L). All researches were performed during the time of diagnosis before specific therapy.
Results: Del13q14 was detected as the only chromosomal abnormality or in combination with other chromosomal disorders in 77 (62%) and 47 (38%) patients accordingly. Patients with a single del13q14 were divided into 2 groups according to the number of cells with this aberration. The first group included 41 (53%) patients with del13q14 in ≥ 60% of cells, the second one – 36 (47%) patients with del13q14 in < 60% of cells. Among patients with del13q14 in ≥60% of cells positive level of protein expression Zap-70 and the content of TK >20 U/L in serum were detected in 39 (95%) and 40 (98%) patients accordingly. At the same time, among patients with del13q14 in < 60% of cells positive expression of Zap-70 and high levels of serum TK were not detected in any case. Median follow-up was 68 months. Median OS in patients with del13q14 in <60% of cells was 144 months, median time to first treatment (TFT) was 42 months. In patients with del13q14 in ≥60% of cells median OS was 65 months, but median TFT – 13 months (P=0.034 and P=0.002, respectively). By univariate analysis, OS was significantly shorter in patients older than 60 years (P=0.017), Binet stage B or C (P<0.001), with del13q14 in ≥60% of cells (P=0.002), the content of TK ≥20 U/L (P=0.023) and the positive expression level of Zap-70 (P<0.001). During undertaking of the multivariate analysis by the independent predictors of OS and TFT the level of expression of Zap-70 (P=0.014; p=0.023) the contents of TK (P=0.036; P=0.009), and the number of cells with del13q14 (cut-off value 60%) (P=0.016; P=0.025) were determined in patients with CLL.
Summary / Conclusion: Patients with del13q14 in ≥ 60% of cells have a poorer prognosis than patients with del13q14 in < 60% of cells. For a more precise stratification of patients into risk groups a set of factors should be used simultaneously, including the number of cells with del13q14, Zap-70 and TK which will identify patients with a poor prognosis more accurately.

P111

FINAL RESULTS OF A MULTICENTER PHASE IB SINGLE AGENT STUDY WITH THE NOVEL ANTI-CD20 MONOCLONAL ANTIBODY UBLITUXIMAB (TG-1101) IN PATIENTS WITH RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)
B Cazin[1,*] S Leprêtre[2], B Coiffier[3], T Aurran[4], G Cartron[5], P Feugier[6], O Brehar[2], A Sadoun[7], P Sportelli[8], H Miskin[8], V Ribrag[9]
[1]Service des Maladies du Sang, Hôpital Huriez, CHRU Lille, Lille, [2]Centre Henri Becquerel, Rouen, [3]Departement d'Hematologie, Centre Hospitalier Lyon-Sud, Pierre-Benite Cedex, [4]Hematology, Institut Paoli-Calmettes, Marseille, [5]Service d'Hématologie-Oncologie Médicale, Hôpital Saint Eloi, Montpellier, [6]Service d'Hématologie, Hôpital Adultes de Brabois, Vandoeuvre Les Nancy, [7]LFB Biotechnologies, Les Ulis, France, [8]TG Therapeutics, Inc., New York, United States, [9]Institut Gustave Roussy, Villejuif, France

Background: Ublituximab (TG-1101, previously LFB-R603) is a novel, chimeric monoclonal antibody (mAb) targeting a unique epitope on the CD20 antigen. Ublituximab has been glycoengineered to enhance affinity for all variants of FcγRIIIa receptors and therefore demonstrates greater antibody-dependent cellular cytotoxicity (ADCC) activity than rituximab and ofatumumab, particularly against tumor cells that express low CD20 levels. A weekly x 4 dose regimen of ublituximab was found to induce rapid, profound and sustained blood lymphocyte depletion in patients (pts) with advanced stage CLL in a first-in human dose-escalation phase I study (Part 1). The second part of the study (Phase Ib) was designed to evaluate a fixed, weekly x 8 dose regimen for safety, pharmacokinetics (PK) and efficacy of ublituximab in pts with CLL relapsed after at least one prior course of therapy with fludarabine.
Aims: Herein, we report the final results of the Phase Ib study.
Methods: From April 2010 to August 2011, 12 pts were enrolled at 9 centers in France and followed for 12 months. Eight infusions of ublituximab were administered once weekly consisting of an initial dose of 150 mg followed by 7 doses of 450 mg, with no maintenance therapy. Safety was the primary endpoint (CTCAE v. 3.0), with PK and efficacy (IWCLL, Hallek 2008) secondary endpoints.
Results: Median age was 69.5 years [62–77], median time from diagnosis to inclusion was 10.4 years [4.0–23.6], median prior therapies was 3 [range 1–8]. Seven pts (58%) received at least one prior rituximab-containing regimen. Abnormal cytogenetics: 10/12 (2 with 17p del). Bulky (>5cm) lymph node enlargement was observed in 4 pts (33%), splenomegaly in 9 pts (75%), and hepatomegaly in 4 pts (33%). Median lymphocyte bone marrow infiltration was 85% [40–94]. PK data showed an increase of mean Cmax, AUC_{∞} and $t_{1/2}$ term from the first to the eighth infusion from 23.4 to 220.5 mg/L, 732 to 50, 760 mg.h/L, and 13.4 to 147.8 h, respectively whereas mean CL decreased from 424 to 38.6 mL/h. Median lymphocyte count at baseline was 46.6 ($x10^9$/L; after 1 month (M1) = 1.5 (94%↓); M4=1.4 (91%↓) and M6=2.0 (89%↓). 12/12 patients (100%) achieved a peripheral lymphocyte response. All pts but one received the planned 8 infusions without any dose reduction. One patient was prematurely withdrawn due to a concomitant secondary leukemia. Most frequent drug-related AEs were infusion related reactions (IRR) (75% of the pts, including 33% of pts with Grade 3 IRR). Other Grade 3/4 AE's > 10% included: neutropenia (67%) and increase ALT/AST (17%). All AEs were reversible spontaneously or with supportive care intervention. Response was evaluated at M4 for the 11 evaluable pts, with an initial response rate of 64% (7/11) with a confirmed response at M6 in 5/11 pts (45%) pts (all PRs). 4/11 pts achieved stable disease. At the 1 year follow-up, no responders had progressed demonstrating all confirmed responses were durable, despite no ublituximab maintenance therapy. Median PFS was not reached at the 12 month follow-up.
Summary / Conclusion: Ublituximab induced a durable 45% ORR in pts with advanced stage CLL at a relatively low dose regimen (total 3300 mg over 8 weeks, with no maintenance). PK data indicates that the dose and the schedule of administration could be optimized. Toxicity was manageable and typical for anti-CD20 therapy, enabling combination with novel agents. Phase I/II studies evaluating ublituximab at doses > 450 mg as a single agent, in addition to combination therapy with lenalidomide in pts with CLL and NHL are currently ongoing. Monthly maintenance with ublituximab has been incorporated into ongoing clinical trials.

P112

CLL CELLS ARE HIGHLY SENSITIVE TO THE INHIBITION OF PI3K-P110 ALPHA ISOFORM WHICH IS ASSOCIATED WITH DOWNREGULATION OF CD23
S Schnabl[1,2,*] M Reiter[1,2], D Demirtas[1,2], R Hubmann[1,2], M Hilgarth[1,2], E Ponath[1,2], U Jaeger[1,2], C Zielinski[1,2], M Shehata[1,2]
[1]Comprehensive Cancer Center, [2]Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: PI3K/Akt signalling cascade is emerging as a promising therapeutic target in chronic lymphocytic leukemia (CLL). However, CLL cells highly express all four isoforms of PI3K (alpha, beta, gamma and delta). Therefore, the advantage of using pan- or isoform-selective PI3K inhibitors remains to be extensively explored.
Aims: The primary aim of the work is to compare the effect of different pan and isoform selective PI3K inhibitors on the viability of CLL cells in a well characterized cohort of CLL patients in terms of clinical stage, cytogenetics and IgVH mutational status.
Methods: Exposure of CLL cells to the inhibitors is performed in suspension culture and in co-culture with bone marrow stromal cells (BMSC) to minimize the spontaneous apoptosis rate of CLL cells. The inhibitors included pan PI3-K inhibitors (LY294002, wortmannin and PI-103), and the isoform selective inhibitors against p110-a: (N-((1E)-(6-Bromoimidazo[1,2-a]pyridin-3-yl)ethylene)-N′-methyl-N″-(2-methyl-5-nitrobenzene)sulfonohydrazide), p110-b: (TGX-221), p110-c: (5-(2,2-Difluoro-benzo[1,3]dioxol-5-ylmethylene)-thiazolidine-2,4-dione) and p110-d: (IC87114 and CAL-101). Cell viability was assessed by FACS (annexin V/Pi staining) and MTT assay. Induction of apoptosis was confirmed by detection of Caspase and PARP cleavage using western blotting. In addition, effects on the activation status of the central PI3K pathway molecules Akt and PTEN were analysed by western blotting and intracellular FACS.
Results: The results revealed that the p110-a isoform selective inhibitor was the most effective in inducing apoptosis in CLL cells compared to other inhibitors at equal concentrations. Dose and time kinetics showed that the IC50 ranged between 10 and 40 nM within 24 hours of incubation with some variation between patients. Inhibition of p110a subunit led to a rapid induction of apoptosis (within 6 hours) at nanomolar concentrations (10-100nM). The induction of apoptosis was accompanied by Caspase and PARP cleavage and a decrease in CD23 surface expression as assessed by FACS. Decrease in CD23 and Mcl-1 expression could also be detected by western blotting. In parallel, p110a-inhibitor induced a significant de-phosphorylation of Akt particularly at Thr308 and de-phosphorylation of PTEN at several residues in its tail domain. PI3K-alpha inhibitor was highly effective in suspension culture and could overcome the supportive effect of BMSC in co-culture. The response to PI3K-alpha was observed in all patients tested independently of the clinical stage, cytogenetics and IgVH mutation status. In addition, downregulation of surface CD23 expression correlated to the response to PI3-K inhibitors.

Summary / Conclusion: The data confirm the importance of PI3K as a therapeutic target in CLL and reveal the high sensitivity of CLL cells to the inhibition of p110a isoform in particular. The results also demonstrate that CD23 expression may represent a reliable biomarker for monitoring the response to PI3-K inhibitors. Therefore, PI3K alpha may represent an important therapeutic target in CLL and warrants further investigation and clinical validation.

CLL PATIENTS CARRYING 13Q DELETION SHOW CLINICAL HETEROGENEITY ACCORDING TO IGVH MUTATIONAL STATUS AND CD38 EXPRESSION

A Visentin[1,*], F Frezzato[1,2], M Castelli[1], V Trimarco[1,2], C Gattazzo[1,2], V Martini[1], L Bonaldi[3], A Martines[3], I Gianesello[1], F Pavanello[1], R Zambello[1,2], M Facco[1,2], G Semenzato[1,2], L Trentin[1,2]
[1]Dept. of Medicine, Hematology and Clinical Immunology Branch, University of Padua, [2]Venetian Institute of Molecular Medicine, [3]Dept. of Surgical Sciences, Oncology and Gastroenterology, University of Padua, PADUA, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is one of the most common and indolent hematological malignancies characterized by a heterogeneous clinical course and outcome. Over the last years several clinical or biological markers have been identified as prognostic factors. In particular, patients carrying chromosome 13q14 deletion (13q-) have been usually considered to have a good prognosis. Despite this, some of these patients require treatment a few years after the diagnosis.
Aims: The aim of this study was to investigate clinical features in 13q- CLL patients by correlating/integrating different prognostic factors, i.e. IgVH mutational status and CD38 expression, in the effort to define a scoring system useful for clinical practice and patients risk stratification.
Methods: Fluorescence *in situ* Hybridization (FISH) was performed in 214 CLL patients, referred to the Hematology Division of Padua University Hospital from 1989 to 2011; 114 out of 214 (53%) showed chromosome 13q14 deletion. Both IgVH mutational status (mutated, MUT or unmutated, UNMUT) and CD38 expression ($CD38^+$ or $CD38^-$; cut-off: 30%, as determined by cytofluorymetric) were available for 105/114 patients. Considering these two parameters in 13q- group, we developed a scoring system assigning score 0 to 13q- patients which were MUT&$CD38^-$, score 1 to 13q- patients which were UNMUT&$CD38^-$ or MUT&$CD38^+$, and score 2 to 13q- patients which were UNMUT&$CD38^+$ (Figure 1A). Statistical analyses for time to first treatment (TTT) and overall survival (OS) were performed using Kaplan-Meier Log-Rank test; p values <0.05 were considered significant.
Results: On the basis of the above mentioned scoring system, 13q- CLL patients were stratified in 3 different groups: 65/105 (59%) patients with score 0; 30/105 (29%) with score 1 and 10/105 (9%) with score 2 (Figure 1B). The number of treated patients was 28% for score 0, 43% for score 1 and 60% for score 2; 2% with score 0, 7% with score 1 and 17% with score 2 patients died. According to this scoring system, the analysis of TTT and OS of our 13q- patients stratified them in 3 statistical different groups (P<0.002 for TTT, Figure 1C and P<0.001 for OS, Figure 1D). In particular, score 0 patients showed an indolent disease and only the 16% of their require therapy after 3 years from diagnosis and @ 5 years OS of 100%; conversely, score 2 patients had an aggressive clinical course with @ 3 years TTT of 70% and @ 5 years OS of about 53%.
Summary and Conclusions: Chromosome 13q deletion has usually been expected to assign a favorable outcome to CLL patients. Despite this, some patients are treated or die few years from the diagnosis, demonstrating that not all 13q- CLL patients have the same clinical behavior, with some of them showing an aggressive clinical course. Herein we have underlined this clinical diversity demonstrating that 13q- patients UNMUT&$CD38^+$ (defined as score 2) have a shorter TTT and OS than score 0 patients (MUT&$CD38^-$). Hence the need to develop a prognostic system, including low risk CLL, that allows risk stratification and helps in timing and choice of therapy as well as to define following scheduling.

Background: Tyrosine kinase inhibitors (TKIs) such as imatinib or dasatinib are first line therapy for chronic phase chronic myeloid leukemia. Studies show that TKIs can modulate cells of the immune system, possibly affecting anti-tumor immunity of treated patients as well as giving rise to immunological adverse events. Myeloid-derived suppressor cells (MDSCs) are a heterogeneous group of myeloid cells that regulate T cell activation during immune responses. MDSCs utilize different mechanisms for suppressing immune responses, including up-regulation of the enzyme arginase 1 (Arg1) which leads to inhibition of T cells and other immune cells. Moreover, MDSCs can affect the immune system by induction of T regulatory cells (Tregs) which regulate the immune system by inhibition of effector cells. MDCSs and Tregs are expanded in patients with different solid tumors, and increased levels have been associated with worse prognosis. The mechanism by which Tregs are induced by MDSCs has not been extensively studied, but involvement of the CD40/CD40 ligand (CD40L) pathway has been suggested.
Aims: To investigate samples from patients treated with imatinib or dasatinib for the presence of immune escape mechanisms such as MDSCs, Arg1 and Tregs and to investigate the CD40 expression. Samples were also analyzed for the presence of natural killer (NK) cells and T memory cells.
Methods: Patient samples were from the clinical trial "Randomized Study Comparing the Effect of Dasatinib and Imatinib on Malignant Stem Cells in Chronic Myeloid Leukemia (NordCML006)". The study was performed according to the declaration of Helsinki and all patients gave their written informed consent. Samples were analyzed at baseline and after one and six months of treatment by flow cytometry and ELISA.
Results: Patient MDSC levels decreased with TKI treatment and at 6 months there was a significant difference compared to baseline (P<0,05). The leukocyte count at baseline, reflecting the tumor burden, correlated with the MDSC level at baseline (Spearman r: 0,6713, P<0,0001). The median Arg1 concentration at baseline (44,8 ng/ml, range 14,5-277 ng/ml) was higher than has been reported for control subjects and treatment with TKIs significantly decreased the level of Arg1 after one and six months (P<0,05 and P<0,05, respectively). The baseline Arg1 concentration was correlated with the level of MDSCs at baseline (Spearman r: 0,5238, P=0,005). CD40 expression on MDSCs was low in patients at baseline (median 12,6%, range 6,5-32,3%) and increased during treatment (6 months: median 33,6%, range 9,2-64,8%) (P<0,05). Treg levels were significantly increased at one and six months of treatment (P<0,05 and P<0,05, respectively). Natural killer cells were increased by TKI treatment (P<0,05 median 10,6%, range3,4-44,4% at baseline and median 15,7%, range2,6-49,0% at 1 month of treatment) and there was a non significant trend towards increasing T memory cells.
Summary / Conclusion: Dasatinib and imatinib decrease MDSC levels while simultaneously promoting expression of CD40 on myeloid cells which may explain the increase of effector lymphocytes such as NK- and memory T cells. Taken together, our results indicate that TKIs, even though shown to be immune inhibitory in many *in vitro* studies, can be immunostimulatory *in vivo* because of a combination of inhibition of regulatory cells and stimulation of effector cells. These results may aid the understanding of which patients could benefit from TKI discontinuation after achieving a complete molecular response.

P114

THE AXIS SHP-1/SHP-2 MODULATES VEGFR2 SIGNALING IN CML CELL LINES: VEGFR2 DEREGULATION MAY BE IMPLICATED IN IMATINIB (IMA) RESISTANCE

N Esposito[1],* C Quintarelli[1], V Manzo[2], I Colavita[2], B De Angelis[1], S Errichiello[1], M Raia[2], L Del Vecchio[2], L Luciano[3], F Pane[1]
[1]Dipartimento di Medicina Clinica e Chirurgia, Università degli Studi di Napoli Federico II, [2]CEINGE-Biotecnologie Avanzate Napoli-Italy, [3]Area Funzionale di Ematologia- II Policlinico – Università degli Studi di Napoli Federico II, Naples, Italy

Background: The Imatinib (IMA) discovery revolutionized the treatment and management of CML patients and represented the gold standard therapy for this disease. However, although the vast majority of patients respond to the therapy, the resistance is emerging as a significant problem. Our previously published data showed that SHP-1 plays a key role in the response to IMA treatment through negative regulation of SHP-2[1]. Thus, we evaluated the putative factors able to activate SHP-2 in Ph+ CML cells resistant to TKI activity (named KCL22R). Gene expression profile of KCL22-R cell line revealed an up-regulation of Vascular Endothelial Growth Factor Receptor-2 (VEGFR-2) respect to the TKI sensitive cell line KCL22S. In this regard, several groups showed that the signaling from VEGFR-2 is necessary for proliferation, chemotaxis and cell survival of several tumor systems.
Aims: The aim of this study is to evaluate a possible involvement of VEGFR-2 signaling in the regulation of IMA responsiveness in CML cells resistant to TKI treatment.
Methods: We assessed the level of gene and protein expression of VEGFR-2 in KCL22 cell lines by RT-qPCR and western blot (WB) analysis. Moreover, we performed co-immunoprecipitation assays to evaluate a putative interaction between the two phosphatases SHP-1 and SHP-2 with VEGFR-2. Then, we carried out WB to specifically demonstrate that this interaction is functional. *in vitro* cellular experiments were done to assess the role of VEGFR-2 to modulating cell viability in CML cells resistant to IMA treatment.
Results: First, we demonstrated that VEGFR-2 is expressed at higher level in KCL22R respect KCL22S cell line, at both mRNA (2.2±1.2 vs 0.1±0.14 VEGFR-2/ABL mRNA copy numbers; P=0.01) and protein level. In addition, we demonstrated that VEGFR-2 forms a complex with SHP-1 and SHP-2 in KCL22S cell line but not in KCL22R cell line, in which we detected only the interaction with SHP-2, since SHP-1 is down-regulated. Indeed, the ectopic SHP-1 expression in KCL22R cell line allow the interaction VEGFR-2/SHP-1. Recently, Bhattacharya *et al*, demonstrated that SHP-1 regulates negatively VEGFR-2 signaling by dephosphorylation of specific tyrosine residues in HUVEC cells. Thus, we hypothesized that SHP-1 may have an important role in the down-regulation of VEGFR-2 signalling in Ph+ cells sensitive to TKI treatment, and on the contrary, the VEGFR-2 activation in resistant Ph+ cells due to the down-regulation of SHP-1 may account for a novel mechanism of tumour escape. Indeed, we demonstrated that VEGFR-2 *activation sites* (Y996 and Y1059) remain phosphorylated after IMA treatment only in KCL22-R but not in KCL22-S cell line and that the ectopic SHP1 expression in resistant cell line is associated with dephosphorylation of the same sites. Thus, to evaluate if the activation status of VEGFR2 was correlated with expression levels of its ligand VEGF, we performed ELISA assay on KCL22 supernatant cells. This analysis revealed that VEGF is equally produced in both sensitive and resistant cell lines and that IMA treatment reduces its level. To better clarify the functional role of VEGFR2 activation in IMA resistant cell line, we treated KCL22S and R with the VEGFR-2 inhibitor *sorafenib*. Sorafenib treatment induced apoptosis in 60% of KCL22R, whereas it does not produced effects on KCL22S viability.
Summary / Conclusion: Taken together, our dataindicate the involvement of VEGFR-2 in the signaling pathways, Bcr-Abl independent, implicated in IMA resistance and that the axis SHP-1/SHP-2 may modulate VEGFR2 signaling in CML cell lines.

SYNERGY BETWEEN JAK INHIBITOR RUXOLITINIB AND TYROSINE KINASE INHIBITORS (TKIS) TO OVERCOME DRUG RESISTANCE RELATED TO BONE MARROW (BM) STROMA MICROENVIRONMENT IN CHRONIC MYELOID LEUKEMIA (CML)

C Quintarelli[1],* B De Angelis[1], S Errichiello[1], S Caruso[1], N Esposito[1], M Raia[2], S Pagliuca[3], M Picardi[3], A Risitano[3], L Luciano[3], S Soverini[4], G Martinelli[4], G Saglio[5], F Pane[3]
[1]Medicina Clinica e Chirurgia, [2]Medicina Molecolare e Biotecnologie Mediche, CEINGE Biotecnologie Avanzate, [3]Medicina Clinica e Chirurgia, Operative Unit of Haematology-II Policlinico Naples , Naples, [4]Haematology/Oncology "L. e A. Seràgnoli", University of Bologna, Bologna, [5]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy

Background: Patients with CML in chronic-phase (CML-CP) treated with Imatinib has shown an overall survival rate of 85% in a 8 year result update of IRIS trial, but only a minority of them achieve complete molecular response (CMR). Although second-generation TKIs yield higher rates of CMR *versus* Imatinib there is no still evidence to support the eradication of CML stem cells. Recent evidence suggests that upon TKI treatment, CML stem cell survival is *BCR-ABL* kinase independent phenomena. The BM is a dynamic microenvironment with high concentration of soluble factors that regulates haematopoiesis, enhances leukemia blast survival and modulates their resistance to pharmacological treatment. Indeed, enhanced survival in leukemia stem cell (LSC) protective microenvironments, such as the BM niche, also contributes to LSC persistence.
Aims: We assess the potential role of BM mesenchymal stroma cells (BM-MSC) in mediating resistance to TKIs in LSC derived from CML patients. Moreover, we evaluate if the IC50 of three clinical relevant TKIs: Imatinib, Nilotinib and Dasatinib significantly increase when Ph+ cell lines are treated in the presence of stroma conditioned media (SCM) produced by BM-MSCordirect MSC interaction.Last, we evaluate if Ruxolitinib synergizes with TKIs in the induction of apoptosis in CML cells.
Methods: K562 Ph+ cell line was treated with TKIs in the presence of either RPMI medium, defined as regular media (RM) or human stroma cell line HS-5 serum-free supernatant, named HS5/SCM. After 72hrs of treatment we evaluate apoptosis induction by Annexin-V staining. IC50 was calculated based on the level of viable cells residual after treatment with increasing doses of drugs in the presence or absence of HS-5/SCM. CD34+ cells from BM samples of CML-CP patients were treated with TKIs and tested for the clonogenic potential in Colony Forming Cell (CFC) assay.
Results: The apoptosis of Ph+ cell line K562, treated with clinical doses of Imatinib, Nilotinib or Dasatinib on HS-5 monolayer is significantly reduced (18%±13%, 50%±6%, or 10%±10%, respectively), respect to RM (46%±12%, 84%±15%, or 53%±20%, respectively). Moreover, the TKI-resistance is also related to soluble factors produced by HS-5 cells. Indeed, apoptosis is greatly reduced when K562 cell line is treated with Imatinib, Nilotinib or Dasatinib in the presence of HS-5/SCM (20%±9%, 29%±18%, or 17%±6%, respectively), respect to RM. Furthermore, the IC50 of Imatinib, Nilotinib or Dasatinib is significantly increased when K562 cell are cultured on HS-5/SCM (5309.29nM, 381.14nM, 2.31nM, respectively) vs the IC50 observed when Ph+ cells are cultured in RM (564.97nM, 14.26nM and 1.13nM, respectively). Moreover, we prove that HS-5/SCM cell exposition induces BCR-ABL independent STAT3 activation, without significant modification of cell cycle phases. These preliminary evidences were further confirmed in CD34+ primary cells derived from BM CML-CP patient's samples. Indeed, Imatinib, Nilotinib or Dasatinib show a slight ability to impair the formation of CML colonies in the presence of HS-5/SCM (55%, 46% and 41% colonies, respectively, relative to untreated controls). However, combination of Ruxolitinib/Imatinib or Ruxolitinib/Nilotinib demonstrated a substantial improvement of reducing the formation of CML colonies, relative to untreated controls (5% and 4%, respectively). Importantly, Imatinib, Nilotinib, and Ruxolitinib, alone or in combination did not significantly impair the formation of normal erythroid and myeloid colonies.
Summary / Conclusion: This data suggests that stroma related drug resistance has a relevant role in TKIs responsiveness in patients with CML. Combination therapy applying TKI and Jak inhibitor Ruxolitinib, has a potential value to overcomethe "protective effect" of BM stroma microenvironment.

P116

CHRONIC MYELOID LEUKEMIA WITH VARIANT T(9;22) REVEALS A DIFFERENT SIGNATURE FROM CASES WITH CLASSIC TRANSLOCATION.

F Albano[1],* A Zagaria[1], L Anelli[1], N Coccaro[1], G Tota[1], A Rossi[1], C Minervini[1], L Impera[1], P Casieri[1], A Minervini[1], G Specchia[1]
[1]DETO, Hematology - University of Bari, Bari, Italy

Background: The t(9;22)(q34;q11) generating the Philadelphia chromosome and the *BCR/ABL1* fusion gene represents the cytogenetic hallmark of chronic myeloid leukemia (CML). About 5-10% of CML cases show variant translocations with the involvement of other chromosomes in addition to chromosomes 9 and 22. The prognostic significance of variant t(9;22) was unclear and debated in the pre-imatinib era, whereas recent studies of large CML series showed that the presence of variant translocations has no impact on the cytogenetic and molecular response or on prognosis. However, the molecular bases of differences between CML patients with classic and variant t(9;22) have never been elucidated.
Aims: The aim of this study is to perform a gene expression profiling (GEP) by microarrays to identify a signature discriminating CML patients bearing variant rearrangements from those with classic t(9;22)(q34;q11) and to unveil the molecular bases of CML heterogeneity in chronic phase.
Methods: Conventional and molecular cytogenetic analyses allowed the identifications of 12 CML cases with classic t(9;22) and 8 cases with variant translocations. Total bone marrow RNA was labeled and hybridized on the Agilent SurePrint G3 Human GE 8x60K Microarray slide. To validate microarray data, quantitative real-time polymerase chain reaction experiments were performed. Microarray data were analyzed using two different gene annotation databases (Database for Annotation, Visualization and Integrated Discovery, DAVID; Ingenuity Pathways Analysis, IPA).
Results: A set of 59 genes was identified as differently expressed in CML cas-

es with variant t(9;22) rearrangements. Querying the DAVID database showed that the enhanced biological process in our gene set involved the intracellular protein kinases cascade. The kinases list included 5 genes: *TRIB1* (tribbles homolog 1), *STK17B* (serine/threonine kinase 17b), *PTK2B* (PTK2B protein tyrosine kinase 2 beta), *C5AR1* (complement component 5a receptor 1) and *ZFP36* (zinc finger protein 36, C3H type, homolog). Further IPA analysis yielded strong indications that 19 out of 59 dysregulated genes from our dataset are involved inthe "Haematological System Development and Function, Tissue Morphology, Cellular Development" network. A central role in this network is played by several proteins that are known to be activated in *BCR/ABL1* cells, namely ERK1/2 (extracellular signal-regulated kinases), p38MAPK (p38 mitogen-activated protein kinase), JNK (c-Jun N-terminal kinase), and cell cycle regulator AKT *(*RAC-alpha serine/threonine-protein kinase). Noteworthy, the upregulated kinase genes, previously revealed by DAVID analysis, are also enclosed in the network identified by IPA. Moreover, TRIB1, PTK2B and C5AR1 kinases are involved in the regulation of the RAS/MAPK pathway.
Summary / Conclusion: In conclusion, our GEP analysis performed on CML cases with variant t(9;22) improved the understanding of the biological mechanisms at the basis of the CML heterogeneity. Overall, our results reveal that in CML cases with variant t(9;22) there is an enhancement of the MAPK pathway deregulation already known to underlie the CML pathogenesis and point out the role of interesting candidate genes, such as *TRIB1, PTK2B,* and *C5AR1*. These findings show that kinases are a common target of molecular alterations in hematological disorders and reinforce the idea that a perturbed action of signal transduction pathways is one of the hallmarks of cancer.

P117

ALIGNMENT STRATEGIES ON INTERNATIONAL SCALE FOR BCR-ABL1 MRNA QUANTIFICATION METHODS: ARE THEY EQUALLY VALID?
C Mauté[1], O Nibourel[2], D Réa[3], V Coiteux[4], N Grardel[2], C Preudhomme[2], J Cayuela[1,*]
[1]Laboratory of haematology, University hospital Saint-Louis, AP-HP, University Paris Diderot, Paris, [2]Laboratory of haematology, CHRU Lille, Lille, [3]Department of Clinical Hematology Immunology Oncology, University hospital Saint-Louis, AP-HP, Paris, [4]Department of Clinical Hematology, CHRU Lille, Lille, France

Background: Serial quantitative measurement of BCR-ABL1 mRNA levels in peripheral blood of patients undergoing tyrosine kinase inhibitor (TKI) therapy have proven relevant to aid clinical decisions. Harmonization efforts for improving comparability of the results between laboratories are ongoing worldwide and it is now accepted that results should be expressed on the international scale (IS). The process by which laboratories can access to IS has been extensively described (S. Branford, blood 2008) and applied to European laboratories under the aegis of the European Treatment and Outcome Study (EUTOS) for CML program. It is based on establishment of a laboratory-specific conversion factor that allows alignment of local results on IS. More recently, a genetic reference panel for quantification of BCR-ABL1 mRNA has been approved by the World Health Organization (WHO) and made available for manufacturers, in order to calibrate secondary reference reagents.
Aims: We report here results from a comparative study performed between two commercial kits designed for quantification of BCR-ABL1 mRNA and calibrated on the WHO reference panel and two "in-house" methods routinely used in two EUTOS French laboratories. Main objectives of this study was (i) to evaluate the comparability of the two IS alignment strategies; (ii) to evaluate the added value of kits on interlaboratory reproducibility and (iii) to measure the impact of a preanalytical delay on the results.
Methods: Overall, 4 methods were compared. M1: "in-house" method developed in Saint-Louis hospital (SLS), Paris; M2: "in-house" method developed in Lille hospital (Lille); M3: Xpert BCR-ABL Monitor (Cepheid) run in SLS and Lille; M4: BCR-ABL MBCR IS-MMR DX (Ipsogen) run in SLS and Lille. Sixty CML patients under TKI therapy, with BCR-ABL1 levels expected between 10 and 0.001%, were included in the study. Upon reception, samples were systematically splitted into two. One part was processed within a working day (D0, <8 hours) and another part was stored at room temperature and processed on the next day (D1, 24-36 hours). Processing included leukocytes retrieval and RNA extraction using Trizol for M1, M2 and M4, or lysis of 0.2ml of blood into the Xpert BCR-ABL Monitor lysis buffer (LB) for M3. Trizol or LB samples harvested at D0 an D1 were dispatched in the 2 laboratories and analyzed using M1, M3 and M4 in SLS or using M2, M3 and M4 in Lille. It is to note (i) that both laboratories are involved in the EUTOS project and have validated their "in-house" method (i.e.: M1 or M2) specific CF and (ii) that M3 and M4 are IS aligned through calibration procedures based on the WHO genetic reference panel. Acceptable concordance between the results of two methods was defined as achievement of 2 of the 3 following landmarks: (i) ≥ 50% between a 2-fold range; (ii) ≥ 75% between a 3-fold range; (iii) ≥ 90% between a 5-fold range. (Müller MC, Leukemia 2009)
Results: Methods M2, M3 SLS, M3 Lille, M4 SLS and M4 Lille fulfilled the acceptability criteria as compared to method M1, suggesting that both alignment strategies on the IS are equally valid. Interlaboratory comparisons showed that "in-house" as well as kit based methods fulfilled the acceptability criteria and led to comparable reproducibility levels. Finally, comparison between D0 and D1 samples showed that acceptability criteria were met for all 4 methods, suggesting that samples may be processed up to one day after their collection.
Summary / Conclusion: All BCR-ABL1 mRNA quantification methods tested in this study, aligned on the IS either by the EUTOS procedure or by the WHO genetic reference panel, give concordant results as defined by our acceptability criteria. The use of CE-IVD labeled kits led to similar interlaboratory reproducibility than "in-house" methods developed in two highly standardized laboratories. A storage period at room temperature of 24 to 36 hours between samples collection and processing did not lead to discordant results. To our knowledge, this is the first study evaluating the two alternative strategies for IS alignment: Eutos versus WHO reference panel calibration.

P118

REDUCED EXPRESSION OF CHIBBY IS A COMPONENT OF BETA-CATENIN ACTIVATION IN CHRONIC MYELOID LEUKEMIA STEM CELLS
E Leo[1,*] M Mancini[1], S Luatti[1], F Castagnetti[1], E Borsi[1], I Iacobucci[1], S Soverini[1], C De Benedittis[1], M Santucci[1], G Martinelli[1]
[1]Department of Experimental Diagnostic and Specialty Medicine - DIMES, Institute of Hematology "L. and A. Seragnoli"-University of Bologna, Bologna, Italy

Background: Chibby (Cby) is a β-catenin antagonist encoded by C22*orf*2 on chromosome 22q13.1 in close proximity to the Bcr breakpoint involved in the Bcr-Abl rearrangement. It hinders β-catenin binding with Tcf/Lef transcription factors, thereby repressing target gene expression, and drives β-catenin nuclear export and cytoplasmatic relocation in a stable tripartite complex encompassing 14-3-3 scaffolding proteins, thereby attenuating β-catenin signaling. Notably, although the Bcr-Abl fusion gene is the causative genetic lesion of chronic myeloid leukemia (CML) and Ph+ acute lymphoblastic leukemia (ALL) the critical signal for proliferation and survival of leukemic stem cells (LSC) is β-catenin.
Aims: The aim of our study was to investigate whether Cby has a role in β-catenin activation in Bcr-Abl+ hematopoiesis and, in particular, in the LSC compartment.
Methods: In first instance we analyzed C22*orf*2 location in Bcr-Abl+ cells. We performed FISH analysis on mononuclear cell fractions (MCF) of 15 CML patients at diagnosis. We used 2 different probes mapping the entire region on chromosome 22q13.1. We then evaluated by means of quantitative PCR and Western blot (WB) analyses the Cby expression levels in mononuclear cell fractions (MNCs) from bone marrow samples of 30 CML patients at clinical diagnosis and 8 ALL patients compared to a pool of MCF from healthy donors. Moreover, we compared Cby expression levels in the putative stem cell compartment (CD34+) and MCF. Finally, we studied the epigenetic modifications (methylation) of the C22*orf*2 promoter in MCF and CD34+ cells of 5 CML patients at diagnosis.
Results: FISH analyses were carried in MCF of CML patients. They showed that one C22*orf*2 allele was invariably translocated to the derivative 9 chromosome and fused to upstream Bcr sequences. WB analyses revealed a significant Cby reduction (>than 70% compared to healthy controls) in the great majority (19/30) of CML patients and all 8 ALL patients. Notably, Cby reduction was associated with a significant increase of nuclear β-catenin. The analysis of gene expression in 4 CML patients at diagnosis and at the moment of major molecular response (MMR) under Nilotinib therapy confirmed that Cby reduction is restricted to the Bcr-Abl+ leukemic clone. However, it was not contingent upon transcriptional events, as proved by the marginal reduction of C22*orf*2 transcripts associated with Bcr-Abl expression. Further analysis carried in 5 CML patients at diagnosis showed that C22*orf*2 transcript levels were significantly reduced in the putative stem cell compartment (CD34+) compared to MCF. These findings support that Chibby transcriptional down-regulation occurs at the level of an early progenitor compartment still retaining stemness traits. Further work provided evidence of the epigenetic control on C22*orf*2 transcription. In particular, we found a significant increment of C22*orf*2 promoter methylation in CD34+ cells from CML patients compared to MCF and to CD34+ cells from healthy donors.
Summary / Conclusion: Our results indicate that transcriptional Cby downregulation associated with Bcr-Abl is restricted to a stem cell compartment and mediated by epigenetic events encompassing the gene promoter methylation. Further investigation is presently underway to evaluate the Bcr-Abl-associated mechanisms affecting the Cby protein stability in more differentiated leukemic progenitors.

P119

DIFFERENTIAL ACTIVATION OF MTOR KINASE IN CHRONIC AND BLASTIC PHASE OF CHRONIC MYELOGENOUS LEUKEMIA

T Stoklosa[1],* E Glodkowska-Mrowka[1], G Hoser[2], I Seferynska[3], P Wlodarski[4]
[1]Immunology, The Medical University of Warsaw, [2]Clinical Cytology, Medical Center of Postgraduate Education, [3]Hematology, Institute of Hematology and Blood Transfusion, [4]Histology and Embryology, The Medical University of Warsaw, Warsaw, Poland

Background: Introduction of tyrosine kinase inhibitors (TKI) into clinical practice transformed chronic myeloid leukemia (CML) into chronic disorder. This holds true for majority of patients, but there is still a significant group of patients who develop resistance to the treatment and progress to blast crisis. Residual leukemia stem cells (LSCs) that are resistant to TKI may play a role of a "ticking bomb" contributing to the relapse of the disease. It has been shown that mTOR (mammalian target of rapamycin) kinase is engaged in BCR-ABL1-positive leukemias, moreover this pathway may be responsible for development of drug resistance in course of CML treatment. Therefore inhibitors of this pathway may provide interesting therapeutic approach to overcome drug resistance and to target LSCs.
Aims: Analysis of mTOR pathway activity in chronic phase of the CML in comparison to acute phase of the disease and potential involvement of ERK (extracellular signal-regulated kinase) also known as MAPK (mitogen-activated protein kinase) pathway in this activation. Evaluation whether rapamycin can overcome resistance to imatinib of non-dividing CD34+ cells pool (containing LSCs).
Methods: In this study primary CD34+ cells were used as well as CML cell lines (human K-562 and murine myeloid 32Dcl3 cells BCR/ABL-transformed). Primary cells were obtained after informed consent from the patients with CML in different stages of disease. CD34+ cells were isolated from peripheral blood leukocytes using magnetic beads systems and were cultured with addition of growth factors or starved. Activation status was determined by Western blotting using phosphospecific antibodies. Response of non-dividing CD34+ cells pool (containing LSCs) to rapamycin and/or imatinib was assessed by flow cytometry using CellTrace® CFSE dye.
Results: We focused our study on CML CD34+ progenitor cell pool from different phases of the disease, which contains primitive LSCs as well as early progenitors. First, we tested the contribution of ERK to activation of mTOR pathway in CD34+ cells. ERK inhibition (by MEK inhibitor -U0126) was effective in cells from all phases of the disease, however the resulting suppression of TORC1 activity varied. In CML-CP CD34+ cells mTOR was inactivated by ERK inhibition, while this effect was not observed in the CML-BC CD34+ cells. This indicates, that mTOR activation mode may change with the progression of CML (becoming ERK independent in more advanced stage of the disease) and that ERK contributes differently to mTOR signaling in chronic and blastic phase of CML. We also showed, that rapamycin in low, selective dose of 20nM effectively inhibited TORC1 in CD34+ CML cells regardless of the phase of the disease. In order to verify whether rapamycin can overcome resistance to imatinib, CML-BC CD34+ were analyzed by flow cytometry for the number of CD34+ CFSE-containing cells upon treatment with imatinib, rapamycin or both inhibitors after several days of culture. We used selective dose of rapamycin, that was shown to inhibit TORC1 in CML-BC CD34+ primary cells and corresponded to the serum level of this inhibitor in clinical conditions, however the number of non-proliferating, CML-BC CD34+ $CFSE^{high}$ cells was unaffected by imatinib, rapamycin or the combination of both of them.
Summary / Conclusion: In summary, we demonstrated, that mTOR activation in CML CD34+ progenitor cells is ERK-dependent in chronic phase of the disease, and ERK-independent in blast crisis. Our results suggest diverse regulation of mTOR pathway during progression of CML. We also showed, that inhibition of BCR-ABL1 and/or TORC1 did not influence the number of non-dividing CD34+ CML cells (which contain LSCs).

MYELOID-DERIVED SUPPRESSOR CELLS ARE INCREASED IN CHRONIC MYELOID LEUKEMIA AND EXERT IMMUNE SUPPRESSIVE ACTIVITY

C Giallongo[1],* N Parrinello[1], D Tibullo[1], P La Cava[1], A Cupri[1], A Romano[1], A Chiarenza[1], F Stagno[1], G Palumbo[1], F Raimondo[1]
[1]clinical and molecular Biomedicine, Section of hematology, Ospedale Ferrarotto, university of Catania, Catania, Italy

Background: In some solid tumors it has been demonstrated that a subpopulation of myeloid cells, defined as "myeloid-derived suppressor cells" (MDSCs), plays an important role in inducing T cell tolerance by production of arginase 1 (arg1) that depletes microenvironment of arginine, an essential aminoacid for T cell function. Since chronic myeloid leukemia (CML) patients have high levels of immature myeloid cells it is of interest to investigate if these cells have MDSCs phenotype and activity.
Aims: The aim of this study was to analyze MDSCs and investigate their immunosuppressive activity in CML patients.
Methods: MDSCs were analyzed in peripheral blood (PB) of healthy donors (HD; n=20) and 30 CML patients at diagnosis. Twenty-one of them were also analyzed during treatment with tyrosine kinase inhibitors (TKIs). Granulocytic MDSCs (G-MDSCs) cells were identified as cells CD11b+CD33+CD14-HLADR-, while the monocytic MDSCs (Mo-MDSCs) as CD14+HLADR by cytofluorimetric analysis. Using real time PCR, arg1 expression was also assessed in PB HD and CML patients at diagnosis and during TKIs therapy Purification of granulocytes, monocytes and lymphocytes from PB was performed by a positive magnetic separation kit (EasySep, STEMCELL Technologies). Arg activity was measured in granulocyte lysates using a colorimetric test after enzymatic activation and arginine hydrolysis. To evaluate the activation of CD3+ T lymphocytes after mitogen stimulation, we analyzed at 24, 48, 72 h the following markers: CD69+, CD71+, DR+. T cell proliferation was analyzed by CFSE labeling after 72 h. Microvesicles (MV) were isolated from CML serum at diagnosis (n=5) by sequential ultracentrifugation.
Results: CML patients showed high levels of Mo- and G-MDSCs at diagnosis in comparison to HD (63±8 and 83±12,2% respectively in CML vs4,9±2,1 and 55,8±5,3% respectively in HD; P<0.001) while after TKIs therapy MDSC levels returned to normal values. Either in PB and in the purified granulocytes subpopulation, arg1 expression was 30 fold higher in CML at diagnosis (P<0.001) than HD and decreased after therapy. Arg enzymatic activity resulted increased in granulocytes of CML patients (n=10) compared to HD (n=10) (P<0.001). The suppressive function of CML granulocytes was measured by their ability to inhibit the proliferation and activation of HD T cells. CML myeloid cells from 4 patients exerted a significantly suppression both on activation and proliferation of HD T cells (P<0.001). CML as well as HD T lymphocytes showed a normal activation *in vitro* which was significantly lost when they was incubated with CML serum (n=4). In addition, an increase of Mo-MDSCs *in vitro* was observed after incubation of HD Mo (n=4) with CML serum (n=6) (29±13%;P<0.0001) or microvescicles (8±2,8%;P<0.05) vs control serum.
Summary / Conclusion: G- and Mo-MDSCs are increased in CML patients at diagnosis and decrease during TKIs treatment. CML granulocytes have high arg1 activity and immunosuppressive activity. Moreover, CML serum as well as CML microvesicles increase the percentage of Mo-MDSCs.

P121

CLINICAL SIGNIFICANCE OF EARLY MOLECULAR RESPONSES IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH FIRST-LINE SECOND-GENERATION TYROSINE KINASE INHIBITORS

S Lee[1],* S Choi[2], S Kim[2], J Bang[2], Y Oh[2], J Park[2], H Jeon[2], E Jang[2], D Kim[1]
[1]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Recent studies have been established the efficacy of second-generation tyrosine kinase inhibitors (2G-TKI) as first-line therapy in chronic myeloid leukemia (CML). 2G-TKI treated patients achieved faster responses compared with imatinib treated patients. Therefore, detailed analyses for clinical significance of early molecular responses in patients treated with 2G-TKI are needed.
Aims: The aim of this study was to evaluate clinical significance of early molecular responses in CML patients treated with first-line 2G-TKI.
Methods: 87 patients were newly diagnosed as CP CML, and started therapy dasatinib (n=13), nilotinib (n=24), bosutinib (n=13), and radotinib (n=37) without prior treatment except hydroxyurea or anagrelide. Among them, 79 patients with available quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) data at 3 months were analyzed for this study. Failure free survival (FFS) includes death resulting from any reason, progression to AP or BP, or treatment failure by ELN.
Results: A total of 79 first-line 2G-TKI treated CP CML patients (including 54 men and 25 women) were included. Their median age was 40 years (range, 18-73). The percentages of patients with low, intermediate and high Sokal risk scores were 42%, 37% and 20%, respectively with unknown Sokal risk scores in 1%. At 3 months, patients showed BCR-ABL1 ≤0.01% (n=2, 2.5%), >0.01 to ≤0.1% (n=11, 13.9%), >0.1 to ≤1% (n=37, 46.8%), or >1 to ≤10% (n=20, 25.3%) or >10% (n=9, 11.4%). For 68 patients with qRT-PCR data at 6 months, they showed BCR-ABL1 ≤0.01% (n=6, 7.6%), >0.01 to ≤0.1% (n=26, 32.9%), >0.1 to ≤1% (n=29, 36.7%), or >1 to ≤10% (n=6, 7.6%) or >10% (n=1, 1.3%).
After a median follow-up of 16.9 months (3.9-65.1 months) after first-line treatment, no progression to AP/BP occurred. At the time of analysis, 61 (77%) patients remained first-line therapy. Primary reasons for first-line therapy discontinuation included loss of CCyR (n=3), primary resistance (n=1), intolerance (n=13), and others (n=1). In patients with BCR-ABL1 ≤10% at 3 months, significantly higher rates of cumulative incidence (CI) of CCyR by 1 year (98% vs 60%, P=0.002) were observed, compared with that of patients with BCR-ABL1 >10%. They also had significantly better 1-y FFS (95.7% vs 60.0%, P=0.003). Patients with BCR-ABL1 ≤1% at 3 months had a trend for better CI of CCyR by 1 year (97.7% vs 85.9%, P=0.061). However, there were no significant differences in 1-y FFS. Molecular response with BCR-ABL1 ≤10% at 6 months was associated with better 1-y FFS (100% vs 94.1%, P<0.001), compared with those who achieved >10% response at 6 months, and BCR-ABL1 ≤1% at 6 months had significantly better 1-y FFS (95.7% vs 60.0%, P=0.003).
Summary / Conclusion: Our data showed that BCR-ABL1 ≤10% at 3 months was a predictor for CI of CCyR at 1year and FFS. BCR-ABL1 ≤10% and ≤1%

cut-offs at 6 months had a significance for FFS. It suggested that the 3 and 6-month qRT-PCR assessment may apply prognostic information in CML patients treated with first-line 2G-TKI. However, further clinical investigations in a larger patient population with longer follow-up are needed.

P122

DEEP SEQUENCING OF THE BCR-ABL KINASE DOMAIN REVEALS A FREQUENCY OF 35INS INSERTION/TRUNCATION HIGHER THAN EXPECTED

C De Benedittis[1,*] S Soverini[1], K Polakova[2], A Brouckova[2], F Castagnetti[1], G Gugliotta[1], F Palandri[1], C Papayannidis[1], H Klamova[2], P Bresciani[3], V Coluccio[3], M Salvucci[4], M Tiribelli[5], T Intermesoli[6], G Binotto[7], I Iacobucci[1], C Venturi[1], M Luppi[3], E Ottaviani[1], M Bochicchio[1], F Cattina[8], M Manuela[1], E Leo[1], T Haferlach[9], A Kohlmann[10], D Russo[8], G Rosti[1], M Baccarani[1], M Cavo[1], G Martinelli[1]
[1]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy, [2]Institute of Hematology and Blood Transfusion, Praha, Czech Republic, [3]Bone Marrow Transplant Unit, Department of Oncology and Hematology, University of Modena, Modena, [4]Hematology, Ospedale Santa Maria delle Croci, Ravenna, [5]Division of Hematology and Bone Marrow Transplantation, Department of Experimental and Clinical Medical Sciences, AOU Udine, University of Udine, Udine, [6]Hematology, Ospedali Riuniti, Bergamo, [7]Department of Clinical and Experimental Medicine, Hematology Section, Padua University School of Medicine, Padova, [8]Chair of Hematology, University of Brescia, Brescia, Italy, [9]MLL Munich Leukemia Laboratoryh, [10]MLL Munich Leukemia Laboratory, Munich, Germany

Background: The spectrum of Bcr-Abl kinase domain mechanisms that confer resistance to tyrosine kinase inhibitors (TKIs) in Philadelphia-positive (Ph+) Leukemia is quite heterogeneous. Not always molecular events underlying drug-resistance can be explained by presence of mutations; Bcr-Abl KD insertions/deletions can be an alternative mutational mechanisms. The recent development of "deep-amplicon sequencing" (DS) technologies has opened the way to a more accurate characterization of molecular aberrations in Ph+ Leukemia with higher sensitivity of screening for know and unknown mutations.
Aims: We took advantage of a DS approach in order to fully characterize the spectrum of insertions and deletions in CML and Ph+ ALL patients who had developed resistance to one or multiple lines of TKI therapy.
Methods: We set up a Bcr-Abl KD mutation screening assay on the Roche GS Junior instrument that allows to reliably detect sequence variants and deletions or insertions with a lower detection limit of 1%. A total of 67 samples from 26 CML and 13 Ph+ ALL patients who had developed resistance to one or multiple TKIs (Imatinib, Dasatinib, Nilotinib) were selected for this analysis. In order to reconstruct the dynamics of growth of mutations we evaluated their presence in a serial follow-up samples collected during TKI therapy in 6 patients.
Results: DS revealed a 35-base insertion (35INS) in 18/26 (69%) CML and 11/13 (84%) ALL Ph+ patients with an abundance from 1% up to 96% of all Bcr-Abl transcripts**.** Interestingly DS highlighted an increased expression of 35INS over time in 6 patients (growth ranged from 2% to 96% within a few months). This insertion is known to retain a stop codon which causes the loss of 653 C-terminal amino acids of Bcr-Abl resulting in early termination and a truncated Bcr-Abl1 protein missing a significant portion of the C-terminal regulatory regions. In addition DS detected 2 in-frame deletions in 3 samples, with an abundance from 2% to 19% . This not previously described variants include a 72-nt deletion (1233-1304) between the junction of Abl exon 6 and 7 that causes the loss of 24 amino acids (aa 359-383) and a 42-nt deletion in exon 7 (1258-1299) which leads to loss of 14 amino acids (aa 371-384).
Summary / Conclusion: Our results show that DS technologies on the GS Junior instrument allow a more accurate characterization of mutational status of patients in comparison to conventional sequencing methods. The higher sensitivity of DS approach allowed to highlight, both in CML and in Ph ALL+ patients, a frequency of 35INS higher than previously reported (60%). The 35INS thus seems to be very frequent in CML and Ph+ ALL patients who develop resistance to one or multiple lines of TKI therapies but its abundance is dynamic in individual patients and seems not to be related to TKI therapy. In line with our results, recent 35INS *in vitro* studies have demonstrated that this insertion is kinase-inactive and should not contribute to TKI-resistance. Although this insertion does not predict for a specific TKIs-resistance its role in Ph+ Leukemia merit additional studies and further analysis of a larger number of samples will be needed to better understand its biological and clinical relevance.

ABERRANT MICRORNA EXPRESSION IN CHRONIC MYELOID LEUKEMIA

O Hershkovitz Rokah[1,*] G Granot[1], A Ovcharenko [1], S Modai [2], M Pasmanik-Chor [3], A Toren[4], N Shomron [5], O Shpilberg [1,6]
[1]Felsenstein Medical Research Center, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Petah Tikva, [2]Department of Cell and Developmental Biology, Sackler School of Medicine, Tel Aviv University, [3]Bioinformatics Unit, Faculty of Life Sciences, Tel Aviv University, Tel Aviv, [4]Department of Pediatric Hematology-Oncology, Safra Children's Hospital, Israel, Tel-Hashomer, [5]Department of Cell and Developmental Biology, Sackler School of Medicine, Tel Aviv University, Israel, Tel Aviv, [6]Institute of Hematology, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Israel , Petah Tikva, Israel

Background: miRNAs are non-coding regulatory RNAs that control gene expression at the post-transcriptional level. Deregulated miRNA expression has been discovered in numerous tumors and it is now clear that they contribute to cancer development and progression. Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder characterized by the fusion oncogene BCR-ABL. This oncogene encodes the tyrosine kinase BCR-ABL whose expression is essential for sustained proliferation of leukemic cells and has become a target for therapy. Imatinib, a selective BCR-ABL tyrosine kinase inhibitor (TKI), induces apoptosis of BCR-ABL+ cells and is currently the first line therapy for newly diagnosed CML patients. Non-negligible incidences of imatinib resistance emphasize the need to identify novel biomarkers significant for CML pathogenesis, progression and resistance.
Aims: Current miRNAs expression data in CML is inadequate and their role in CML is still poorly understood. We aim to find miRNAs acting as biomarkers in CML pathogenesis. We will also determine potential target genes and signaling pathways affected by these signature miRNAs.
Methods: miRNA expression was profiled using Agilent human miRNA microarrays and verified with Applied Biosystems TaqMan. Results were analyzed with Partek genomics suite software. Bioinformatics analysis was performed using: Ingenuity systems, KEGG database, Venn diagrams
Results: We used 2 BCR-ABL+ cell lines, K562 and Meg-01 to identify a CML specific, BCR-ABL–dependent miRNA expression pattern. MiRNA expression profiling was performed in reference to a pool of healthy blood. In addition, we studied the expression profile of K562 cells treated with imatinib and dasatinib. According to unsupervised hierarchical clustering, healthy blood samples were clustered separately from K562 and Meg-01 cells. Untreated K562 cells were clustered separately from treated ones and imatinib treated K562 cells were clustered closely to dasatinib treated cells. Validation was done by real-time PCR. We continued by focusing on miRNAs whose expression level in K562 and Meg-01 cells was opposite to their expression in healthy blood. Venn diagram revealed 73 miRNAs meeting this criterion. Within these miRNAs, we focused on those whose expression in K562 cells was routed back to normal levels following TKI treatment. Fourteen miRNAs; miRNA-9, 23b, 30e, 132, 154, 193b, 320a, 320b, 454, 500, 564, 671-5p, 765, and 892 satisfied this criterion and were further analyzed. Of these miRNAs, miRNA-9 whose expression was high in the CML cell lines was also high in 30% of the tested CML patients. Similarly, miRNA-454 whose expression was low in the CML cell lines was also low in 30% of the tested CML patients. The expression of both of these miRNAs was routed back to normal levels in these patients following imatinib treatment. TargetScan revealed that miR-454 targets genes such as TGFβR1, p21, E2F2, MAPK1, and SMAD4 known to be associated with CML. MiR-9 was found to target ACVR1B, CCNDBP1, LZTS2, SOCS4 and BCL2L11. Reassuringly, the analysis identified CML as the main diseases associated with these miRNAs. MAPK, ErbB, mTOR and focal adhesion were the central molecular pathways related with these expression patterns.
Summary / Conclusion: Further patient studies are needed however, we hope that with these preliminary data, we will identify novel deregulated miRNAs and highlight new candidate gene targets allowing for a better understanding of the molecular mechanism underlying CML development and propose possible new avenues for therapeutic treatment.

P124

A NEW NON CANONICAL ROLE OF IKB ALPHA IN CHRONIC MYELOID LEUKEMIA PATHOGENESIS

S Crivellaro[1,*] C Panuzzo[1], G Carrà[1], F Crasto[1], R Lorenzatti[1], F Daraio[1], F Carnuccio[1], G Saglio[1], A Morotti[1]
[1]Clinical and biological sciences, San Luigi Hospital, turin, Italy

Background: Background: IkappaBalpha (IκBα) is commonly known as inhibitor of the transcriptional factor (TF) NFκB. Under specific stimuli IκBαis phosphorylated, subsequently ubiquitinated and eliminated by proteasome. As consequence free NFκB enters the nucleus and regulate the transcription of many genes involved in immune and inflammatory responses, as well as genes regulating cell proliferation and survival, including IκBα.
Aims: Aims: In recent years many studies have focused their attention on IκBα; it has been found involved and deleted in some disease such as Hodgkin

lymphoma and glioblastoma, suggesting its important rule as tumor suppressor. Moreover IκBαis described to be able to physically interact with the tumor suppressor protein p53 and as consequence to decrease the p53 transcription activity. For these reasons our group decided to study IkBαin Chronic myeloid leukaemiaIκBα, where its rule is poorly investigate.
Methods: Methods: mRNA derived from 25 CML Philadelphiapositive (Ph+) chronic phase and 8 normal donor bone marrow were analyzed for IκBαexpression with real-time quantitative PCR. Subsequently fresh cells derived from patients were used for immunoprecipitation, western blot analysis and immunofluorescence assay, in order to understand protein level and localization. Ph+ cells were also incubated with 10 μM Imatinib mesilate, the common Bcr-Abl inhibitor, for 6 hours and subsequently processed for WB and IF.
For biochemical studies, 293T cells were transfected with IκBαexpression vector alone or in combination with Bcr-Abl expression vector and analysed after treatment with 10 μM Imatinib mesilate and MG-132, a known inhibitor of proteasome.
Results: Results: Despite real time quantitative analysis shown no significant difference between CML patients at diagnosis and control samples, IκBαprotein level was increased in patients greater than in donors. This results was confirmed both by western blot of patients cells lysate than immunofluorescence, where we observed a strong cytoplasmatic IκBαlocalization. After Imatinib incubation, CML patients cells show reduced levels of IkBα, suggesting a strong control kinase-dependent. To investigate this hypothesis we performed the same experiments in 293T cells transiently transfected with IκBαand Bcr/Abl. *in vitro* studies confirmed all our observations; Bcr/Abl plasmid transfection didn't modify the IκBαmRNA, but we observed a strong increased of IκBαprotein; by immunofluorescence we confirmed that also IκBαlocalization, that is mainly diffuse in nucleus and cytoplasm when it is alone, became predominantly cytoplasmatic when it is co-transfected with Bcr/Abl. Treatment of 293T cells with MG-132, a proteasome inhibitor, shown a strong increase of IκBαonly when it is transfected alone, suggesting the ability of Bcr/Abl to stabilize IκBαproteinat a post-translational level. The non canonical IκBαrole as interactor of p53 led us to investigate this mechanism in our CML Ph+ model; in 293T transfected we shown that in presence of Bcr/Abl these two protein physically interact, in a stronger way than in basal condition and as a consequence p53 activity is drastically reduced. The same results was also confirmed in CML patients.
Summary / Conclusion: Summary/conclusions: this work shows how Bcr-Abl induces an higher amount of IκBαprotein and as consequence promotes IκBα-p53 interaction. It will be important to analyse if Imatinib is able to dissociate the interaction between IκBαand p53, in order to identify a new role of p53 on cellular response after tyrosine kinase treatment.

P125

L-AMINO ACID OXIDASE ISOLATED FROM BOTHROPS PIRAJAI INDUCES APOPTOSIS IN BCR-ABL POSITIVE CELLS AND POTENTIATES IMATINIB MESYLATE EFFECT

S Burin[1,*] L Rocha Ayres[1], R Neves[1], LAmbrósio[1], F Morais[1], M Baruffi[1], S Sampaio[1], L Pereira-Crott[1], F Castro[1]
[1]Department of Clinical, Toxicological and Bromatological Analysis, School of Pharmaceutical Sciences - University of Sao Paulo, Ribeirão Preto, Brazil

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the presence of Philadelphia chromosome and by *BCR-ABL* which encodes the BCR-ABL oncoprotein. Although imatinib mesylate (IM) is effective for CML treatment, patients in accelerated and blastic phases of the disease are often refractory to this therapy. Therefore potential new drugs are being investigated to improve the efficiency of the CML therapy. The L-amino acid oxidase from *Bothrops pirajai* (BpirLAAO-I), a toxin isolated from snake venoms is capable of inducing apoptosis in various tumor cell lines.
Aims: 1) To evaluate the BpirLAAO-I effect on BCR-ABL positive cells, 2) To determine the BpirLAAO-I combined with IM effect on HL-60.BCR-ABL. 3) To evaluate the BpirLAAO-I effect on normal peripheral blood mononuclear cells (PBMC).
Methods: To determine the BpirLAAO-I potential as apoptosis inducer, a hundred thousand cells of HL-60 (sensitive to chemotherapeutic drugs) and HL-60.BCR-ABL (HL-60 cells transfected with *BCR-ABL* gene) were cultured with different concentrations of BpirLAAO-I (0.5; 1.0; 1.5; 2.0; 2.5 and 5.0μg/mL) for 18h. One million cells of HL-60.BCR-ABL were also incubated with 10μM IM during 2 and 18h or with 10 μM IM combined with BpirLAAO-I at the concentrations of 0.5; 1.0; 1.5; 2.0 and 2.5 μg/mL for 18h. Also 1mM of Actinomicin-D (ACT-D), an apoptosis inducer agent was used as control. Apoptosis was quantified by Hypotonic Fluorescent Solution (HFS) method by flow cytometry and the results were expressed as the mean of the percentage of hypodiploid nuclei. The HL-60 and HL-60.BCR-ABL apoptosis activation was confirmed detecting caspases3, 8 and 9 expression by Western blot. The phosphotyrosine and c-abl expression was detected to evaluate the BCR-ABL kinase inhibition also by Western blot. To evaluate the effect on normal PBMC, five hundred thousand cells were treated with different concentrations of BpirLAAO-I (3.125; 6.25; 12.5; 25.0 and 50.0μg/mL) and the cytotoxicity assay was performed by MTT. The results were expressed as percentage of cell viability.
Results: The BpirLAAO-I was able of inducing apoptosis on HL-60 and HL-60.BCR-ABL cell lines in a dose-dependent manner and was capable of inducing apoptosis in HL-60.BCR-ABL mainly in concentration of 2.5 ug/mL (52.37% ±3.2). As expected the ACT-D induced apoptosis only in HL-60 (76.9%±6.1). The HL-60 and HL-60.BCR-ABL apoptosis was confirmed by caspase3, 8 and 9 activation. We also observed a significant increase of apoptosis when BpirLAAO-I is combined with IM on HL-60.BCR-ABL compared to these cells treated only with IM or with BpirLAAO-I. The data obtained from the association of BpirLAAO-I with IM by Western blot suggested that BpirLAAO-I potentiates the inhibition of BCR-ABL tyrosine kinase activity. BpirLAAO-I did notinduced cytotoxicity against normal PBMC.
Summary / Conclusion: The results indicate that BpirLAAO-I presents a antileukemic potential against HL-60.BCR-ABL cells and potentiates IM effect but not affects PBMC normal cells. Since some patients are resistant to IM, the description of news drugs or adjuvant for CML treatment is relevant.

P126

IL-2, IL-12 AND IL-15 PREVENT REACTIVE OXYGEN SPECIES ACCUMULATION ON NATURAL KILLER CELLS FROM CHRONIC MYELOID LEUKEMIA PATIENTS FOLLOWING INTERFERON-ALPHA, IMATINIB AND DASATINIB THERAPY

D Silva[1], P Couceiro[2], M Ferreira-Teixeira[1,2], P Freitas-Tavares[3], P Santos[1,4,*]
[1]Instituto de Imunologia, Faculdade de Medicina, Universidade de Coimbra, [2]Laboratorio de Imunologia e Oncologia, Centro de Neurociencias e Biologia Celular, Universidade de Coimbra, [3]Serviço de Hematologia, Centro Hospitalar e Universitario de Coimbra, [4]Laboratorio de Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal

Background: Tyrosine kinase inhibitors (TKIs) change dramatically the oncologic treatment in chronic myeloid leukemia (CML) as also in other tumors. However the complete remission of the disease is normally not achieved but instead the patient enters in a chronic free symptomatic state during TKI administration. Cytotoxic lymphocytes such NK cells could have an important contribution in immunotherapy against tumors. However, in many cancers (e.g. CML), extracellular reactive oxygen species (ROS) produced by phagocytes are the main responsible for the immunosuppressive state of NK cells due to the uncontrolled expansion of myeloid cells. NK cells can perform lytic action over CML cells. However, they normally have decrease expression of membrane receptors *in vivo,* which are necessary for the cytotoxic action over BCR-ABL positive cells.
Aims: We aimed to investigate alterations of ROS levels in NK cells of CML patients due to oxidative burst from phagocytes, taking into account the type of treatment and disease progression.
Methods: In this work, we analysed 109 peripheral blood samples from 50 CML patients. CML patients were under IFN-α, Imatinib or Dasatinib therapy. Production of ROS was evaluated using flow cytometry by the conversion of dihydrorhodamine 123. In addition, peripheral blood NK cells and monocytes from 6 healthy individuals were sorted and co-cultured under different conditions, to evaluate the NK cell capacity to resist to ROS production.
Results: As expected, myeloid cells presented a substantial increase of ROS production in peripheral blood of CML patients. However, we also found chronic increased ROS levels in blood NK cells of CML patients comparing to healthy controls after *in vitro* PMA stimulation. We found that $CD56^{dim}$ $CD16^{+}$ NK cells had increased levels of ROS than $CD56^{bright}$ $CD16^{-}$ subset, confirming an increased susceptibility of the cytotoxic subset. The expression of NKp46 and CD16, two important receptors in antitumor response, was significantly decreased in NK cells from CML patients. TKIs were found to influence ROS levels in NK cells, mainly in patients treated with Imatinib 600 mg. IFN-α revealed a minor impact on ROS in NK cells. Interestingly, stimulation of NK cells with IL-2, IL-12 and IL-15 before contact with stimulated monocytes revealed a protective role, decreasing ROS accumulation in sorted NK cells from healthy controls.
Summary / Conclusion: NK cells from CML patients presented a significant increase of ROS levels. A combination of costimulatory cytokines (IL-2, IL-12 and IL-15) prevents NK cells from immunosuppressive state induced by myeloid cells. Refinement of current therapeutic protocols increasing NK cell functional properties seems to be a promising field to explore in CML therapy.

P127

EFFECT OF NILOTINIB ON THE FUNCTION OF CAROTID ARTERY ENDOTHELIAL CELLS

A Katgı[1], A Gökbulut[2], Ö Sevindik[1,*] F Yüksel[1], Ş Solmaz[1], G Özsan[1], Y Baran[2], Ö Pişkin[2]
[1]Department of Hematology, Dokuz Eylul University, [2]Department of Molecular Biology and Genetics, Izmır Instıtute of Technology, Izmır, Turkey

Background: Chronic myeloid leukemia is a clonal myeloproliferative disorder caused by abnormally proliferating hematopoietic stem cells. CML is treated

with tyrosine kinase inhibitors that inhibit BCR-ABL1 chimeric protein. Nilotinib is a more active second generation tyrosine kinase inhibitor, synthetically derived from imatinib. There have been concerns about the possible pro-thrombotic effects of nilotinib especially on patients having cardiovascular risk factors. The potential mechanism behind the increased risk of thromboembolic events is still not clear.

Aims: In this study, we aimed to evaluate possible harmful effects of nilotinib on endothelial cells. To this aim, we examined proliferative capacity and secretory functions of healthy human carotid endothelial (HCtAE) cells in response to Nilotinib.

Methods: MTT cell proliferation method was used to determine antiproliferative effects of Nilotinib on HCtAE cells. HCtAE cells were incubated 5-, 10- and 100 nM doses of Nilotinib for 72 h. Then, in order to assess the endothelial function, Nitric Oxide (NO), von Willebrand Factor (vWF), tissue plasminogen activator (tPA), plasminogen activator inhibitor 1 (PAI 1) and endothelin 1 (secreted from endothelial cells) levels were evaluated with ELISA from tissue culture supernatants.

Results: There were slight decreases in cell proliferation in response to Nilotinib. Nilotinib increased the secretion of t-PA, PAI 1 and vWF in a dose dependent manner when compared with untreated control group. ET-1 secretion was lower in 5 nM and higher in 10 and 100 nM Nilotinib treated cells as compared to untreated cells. Regarding NO secretion, lower levels were observed in 5 nM and 10 nM and higher levels were detected in 100 nM Nilotinib treated cells as compared to untreated control group cells.

Summary / Conclusion: It cannot be explicitly concluded that nilotinib effects the endothelial cell functions in a pro-thrombotic or anti-thrombotic fashion. In addition, the results obtained from this *in vitro* designed study may not correctly reflect the *in vivo* affect of the drug. We may finally conclude that our study is a preliminary pilot study trying to establish the effect of nilotinib on carotid artery endothelial cells. Some further studies may clarify the possible pathogenetic mechanisms involved in the pro-thrombotic process caused by nilotinib and may induce therapeutic approaches to decrease the incidence of this harmful side effect.

STANDARDIZATION OF MRD DETECTION IN CML BY USE OF A PEER-GROUP CONVERSION FACTOR

E Dumoulin[1],* F Nollet[1], J Billiet[1], J Emmerechts[1]
[1]Department of Laboratory Medicine, Hematology, AZ Sint-Jan, Bruges, Belgium

Background: The goal of treatment with tyrosine kinase inhibitors in patients with CML is achieving a major molecular response (MMR). Due to the complexity of the reverse-transcription quantitative polymerase chain reaction (RQ PCR) for measurement of the BCR-ABL fusion transcripts and the use of different control genes, a universal and reproducible unit of reporting is mandatory for standardization. In 2006 an international scale (IS) was proposed where 100% IS defined the standardized baseline and 0.1% IS defined MMR. In order for laboratories to report results in IS, the European treatment outcome study (EUTOS) for CML has proposed the concept of reference laboratories. By a hierarchical and serial strategy of sample exchange a conversion factor (CF) is calculated for each participating laboratory. Since July 2010 an increasing number of participants of the external quality assessment scheme of UKNEQAS (Sheffield, UK) report results in the IS. In 2010 the World Health Organization established primary reference material for manufacturers. Subsequently, secondary reference material recently became available for clinical laboratories. However, to date variability in test results between laboratories remains high and as CF's might need to be recalculated over time, the use of reference material is expensive and time-consuming.

Aims: The aim of this study is to establish a laboratory-specific CF by making use of the available results of an external quality assessment scheme (UKNEQAS) for BCR-ABL fusion transcript analysis and to confirm this method by use of reference material.

Methods: RQ PCR was performed on two ViiA 7 Real –Time PCR Systems (Applied Biosystems, Foster City, CA, USA) according to the guidelines of the Europe Against Cancer (EAC) program. ABL was used as a control gene and results were reported as ratios (BCR-ABL/ABL %). Analytical sensitivity was determined by calculating the chance of detecting 5 plasmid BCR-ABL molecules when each sample was analyzed in duplicate. A lab-specific CF was calculated by comparing our pre-conversion results for 10 past UKNEQAS samples (period July 2010 to July 2012) with the mean post-conversion values reported by the UKNEQAS. The newly defined CF was confirmed by the use of reference material (Philadelphia p210 Q-P210 standard).

Results: Based on the UKNEQAS results, a CF of 0.37 and 0.46 was calculated for both analyzers, respectively. An analytical sensitivity of 5 molecules BCR-ABL was accepted with the chance of having a false negative result of 1.63%, corresponding to 0.011% IS (95% CI: 0.007-0.015) for both systems after conversion with our newly defined CF. Highly similar CF's were obtained for both systems when using the commercial reference material (0.41 and 0.46 respectively), confirming the calculated CF's based on peer-group comparison.

Summary / Conclusion: In conclusion, we propose a novel approach for standardization of molecular monitoring of BCR-ABL in patients with CML. We believe this is an achievable and acceptable, less time-consuming and less expensive approach for routine laboratories as compared to the EUTOS concept of reference laboratories and commercial reference material. Whether the use of a conversion factor based on peer group comparison will improve between-laboratory variability remains to be elucidated.

P129

BIOLOGICAL CHARACTERISTICS AND DYNAMICS OF BCR-ABL1 MULTIPLE MUTATIONS IN TYROSINE KINASE INHIBITOR RESISTANT CML

S Kim[1],* S Choi[1], S Lee[1], J Bang[1], H Jeon[1], Y Oh[1], J Park[1], E Jang[2], D Kim[1,2]
[1]Cancer Research Institute, The Catholic University of Korea, [2]Division of Hematology, St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: BCR-ABL1 kinase domain (KD) point mutation causes resistance to tyrosine kinase inhibitors (TKI) in chronic myeloid leukemia (CML) patients through impaired binding of TKI to the target site. Recent studies have reported that multiple mutations detected in 2-9% of patients with imatinib (IM)-resistant CML were associated with poor response rate and survival outcomes. However, biological characteristics and dynamics of multiple mutations are still not assessed with a quantitative serial follow-up data in the same populations.

Aims: The aim of this study was to investigate biological characteristics and dynamics of multiple mutations in the serial samples from the patients carrying multiple mutations using subcloning and sequencing.

Methods: Since 2002, 414 CML patients were screened for mutation analysis due to sign of resistance to TKIs including imatinib (IM), nilotinib (NIL), dasatinib (DAS), bosutinib (BOS), radotinib (RAD) or ponatinib (PON) at Seoul St Mary's Hospital using direct sequencing and allele specific oligonucleotide-polymerase chain reaction (ASO-PCR). Among them, 31 patients carried ≥ 2 BCR-ABL1 kinase domain mutations. We analyzed 137 samples from these 31 patients using subcloning and sequencing (in total, 2737 colonies were sequenced). By cloning and sequencing, two or more missense mutations present in the same clone were defined as compound mutation and co-existence of single missense mutations in the separated clones was defined as polyclonal mutation. Co-existence of single missense mutation and compound mutation harboring two or more missense mutations in the same clone was defined as mixed mutation.

Results: In a total of 2737 colonies from 137 samples, 1596 (58%) colonies harbored compound mutations with a median 2 (range, 2 – 7) mutations, and 905 (33%) colonies with a single mutation and 236 (9%) colonies with wild type were observed. We identified 700 different mutations encompassing 278 residues in the kinase domain. The residues most frequently involved in missense mutations were T315 (11.5%), E255(5.4%), M244 (4.2%), V299 (4.1%), E459 (3.5%), F359 (2.9%), and Y253 (2.9%). By cloning and sequencing of each sample, most samples (117/137, 85%) was in the type of mixed mutation, that is co-existence of single missense mutation and compound mutation harboring two or more missense mutations in the same clone. In the next sample from the time of first detection by cloning and sequencing, multiple mutations were changed though different ways; among 30 patients with available next sample, 9 (30%) patients had an acquisition of different point mutation in same clone. In 33% (8/30) patients, new mutation occurred in separate clones. Each sample was observed in AP or BP (23%; 31/137) and CP (77%; 106/137), and on therapy with IM (12%, 16/137), NIL (15%, 21/137), DAS (35%, 48/137), BOS(4%, 6/137), RAD (3%, 4/137), PON (10%, 14/137), and others (18%, 25/137).

Summary / Conclusion: Our data by subcloning and sequencing showed basic characteristics and dynamics of multiple mutations. Samples harboring

multiple mutations showed mixed patterns with co-existence of single missense mutation and compound mutation. Variable dynamic changes of each clone were observed, including an acquisition of different point mutation in same clone and new mutation development in separate clones. In the meeting, we will show further analyzed data about the effect of prior drug exposure and BCR-ABL1 tyrosine kinase activity on dynamical change of multiple mutations.

P130

ESTIMATION OF THE CURRENT SURVIVAL MEASURES IN CHRONIC MYELOID LEUKEMIA: METHODOLOGY AND NEW SOFTWARE TOOLS

J Mayer[1,2,*] T Pavlik[3], E Janousova[3], H Klamova[4], D Zackova[2], Z Racil[1,2], K Machova[4], V Nemethova[2], J Brezinova[4], P Cetkovsky[4], L Dusek[3]
[1]CEITEC, Masaryk University Brno, [2]Masaryk University and University Hospital Brno, [3]Masaryk University, Brno, [4]Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Common ways of survival assessment, the leukemia-free survival (LFS) and the cumulative incidence (CI), are not fully comprehensive for the outcome assessment in chronic myeloid leukemia (CML) because these measures do not account for multiple relapses and leukemia-free periods during the treatment course. Therefore, the concept of the so-called current survival measures, which accounts for the proportion of patients who have lost the first disease remission as well as the proportion of leukemia-free patients who achieved the subsequent remissions, has recently become discussed in the literature. Proper estimation methods and publicly available software tools are needed to make the current survival measures widely usable.
Aims: To demonstrate the validity of the current survival measures. To introduce the methodology, software, and web-based calculator for the CCI and CLFS estimation.
Methods: The current survival measures, the CCI and CLFS, were estimated using nonparametric statistical methods, which are commonly used in survival analysis (Pavlík *et al*, BMC Med Res Methodol. 2011; 11:140). R software package currentSurvival (http://cran.r-project.org/web/packages/currentSurvival/) was also made publicly available for the CCI and CLFS calculation. Moreover, a web-based calculator at http://www.iba.muni.cz/data-analysis-tools/currentSurvival/ will be launched on May 1st 2013. In total, 233 Czech CML patients in chronic phase received the first-line imatinib between July 2003 and December 2011; records were registered in the Czech database INFINITY (http://www.leukemia-cell.org/en/databaze/).
Results: Regarding all 233 patients, the estimated CCI at 3 and 5 years after starting imatinib therapy was 75.4% and 73.4%, respectively. On the other hand, the common CI at 3 and 5 years after starting imatinib was estimated as 85.2% and 87.1%, respectively. Thus, the estimated difference between the CCI and CI curves reached 9.8% and 13.7% at 3 and 5 years after starting imatinib, respectively. Only 185 patients (79.4%) who achieved at least one CCgR were available for the CLFS calculation. The estimated CLFS at 3 and 5 years after achieving the first CCgR was 90.9% and 92.8%, respectively. The LFS was estimated as 74.2% and 64.0% at 3 and 5 years after achieving the first CCgR, respectively. Therefore, at 3 and 5 years after the achievement of the first CCgR, the difference between the CLFS and LFS estimates reached 16.7% and 28.8%, respectively.
Summary / Conclusion: The common CI overestimates the probability of being alive and in CCgR after initiating imatinib therapy, whereas the common LFS underestimates the probability of being alive and in CCgR after the achievement of first CCgR on the imatinib therapy. Thus, both current survival measures, the CCI and CLFS, more reliably illustrate a CML patient's disease status in time because they account for multiple leukemia-free periods during the treatment course. Moreover, the methodology for CCI and CLFS estimation is now available for public use in the form of either R software package currentSurvival or web-based calculator.

P131

10058-F4 A SMALL MOLECULE C-MYC INHIBITOR DECREASES CIP2A AND REDUCES BCR-ABL1 TYROSINE KINASE ACTIVITY IN CHRONIC MYELOID LEUKAEMIA (CML)

C Lucas[1,*] R Harris[1], A Giannoudis[1], R Clark[1]
[1]Molecular and Clinical Cancer Research (Haematology), University of Liverpool, Liverpool, United Kingdom

Background: Disease progression in CML is associated with inhibition of the phosphatase PP2A. PP2A is functionally impaired by cancerous inhibitor of PP2A (CIP2A), leading to the stabilisation of c-Myc. CIP2A protein is a prospective biomarker of disease progression in imatinib treated CML patients (Lucas *et al* Blood 2011; 117: 6660-8). We have previously shown that CIP2A is not suppressed by imatinib treatment and that CIP2A levels rise as patients progress into blast crisis. Moreover, high CIP2A levels are associated with high c-Myc and high BCR-ABL1 tyrosine kinase activity.
Aims: The aim of this work was to inhibit c-Myc using the small molecule inhibitor 10058-F4 in order to disrupt the CIP2A/c-Myc interaction and thus attempt to suppress CIP2A indirectly.
Methods: Cell lines and newly diagnosed chronic phase patients cells were cultured with 60μM 10058-F4 for 48 hours. CIP2A, PP2A, pY^{307}-PP2A and c-Myc and pS^{62}-c-Myc proteins were assessed by flow cytometry and western blotting. mRNA expression was assessed using the Taqman expression assays. c-Myc siRNA was transfected into K562 cells for 72 hours.
Results: 10058-F4 inhibited both c-Myc and pS^{62}-c-Myc (P=0.003) in K562 cells. Reduction in c-Myc protein resulted in a concomitant decrease in both CIP2A protein levels (P=0.003) and BCR-ABL1 tyrosine kinase activity (P=0.003). 10058-F4 treatment decreased both c-Myc and BCR-ABL1 mRNA expression (P=0.002 and P=0.004 respectively). No effect on CIP2A mRNA expression was observed. To investigate whether the decrease in CIP2A protein was a direct result of c-Myc reduction or an indirect effect via BCR-ABL1, AGS cells (a gastric carcinoma line which is CIP2A positive but BCR-ABL1 negative) were treated with 10058-F4 for 48 hours. Again, c-Myc inhibition resulted in a decrease in CIP2A (P=0.001); thus, the decrease in CIP2A is a direct result of c-Myc inhibition and not due to BCR-ABL1. Importantly, the effect of 10058-F4 on decreasing BCR-ABL1 in CML cells is a result of the reduction in both c-Myc and CIP2A, implying that both are upstream of BCR-ABL1. Knockdown of c-Myc resulted in increased PP2A activity, decrease in CIP2A levels (P=0.004) and decreased BCR-ABL1 tyrosine kinase activity (P=0.001). These data suggest that c-Myc and CIP2A act to stabilise each other at the protein level.
Newly diagnosed chronic phase patients cells were cultured with 60μM 10058-F4 for 48 hours (n=6). In samples with high CIP2A protein expression, c-Myc inhibition led to a significant reduction in both CIP2A and BCR-ABL1 tyrosine kinase activity. BCR-ABL1 tyrosine kinase activity was also reduced in samples with low CIP2A expression, suggesting that c-Myc inhibition would be advantageous to all CML patients.
Summary / Conclusion: CIP2A can be targeted by using c-Myc as a surrogate target. Inhibition of c-Myc in K562 and CML primary cells either with 10058-F4 or c-Myc siRNA resulted in the reactivation of PP2A, a decrease in CIP2A and a decrease in BCR-ABL1 tyrosine kinase activity. c-Myc may contribute to disease progression by promoting aneuploidy as a result of deregulated cell division and increased mismatch repair, as well as stabilising CIP2A. Both c-Myc and CIP2A are therefore attractive therapeutic targets for preventing disease progression.

Chronic myeloid leukemia - Clinical 1

IMPACT OF DRUG TRANSPORTER ABCG2 HAPLOTYPES IN MOLECULAR RESPONSE OF CML PATIENTS IS MODULATED BY IMATINIB DAILY DOSE

M Delord[1,*] P Rousselot[2], J Cayuela[3], F Sigaux[3], J Guilhot-Gaudeffroy[4], C Preudhomme[5], F Guillot-Gaudeffroy[6], P Loiseau[7], E Raffoux[8], D Geromin[3], E Génin[9], F Calvo[10], H Bruzzoni-Giovanelli[11]
[1]Recherche clinique, Institut Universitaire d'Hématologie, Paris, [2]Service hématologie, Hopital Mignot, Versailles, [3]Laboratoire central d'hématologie, Hôpital Saint Louis, Paris, [4]Centre d'Investigation Clinique, inserm, Poitier, [5]Laboratory of Hematology, Biology and Pathology Center, Inserm, U837, Team3, Cancer Research Institute of Lille, Lille, [6]Centre d'Investigation Clinique, University Hospital of Poitiers, Poitier, [7]Service d'Immunologie et Histocompatibilité, [8]Service des Maladies du Sang, Hôpital Saint Louis, [9]Determinants génétiques des maladies humaines, Inserm UMR 946 , [10]Centre d'Investigations Cliniques, Hôpital Saint-Louis, [11]Centre d'Investigations Cliniques, Hôpital Saint Louis, Paris, France

Background: Imatinib and other tyrosine kinase inhibitors (TKIs) have revolutionized the therapy of chronic myelogenous leukemia (CML). Along with parameters such as the initial Sokal score, comorbidities, age, co-medications clinicians need patient-related parameters such as specific genetic profile related to response or tolerance in order to optimize treatment strategies. Preliminary studies have reported polymorphisms in candidate genes like OCT1, ABCG2 or MDR1 implicated in response to imatinib. However, no systematic association study was performed testing constitutive variations in drug transporter genes and allocated dose of imatinib. *This study was approved by the local Human Ethics Committee. Written informed consent was obtained from all patients prior to study participation.*
Aims: To evaluate the role of constitutive variations in drug transporter genes on imatinib response using longitudinal data relative to molecular response in CP-CML patients allocated to either imatinib 400 mg/day or 600mg/day.
To validate results according to early molecular responses (BCR-ABL^{IS} at 3 months <10%) and response of interest (BCR-ABL^{IS} at 12 months ≤ 1%, BCR-ABL^{IS} at 18 months ≤0.1%).
Methods: We use a custom DNA chip covering 857 SNPs covering 94 drug transporter genes to analyses two independent cohorts of CP-CML patients. The first (St-Louis hospital cohort) composed of patients treated with imatinib 400 mg/day (*n*=105) and the second cohort (SPIRIT cohort) composed of patients from the SPIRIT randomized clinical trial allocated to 400 mg/day (*n*=132) or 600mg/day (*n*=107). Association study was performed on cumulative incidence of major molecular response (CI-MMR) using the Fine & Gray model. (Switch in treatment due to treatment toxicity was the competing event).

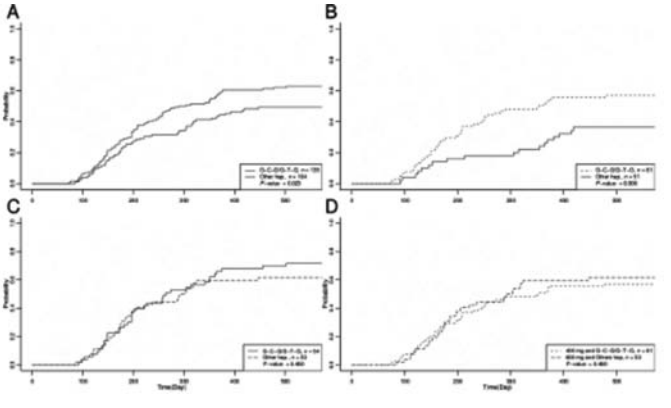

Figure 1.

Results: Two "favorable" haplotypes of ABCG2 gene were associated to higher CI-MMR in patients allocated to imatinib 400 mg/day but not in patients allocated to imatinib 600 mg/day. Patients allocated to imatinib 400 mg/day with at least one copy of the favorable haplotypes had similar outcome as compared to patients with common haplotype receiving 600 mg/day. Interestingly, these favorable haplotypes were common: about half the population present at least one copy of these haplotypes. Quadrant A, B and C of the figure illustrate discrimination of patients with respect to ABCG2 haplotypes globally, in the 400 mg/day arm and in the 600 mg/day arm respectively. Quadrant C shows the similar outcome of patients allocated to imatinib 400 mg/day with favorable haplotype *versus* patients allocated to imatinib 600 mg/day with common haplotype. As expected results were validated in term of early molecular responses (BCR-ABL^{IS} at 3 <10%) and response of interest (BCR-ABL^{IS} at 12 months ≤1%, BCR-ABL^{IS} at 18 months ≤0.1%) only in patients allocated to imatinib 400 mg/day.
Summary / Conclusion: Here we show that response to imatinib is determined by constitutive haplotypes in drug-transporter genes such as ABCG2 in a dose dependent fashion. Moreover, higher response associated with high doses of imatinib could also be reached by patients having favorable haplotypes while treated at low intensity. As about half of the population is targeted by the favorable haplotype, the ABCG2 status in newly diagnosed CP-CML patients could help clinicians to optimize treatment strategies.

Background: Nilotinib (NIL) induced significantly faster and deeper molecular responses than imatinib (IM) in the ENESTnd trial. The 12-month results of the ENESTcmr study demonstrated that patients (pts) on IM with ongoing BCR-ABL positivity who switched to NIL achieved faster, deeper molecular responses than pts remaining on IM.
Aims: The ENESTcmr study evaluates the potential benefit of switching pts with persistent residual disease on long-term IM therapy to NIL. Here, we report the 24-month follow-up of this study.
Methods: ENESTcmr includes pts with Philadelphia chromosome–positive (Ph+) CML-CP who achieved a complete cytogenetic response (CCyR) but had detectable BCR-ABL transcripts after ≥2 years of IM therapy. Pts were randomized to continue their IM dose (400 or 600 mg once daily [QD; n=103]) or switch to NIL 400 mg twice daily (BID; n=104). Molecular response (including major molecular response [MMR, BCR-ABL^{IS} ≤0.1%] and MR$^{4.5}$ [BCR-ABL^{IS} ≤0.0032%]) was determined by RQ-PCR. Confirmed undetectable BCR-ABL was achieved if 2 consecutive samples (with sensitivity of ≥ 4.5 logs) had negative RQ-PCR results.
Results: With 24 months of follow-up, 77% and 91% of pts remained on study in the NIL and IM arms, respectively. The higher rates of discontinuation with NIL were expected, as these pts switched to a new therapy from a well-tolerated long-term therapy. Most discontinuations occurred within the first 12 months on study, with comparable rates of discontinuation across arms between 12 and 24 months. By 24 months, confirmed undetectable BCR-ABL was achieved by significantly more pts who switched to NIL vs pts continuing IM (22.1% vs 8.7%; P=.0087). Twice as many pts achieved and maintained undetectable BCR-ABL on 3 consecutive assessments on NIL vs IM (n=10 vs 5). The increase in the proportion of pts with undetectable BCR-ABL from month 12 to 24 was higher in the NIL arm (9.6 percentage points) vs the IM arm (2.9 percentage points). In pts without MR$^{4.5}$ at study start, significantly more pts in the NIL arm achieved MR$^{4.5}$ by 24 months than in the IM arm (42.9% vs 20.8%; P=.0006), and more pts maintained MR$^{4.5}$ (or better) on 3 consecutive assessments with NIL vs IM (n=18 vs 6). Rates of MR$^{4.5}$ were superior on NIL regardless of response at study start (Table 1), but the difference between the treatment arms was particularly pronounced in pts without MMR at study start (MR$^{4.5}$ achieved in 29.2% vs 3.6% of pts on NIL vs IM; P=.016). No pt without MMR at study start who continued on imatinib achieved confirmed MR$^{4.5}$ or undetectable BCR-ABL (on 2 consecutive assessments). No pt progressed to accelerated phase/blast crisis since the 12-month follow-up. Events were experienced by 3 pts on NIL (confirmed loss of MMR, n=2; death, n=1) and 7 on IM (confirmed loss of MMR, n=4; confirmed loss of CCyR, n=3). Prior interferon therapy (with vs without) and length of prior IM therapy (≤ 36 vs > 36 months) did not significantly affect the rate of MR$^{4.5}$ in either treatment arm. The safety profiles of NIL and IM were consistent with previous studies.
Summary / Conclusion: In pts with detectable residual disease on long-

term IM therapy, NIL induced deeper molecular responses than continued IM, and these responses were more frequently maintained in consecutive assessments. The difference between arms in rates of $MR^{4.5}$ and undetectable BCR-ABL increased between 12 and 24 months. These deeper molecular responses achieved after switch to NIL may increase eligibility for tyrosine kinase inhibitor–free remission studies.

Med. Klinik, Universitätsmedizin Mannheim, Mannheim, Germany, [8]ARIAD Pharmaceuticals, Inc., Cambridge, United States, [9]CIC Inserm 0802, CHU de Poitiers, France, [10]Universitätsklinikum Jena, Jena, Germany, [11]Imperial College, London, United Kingdom, [12]University of California San Francisco, San Francisco, [13]Huntsman Cancer Institute University of Utah, Salt Lake City, United States

Background: BCR-ABL kinase domain mutations frequently cause tyrosine kinase inhibitor (TKI) failure in chronic myeloid leukemia (CML). Ponatinib, a potent oral pan-BCR-ABL TKI, has shown preclinical activity against all single mutants tested, including T315I.

Aims: The impact of baseline (BL) mutations on response to ponatinib (45 mg once daily) and the end of treatment (EOT) mutation status in patients discontinuing treatment were evaluated in the phase 2 PACE trial.

Methods: Data for chronic phase (CP) CML patients are described herein; data for patients with advanced disease will be presented. Heavily pretreated CP-CML patients (94% received ≥2 prior TKIs, 60% received ≥3 prior TKIs) resistant or intolerant to dasatinib or nilotinib (N=203) or with T315I confirmed at BL (N=64) were enrolled. Among CP-CML patients receiving prior dasatinib or nilotinib (n=256), 84% were resistant to dasatinib and/or nilotinib, 16% were intolerant only. The primary endpoint was major cytogenetic response (MCyR). Minimum follow up at analysis (9 Nov 2012) was 12 mos (median 15 [0.1-25] mos). Sanger sequencing was performed at a single central laboratory.

Results: At BL, no mutations were detected in 136 (51%) patients, 1 mutation was detected in 105 (39%) patients, ≥2 mutations were detected in 26 (10%) patients; 27 unique mutations were observed. Responses were observed regardless of BL mutation status. MCyR rates were: 56% overall, 49% in patients with no mutations, 64% in patients with 1 mutation, 62% in patients with ≥2 mutations; 57% in patients with mutation(s) other than T315I (n=67), 74% in patients with T315I only (n=50), 57% in patients with T315I + other mutation(s) (n=14). Although higher response rates were observed in patients with T315I, multivariate analyses have shown that T315I is not an independent predictor of response. Responses (MCyR) were seen against each of the 15 mutations present in >1 patient at BL: T315I 45/64 (70%), F317L 11/22 (50%), F359V 6/13 (46%), G250E 7/8 (88%), E255K 6/8 (75%), M244V 3/5 (60%), V299L 3/5 (60%), H396R 1/5 (20%), F359I 3/4 (75%), F359C 1/4 (25%), E459K 3/3 (100%), E355A 1/2 (50%), L248V 1/2 (50%), Y253H 1/2 (50%), E255V 1/2 (50%). Ninety-nine patients discontinued (35 adverse event, 20 progressive disease, 14 withdrawal by subject, 11 lack of efficacy, 8 physician decision, 11 other). Of the 99 patients discontinuing, 56 patients had EOT mutations assessed. 5 patients lost a mutation, 46 had no change, and 5 gained mutations. In 2 of the 5 patients, single mutations were newly detected at EOT (E255V [10% of transcripts]; T315I [100% of transcripts]); both patients had a prior history of the same mutation, and responses were achieved in other patients with these mutations at BL. In the other 3 patients, multiple mutations were newly detected at EOT (T315I/M351T [100%/40% of transcripts]; T315I/F359V [100%/90% of transcripts]; Y253H/F359V [100%/100% of transcripts]). In all 3 patients, 1 of the mutations was present at BL and/or the patient had a prior history of 1 or both mutations. In 1 patient, the multiple mutation Y253H/F359V may have been associated with progressive disease; the avg dose intensity of ponatinib in this patient was 26 mg/day. Overall, 11 patients lost MCyR (none with T315I at BL); 6 of the 11 discontinued, and 4 had EOT mutations assessed and no changes from BL were observed (Table 1).

Summary / Conclusion: Responses to ponatinib were observed regardless of BL mutation status. No single mutation conferring resistance to ponatinib in CP-CML has been observed to date. Data with a minimum follow up of 18 mos will be presented. NCT01207440.

Background: Combining Imatinib (IM) with pegylated interferon alfa2a (PegIFN) seems to improve molecular responses for *de novo* chronic phase CML (CP-CML) patients (pts) compared to IM. Second generation TKI (TKI2) such as nilotinib induce higher levels of cytogenetic and molecular responses than IM in the first line for CP-CML.
Aims: This is the M15 update of the use of nilotinib+PegIFN for front line therapy in CP-CML pts.
Methods: This is a 2-step study, where pts were assigned first to PegIFN (±HU) for 4 wks (90 µg/wk) prior to a combination of nilotinib 300 mg BID+PegIFN 45 µg/wk for ≥ 1 year. The primary endpoint was the rate of $MR^{4.5}$ by M12 confirmed on 2 datapoints. Molecular assessments were centralised and expressed as $BCR\text{-}ABL^{IS}$ in %. All pts have signed up an informed consent to enter the study.
Results: Forty one pts (+1 screen failure) were enrolled in a first step and 20 additional pts were planned if the primary endpoint would not been reached in the first cohort. The current median FU is 20.5 (17–23.2) months (M). Sokal and Euro scores were high for 15% and 5%, interm. for 41% and 54% and low for 44% and 41% respectively. Eutos score was high for 2 pts. Median age was 53 (23-85) years. Two pts had a masked Ph, 3 a variant form, and 1 had an ACA, all pts had a "M" BCR transcript. CHR was obtained in 5%of pts at M1 and 100% at M3. Analysed in ITT, the rates of CCyR at M3, 6, and 12 (= at2,5, 8 and 11 M of TKI2) were 39%, 56%, 71% respectively. Overall 75.6% of pts were in MMR at M12 and 80.6% at M15. The $MR^{4.5}$ rates increase with time: 9.8% at M6 to 29.3% at M15, and the MR^5 rates followed the same pattern (Figure 1). Of note, 87% of pts had a $BCR\text{-}ABL^{IS}$ ≤10% at M3 and, at M12, had significantly higher rates of MMR (77% vs 20%, P=0.028) and $MR^{4.5}$ (20% vs 0%, P=0.034) than pts >10%. One pt progressed to myeloid blast crisis at M6 with no detectable BCR-ABL mutation, and is alive after allogeneic SCT. At last FU, 7 pts went out of study:M2 for non-observance, M6 for seizures related to an extra-dural hematoma in a non-thrombocytopenic pt, M6 for recurrent grade 3 hepatic toxicity, M9 for recurrent grade 3 pruritus, M15, 18 & 18 for coronary stenoses. The mean doses of PegIFN/Wk during the first year were 32.8 µg/wk, significantly higher in pts achieving $MR^{4.5}$ at M12 (45.3 vs 30.2 µg/wk, P=0.02) and the mean doses of nilotinib during the first year (493 mg/day) were not different in pts achieving $MR^{4.5}$ at M12 (505 vs 490 mg/day, P=0.68). At M15, the rate of grade 3-4 hematologic toxicities overall were anemia 2%, thrombocytopenia 24%, neutropenia 24% and pancytopenia 2% of pts. These occurred mainly during M1-M3 (22% neutropenia, 24% thrombocytopenia, 2% pancytopenia, 2% anemia), rarely during M3-M6 (7% neutropenia, 2% thrombocytopenia) and never thereafter. Grade 3-4 non-hema toxicities followed a similar pattern, and overall we observed 20% liver toxicities, 15% of neuro-psy episodes, 10% gut/pancreas disturbances, 2% arthro-myalgias. Three late coronary stenoses occurred at M15, 18 & 18, although no case of PAOD has been reported to date.
Summary / Conclusion: The combination of nilotinib+PegIFN is relatively well tolerated despite frequent initial hematologic toxicities, and provides high rates of $MR^{4.5}$ at M12 and beyond. The cohort n°2 will not be enrolled as the M12 $MR^{4.5}$ rates are beyond planned initial expectations. The M15 and M18 updates will be presented during the meeting

Background: Early cytogenetic and molecular responses have been associated with a better outcome in patients treated with imatinib, dasatinib, or nilotinib frontline. In particular, BCR-ABL transcript level < 10% at 3 months correlated with: increased 2-year cumulative incidence of CCyR, MMR, and $MR^{4.5}$ with dasatinib (Marin D *et al*, Blood 2012); better progression-free survival (PFS) and overall-survival (OS) at 3 years, with dasatinib (DASISION; Saglio G *et al*, ASH 2012, abs. 1675); higher probability of future MMR and $MR^{4.5}$, and better PFS and OS, with nilotinib (ENESTnd; Hochhaus A *et al*, ASH 2012, abs. 167). There is increasing interest in identifying as early as possible patients who will not respond optimally to tyrosine kinase inhibitors in order to consider treatment modifications.
Aims: To evaluate the impact of BCR-ABL transcript level and cytogenetic response at 3 months on subsequent response and outcome in an independent cohort of patients treated with frontline nilotinib-based regimens in Italy (CML Italian Registry of Nilotinib).
Methods: The CML Italian Registry of Nilotinib includes 215 patients, enrolled in 2 multicenter phase II studies conducted by the GIMEMA CML WP (ClinicalTrials.gov. NCT00481052 and NCT00769327) or treated at the Bologna University Hospital, with nilotinib 300 mg or 400 mg BID as initial treatment. The median age was 53 years (range 18–86). Ten out of 215 patients (5%) had a high EUTOS score. The median follow-up was 33 months (range 21–51 months). At 3 months 196/215 (91%) and 189/215 (88%) patients were evaluable for the molecular and cytogenetic response, respectively. BCR-ABL transcript levels were: ≤1% in 88%; >1% to ≤ 10% in 11%; > 10% in 1%; given the very low proportion of patients with a BCR-ABL > 10% (n. 2), patients have been divided into 2 groups, with a transcript level ≤1% (n=173, 88%), or >1% (n=23, 12%). Cytogenetic response was: MCyR 93% (CCyR 84%; PCyR 9%); less than MCyR 7%. We analysed the rate of MMR at 1 year, and the failure-free survival (FFS, according to ELN 2009 definitions), PFS, and OS (any death included) according to the BCR-ABL transcript levels and to the cytogenetic response at 3 months.
Results: Patients with BCR-ABL <1% at 3 months had a higher rate of MMR at 12 months with respect to those with a transcript level ≤1% (79% vs. 35%, P<0.001). A lower transcript level at 3 months correlated with a better 3-years FFS (92% vs. 74%; P<0.001) and PFS (95% vs. 83%; P=0.009) and a similar OS (96 vs. 86%; P=0.059). Patients with a MCyR at 3 months vs. patients with less than a MCyR had higher rates of MMR at 12 months (77% vs. 46%; P=0.02). Moreover, patients in MCyR at 3 months had a better 3-years FFS (92% vs. 69%; P=0.001) and PFS (96% vs. 77%; p 0.001), but similar OS (96% vs. 92%; P=0.48). Patients with a CCyR at 3 months vs. patients with less than a CCyR had higher rates of MMR at 12 months but similar FFS, PFS, and OS (data not shown).
Summary / Conclusion: In our national experience a very small proportion of patients treated frontline with nilotinib failed to achieve a reduction to < 10% level of BCR-ABL transcript (2/196 or 1%). The cut-off of 1% of BCR-ABL at 3 months in our experience is a reliable surrogate marker of response at 1 year (MMR) and outcome (PFS and FFS), along with the level (MCyR) of cytogenetic response achieved. The absence of these early responses may represent an adverse factor to be considered in the management of patients treated with nilotinib frontline.

Background: Second generation tyrosine kinase inhibitors (TKIs) induce higher cytogenetic and molecular response rates with respect to imatinib (IM) in chronic myeloid leukemia (CML) patients in early chronic phase, but outcome differences have not been clearly demonstrated and IM still represents an important frontline therapeutic option. Early response-related prognostic factors are extremely relevant to optimize the treatment strategy and to consider a switch to 2nd line therapy in patients who are not able to achieve an optimal response. In IM-treated patients, BCR-ABL^{IS} transcript levels >10% at 3 months and >1% at 6 months were able to identify high-risk groups (Marin *et al*, JClinOncol 2011; Hanfstein *et al*, Leukemia 2012). Similar analysis were performed within the IM arms of the ENESTnd trial (Hochhaus *et al*, EHA 2012) and the DASISION trial (Jabbour *et al*, EHA 2012).

Aims: To investigate the prognostic impact of a large BCR-ABL^{IS} transcript amount at 3 and 6 months (in particular, ≤1% vs >1%) on the subsequent response and the long-term outcome of CML patients treated frontline with IM, describing the characteristics of patients with higher transcript levels.

Methods: 559 patients enrolled within 3 trials of the GIMEMA CML WP (ClinTrialsGov NCT00514488/NCT00510926, observational trial CML023) were analyzed. Evaluable QPCR sample at 3 and 6 months: 487/559 (87%) and 492/559 (88%), respectively.Definitions: major molecular response (MMR): BCR-ABL^{IS} ratio <0.1%; molecular response with 4.0-log reduction (MR$^{4.0}$): BCR-ABL^{IS} ratio <0.01% (at least 10.000 ABL copies); failure: according to 2009 ELN recommendations; progression: transformation to advanced phases; all deaths. at any time and for any reason, were included. Patients with events or censored within 3 or 6 months were excluded from the respective analysis.

Results: Median age: 52 years (range 18-84). IM dose: 76% 400 mg, 24% 800 mg. Overall risk distribution: high Sokal score: 22%; high EUTOS score: 7%. Median follow-up: 76 months (range: 7-99; 95% of patients with at least 5-year observation). BCR-ABL^{IS} ratio at 3 months: ≤1% in 336/487 (69%), >1% to ≤10% in 120/487 (25%) and >10% in 31/487 (6%). BCR-ABL^{IS} ratio at 6 months: ≤1% in 425/492 (86%), >1% to ≤10% in 54/492 (11%) and >10% in 13/492 (3%). As expected, baseline characteristics of patients with higher BCR-ABL^{IS} transcript levels were different with respect to patients with lower levels: patients with BCR-ABL^{IS} ratio >1% at 3 months had lower hemoglobin concentration, higher blast % in peripheral blood (PB), larger spleen, higher Sokal and EUTOS scores (patients with BCR-ABL^{IS} ratio >1% at 6 months, in addition, showed also a higher frequency of CCA in Ph+ cells). A detail of response and outcome according to transcript levels at 3 and 6 months is presented in Table 1.

Summary / Conclusion: In a multicentric nationwide experience, the proportion of patients with BCR-ABL^{IS} transcript levels >10% at 3 and 6 months was low. The risk distribution and the presence of a proportion of patients treated with high-dose IM may explain, at least in part, the differences with other published reports. At 3 and 6 months, a BCR-ABL^{IS} cutoff of 1% was a reliable surrogate marker of response and outcome. A cutoff of 10% identified, at 3 and 6 months respectively, two smaller cohorts with inferior response rates, lower failure-free survival, lower progression-free survival and lower overall survival, but the outcome differences did not result statistically significant, probably due to the small number of patients with a BCR-ABL^{IS} ratio >10%. A BCR-ABL^{IS} level >1% at 3 and 6 months represents a warning, requiring a close monitoring. A switch to 2nd generation TKIs should be considered.

Acknowledgments: University of Bologna, BolognaAIL, COFIN, Fondazione Carisbo.

TARGETED NEXT-GENERATION SEQUENCING FOR THE IDENTIFICATION OF GENOMIC BCR-ABL1 FUSION JUNCTIONS TO QUANTIFY RESIDUAL DISEASE IN CML PATIENTS IN CMR

M Alikian[1,2,*] P Ellery[1], G Gerrard[1], T Aitman[3], L Games[3], D kasperaviciute[3], K Rekopoulou[3], D Milojkovic[1], D Marin[1], J Goldman[1], J Apperley[1], L Foroni[2], A Reid[2]

Background: Recent studies indicate that 40% of CML patients who achieve complete molecular remission (CMR) on imatinib remain disease-free after drug discontinuation, raising the possibility of an "operational cure". However, the safe introduction of a TKI withdrawal policy would require a reliable and cost effective method of identifying patients with the lowest likelihood of relapse, which is likely to be related to presence residual disease. Preliminary data suggest that PCR of genomic DNA might be more sensitive for the detection of residual disease than one that relies on cDNA and may therefore help to predict outcome post-withdrawal. However, the former method is arduous since it requires a customised patient-specific assay.

Aims: Here we describe a method based on targeted-next-generation sequencing allowing identification of BCR-ABL1 breakpoints from enriched genomic BCR and ABL1 DNA followed by rapid generation of DNA-based qPCR assays.

Methods: The location of the BCR-ABL1 fusion junction was mapped in disease samples from 30 CML patients using Illumina's MiSeq platform. A custom TruSeq DNA target enrichment kit (Illumina) was used to enrich for the BCR and ABL1 genes. The enriching probes were designed via the online tool Design Studio covering both genes plus 50kb upstream and downstream of *BCR* and *ABL1*, respectively. The workflow involved sample quantification, library prep, multiplexed sample pooling (10 sample/run), enrichment-probe hybridisation, template preparation, and sequencing. Subsequent mapping of t(9;22) translocation junctions was performed via a custom designed bioinformatics algorithm.

Results: All breakpoints were successfully mapped. DNA qPCR assays were designed and validated for 9 patients. In clinical samples from patients in complete molecular remission, the RT-qPCR assays detected residual disease in three out of nine patients, demonstrating that DNA-qPCR can detect residual disease in patient samples in which CML cells persist below the detection threshold of RT-qPCR. Furthermore, since assay performance criteria were optimal, we presume that disease levels in the remaining 6 were exceedingly low or completely absent, consistent with the notion that residual disease levels may differ in "CMR" patients.

Summary / Conclusion: NGS-facilitated DNA-qPCR may therefore prove valuable for the stratification of patients with low levels of residual disease and, therefore, in the identification of patients for whom TKI therapy could be safely reduced or stopped.

Background: Imatinib (IM) is the standard front line therapy for CP-CML resulting in complete cytogenetic response (CCyR) and major molecular response (MMR) for almost 2/3 of patients (pts). CCyR is associated with improved survival and MMR with progression free survival and stability of the response. Around 10% of these pts achieve a durable undetectable molecular response allowing them candidates for cessation of TKI's according to the STIM study: Sokal risk score, duration of IM, and sex were predictive for the maintenance of molecular response.Before the IM era and besides allogeneic hematopoietic stem cell transplantation, interferon alpha (IFNα) based regimens were used for CML treatment. Maintenance of CCyR and MMR after discontinuation of IFNα has also been reported for rare pts.
Aims: The aim of this study was to analyse the characteristics and molecular response pattern of CML pts after long term discontinuation of IFNα.
Methods: Between 2011 and 2012, 77 CP-CML pts treated with IFNα based regimens and in remission without therapy after IFN discontinuation were reported from 10 European centers. This analysis has been performed on the 60 consecutive cases with an assessable molecular follow-up.
Results: All pts had their CML diagnosed between 1980 and 2001. Median age was 45 years, 57% were female. Sokal risk score was low, intermediate and high for 43 (74%), 13 (22%) and 2 pts respectively. At IFNα discontinuation, all pts were in CCyR. Molecular response was assessed either by non quantitative polymerase chain reaction (PCR n=28) or quantitative PCR (RTQPCR n=28) depending on the technique locally available at that time. Among them, 18 pts had a negative PCR and 20 had an undetectable BCR-ABL transcript by RTQPCR. During follow-up, all pts maintained CCyR: 28 had a sustained undetectable residual disease (UND-MRD) confirmed by RTQPCR, while MRD was detectable in 28. In that latter group, MRD was between 0.1 and 0.001% for the majority of pts (n=25), fluctuation between 1 and 0.001% was observed in 2 cases, and transcript was stable between 1 and 0.1% for 1 pt. Therefore, we distinguished 2 groups: sustained UND-MRD (n=28) or detectable MRD (n=27). As the median follow-up after IFN discontinuation was 125 (41-227) and 119 (43-215) months respectively, comparison between the 2 groups was performed. No difference in term of age, gender, CML presentation, response to IFN was detected. MCyR was more rapidly achieved in the UND- than in the positive MRD group (6.67 versus 12.09 months, P=0.010) but not significantly CCyR (P=0.053) and not for MMR (P=0.913). Median IFN exposure was longer in the detectable MRD group (99 (7-180) vs 75 months (23-191) P=0.030) that suggests a slower response. At the last molecular assessment, 4 pts had lost MMR after a median time off-IFN of 129 months (85-205). All of them had a detectable MRD after IFN discontinuation. Two pts died from other reason than CML.
Summary / Conclusion: This study describes a cohort of CML pts who still maintained their CCyR without treatment after long term IFN discontinuation, whatever their distribution within two groups according to the molecular response pattern: sustained UND or detectable MRD.
Based on a long follow-up, this study illustrates also that "operational cure" of CML does not require the complete eradication of the residual disease.

P140

EFFICACY AND SAFETY OF RADOTINIB IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH FAILURE TO IMATINIB OR IMATINIB PLUS DASATINIB: 12-MONTH MINIMUM FOLLOW-UP UPDATE

Co., Ltd, Yongin, [14]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Radotinib is an orally active, selective Bcr-Abl1 tyrosine kinase inhibitor (TKI), approved for patients with chronic phase chronic myeloid leukemia (CP-CML) resistant to or intolerant of imatinib±dasatinib in Korea. The preliminary phase 2 result of radotinib has been reported to be one of treatment options in patients with TKI-failed CP-CML (Kim SH *et al*., Blood (ASH Annual Meeting Abstracts), Nov 2012; 120:695).
Aims: Here, we update the clinical efficacy and safety results in imatinib or imatinib+dasatinib failed patients with a minimum follow-up of 12 months.
Methods: Philadelphia chromosome - positive (Ph^+) CP-CML patients who failed or were intolerable to TKIs (imatinib or imatinib + dasatinib) were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400 mg twice daily. The primary end point was an achievement of major cytogenetic response (MCyR, Ph^+£35%) by 12 months. Safety parameters were also analyzed.
Results: A total of 77 CP CML patients (18 years of age or over) were enrolled from 12 sites in Korea, India, and Thailand. This analysis includes data from last enrolled patient who received at least 12 months of radotinib therapy. The median age of patients was 43 (range; 22-75) years, and 65 (84.4%) were imatinib-resistant including 3 patients who have dasatinib intolerance with imatinib resistance and intolerance and 12 (15.6%) were imatinib-intolerant including 1 patient who have dasatinib intolerance with imatinib intolerance. With a median follow-up of 23.4 months, treatment with radotinib is ongoing in 36 patients (46.7%) and 33 patients (42.9%) discontinued the treatment including two deaths (2.6%). Median duration of radotinib exposure was 378 (8-1050) days. Overall MCyR rate was 64.9%, including 36 patients (46.8%) complete cytogenetic response and 14 patients (18.2%) partial cytogenetic response. Among the 14 patients with known BCR-ABL1 KD abnormality at baseline, 43% achieved MCyR and 21% achieved CCyR. And MCyR and CCyR rates were higher in patients without mutation. The median time to MCyR was 2.8 months (85 days) and the median duration of MCyR was 20.2 months. Of patients achieving complete cytogenetic response, 30.5% (11/36) achieved major molecular response. Within follow-up durations, 55 patients (71.4%) required dose interruption and 53 patients (68.8%) had dose reduction. Most common grade 3/4 hematologic and laboratory adverse events (AEs) were thrombocytopenia (29.9%), neutropenia (10.4%), anemia (6.5%), and hyperbilirubinemia (33.7%). Common non-hematologic AEs (≥10%) were rash (23.4%), fatigue (16.9%), pruritus (14.3%), headache (13.0%), decreased appetite (10.4%) myalgia (10.4%) and nausea (10.4%). The majority of AEs were easily manageable with temporal dose interruption and/or reductions. In all patients with CP-CML treated with second-line radotinib, estimated progression-free survival and overall survival rate by 12months was 86.3% (95% CI, 75.1-92.7%) and 96.1% (95% CI, 88.4-98.7%), respectively. The PFS rate was higher among patients without a baseline mutation compared with those who had baseline mutations at both 12 months (90.3% vs 69.6%; P=0.0518) and 24 months (83.3% vs 60.9%; P=0.0364).
Summary / Conclusion: With a minimum follow-up of 12 months, radotinib continues to demonstrate efficacy and maintains tolerability in patients with both imatinib or imatinib+dasatinib failed CP-CML. Most of the AEs occurred in the early treatment period, were tolerable, and were easily controlled by dose interruption or reduction.

Table 1. Summary of patients' characteristics, efficacy and safety profile.

Total patients		N=77
Age		47 (24-76) years
Gender	male	54 (70.1%)
	female	23 (29.9%)
Disease status at screening	**Imatinib resistance**	**65 (84.4%)**
	+ dasatinib intolerance	3 (3.9%)
	Imatinib intolerance	**12 (15.6%)**
	+ dasatinib intolerance	1 (1.3%)
Cytogenetic response	Complete cytogenetic response	36 (46.7%)
	Partial cytogenetic response	14 (18.2%)
Dose modification	Dose interruption	55 (71.4%)
	Dose reduction	53 (68.8%)
Grade 3/4 hematologic adverse events	Thrombocytopenia	23 (29.9%)
	Neutropenia	8 (10.4%)
	Anemia	5 (6.5%)
The most common grade 3/4 laboratory adverse event	Hyperbilirubinemia	26 (33.7%)
Common non-hematologic adverse events (> 10%)	Rash	18 (23.4%)
	Fatigue	13 (16.9%)
	Pruritus	11 (14.3%)
	Headache	10 (13%)
	Decreased appetite	8 (10.4%)
	Myalgia	8 (10.4%)
	Nausea	8 (10.4%)

Background: Nilotinib is a potent and selective BCR-ABL inhibitor approved for the frontline treatment of CML. The latest update (4-year follow-up) of the ENESTnd study demonstrated sustained superiority of nilotinib vs. imatinib, with a confirmed significantly decreased risk of progression to accelerated-blast phase (AP/BP) and a higher rate of molecular responses, which were faster and deeper than those observed with imatinib (Kantarjian H *et al*, ASH 2012, abstract 1676). This extended the patient population achieving deeper responses that may potentially enter into Treatment Free Remissions (TFR) trials in the near future. It is important to understand, in patients (pts) treated for a long period with nilotinib, which characteristics are associated with a deep molecular response.

Aims: To evaluate the long-term (5-year minimum follow-up) results, and, in particular the stability of the deep molecular response ($MR^{4.0}$), of pts treated frontline with nilotinib in an investigator-initiated phase II study (GIMEMA CTs CML/0307).

Methods: The GIMEMA CML WP conducted a multicentre phase 2 trial with nilotinib 400mg BID as frontline therapy (ClinicalTrials.gov.NCT00481052). Median follow-up for the present analysis was 55 months (range: 50-62 months). Definitions: $MR^{3.0}$: detectable disease <0.1% BCR-ABL^{IS}; $MR^{4.0}$: either detectable disease ≤0.01% BCR-ABL^{IS} or undetectable disease in cDNA with >10,000 ABL transcripts; stable deep molecular response: $MR^{4.0}$ in at least 3 samples over ≥1 year period without any result with less than $MR^{4.0}$; failures: according to the 2009 ELN recommendations; events: failures and treatment discontinuation for any reason. All analyses have been conducted according to the intention-to-treat principle.

Results: 73 pts enrolled: median age 51 years; 45% low, 41% intermediate and 14% high Sokal risk. Two pts never achieved a $MR^{3.0}$, 1 of these pts progressed to AP/BP (see below), the other is in stable and confirmed CCyR at 48 months. Only 3 pts had a confirmed loss of $MR^{3.0}$ due to poor adherence (all 3 are still on nilotinib). The overall estimated probability of $MR^{4.0}$ was 82%, with a median time to $MR^{4.0}$ of 18 months. During the 3rd year of therapy, 56/73 (76%) pts obtained a $MR^{4.0}$ at least once, stable in 16/73 (22%) pts; fluctuations around $MR^{4.0}$ (always in $MR^{3.0}$) in 37/73 (51%) pts; fluctuations with unconfirmed loss of $MR^{3.0}$ in 3/73 (4%) pts. During the 4th year of therapy (months 37-48), 57/73 (78%) pts had a $MR^{4.0}$ at least once, stable in 21/73 (29%) pts; fluctuations around $MR^{4.0}$ (always in $MR^{3.0}$) in 33/73 (45%) pts; fluctuations with unconfirmed loss of $MR^{3.0}$ in 3/73 (4%) pts. Overall, 19/73 pts (26%) showed a stable $MR^{4.0}$ during the 3rd and 4th year of therapy. Final analysis of the 5th year of therapy is still ongoing and will be presented. Only one patient progressed at 6 months to AP/BP and subsequently died (high Sokal risk, T315I mutation). Overall, 11 pts (15%) permanently discontinued nilotinib: 1 progression to AP/BP; 1 unrelated-death; 7 adverse events; 2 refusal. The estimated probability of overall survival, progression-free survival and failure-free survival was 97% at 5 years; the estimated probability of event-free survival was 83% at 5 years.

Summary / Conclusion: After 5 years of follow-up, the great majority of pts are still on nilotinib, and a significant proportion have a stable deep molecular response ($MR^{4.0}$) and may potentially enter into Treatment Free Remissions (TFR) trials.

Background: With many treatment options for chronic myeloid leukaemia (CML) providing similarly fortunate survival probabilities, endpoints like health-related quality of life (HRQoL) move into focus. HRQoL might be essential for deciding on treatment strategies. Data on HRQoL in CML are rare (Efficace *et al*., 2011), especially for patients after HSCT.

Aims: We sought to evaluate HRQoL in German patients who had been registered in the prospective, randomized CML studies II to IV (Hehlmann *et al*., 2011, 2007 and 2003). Main interest was the comparison of HRQoL between different treatment strategies.

Methods: In December 2010, the EORTC QLQ 30 questionnaire (including global health status and five functioning scales) was sent out to 241 German CML study participants. With all scales ranging from 0 to 100, 8 points is regarded as a minimally important difference suggesting benefit or harm (Efficace *et al*., 2013). To investigate whether participation could be assumed to be "random", baseline data of responders (R) and non-responders (NR) were compared. Associations between two variables were assessed by the Fisher or Mann-Whitney tests, as appropriate. Level of significance was 0.05.

Results: *A* total of 1634 patients of CML studies I-IV could have received the questionnaire. During January to April 2011, 858 questionnaires (53%) were sent back. Fifteen study centres denied participation. Compared to NR, R were older (median age: 55 (NR) vs. 58 (R), P=0.0426); years since diagnosis (median 6.5 (R) vs. 7.4 (NR)) and the percentage that had been transplanted were lower (18% (R) vs. 24% (NR)). No statistically significant differences were observed regarding sex, Euro score (Hasford *et al*., 1998), or time since transplantation. With 517 patients, 60% (of 858) received 400mg imatinib mono-therapy when answering the questionnaire and 102 (12%) were off therapy after HSCT. Less than 10% received either higher-dose imatinib mono-therapy, imatinib 400 mg + AraC or interferon, nilotinib, or dasatinib. Time since diagnosis was ≤3 years in 156 (18%), > 3 and ≤ 7 years in 309 (36%), and >7 years in 393 (46%) of the patients. Women (352 of 858, 41%) perceived a statistically significant reduction in global health status (mean: 63, P<0.001), role (65, P=0.0016), emotional (60, P=0.0002), and physical functioning (75, P<0.0001) when compared to males (means: 69, 72, 68, and 83 respectively). Cognitive (mean: 77, all) or social functioning (69, all), age, time since diagnosis, and the percentage of transplantations were not significantly different between the sexes. Time since diagnosis was >7 years for 100 patients off therapy after HSCT and for 203 patients receiving imatinib 400 mg mono-therapy. In comparison, global health status (71 vs. 65, P=0.252) and physical functioning (84 vs. 75, P=0.0003) were higher in the off-therapy group. Additional adjusted analysis including age groups will be presented.

Summary / Conclusion: In this cross-sectional study, women showed an impaired global health status, role, emotional, and physical functioning compared to males. In the latter two cases, this perception met the definition of a clinically relevant difference. Long-term survivors of HSCT had an at least comparable overall global health status and a better physical functioning when compared to patients on imatinib treatment more than 7 years after diagnosis. However, the younger age of transplanted patients has also to be taken into account.

P143

WHICH METHOD BETTER EVALUATES MOLECULAR RESPONSE IN IMATINIB TREATED NEWLY DIAGNOSED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS, BCR-ABLIS OR LOG REDUCTION FROM THE BASELINE LEVEL?

Y Qin[1],* Q Jiang[1], H Jiang[1], J Li[1], L Li[1], H Zhu[1], Y Lai[1], X Lu[1], Y Liu[1], B Jiang[1], X Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology,

Beijing, China

Background: The molecular response of chronic myeloid leukemia (CML) patients by tyrosine kinase inhibitor treatment could be evaluated either by the BCR-ABL mRNA levels on the international scale (IS) or by the log reduction from the laboratory's individual baseline level. Conversion to the IS is achieved by the application of laboratory specific conversion factors which are acquired through sample exchange with reference laboratories. Because a three log reduction from the laboratory's individual baseline level usually does not equal to 0.1%^{IS} for non-reference laboratories, the patients' molecular response evaluated by these two methods might be different. To date, there is no comparison on these two evaluation methods.
Aims: We tried to investigate which method better evaluates molecular response in imatinib treated CML patients.
Methods: We compared the two evaluation methods in 248 consecutive imatinib treated newly diagnosed chronic phase CML patients. Bone marrow (BM) aspirations for morphology and cytogenetics were performed every 3 to 6 months until complete cytogenetic response (CCyR) was achieved, then every 6 to 12 months, and BCR-ABL mRNA levels were tested in the peripheral blood (PB) or BM samples every 3 to 6 months by real-time quantitative PCR. Only the BCR-ABL mRNA levels in PB were analyzed in the current study. All samples were collected with informed consent. Our laboratory acquired CF by sample exchange with international reference laboratory in Adelaide, Australia. Progression was defined as death for any reason and the development of accelerated-phase or blast-crisis CML as defined by the ELN.
Results: Achieving major molecular response (MMR) during treatment evaluated by them similarly predict progression free survival (PFS, all P<0.0001), whereas significantly more patients were defined as MMR by IS than by log reduction method (173/220 vs 137/220, 78.6% vs 62.2%, P<0.0001) and all MMR patients were alive without progression. Furthermore, the patients' molecular response at 3 and 6 months evaluated by them had similar predictive value on their cytogenetic response at 12 months and molecular response at 18 months: ≤10%^{IS}/ ≥1 log reduction of BCR-ABL at both 3 months (n=65) and 6 months (n=77) associated with CCyR at 12 months (all P<0.001); ≤1% ^{IS} /≥ 2 log reduction of BCR-ABL at both 3 months (n=66) and 6 months (n=77) associated with achieving MMR at 18 months (all P <= 0.003). Both ≤ 10% ^{IS} and ≥1 log reduction of BCR-ABL at 3 months (n=79) and ≤1% ^{IS} at 6 months (n=92) significantly associated with PFS (P=0.0011, 0.0090 and 0.0064), whereas ≥2 log reduction at 6 months (n=92) did not significantly associated with PFS (P=0.11) (Figure 1). Both ≤ 1% ^{IS} and ≥2 log reduction of BCR-ABL in PB significantly associated with CCyR in corresponding BM (all P<0.001). For BM samples with CCyR, there were significantly more corresponding PB samples with ≤1% ^{IS} than those with ≥2 log reduction of BCR-ABL (171/185 vs 134/185, 92.4% vs 72.4%, P<0.001). We further compared the molecular responses in our center to those of Germany CML Study IV on the premise of similar cytogenetic response: the proportions of patients with BCR-ABL^{IS} ≤1%, >1-10% and >10% in Germany trial were very similar to those with BCR-ABL^{IS}, but significantly different from those evaluated by log reduction method in our center.
Summary / Conclusion: The molecular response evaluated by BCR-ABL^{IS} has a similar trend in predicting PFS and response, but can better differentiate patients compared to that by log reduction method. Furthermore, the IS makes the molecular response results reported by the different laboratories comparable.

Background: The recent several reports to assess whether imatinib (IM) can be discontinued in chronic myeloid leukemia (CML) patients have shown that IM discontinuation can be employed based on clinical study in patients who had enough IM therapy and UMRD durations prior to IM discontinuation. However, further validation on precise indications for tyrosine kinase inhibitor (TKI) cessation is needed.
Aims: This study is performed to identify predictor of successful TKI discontinuation for CML patients achieving undetectable molecular residual disease (UMRD) for at least 1 year.
Methods: A total of 74 patients discontinued IM therapy, including 59 patients enrolled on the Korean Imatinib Discontinuation Study (KIDS) and 15 patients with TKI discontinuation due to patient's request (n=11), major surgery (n=2) and drug related adverse event (n=2) after achieving a UMRD. In this study, 23 patients with previous allogeneic stem cell transplantation were included. 71 patients received only IM; upon the intolerance of IM, 3 patients were given a new TKI (DAS = 1, NIL = 1, BOS = 1) before TKI discontinuation with achieving a UMRD for at least 1 year. For the patients enrolled on KIDS, molecular response was monitored using quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) assay every month up to 6 month follow-up, every 2 months up to 12 month follow-up, and every 3 months thereafter, whereas in real practice qRT-PCR was monitored normally every 3 months. The loss of MMR and UMRD were defined on 2 consecutive assessments, and if loss of MMR occurred, IM treatment was re-introduced.
Results: A total of 74 UMRD patients (including 34 men and 40 women) were analyzed. Their median age was 45 years (range, 19-74). The percentages of patients with low, intermediate and high Sokal risk scores were 38%, 31% and 18%, respectively with unknown Sokal risk scores in 14%. Prior to discontinuation, the median time to UMRD was 26.2 months (range, 0.5-104.6 months) and the median TKI duration was 86.5 months (range, 17.7-129.5 months) including 45.6 months (range, 13.6-105.7 months) of sustained UMRD.
After a median follow-up of 16.2 months since discontinuation of TKI, loss of MMR was observed in 12 non-transplant patients after a median time of 3.6 months (range, 1.9 - 7.6) of treatment discontinuation. Loss of UMRD was detected in 14 non-transplant patients. The 12-month probability of sustained MMR and UMRD were 80.3% and 76.6%, respectively. Probabilities for sustained MMR and UMRD were 62.8% and 68.6% in non-transplant group, respectively. 3 patients received with 2G TKI showed sustained MMR and UMRD. All 13 patients who lost MMR were re-treated with IM for a median of 12.1 months (range, 3.7 - 17.9 months). 11 of these patients re-achieved MMR at a median of 1.8 months (range, 0.9 - 2.8 months) after resuming IM therapy and 7 of these patients re-achieved UMRD at a median of 5.6 months (range, 2.8 - 12.1 months). Univariate analysis of factors affecting loss of MMR showed that TKI duration and UMRD duration before treatment discontinuation had a higher 12-month probability of sustained MMR.
Summary / Conclusion: Although probability of sustained molecular response is relatively lower than those of our previous KIDS, our data suggested TKI may be discontinued in CML patients with undetectable molecular residual disease for at least 1 year, with utilizing increasingly sensitive PCR technology. To make more concrete conclusion, further clinical investigation on a large patient population and much longer follow-up are needed.

P145

COMBINATION OF EUTOS SCORE AND 3-MONTHS BCR-ABL TRANSCRIPT LEVEL IDENTIFIES A DISTINCT SUBGROUP OF ECP-CML PATIENTS WITH HIGH RISK OF NON OPTIMAL RESPONSE AND IMATINIB DISCONTINUATION

G Binotto[1,*] M Tiribelli[2], M Bonifacio[3], E Maino[4], E Calistri[5], A Branca[1], F De Marchi[2], R Bertorelle[6], F Gherlinzoni[5], G Pizzolo[3], R Fanin[2], G Semenzato[1]
[1]Department of Medicine, Hematology and Clinical Immunology, University of Padova, Padova, [2]Division of Hematology and Bone Marrow Transplantation, Department of Experimental and Clinical Medical Sciences, AOU Udine, University of Udine, Udine, [3]Department of Medicine, Section of Hematology, University of Verona, Verona, [4]Hematology Unit, Dell'Angelo Hospital, Venezia-Mestre, [5]Hematology Unit, Ca' Foncello Hospital, Treviso, [6]Immunology and Molecular Oncology Unit, Istituto Oncologico Veneto, IRCCS, Padova, Italy

Background: Response to TKI is considered the strongest predictor of long-term outcome in CML patients. Effective treatment overcomes the negative impact of most prognostic factors, including Sokal and Hasford scores and recent data demonstrated that an early molecular response is strictly related to the outcome. In fact, missing the 10% BCR-ABL landmark at 3 months predicts inferior long-term survival. The 'EUTOS Score' combines baseline spleen size and peripheral blood basophils to foresee the achievement of complete cytogenetic remission (CCyR) and progression-free survival (PFS). Since its efficacy is still matter of debate, the predictive power of EUTOS in discriminating poor risk patients could be improved if associated with early molecular response assessment.
Aims: We tested whether a combination of EUTOS score and 3-months BCR-ABL transcript level identifies a poor prognosis population of CML patients.
Methods: 148 ECP CML patients treated with front-line standard dose imatinib (400 mg daily) at 5 major hematological centres in the north-eastern area of Italy were evaluated. Partial cytogenetic response (PCyR) and complete cytogenetic response (CCyR) were defined as 1–35% and 0% Ph+ metaphases, respectively; major molecular response (MMR) was defined as BCR-ABL <0.1%IS. For the purpose of the analysis patients were stratified into 3 subgroups according to EUTOS and 3-months molecular response ("good": low EUTOS score and ≤10%IS BCR-ABL transcript level; "intermediate": high EUTOS score or >10%IS BCR-ABL; "poor": high EUTOS score and >10%IS BCR-ABL). TTF was measured from the start of imatinib to the date of any of the following events: progression to accelerated or blastic phase, death for any cause at any time, primary or secondary hematologic or cytogenetic resistance leading to imatinib discontinuation. PFS was measured from the start of imatinib to the date of progression to accelerated or blastic phase or death for any cause at any time. Survival probabilities were estimated by the Kaplan-Meier method and compared by log rank test; differences among variables were evaluated by the Chi-squared test or by Cochran–Mantel–Haenszel test.

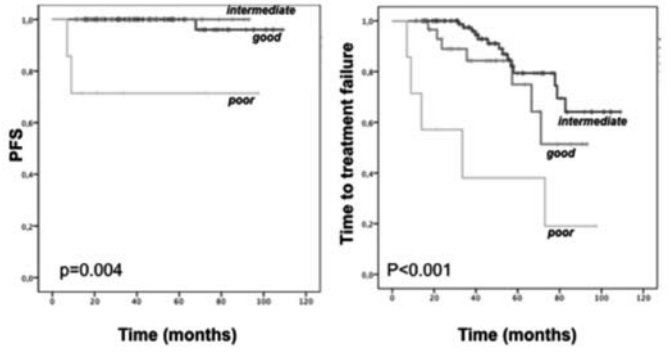

Figure 1. Progression-free survival and time to imatinib treatment failure according to aggregated EUTOS score-3 months molecular response patients stratification.

Results: The median age was 55 years (range 19–84), with 80 males and 68 females. The median follow-up was 42.7 months (range 11–109). The median time from diagnosis to imatinib therapy was 0.9 months (range 0-7.9). The distribution according to the EUTOS score was: 132 patients (89.2%) low risk; 16 patients (10.8%) high risk ; 3-months BCR-ABL transcript was ≤10% in 114 (79.2%) patients, >10% in 30 (20.8%). Patients with "good risk", "intermediate risk" and "poor risk" profile were 72.1%, 22.1% and 4.7%, respectively. The "optimal response" endpoints to imatinib were: 6 months PCyR: 91.7% vs 76.7% vs 42.9%; 12 months CCyR: 91.8% vs 65.4% vs 28.6%; 18 months MMR: 76.7% vs 27.3 vs 25% (differences among groups were significant except for intermediate vs poor profile). Imatinib discontinuation rate for failure was significantly different between poor risk group compared with intermediate and low risk (71.4% vs 21.2% and 13%; P=0.008, P<0.0001 respectively), as well as PFS and TTF (Figure 1). Remarkably, all progressions to blast crisis were observed in "poor risk" group.

Summary / Conclusion: Combination of High EUTOS score and 3-months BCR-ABL transcript level higher than 10% IS identifies a subpopulation of CML patients with significant probability of treatment failure and poorer outcome. Early switch to alternative treatment strategies (including allo-BMT) should be considered for these patients.

P146

EFFICACY OF NILOTINIB VERSUS HIGH-DOSE IMATINIB IN EARLY CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WHO HAVE SUBOPTIMAL MOLECULAR RESPONSES TO STANDARD-DOSE IMATINIB: MULTICENTER RE-NICE STUDY

S Choi[1,*] S Lee[2], S Kim[1], Y Oh[1], J Bang[1], J Park[1], H Jeon[1], R Woodman[3], T Szczudlo[3], S Jootar[4], H Kim[5], S Sohn[6], J Park[7], S Kim[8], D Zang[9], S Oh[10], D Kim[2]

Background: Achievement of major molecular response (MMR) is a significant prognostic factor in chronic myeloid leukemia (CML) as it has been shown to be associated with longer duration of complete cytogenetic response (CCyR) and long-term progression-free survival (PFS). In IRIS study, patients who achieved both CCyR and MMR showed a higher PFS, compared to those who had CCyR without MMR. Compared to standard dose of imatinib, higher doses of imatinib and second-generation tyrosine kinase inhibitor are expected to yield higher CCyR and MMR rates in patients with CP CML who are resistant to imatinib.
Aims: In this study, the efficacy of nilotinib and high-dose imatinib was investigated in suboptimal molecular response patients who received first line imatinib therapy at a daily dose of 400 mg.
Methods: Early CP CML patients who have achieved CCyR but no MMR after at least 18 months and up to 24 months on first line imatinib therapy at a daily dose of 400 mg were enrolled in this clinical trial, and informed consents were obtained prior to participation. In nilotinib arm, patients received 400 mg BID (800 mg/day), and patients received 400 mg BID (800 mg/day) in high-dose imatinib arm. To assess the drug efficacy, cytogenetic and quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) assays were performed at regular intervals, and baseline mutational analysis was conducted for every patient with subsequent mutational analyses to demonstrate either lack of response or disease progression. Primary endpoint is to evaluate the cumulative MMR rates by 12 months, and secondary endpoints are to evaluate the cumulative CMR rates and time to and duration of MMR and CMR during further 24 month follow-up. PFS and safety profiles will also be assessed.

Table 1. Characteristics of patients and autcomes.

Outcomes			
Cross-over during study†, N (%)	12/49 (24)	0/24 (0)	12/25 (48)
Cumulative incidence of MMR by 12 months*,%	-	43.7	32.7
MMR achievement by 12 months, N (%)	-	10/24 (42)	7/25 (28)
Overall MMR achievement‡, N (%)	-	17/24 (71)	8/25 (32)
Loss of MMR	0/49 (0)	0/24 (0)	0/25 (0)
Loss of CCyR	0/49 (0)	0/24 (0)	0/25 (0)
Progression to AP or BC	0/49 (0)	0/24 (0)	0/25 (0)
Death	0/49 (0)	0/24 (0)	0/25 (0)

‡ Overall 5 patients have achieve MMR.
* P=0.379
† Two patients cross-over before 12 months follow-up, ten patients cross-over after 12 months follow-up.

Results: With a data cut-off date of 01 Feb 2013, a total of 49 patients were randomized into nilotinib arm (n=24) or high-dose imatinib arm (n=25). With a median follow-up of 24 months (range, 1 - 50 months), all patients have maintained CCyR without progression to advanced disease, and decrease in BCR-ABL1 transcript level was observed. Cumulative MMR rates by 12 months were not significantly different between nilotinib arm compared to high-dose imatinib arm (43.7% vs. 32.7%, P=0.379). Four patients in nilotinib arm and two patients in high-dose imatinib arm achievedMR$^{4.0}$ by last follow-up. Twelve patients in high-dose imatinib arm crossed over to the nilotinib arm at a median of 14 months (range, 3-27 months) due to lack of response (n=10) and intolerance (n=2). Post-crossover, three patients have achieved MMR by 12 months at a median of 6 months (range, 3-12 months) and cumulative MMR rates was 27.8%. By last follow-up, five patients have achieved MMR at a median of 18 months (range, 3-33 months).
Overall, the patients treated with high-dose imatinib showed toxicities more frequently, such as leukopenia, thrombocytopenia, edema and decreased phosphate. Although toxicity was observed in both arms, all patients currently maintain the initial dose.
Summary / Conclusion: These preliminary results demonstrate that early switching to nilotinib or high-dose imatinib could be recommended in suboptimal molecular responders. When the tolerability of treatment was considered, switching to nilotinib may be preferred. Through further clinical investigation on a large patient population and longer period of observation, the efficacy of early intervention of suboptimal molecular response using nilotinib or dose escalation of imatinib will be assessed.

P147

OCT1 GENETIC VARIANTS ARE ASSOCIATED WITH LONG TERM OUTCOMES IN IMATINIB TREATED CML PATIENTS

M Koren-Michowitz[1,*] Z Bozaglo[2], M Schwarz [3], E Ribakovsky[1], I Pessach[1], N Amariglio[1], T Tohami[1], K Beider [1], P Le-Coutre [3], A Nagler[1]
[1]Sheba Medical Center, [2]Bar Ilan University, Ramat Gan, Israel, [3]Campus Virchow Klinikum Charité, Berlin, Germany

Background: Treatment with the tyrosine kinase inhibitor (TKI) imatinib has become the cornerstone of CML therapy and has markedly changed the outcome of this disease. While most patients in early chronic phase started on imatinib achieve major responses, longer follow up of the pivotal IRIS study has shown that only 63% of patients remaining on imatinib at 6 years were still in a CCyR.Currently, the only pre-treatment predictive features for treatment response are disease associated clinical scores including the Sokal and the recently introduced EUTOS scores. The human organic cation transporter 1 (OCT1) effectively mediates the active transport of imatinib into cells (influx pump), and its inhibition decreases the intracellular concentration of imatinib. Single nucleotide polymorphisms (SNP) in hOCT1 were previously reported to predict response and resistance to imatinib therapy.
Aims: To study whether hOCT1 genetic variants are associated with long term outcomes in CML.
Methods: We studied 4 non-synonymous genetic variants in hOCT1, rs683369, rs628031, rs12208357 and rs41267797 using the Sequenom MassARRAY platform (Sequenom, San Diego, CA, USA) in 167 CML patients. Frequency of the genetic variants was associated with clinical outcomes.
Results: Median age at CML diagnosis was 55 years (18-80), F/M 55/112, and most patients were diagnosed (76%) and treated (70%) with imatinib in CP. Overall, 93%, 74%and 56% of evaluable patients achieved CHR, CCyR and MMoR, respectively, during treatment with imatinib. Frequency of the different alleles in the study population was consistent with reported frequency in Caucasians according to the NCBI dbSNP database. There was no difference between the response rates when comparing between the different allele variants for each of the SNP studied. Sixty-six patients were studied for the presence of kinase domain mutation (KD) due to imatinib suboptimal response or failure, resulting in the discovery of KD mutations in 15 (23%). Patients with rs628031 AA/GA genotypes had a higher frequency of KD mutations compared to the GG genotype (8/16 vs. 5/27, P=0.04). With a median follow up of 80 months, the median EFS was 109 months and median OS was not reached for the entire cohort. Median EFS in CP was shorter in patients with the rare genetic variants (comparing heterozygous + homozygous minor allele frequency with homozygous major allele frequency) for all studied SNPs, with statistical significance for rs628031 genotype AA/AG compared with the GG genotype (EFS 61 months and not reached, respectively, P=0.03) and borderline significance for rs12208357 genotype CT compared with CC (EFS 58 and not reached, respectively, P=0.09). In multivariate analysis rs628031 genotype remained an independent predictor for EFS with a hazard ratio of 1.9, 95% CI 1-3.8, P=0.006. There was a trend for lower OS for patients with the AA/AG rs628031 genotypes compared with GG genotype (P=0.09).
Summary / Conclusion: hOCT1 rs628031 AA and AG genotypes are associated with worse long term outcomes in CP CML. Consideration should be given to incorporation of genotypic variables into pretreatment risk stratification of CP CML patients. With availability of several TKIs for first line therapy in CML, this data could potentially assist in the decision to choose one TKI over the other in the specific patient.

P148

ASSESSMENT OF EARLY CYTOGENETIC RESPONSE AS A PREDICTOR OF LONG-TERM CLINICAL OUTCOMES IN A PHASE 1/2 STUDY OF BOSUTINIB IN CHRONIC PHASE (CP) CHRONIC MYELOID LEUKEMIA (CML)

J Cortes[1,*] C Gambacorti-Passerini[2], H Kantarjian[1], H. Khoury[3], A Hochhaus[4], M Baccarani[5], J Lipton[6], J Apperley[7], S O'Brien[8], E Leip[9], M Shapiro[9], T Brümmendorf[10,11]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]University of Milano-Bicocca, Monza, Italy, [3]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [4]Universitätsklinikum Jena, Jena, Germany, [5]University of Bologna, Bologna, Italy, [6]Princess Margaret Hospital, Toronto, ON, Canada, [7]Hammersmith Hospital, London, [8]University of Newcastle, Newcastle Upon Tyne, United Kingdom, [9]Pfizer, Cambridge, MA, United States, [10]Universitätsklinikum Hamburg-Eppendorf, Hamburg, [11]Universitätsklinikum Aachen, RWTH Aachen, Germany

Background: Bosutinib (BOS) is an oral, dual Src/Abl tyrosine kinase inhibitor approved for the treatment of Ph+ CML following resistance/intolerance to prior therapy.
Aims: This retrospective landmark analysis investigated early response to BOS as a predictor of long-term outcomes in CP CML patients (pts) receiving BOS as second-line (CP 2L; after imatinib [IM] only) or third/fourth-line (CP 3L; after IM + dasatinib [DAS] and/or nilotinib [NIL]) therapy.
Methods: In this phase 1/2, open-label trial, pts aged ≥18 y with CP CML received oral BOS starting at 500 mg/d. Pts evaluable for cytogenetic response (CyR) had received ≥1 BOS dose and had a valid baseline assessment. Pts evaluable for molecular response (MR) had received ≥1 BOS dose; pts in China, India, Russia, and South Africa were not evaluable due to logistical constraints. MR was not evaluated using the International Scale. *P* values for association of response with cumulative incidence distribution of progression or death (P/D; including lack of efficacy) were based on Gray's test; *P* values for association of response with overall survival (OS) distribution were based on log-rank test. P values >0.05 were considered not statistically significant.

Table 1.

	Cumulative progression/death			Overall survival		
Response	n evaluable	Probability at 24 mo (95% CI)	*P* value	n evaluable	Probability at 24 mo (95% CI)	*P* value
CP 2L; by 3 mo						
MCyR	95	12% (7-21)	0.002	96	98% (92->99)	0.005
No MCyR	157	25% (19-33)		186	88% (82-92)	
CP 2L; by 6 mo						
MCyR	119	14% (9-21)	<0.001	126	97% (92-99)	0.011
No MCyR	101	27% (20-37)		151	88% (82-93)	
CP 2L; by 9 mo						
MCyR	129	13% (9-21)	<0.001	141	96% (92-99)	0.009
No MCyR	80	28% (19-39)		134	89% (82-93)	
CP 3L; by 3 mo						
MCyR	28	21% (11-44)	0.049	28	88% (68-96)	0.232
No MCyR	67	39% (29-53)		87	86% (76-92)	
CP 3L; by 6 mo						
MCyR	36	19% (10-38)	0.018	40	92% (77-97)	0.027
No MCyR	38	42% (29-62)		72	84% (73-91)	
CP 3L; by 9 mo						
MCyR	34	15% (7-33)	0.026	40	95% (80-99)	0.022
No MCyR	28	36% (22-59)		68	88% (77-94)	

Results: A total of 288 CP 2L pts and 119 CP 3L pts were enrolled. Median BOS duration was 22.1 mo (range 0.2-60.8) for CP 2L pts and 8.6 mo (range 0.2-60.8) for CP 3L pts. Time from the last enrolled pt's first dose to the data cutoff was 24 mo; median follow-up duration was 31.8 mo (range 0.6-66.0) for CP 2L pts and 31.4 mo (range 0.3-66.0) for CP 3L pts. Among 266 evaluable CP 2L pts, a major CyR (MCyR) was newly attained or maintained from baseline by 157 (59%) pts, including 128 (48%) pts with a complete CyR (CCyR). A MCyR was attained/maintained by 45/110 evaluable CP 3L pts, including 35 (32%) pts with a CCyR. The Kaplan-Meier probability of maintaining a MCyR at 2 y was 77% (95% CI 69-83) for CP 2L pts and 71% (54-83) for CP 3L pts. A major MR (MMR) was achieved by 69/200 (35%) evaluable CP 2L pts and 17/106 (16%) evaluable CP 3L pts. In CP 2L pts, attaining/maintaining a MCyR by Month3, 6, 9, and 12 on BOS versus no MCyR was significantly associated with a lower cumulative incidence of on-treatment P/D and longer OS (*Table*; Month 12 not shown). Similar results were observed when the analysis evaluated patients attaining/maintaining a CCyR versus partial cytogenetic response versus no MCyR separately. In CP 3L pts, a borderline significant association between attaining/maintaining a MCyR versus no MCyR by Month 3 was found for on-treatment P/D, but not OS; however, both analyses achieved significance at later response time points (Table 1). Achievement of a MMR by Month 3 versus no MMR was not predictive of on-treatment P/D in CP 2L and CP 3L pts, although a numerically lower cumulative incidence was observed (CP 2L, 5% [95% CI 1-34] vs 20% [15-28]; CP 3L, 11% [2-71] vs 35% [26-48]). There was also no significant association between response by Month 3 and OS in the CP 2L (100% [not estimable to 100] vs 90% [84-93]) and CP 3L cohorts

(75% [32-93] vs 88% [79-93]).
Summary / Conclusion: Early attainment or maintenance of a MCyR by CP 2L pts was associated with a decreased likelihood of on-treatment P/D and better OS. Among CP 3L pts, association with long-term outcomes was borderline for MCyR by Month3, but significant for MCyR by Months6, 9, and 12. Achievement of MMR by Month 3 was not predictive of long-term outcomes in either cohort, perhaps due to the fewer number of pts with MMR, thus increasing variability in the long-term estimates.

P149

DISCONTINUATION OF IMATINIB (IM) IN PEDIATRIC CHRONIC MYELOID LEUKEMIA (CML) PATIENTS WITH SUSTAINED COMPLETE MOLECULAR REMISSION (CMR)

F Giona[1,*] A De Vellis[1], M Moleti[1], E Gottardi[2], M Rea[1], M Nanni[1], A Testi[1], D Diverio[1], G Saglio[2], R Foà[1]
[1]Department of Cellular Biotechologies and Hematology, Sapienza University of Rome, Rome , [2]Department of Clinical and Biological Science, University of Turin at Orbassano, Turin, Italy

Background: Results from the Stop IMatinib (STIM) trial suggest that IM may be discontinued in adult CML patients with long-lasting CMR.
Aims: The aim of this study was to assess the possibility of IM discontinuation in pediatric CML patients with sustained CMR.
Methods: From March 2001, 14 pediatric CML patients in chronic phase (CP) (7 M and 7 F), with a median age at diagnosis of 11 years (range: $5^{11/12}$–$17^{10/12}$) were treated with IM at a dosage of 340 mg/m^2/day, according to the local guidelines for children and adolescents with CML. Three patients had an available HLA identical sibling and 6 had previously received alpha-Interferon. Cytogenetic analysis was performed on bone marrow (BM) before and during IM therapy, at planned intervals, while FISH was carried out at complete cytogenetic response (CCyR); quantitative RT-PCR was assessed on peripheral blood (PB) monthly and on BM every 3 months, according to the European LeukemiaNet recommendations for minimal residual disease quantification. Major molecular response (MMR) is defined as ≤0.1% BCR-ABL IS, while CMR is considered as ≤0.01% BCR-ABL IS. Minimum follow-up is 18 months.
Results: The dosage of IM was modulated according to hematologic toxicity and/or appearance of WHO≥2 side-effects, mostly during the first 6 months of treatment (median administered dose: 250 mg/m^2/day). Two patients (14%) stopped IM after 32 days and 2 months, respectively, because of severe extrahematological toxicity. A CCyR was achieved in all 12 evaluable patients after a median time of 6 months (range 3-12 months). As shown in Figure 1, 10/11 evaluable patients (91%) achieved a molecular response (CMR or MMR), including two with a HLA identical sibling, both on PB and BM. Seven out of 11(64%) evaluable patients obtained a CMR both on PB and on BM after a median time of 14 months (range: 8-41) and 15 months (range: 12-44), respectively. Since December 2007, with the aim of reducing the risk of bone alterations and longitudinal growth impairment[1], 6 patients with sustained CMR (≤0.0032% BCR-ABL IS) and 1 adolescent with MMR long-lasting >12 months received IM at a same daily dosage for 3 weeks a month (intermittent IM). After 96, 95 and 93 months of treatment, IM was discontinued in 3 patients (including one with a HLA identical sibling) in CMR (≤0.0032% BCR-ABL IS) for 81, 73 and 72 months, respectively. After IM discontinuation, all patients continued to be monitored by quantitative RT-PCR on PB monthly and on BM every 6 months. As of February 2013, all of them continue to be in CMR (≤0.0032% BCR-ABL IS) without any treatment after 25, 25 and 46 months from IM discontinuation, respectively.
Summary / Conclusion: These results suggest that IM can be safely discontinued in pediatric CML patients with a CMR (≤0.0032% BCR-ABL IS) lasting more than 6 years. International cooperative studies on a lager cohort of pediatric patients are necessary to confirm these promising results which raise the possibility that children with CML might be cured with tyrosine kinase inhibitors alone.

MECHANISM OF IMPAIRED GLUCOSE METABOLISM DURING NILOTINIB THERAPY IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA

Z Racil[1,2,*] F Rázga[1], J Drapalova[3], L Buresova[4], D Zackova[1], M Palackova[1], L Semerad[1], L Malaskova[5], M Haluzik[3], J Mayer[1,2]
[1]Department of Internal Medicine, Hematology and Oncology , Masaryk University and University Hospital Brno, [2]CEITEC - Central European Institute of Technology, Masaryk University Brno, Brno, [3]3rd Department of Medicine, 1st Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, [4]Institute of Biostatistics and Analyses, Masaryk University Brno, [5]Department of Clinical Biochemistry, University Hospital Brno, Brno, Czech Republic

Background: Hyperglycemia represents frequent adverse event reported in chronic myelogenous leukemia (CML) patients treated with nilotinib.
Aims: To determine the major mechanism of glucose metabolism impairment, we performed a metabolic analysis using an oral glucose tolerance test as well as assessment of incretins and adipokines at baseline and after 3 months of nilotinib treatment in patients with CML.
Results: 10 patients were included in our study. 40% received nilotinib as first line, and 60% as second or subsequent line. 50% of patients received 600 mg and 50% received 800 mg of nilotinib/day. The median nilotinib C_{trough} was 1510 (411-2973) ng/ml, median BMI was 27.2 (23.4-32.7) kg/m^2, and median waist circumference was 93.5 (77.0-108.0) cm. Fasting, 1-, and 2-hour plasma glucose concentrations obtained during the OGTT significantly increased after 3 months of nilotinib therapy (Table). 2 patients fulfilled criteria of DM and 2 displayed IGT based on the OGTT. Nilotinib administration significantly increased fasting insulinaemia (Table 1).

Table 1.

	Start median (range)	Month 3 median (range)	p
Fasting glucose [mmol/l]	5.25 (4.8 - 6.1)	5.8 (5.2 - 12.7)	**0.009**
Fasting insulin [µIU/ml]	16.6 (10.8 - 69.0)	27.8 (17.2 - 61.9)	**0.049**
Fasting C-peptide [pmol/ml]	0.87 (0.54 - 2.40)	0.94 (0.55 - 2.21)	0.275
Fasting HbA1c [%]	3.80 (3.4 - 4.2)	3.9 (3.2 - 4.7)	0.725
Incretins			
Fasting GLP-1[pM]	5.4 (4.7 - 6.5)	5.3 (4.6 - 6.4)	0.106
2-hour stimulated GLP-1 [pM]	6.3 (4.7 - 10.5)	6.4 (4.5 - 10.5)	0.160
Fasting GIP [pg/ml]	49.5 (22.9 - 120.5)	58.5 (14.6 - 104.2	0.922
2-hour stimulated GIP [pg/ml]	236.3 (47.2 - 332.2)	150.2 (73.8 - 270.8)	0.232
Adipokines			
Fasting FABP [ng/ml]	15.7 (5.3 - 37.5)	17.3 (5.6 - 55.3)	0.241
Fasting adiponectin [mg/l]	13.8 (0.7 - 45.1)	7.8 (1.0 - 22.3)	**0.027**
Serum lipids			
Total cholesterol [mmol/l]	4.75 (3.5-6.6)	5.35 (4.5-7.0)	**0.013**
Triglycerides [mmol/l]	1.03 (0.58-2.8)	1.29 (0.6-3.0)	0.432
HDL cholesterol [mmol/l]	1.50 (0.7-2.2)	1.45 (0.8-2.3)	0.152
LDL cholesterol [mmol/l]	2.55 (1.6-4.4)	2.80 (2.3-4.8)	**0.020**
Non-HDL cholesterol [mmol/l]	2.90 (1.9-5.3)	3.45 (2.6-6.0)	**0.011**

Moreover, there was also a trend of higher postprandial insulinaemia obtained during OGTT at the 3rd month of treatment (Table 1). C-peptide concentrations (fasting and during OGTT) and fasting HbA1C did not significantly change (Table 1). Insulin resistance as calculated by HOMA2-IR, significantly increased during nilotinib therapy (P=0.008). Moreover, the derived insulin sensitivity index HOMA2
Summary / Conclusion: We proved that rapid insulin resistance, compensatory hyperinsulinaemia, and hypoadiponectinaemia develop after initiation of nilotinib therapy, which clarifies not only the mechanism of impaired glucose metabolism, but also at least partially explains the fast development of dyslipidaemia and peripheral artery occlusion in nilotinib-treated CML patients.

EVALUATION OF CROSS-INTOLERANCE BETWEEN BOSUTINIB AND PRIOR TYROSINE KINASE INHIBITOR THERAPY IN PATIENTS WITH PHILADELPHIA CHROMOSOME–POSITIVE (PH+) LEUKEMIA

J Cortes[1,*] J Lipton[2], H Kantarjian[1], H Khoury[3], A Hochhaus[4], M Baccarani[5], S Durrant[6], S Assouline[7], D Kim[8], T Brümmendorf[9,10], E Leip[11], N Besson[12], K Turnbull[11], M Shapiro[11], C Gambacorti-Passerini[13]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]Princess Margaret Hospital, Toronto, ON, Canada, [3]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [4]Universitätsklinikum Jena, Jena, Germany, [5]University of Bologna, Bologna, Italy, [6]Royal Brisbane Hospital, Herston, Australia, [7]McGill University, Montreal, QC, Canada, [8]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, [9]Universitätsklinikum Aachen, RWTH Aachen, [10]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [11]Pfizer, Cambridge, MA, United States, [12]Pfizer Global Research and Development, Paris, France, [13]University of Milano-Bicocca, Monza, Italy

Background: Bosutinib (BOS) is an orally active, dual Src and Abl tyrosine kinase inhibitor (TKI) approved in the United States for treatment of Ph+ chronic myeloid leukemia (CML) following resistance or intolerance to prior therapy. Prior reports indicated the BOS toxicity profile is primarily characterized by hematologic adverse events (AEs), gastrointestinal AEs, and rash.
Aims: To evaluate the potential for cross-intolerance between BOS and prior TKI therapy.
Methods: In this phase 1/2 study, BOS was evaluated at a starting dose of 500 mg/day in patients (pts) with chronic phase (CP) CML or advanced leukemia (ADV; accelerated/blast phase CML or Ph+ acute lymphoblastic leukemia) after imatinib (IM) only or after IM plus dasatinib (DAS) and/or nilotinib (NIL). Pts were evaluated for cross-intolerance (AEs leading to permanent treatment discontinuation of both BOS and prior TKI therapy) and subsequent occurrence of

these AEs on BOS.
Results: Median (range) duration of BOS treatment was 24.6 (0.2-72.3) mo for 286 2nd-line CP CML pts (prior IM only), 8.6 (0.2-60.8) mo for 119 3rd/4th-line CP CML pts, and 4.0 (0.03-63.8) mo for 165 2nd- to 4th-line ADV pts. The *Table* lists individual AEs leading to discontinuation from prior TKI therapy in ≥5 pts, along with subsequent occurrence of these AEs on BOS (gr 3/4 AE or leading to BOS discontinuation). Intolerance to prior IM was reported for 122 CP CML and 50 ADV 2nd- to 4th-line pts. The most common AEs associated with IM intolerance were cytopenias; 29/57 (51%) CP CML pts and 4/9 (44%) ADV pts with IM intolerance due to cytopenias experienced the same grade 3/4 event on BOS, while cross-intolerance due to cytopenias occurred in 12/57 (21%) CP CML pts and 2/9 (22%) ADV pts. Total numbers are lower for non-hematologic AEs commonly associated with IM intolerance (*Table*). Although diarrhea is the most frequently reported AE on BOS, only 4/10 (40%) CP CML pts and 2/4 (50%) ADV pts with IM intolerance due to diarrhea subsequently experienced grade 3/4 diarrhea on BOS, and 2/10 (20%) CP CML pts and 0/4 ADV pts experienced true cross-intolerance due to diarrhea. Intolerance to prior DAS (after IM) was reported for 21 CP CML and 21 ADV 3rd/4th-line pts. The most common AEs associated with DAS intolerance were pleural effusion (n=19 CP CML, n=6 ADV) and thrombocytopenia (n=8 CP CML, n=5 ADV). In pts with DAS intolerance due to thrombocytopenia, grade 3/4 thrombocytopenia was experienced by all pts on BOS; however, cross-intolerance was observed in 4/8 (50%) CP CML pts and 1/5 (20%) ADV pts. Pleural effusion occurred on BOS; however, there was no cross-intolerance (Table 1). Neither of the 2 pts with DAS intolerance due to diarrhea (both CP CML pts) experienced cross-intolerance. An additional 2 CP CML and 5 ADV 3rd/4th-line pts had intolerance to prior NIL (after IM), including intolerance due to rash (n=3), thrombocytopenia (n=2), neutropenia (n=1), and headache and pleural effusion (n=1); however, none of these patients experienced cross-intolerance and discontinued BOS due to the same AE. No deaths due to the AEs leading to prior TKI discontinuation were reported on BOS in pts with cross-intolerance.
Summary / Conclusion: Hematologic cross-intolerance between BOS and recent IM or DAS therapy was relatively low among both CP CML and ADV pts, although many pts experienced the same grade 3/4 cytopenia on BOS. Cross-intolerance due to nonhematologic AEs, including diarrhea, was rare. These results suggest that most pts intolerant to prior TKI therapy will tolerate long-term therapy with BOS.

Table 1.

Reason for intolerance	n	Experienced same grade 3/4 AE on BOS	Discontinued BOS due to same AE
CP CML – IM intolerance	122	39 (32%)	20 (16%)
Thrombocytopenia	29	19 (66%)	7 (24%)
Neutropenia	19	6 (32%)	3 (16%)
Rash	18	2 (11%)	1 (6%)
Anemia	14	3 (21%)	0
Edema	12	0	0
Diarrhea	10	4 (40%)	2 (20%)
Bone marrow failure	7	5 (71%)	4 (57%)
Fatigue	7	0	1 (14%)
Myalgia	5	1 (20%)	0
Vomiting	5	1 (20%)	1 (20%)
CP CML – DAS intolerance	50	16 (32%)	7 (14%)
Pleural effusion	19	3 (16%)	0
Thrombocytopenia	8	8 (100%)	4 (50%)
Pancytopenia	5	0	0
ADV – IM intolerance	21	6 (29%)	2 (10%)
Thrombocytopenia	5	4 (80%)	2 (40%)
ADV – DAS intolerance	21	10 (48%)	1 (5%)
Pleural effusion	6	2 (33%)	0
Thrombocytopenia	5	5 (100%)	1 (20%)

Hodgkin Lymphoma

P152

FLOW CYTOMETRY EARLY DETECTION OF CD4+CD26-CD38+ LYMPHOCYTES SUBSET IN LYMPH NODES OF HODGKIN LYMPHOMA

Rosa Di Gaetano[1,*] Valentina Gasparetto[1], Andrea Padoan[2], Laura Candiotto[1], Barbara Callegari[1], Giuseppe Tagariello[1]
[1]Haematology, Castelfranco Veneto Hospital, Castelfranco Veneto, [2]Medicine, University oif Padua, Padua, Italy

Background: Hodgkin lymphoma is classically histological diagnosed by a minority of neoplastic cells, the Hodgkin and Reed-Sternberg cells, within a typical inflammatory microenvironment. It is now recognized as the majority of these T CD4 cells are T regulatory and they play an important role in the suppressing effectors and contribute to tumor persistence.
Aims: During this 12-year period our first purpose was to analyze the non-clonal lymphoid, inflammatory and infiltrating cells in HL (108) and to assess the expression of CD26 on the T CD4 total population with other markers of activation such as CD38 with the scope to identify the $CD4^{+}CD26^{dim/neg}CD38^{+}$ subset specific of HL.
Methods: We performed lymphocyte immunophenotyping by flow cytometry from lymph node samples suspected of lymphoma during a 12-year period (2000-2012), to early identify Hodgkin-specific subset and potential biomarkers related to T regulatory cells. We measured CD3, CD19 and the T CD4+CD26-CD38+ subset in lymphocytic infiltrate of 108 lymph nodes, concurrently histological diagnosed as Hodgkin lymphomas and in 43 benign reactive lymphoid hyperplasia. The same subsets were analysed into the peripheral blood of a proportion of both groups and in 20 healthy blood donors as controls.
Results: Compared to benign reactive lymphoid hyperplasia, Hodgkin lymphoma shows statistically significant differences between the two reactive micro environmental populations: decreased CD19+ cells (39% vs 23%; P<0.001), increased CD3+ (58%; vs 74%; P<0.001) and CD4+CD26-CD38+ cells (11,5% vs 38%; P<0.001). Using the co expression markers CD38 and CD26 for ROC curve analysis (area = 0,8639), results confirm that CD4+CD26-CD38+ subset is strongly expresses in HL.
Summary / Conclusion: Although flow cytometry analysis is not routinely applied in lymphomas our findings suggest it may be useful in the characterization of the cellular para-neoplastic inflammatory background of Hodgkin lymphoma. Detection of CD4+CD26-CD38+ cells by flow cytometry seems able to identify in a quick and easy way, different cellular patterns to distinguish Hodgkin lymphoma from benign reactive lymph nodes as well as to explore the activity of T regulatory cells.

P153

FIRST-LINE TREATMENT OF ADVANCED STAGE HODGKIN LYMPHOMA – FINAL RESULTS OF A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

M Rancea[1,*] N Skoetz[2], S Trelle[3], H Haverkamp[4], A Engert[5], P Borchmann[6]
[1]Department I of Internal Medicine, University Hospital of Cologne, Cochrane Haematological Malignancies Group, [2]Cochrane Haematological Malignancies Group, Department I of Internal Medicine, Univeristy Hospital of Cologne, Cologne, Germany, [3]CTU, Institute of Social and Preventive Medicine, Bern, Switzerland, [4]German Hodgkin Study Group, [5]Department I of Internal Medicine, University Hospital of Cologne, [6]German Hodgkin Study Group, Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Hodgkin lymphoma (HL) in advanced stages can nowadays be cured with different combined-modality approaches, but the debate whether $BEACOPP_{escalated}$ (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, prednisone) or ABVD (doxorubicin, bleomycin, vincristine, dacarbazine) is superior is still ongoing. ABVD results in a lower progression-free survival, but might be better tolerable than $BEACOPP_{escalated}$. With regard to the most important patient-related outcome overall survival (OS) no high-level evidence supporting one or the other strategy has been generated up to date.
Aims: To assess the efficacy (OS, freedom from treatment failure, FFTF) and safety (secondary neoplasia) of different first-line treatment strategies over standard ABVD and to provide a hierarchy of the regimens for patients with advanced stage HL.
Methods: We developed sensitive search strategies for CENTRAL, MEDLINE, and conference proceedings from 01.1980 to 09.2012, additionally, we obtained missing data from investigators. Two authors independently screened search results, extracted data, and assessed quality of trials. We pooled data using network meta-analysis and combined direct with indirect comparisons with Bayesian random-effects models. Results were reported relative to ABVD, indicating superiority of ABVD if hazard ratio (HR) > 1.
Results: The search resulted in2,229 relevant references, of which 74 publi-

cations with 14 randomised controlled trials evaluating eleven different regimens were included. Overall, we judged the methodological quality of trials as high. Six cycles $BEACOPP_{escalated}$ (HR = 0.38, 95% credible intervals (CrI) 0.20 to 0.75) and eight cycles BEACOPP-14 (HR = 0.43, 95% CrI 0.22 to 0.86) were associated with the lowest risk of mortality and showed a 98% probability to be the best treatment regimens for patients with advanced HL (see forest plot of overall survival). Additional standard meta-regression estimated an 89% five-year survival rate for ABVD, resulting in a five-year survival benefit of 7% for both regimens: six cycles $BEACOPP_{escalated}$ (95% CrI 3% to 10%) and eight cycles BEACOPP-14 (95% CrI 2% to 9%) as compared to ABVD. These results were confirmed by the reconstructed digitised individual patient analysis, that included 10,042 patients and 1,189 deaths over 47,033 patient-years of follow-up. OS was increased by 10% (95% CI 3% to 15%) at five years with six cycles $BEACOPP_{escalated}$ compared to ABVD.

Freedom from treatment failure showed similar results: six cycles $BEACOPP_{escalated}$ have a 66% probability to be the best treatment regimen (HR = 0.37, 95% confidence interval (CI) 0.12 to 1.08) and eight cycles BEACOPP-14 have a probability of 15% to be the best (HR = 0.51, 95%CI 0.16 to 1.48). Overall, the assessment of between-trial heterogeneity was low: τ^2=0.01 for OS and τ^2=0.05 for FFTF.

Data for secondary malignancies was provided by twelve trials with 50,736 patient-years of follow-up. A total amount of 327 secondary malignancies and 109 leukaemias occurred. The low number of included trials led to wide overlapping credible intervals which additionally included the null effect. The low number of events made quantification of the risks associated with each regimen impossible.

Summary / Conclusion: This network analysis of different first-line treatment strategies for patients with advanced stage HL has shown a relevant benefit for FFTF and OS with six cycles $BEACOPP_{esclated}$ and eight cycles BEACOPP-14 as compared to standard ABVD. The OS difference to ABVD is not only highly significant but also relevant for patients with advanced stage HL.

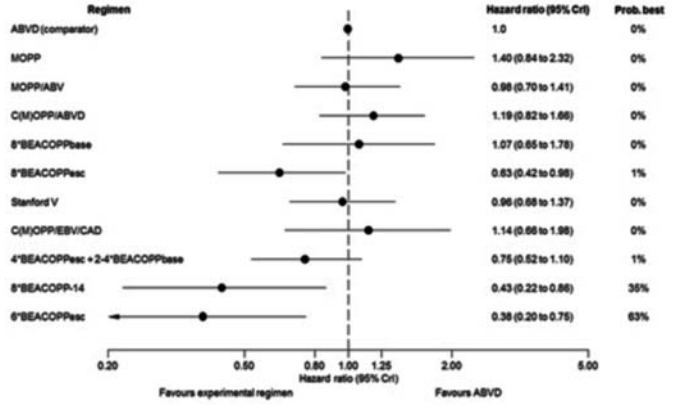

Figure 1.

P154

UNMANIPULATED HAPLOIDENTICAL BONE MARROW TRANSPLANTATION FOLLOWING NON MYELOABLATIVE CONDITIONING AND POST-TRANSPLANTAT CYCLOPHOSPHAMIDE FOR ADVANCED HODGKIN'S LYMPHOMA

A Bacigalupo[1], L Castagna[2],* A Raiola[1], A Ghiso[1]
[1]Hematology, IRCCS San Martinoi-IST, Genova, [2]Hematology, IRCCS Humanitas, Milano, Italy

Background: Patients with Hodgkins Disease (HD) not responding to or relapsing soon after first line therapy, are at high risk of failure: typically these patients receive multiple lines of therapy , including an autograft, and are then considered for an allogeneic transplant. The Baltimore group has described encouraging results in advanced HD patients, using haplo-identical family donors (HAPLO) and high dose post-transplant cyclophosphamide (PT-CY) fro graft versus host disease (GvHD) prophylaxis.

Aims: We have reported 2 years ago our initial experience in advanced HD patients grafted from HAPLO donors: the aim of this study is to update that initial experience with a longer follow up .

Methods: Twentysix patients with advanced HD, received a unmanipulated bone marrow transplant (BMT) from a HAPLO family donor, following a non myeloablative conditioning , including fludarabine, low dose cyclophosphamide and 2 Gy total body irradiation. All patients received PT-CY, mycophenolate and a calcineurin inhibitor for GvHD prophylaxis. All patients had received a previous autograft, and 65% had active disease at the time of BMT.

Results: Sustained engraftment of donor cells occurred in 25 patients (96%), with a median time to neutrophil recovery (>0.5x10^9/L) and platelet recovery (> 20x10^9/L) of +18 and +23 days from BMT. The incidence of grade II – IV acute GVHD and of chronic GVHD was 24% and 8%. With a median follow up of 24 months (range 18 – 44) 21 patients are alive, 20 disease free. The cumulative incidence of transplant related mortality (TRM) and relapse was 4% and 31% The actuarial 3 year survival is 77%, the actuarial 2 year progression free survival is 63%.

Summary / Conclusion: In conclusion we confirm that high dose PT-CY is effective as prophylaxis of GVHD after HLA haploidentical BMT, can prevent rejection and does not appear to eliminate the allogeneic graft versus lymphoma effect.

P155

A SIMPLE, ACCESSIBLE NEW TOOL TO DEFINE HIGH RISK PATIENTS IN CLASSICAL HODGKIN LYMPHOMA BASED ON VALIDATION OF PRE-EXISTING BIOMARKERS

P Greaves[1],* A Wilson[2], J Matthews[1], J Gribben[1]
[1]Centre for Haemato-Oncology, Bart's Cancer Institute, Queen Mary University of London, [2]Centre for Haemato-Oncology, Bart's Cancer Institute, Queen Mary, University of London, London, United Kingdom

Background: Identifying patients with classical Hodgkin lymphoma (CHL) who will fail conventional therapy is essential to guide treatment, but historic scoring systems (e.g. International Prognostic Score/IPS) fail to stratify patients adequately and few patients fall into higher risk categories. The immune microenvironment of a tumour and dysfunctional systemic immunity are key components of cancer pathogenesis, and recent biomarkers of outcome in CHL have confirmed this. Many novel markers have been proposed but fail to enter clinical use due to complexity or expense of technology (e.g. gene expression profiling) or failure to validate markers in independent datasets. The adverse impact of monocytes/macrophages on tumour progression is well described in CHL. A Mayo clinic study (Porrata *et al*. Haematologica 2012; 97(2): 262-9) reported a ratio of absolute lymphocyte and monocyte counts (ALC/AMC) at diagnosis to be associated with poorer clinical outcomes. Validation using their designated cutpoint of 1.1 in independent patient cohorts has not been published to our knowledge.

Aims: We set out to validate routine markers of immune function, some already incorporated into prognostic strategies (albumin, white cell count and ESR), as well as the Mayo ALC/AMC score, and derive optimal cutpoints on other markers (beta-2-microglobulin/B2MG, C-reactive protein/CRP, Ferritin, IgG & IgM) in a new patient cohort. Since interim PET proved to be the most robust early indicator of outcome, this was also assessed in our cohort.

Methods: All HIV negative patients aged >16 years treated at Bart's Hospital London between 2005 and mid-2012 were included, all of whom received ABVD as first line, with standard salvage and intention to treat with BEAM/autologous stem cell rescue in the case of first line treatment failure. The final cohort comprised 88 patients, 48% male, age 16-65 (median 32), median follow up 3.5 years (0.24-8 yrs), 52% advanced stage. Pre-published cutpoints were used for ALC/AMC (1.1) and IPS indices and for ESR (30 & 50mm/hr) for early unfavourable disease according to the German Hodgkin Study Group (GHSG). The xtile software package determined cutpoints for other markers. Survival differences were determined using the Kaplan Meier (KM) method, reported as 3-year overall (OS) and progression-free survival (PFS). Statistically significant differences between groups were determined using the log rank method on pre-determined cutpoints, or corrected based on xtile test/validation methodology.

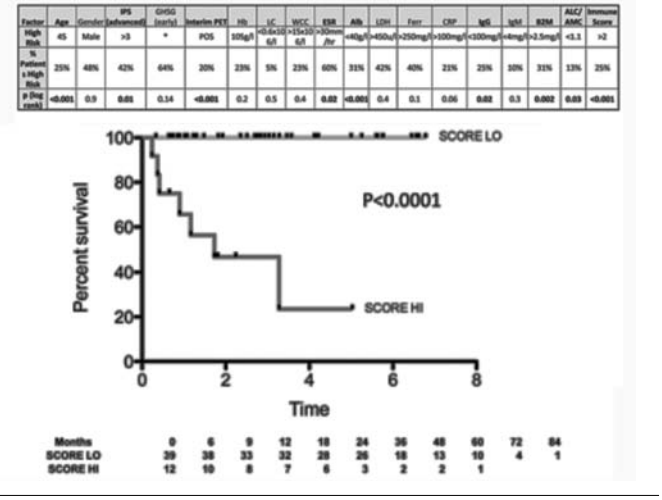

Figure 1. Risk factors assessed with p values according to univariate analysis and resulting "immune score" stratifying all patients.

Results: There were 26 progressions and 14 deaths in our cohort. Patients with early stage disease had 95% OS vs 70% with advanced. Performance of all prognostic scores and biomarkers in the univariate analysis is summarised in the Figure 1. Combining the laboratory biomarkers which significantly discriminated prognostic groups using cutpoints validated in, or derived from this cohort, we developed an 'immune status' prognostic score of adverse results: albumin<40 g/L, ALC/AMC<1.1, B2MG>2.5 mg/L, ESR>30mm/hr & IgG<100 mg/L. 2 groups were defined with 51 patients having a full complement of lab results. In the good risk group (score <3 factors) there were no deaths, and only 5 progressed, 4 of whom were successfully salvaged and are in remission after three years. In the poor risk group (score 3-5) all deaths were captured. KM analysis based on this stratification revealed the good risk group had 3 year PFS 82% and OS 100% and the poor risk group had PFS 39% and OS 43% (P<0.001).
Summary / Conclusion: We confirm limited prognostic ability of the GHSG and IPS systems, and excellent performance of interim PET. The most robust 'lab standard' biomarkers in our cohort were albumin, ESR, IgG, B2M and ALC/AMC ratio which combined into a highly discriminatory score predicting OS/PFS. This cheap, accessible, simple tool may be taken forward and validated in further patient cohorts.

P156

PHASE 1/2 STUDY OF BRENTUXIMAB VEDOTIN IN PEDIATRIC PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA OR SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA: INTERIM PHASE 1 SAFETY AND PHARMACOKINETIC DATA

F Locatelli[1,*] L Gore[2], C Mauz-Körholz[3], A Rosolen[4], J Landman-Parker[5], J de Toledo[6], A Beishuizen[7], A Fasanmade[8], J Wang[8], H Fingert[8], R Labotka[8], K Neville[9]
[1]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [2]Children's Hospital Colorado, Aurora, United States, [3]Universitaetsklinikum Halle, Halle, Germany, [4]Università di Padova, Padova, Italy, [5]Hopital D'Enfants Armand-Trousseau, Paris, France, [6]Hospital Infantil Vall d'Hebron, Barcelona, Spain, [7]Erasmus MC - Sophia Children's Hospital, Rotterdam, Rotterdam, Netherlands, [8]Millennium: The Takeda Oncology Company, Cambridge, [9]Children's Mercy Hospital, Kansas City, United States

Background: Brentuximab vedotin is a CD30-targeted antibody conjugated by a protease-cleavable linker to a microtubule-disrupting agent, monomethyl auristatin E (MMAE). Data for brentuximab vedotin in children are encouraging, but limited. A retrospective analysis of 4 studies allowing enrollment of children with CD30-expressing malignant lymphomas showed that 9 pediatric patients (pts; median age 16 y; 5 Hodgkin lymphoma [HL]; 4 systemic anaplastic large-cell lymphoma [sALCL]) received brentuximab vedotin 0.8 or 1.2 mg/kg weekly for 3 of 4 weeks, or 1.2 or 1.8 mg/kg every 21 days (Q3wk). 6/9 pts (2/5 HL; 4/4 sALCL) had complete remissions (CR); 5/6 pts with CR remained in remission after 6–15+ months of follow-up. Adverse events (AEs) were manageable, with a safety profile similar to that documented in adult pts. No common Gr ≥3 events were observed; there were no discontinuations due to an AE. This study was designed to evaluate safety, pharmacokinetics (PK) and antitumor activity of brentuximab vedotin in pediatric pts.
Aims: The phase 1 portion of this phase 1/2, open-label, multicenter study aims to evaluate the safety, PK, and recommended phase 2 dose (RP2D) of brentuximab vedotin in children with relapsed or refractory (RR) CD30-expressing HL and sALCL (off-label use). Here we report preliminary phase 1 safety and PK data.
Methods: Consenting pts aged 2 to <18 years with any RR CD30-positive hematologic malignancy (5 to <18 years for HL) were eligible for phase 1. Pts received brentuximab vedotin by IV infusion Q3wk. The phase 1 starting dose was 1.4 mg/kg, escalated to 1.8 mg/kg following a 3+3 design. Blood samples for PK analysis were collected immediately before and 5 mins after the infusion on day 1 of all cycles; one sample was drawn on days2,3,5, 14 of cycles 1 and 8, and days2,3, 5 of cycle 2.
Results: 12 pts (median age 14.5 y [range 9–17]; 8M, 4F; 10 HL, 2 sALCL) received brentuximab vedotin (mg/kg/dose: 1.4, n=3; 1.8, n=9). The 1.8 mg/kg cohort was expanded from 6 to 9 pts to increase the total phase 1 pediatric experience to 12 pts before the phase 2 portion. At data cut-off, pts had received a median of 4 cycles (range, 1–10). 11 pts (92%) had ≥1 drug-related adverse event (DRAE): 2 at 1.4 mg/kg, 9 at 1.8 mg/kg. 5 pts (42%) had Gr ≥3 DRAEs: 1 at 1.4 mg/kg, 4 at 1.8 mg/kg. The most frequent (≥15%) treatment-emergent AEs were nausea (50%), abdominal pain, diarrhea (25% each), upper abdominal pain, cough, fatigue, hypoklaemia, leukopenia, decreased lymphocyte count, neutropenia, pain, paresthesia, pyrexia, vomiting, weight loss (17% each). 1 pt (8%) discontinued due to a DRAE of Gr 3 hepatotoxicity. 6 severe AEs were reported in 4 pts at 1.8 mg/kg: Gr 2 supraventricular tachycardia in 1 pt, unrelated to treatment; related Gr 3 febrile neutropenia and related prolonged Gr 3 hepatotoxicity in 1 pt (1.8 mg/kg; both dose-limiting toxicities); Gr 3 bronchospasm and Gr 2 laryngeal edema in 1 pt; 1 cardiac arrest resulting in death, unrelated to treatment. Median concentration-time profiles for brentuximab vedotin and MMAE are presented for the 2 dose cohorts.
Summary / Conclusion: Brentuximab vedotin was generally well tolerated in children with RR CD30-positive HL or sALCL up to 1.8 mg/kg Q3wk. For the majority of pts, toxicities were generally mild to moderate and did not lead to discontinuation. Similar to adults, 1.8 mg/kg is the RP2D for children with CD30-positive RR HL or sALCL. PK analyses showed dose-dependent exposure in these patients. The phase 2 portion of this study is ongoing.

P157

METABOLIC TUMOR VOLUME BY PET/CT AS A CLINICAL PARAMETER TO DETERMINE THERAPEUTIC MODALITY IN THE EARLY STAGE HODGKIN'S LYMPHOMA.

M Song[1,*] J Chung[1], J Lee[2], J Moon[3], S Lee[4], J Hong[5], S Lee[6]
[1]hematology, Pusan National University Hospital, Busan, [2]hematology, Chonnam National University Hwasun Hospital, Hwasun, [3]hematology, Kyungpook National University Hospital, Daegu, [4]hematology, Busan Paik Hospital, Busan, [5]hematology, Gachon University Medical Center, Incheon, [6]hematology, Dong-A Medical Center, Busan, Korea, Republic Of

Background: stage Hodgkin's lymphoma (HL). Although 70 to 80% of patients were cured with this treatment, radiation related late toxicities such as second cancer and cardiovascular event remained the serious complication. A current treatment standard for the early stage HL is combined modality treatment (CMT) including chemotherapy such as adriamycin, bleomycin, vinblastine and dacarbazine (ABVD) regimen and involved-field radiation therapy (IF-RT). This treatment modality was an attempt to reduce the late toxicity by RT field and doses. However, it is unclear whether long term late toxicities were reduced with IF-RT. Recent several studies have suggested that ABVD therapy alone is a reasonable treatment option for favorable early stage HL. Positron emission tomography/computed tomography (PET/CT) is a promising methology to measure metabolic activity of active tumor burden in HL and Non-Hodgkin's lymphoma (NHL). We showed metabolic tumor volume (MTV) by PET/CT was an important clinical factor to reflect active tumor burden in NHL.
Aims: We investigated whether ABVD alone in early stage HL would lead to control of the disease similar to CMT using metabolic tumor volume (MTV) measured by PET/CT.
Methods: One hundred twenty seven patients with early stage HL between 2006 and 2011 in six medical center underwent PET/CT at diagnosis were enrolled. Treatment schedules were given as follows : 66 patients received six cycles of ABVD regimen. Other 61 patients received IF-RT (the dose, 30Gy) after four to six cycles of ABVD regimen. The median follow-up time was 47.8 months (range, 13.0-78.5 months). PET images were interpreted by nuclear physicians of the each institution. Then, the data were reviewed by a nuclear medicine expert in Pusan National University Hospital. MTV was delineated on the PET images by a pathologic ≥ standard uptake volume (SUV) 2.5 (Syntegra, version 2.1E, Philips Co.).

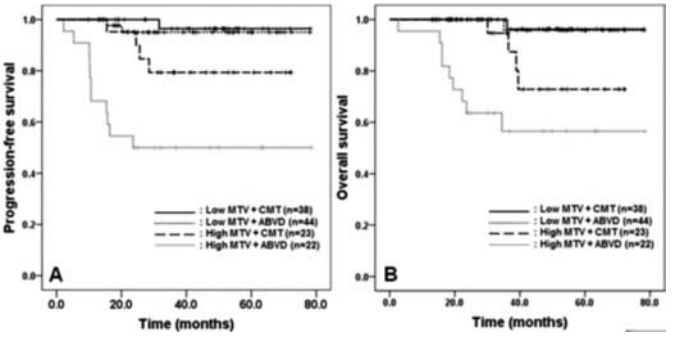

Figure 1.

Results: The male to female ratio was 1.4 : 1. Median age at diagnosis was 42 years (range, 18-78 years). Twenty five patients had B symptoms. Nodular sclerosis subtype was the predominant histology (55 patients), with 41 patients presenting with mixed-cellularity, 20 with lymphocyte-rich and 11 with lymphocyte-depleted subtype. Twenty-seven patients were stage I and 100 patients were stage II. Seventy-eight patients had more than 3 involved sites and 19 patients had mediastinal disease. Bulky disease was present in 27 patients.
The cut-off value of MTV was calculated by ROC curve analysis and the ideal value was 198 cm^3. The clinical outcomes were compared according to several prognostic factors (age ≥ 50 years, male, ECOG PS ≥2, stage II, B symptom, ≥ 3 involved sites, bulky disease, extranodal site, large mediastinal mass, CMT, elevated ESR and high MTV [≥198 cm^3]). Five factors including age ≥ 50 years, B symptom, bulky disease, large mediastinal mass and high MTV) had clinical significant values in univariate analysis (PFS, age ≥50 years [P=0.029], B symptom [P<0.001], bulky disease [P<0.001], large mediastinal mass [P=0.001] and high MTV [P<0.001]; OS, age ≥50 years [0.044], B symptom [P=0.001], bulky disease [P<0.001], large mediastinal mass [P=0.004] and high

MTV [P=0.001]). In multivariate analysis, age ≥50 years (PFS, HR=4.426, 95%CI=1.650-11.802, P=0.003; OS, HR=4.327, 95% CI=1.485-12.607, P=0.007), B symptoms (PFS, HR=4.239, 95%CI=1.510-11.899, P=0.006; OS, HR=3.549, 95% CI=1.089-11.568, P=0.036) and high MTV (PFS, HR=8.733, 95%CI=1.744-3.728, P=0.008; OS, HR=12.586, 95% CI=2.026-78.194, P=0.007) were significant prognostic factors in PFS and OS.

In the analysis of survival according to MTV and therapeutic modality (CMV vs. ABVD only), PFS and OS of high MTV group treated with ABVD only were lower than others groups (PFS, P< 0.001; OS, P<0.001, Figure 1).

Summary / Conclusion: MTV as a clinical parameter of tumor burden was an significant prognostic factor, that would be helpful for deciding therapeutic modality in early stage HL.

P158

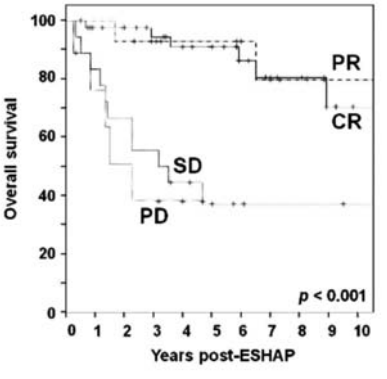
ESHAP AS SALVAGE THERAPY FOR RELAPSED OR REFRACTORY HODGKIN'S LYMPHOMA

J Labrador[1,*] M Cabrero-Calvo[1], E Pérez-López[1], L López-Corral[1], M Mateos[1], F Sánchez-Guijo[1], L Vázquez[1], J Bastida[1], O López-Godino[1], M López-Parra[1], J San Miguel[1], M Caballero[1], R García-Sanz[1]
[1]Hematology, Hospital Universitario de Salamanca, Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain

Background: The management of relapsed and/or refractory Hodgkin Lymphoma (RR-HL) remains a current challenge for hematologists, since more than a half of such patients cannot be cured from this typically curable disease. Current standard of care includes a salvage chemotherapy followed by autologous stem cell transplantation (ASCT). However, one of the most debatable key points in this strategy is what could be the best salvage protocol. It should introduce drugs not previously used in the patient in order to induce maximum response, but with a reasonable toxicity profile, including the avoidance of any stem cell impairment. A large number of salvage regimens have been published. However, there are no randomized trials comparing it.

Aims: We report our experience and long-term results with the ESHAP (etoposide, steroid, cytarabine, cisplatin) regimen in RR-HL patients with the intention to proceed to ASCT.

Methods: We conducted a retrospective study with 82 consecutive patients with RR-HL who received ESHAP as salvage therapy in order to achieve effective cytoreduction and proceed to ASCT with the BEAM conditioning in CR or with low residual disease. Forty-one out of 82 patients (50%) were considered to be refractory to front-line therapy.



CR: Complete response; PR: Partial response; SD: Stable disease; PD: Progressive disease.

Figure 1. Overall survival in RR-HL according to the response to salvage treatment with ESHAP.

Results: This regimen provided an overall response rate (ORR) of 67% with a 50% complete response (CR) rate, with a median of two cycles of ESHAP. Three disease characteristics at ESHAP retained their adverse influence on CR rate on multivariate analysis: refractory disease or ≥2nd relapse, B symptoms and mediastinal involvement. Twenty eight out of 82 patients (34%) received additional salvage therapy after ESHAP treatment in order to proceed with the ASCT and 26/28 patients finally underwent SCT. In total, 75/82 patients (91%) received hematopoietic SCT: 71 ASCT and 4 allogeneic SCT from related donor. The response rate after the transplant among patients who received autologous or allo-SCT was improved to an ORR of 84% (63/75) and CR rate of 82.6% (62/75). The mean follow-up after ESHAP administration was 70.2±41months. The median progression-free survival (PFS) was 52 months (95% CI 7.2-96.7) and the time to progression (TTP) was 56 months (95% CI 11.5-100.5). Overall survival (OS) at 2 and 5 years were 80.5% and 72.6%, respectively. At the time of reporting, 70.7% patients are still alive. On multivariate analysis, CR achievement after ESHAP was the most important prognostic factor influencing PFS (78% *vs.* 15.5% at 5 years) and TTP (80% *vs.* 19% at 5 years). Patients who achieved PR or CR in pre-transplant evaluation also retained its favorable prognostic value in both, PFS and TTP. The response to ESHAP was the most important prognostic factor for OS (91 *vs.* 36% at 5 years) in the multivariate analysis, without significant differences between CR and PR patients (Figure 1). Forty one percent of patients experienced hematological toxicity ≥3, but only 10% had grade 4 neutropenia and <10% of patients developed neutropenic fever, with no toxic deaths. In addition, most of our patients (94%) scheduled to receive ASCT could be adequately mobilized for stem cell collection under the ESHAP regimen. In the present series, after a long time follow-up, the incidence of second malignancies was 7.3%, mostly myelodysplastic syndromes.

Summary / Conclusion: ESHAP regimen is a safe and efficient therapeutic option for patients with RR-HL who are candidates to ASCT, since it combines a high response rate and a high mobilizing potential with low toxicity profile. However, further studies to refine this regimen with the addition of new drugs or small dose/density changes should be considered in selected patients who have less possibility with the protocol as it is currently defined.

P159

SOLUBLE CD30 LEVELS UNDER BRENTUXIMAB VEDOTIN THERAPY

E Porpaczy[1,2,*] A Schiefer[3], N Olah[4], C Skrabs[4,5], M Krauth[5,6,7], P Knoebl[5,6], A Hauswirth[5,6], W Sperr[5,6], S Reichmann[8], M Schneeweiss[9], S Knapp[4], K Vanura[4,5], U Jaeger[4,5]
[1]Department of Medicine I, Division of Hematology and Hemostaseology, [2]Comprehensive Cancer Center Vienna, Medical University of Vienna, Vienna, Austria, [3]Clinical Institute of Pathology, [4]Medical University of Vienna, Vienna, Austria, [5]Comprehensive Cancer Center Vienna, [6]Department of Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, [7]MLL Munich Leukemia Laboratory, Munich, Germany, [8]Department of Medicine I, Division of Infectious Diseases and Tropical Medicine, [9]Department of Medicine I, Laboratory of Infection Biology, Medical University of Vienna, Vienna, Austria

Background: Targeted therapy with the anti-CD30 antibody Brentuximab Vedotin (BV) has shown promising results in patients with relapsed or refractory CD30 positive neoplasms such as Hodgkin´s disease (HD) or anaplastic large cell lymphoma (ALCL). However, many patients relapse during or early after treatment with BV. The soluble form of the target surface receptor (sCD30) can be measured in serum and may therefore serve as biomarker for prediction of response and monitoring during therapy. No data are currently available on serum kinetics of sCD30 during treatment with BV.

Aims: To determine sCD30 serum levels during treatment with BV and to correlate levels with clinical outcome.

Methods: Eight HD and 2 ALCL patients, all refractory to prior treatments, received BV and were included in this study. Soluble CD30 levels, measured by ELISA, were determined during BV treatment. Therapy response was determined by clinical signs (B-symptoms, lymph node size) and radiological techniques (PET, PET-CT, CT and/or sonography). Kaplan Meier survival analysis was performed using SPSS 17.0 (SPSS Inc., Chicago, USA). P-values <0.05 were considered significant.

Results: All HD patients received at least 6 cycles of BV (range: 6-12 cycles), ALCL patients received 4 cycles each. All patients showed rapidly decreasing sCD30 levels already after the first two cycles. This matched clinical signs of therapy response. Among HD patients, 3 showed sCD30 levels less than 40 ng/ml already after the first cycle and had durable remissions. One of these 3 patients relapsed after 31 weeks. The other 2 patients, still being in complete remission (CR) after 24 and 50 weeks, underwent successful autologous stem cell transplantation and are still in CR to date (43 and 78 weeks, respectively). The other patients (5/8) did not reach sCD30 levels < 40 ng/ml and had shorter remission durations (6, 10, 11, 14 and 30 weeks; P=0.019) (Figure 1). Continuously increasing sCD30 levels were observed about two months before first clinical signs of relapse. Notably, therapy response was independent of histologic subtypes. In 2/5 patients who repeatedly relapsed after BV treatment, re-administration of BV was started after 7 and 8 months and unsuccessful treatments with other regimens. However, due to lack of response to BV, treatment was abandoned after 3 and 2 cycles, respectively. Compatible with this clinical course, sCD30 serum levels did not decrease. Unlike CD20 expression of tumor cells after Rituximab administration in other lymphomas, CD30 expression in tumor samples remained unaffected by BV as determined by immunohistochemistry. In comparison, both ALCL patients had much higher initial sCD30 levels than HD patients (median 6854 ng/mL vs. 122,2 ng/mL). One patient responded to BV with a sCD30<50 ng/mL five days after the first cycle and was in remission for 40 weeks. The second ALCL patient showed the lowest sCD30 level (81,48 ng/mL) after the second cycle of BV. However, this patient relapsed two weeks later.

Summary / Conclusion: We report first data on sCD30 serum levels in patients with HD or ALCL under treatment with BV. Although investigated in a small cohort, our data suggest that i) MH patients under BV treatment with sCD30 levels rapidly approaching less than 40 ng/ml) have durable clinical remissions; ii) continuously increasing sCD30 levels occur shortly before relapse; and iii)

CD30 expression persists in tumor tissue samples during and after BV treatment when patients have relapsed. Soluble CD30 may therefore serve as biomarker for monitoring under anti-CD30 directed therapy.

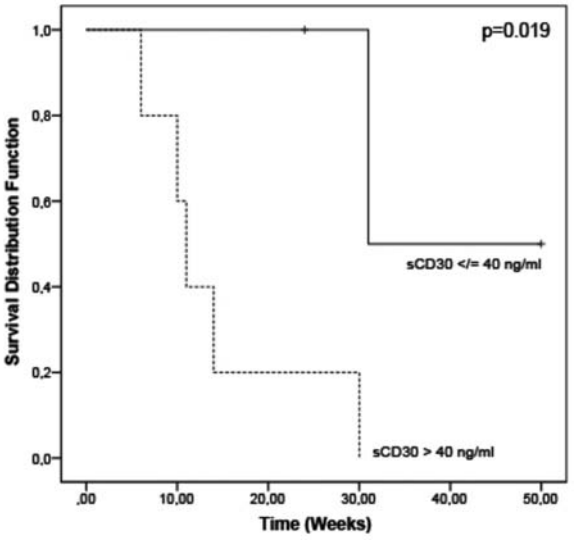


Figure 1. Time to relapse of Hodgkin's Disease patients during/after treatment with Brentuximab Vedotin. Patients not reaching soluble CD30 serum levels <40 ng/mL during treatment (broken line) had shorter remission times (P=0.019).

P160

THE LYMPHOCYTIC HISTOPATHOLOGIC SUBTYPES OF HODGKIN LYMPHOMA (HL): CLINICAL PRESENTATION AND LONG-TERM OUTCOME IN A CASE SERIES OF 61 PATIENTS

A Kanellopoulos[1],* M Angelopoulou[1], G Boutsikas[1], K Petevi[1], G Gainaru[1], Z Galani[1], E Sinni[1], M Siakantaris[2], M Moschogiannis[3], P Tsaftaridis[1], V Komninaka[1], M Dimopoulou[1], E Plata[1], X Yiakoumis[3], P Tsirkinidis[4], P Flevari[1], L Papageorgiou[1], K Koutsi[1], A Zannou[1], V Telonis[1], A Bilalis[1], E Papakostas[1], J Meletis[1], G Pangalis[3], T Vassilakopoulos[1]

Background: Nodular lymphocyte predominant HL (NLPHL) and lymphocyte rich classical HL (LRCHL) are rare subtypes of HL. Relevant data derived from homogeneously treated patient populations are scarce.
Aims: The evaluation of clinical manifestations and long-term prognosis of patients with (NLPHL) and (LRCHL), compared with other histologic subtypes of HL under ABVD or equivalent chemotherapy with or without radiotherapy (RT).

Table 1.

	HISTOPATHOLOGIC SUBTYPES			
Patients	NLPHL	LRC	Others	p
	(n=28)	(n=33)	(n=719)	
Age (median, range)	38.5 (17-73)	43 (15-76)	30 (14-82)	0.002
Males	75%	72%	61%	0.003
Stage I/II/III/IV	6%/26%/14%/	42%/33%/6%	20%/30%/18%/	<0.001
B-symptoms	11%	3%	34%	<0.001
Marrow involvement	0	3%	6%	0.37
Pure infradiaphragmatic disease (for stages I/II)	38%	15%	8%	<0.001
Anemia (Hb<10.5 g/dl)	11%	18%	42%	<0.001
WBC≥10x10⁹/L	14%	22%	44%	<0.001
Lymphocytopenia (IPS definition)	4%	3%	9%	0.39
PLT >400x10⁹/L	0	6%	27%	<0.001
ESR ≥50 mm/h	8%	7%	50%	<0.001
↑ LDH	8%	6%	28%	0.002
Albumin <4 g/dL	4%	20%	41%	<0.001
↑ CRP (>5 mg/L)	39%	29%	75%	<0.001
CRP ≥30 mg/L	0	6%	51%	<0.001
5-year tumor control	80%	88%	79%	0.34
5-year event free survival	76%	85%	77%	0.39
10-year overall survival	77%	89%	85%	0.93
10-year disease specific survival	95%	100%	90%	0.24

Methods: Retrospective study of 780 patients with histologicaly-confirmed diagnosis of HL, treated at our center. Histologic material was evaluated or reviewed at major Haematopathology referral centers according to current classification criteria. With respect to histopathologic subtype, the distribution of patients was: NLPHL 28 (3.6%), LRCHL 33 (4.2%), nodular sclerosis 545 (69.9%), mixed cellularity 158 (20.3%), lymphocyte depleted 3 (0.4%). The patients were assessed according to their clinical-laboratory features at presentation, and their course after treatment with ABVD or equivalent regimens ±RT.
Results: Patients with NLPHL and LRCHL were clinically similar, with the exception of slightly more frequent pure infradiaphragmatic localization in those with NLPHL (P=0.07). Compared with the others, patients with NLPHL and LRCHL tended to be male and older, asymptomatic, with more limited disease and higher incidence of pure infradiaphragmatic involvement (Table). Moreover, NLPHL and LRCHL very rarely had markedly abnormal laboratory features compared with the more common forms of classical HL (with the exception of the rather infrequent severe lymphocytopenia) (Table 1). Despite those differences, disease control and overall survival were similar among all histologic subtypes, as shown in the table.
Summary / Conclusion: NLPHL and LRCHL are rare subtypes of HL with distinct demographic and clinical features, that favor their separation from the common subtypes of classical HL. At present, in our series, the outcome of patients with NLPHL and LRCHL resembles that of patients with the other subtypes of HL.

P161

LONG TERM RESULTS OF MONOCENTRIC PROSPECTIVE STUDY OF VEBEP PLUS RADIOTHERAPY REGIMEN IN NEWLY DIAGNOSED EARLY-UNFAVORABLE STAGE HODGKIN LYMPHOMA

S Pagliuca[1], M Raimondo[1], S Basile[1], M Di Perna[1], N Pugliese[1], F Pane[1], M Picardi[1],*
[1]hematology, Federico II naples, Naples, Italy

Background: The gold standard therapy for early unfavorable Hodgkin Lymphoma (HL) has not reached a consensus yet. At present, ABVD followed by 30 Gy Involved Field Radiotherapy (IFRT) is the most emploied strategy in such patients. More aggressive regimens, such as BEACOPP escalated and/or BEACOPP baseline, in association with IFRT, may improve disease control in comparison with ABVD. Data from GHSG HD11 trial in early unfavorable HL showed that 5-year Freedom From Treatment Failure (FFTF) and Overall survival (OS) following BEACOPP baseline (4 cycles) plus 20 Gy IFRT were not significantly better than ABVD (4 cycles) plus 30 Gy IFTR: 87% *vs.* 85% and 94% *vs.* 95%, respectively. In addition, short- and long-term toxicity, as well as incidence of secondary neoplasms, were higher in BEACOPP *vs.* ABVD arm.
Aims: We propose mature results of this monocentric prospective study in order to define an alternative intensive and low toxic regimen for early unfavorable HL. Analysis of survival rates was focused on Disease Free Survival (DFS), as primary endpoint and OS, as secondary endpoint. Complete Remission Rate (CRR) and early and late toxicity rates were also estimated.
Methods: In this study, patients 18-65 year-old with newly diagnosed early unfavorable stage HL (according with GHGS criteria) were treated with six courses of VEBEP regimen (vinblastine 6 mg/m^2 dd 1 and 15 *i.v.*, epirubicine 40 mg/m^2 dd 1 and 15 *i.v.*, bleomicine 10 mg/m^2 dd 1 and 15 *i.v.*, etoposide 80 mg/m^2 dd 1-3 and 15-17 *i.v.*, and prednisone 40 mg/m^2 dd 1-5 and 15-19 orally; twice week G-CSF prophylaxis). Chemotherapy was followed by 32 Gy IFRT. Complete remission was defined according to revised criteria of the International Harmonization Group and the assessment of response was ^{18}FDG-PET/TC based. The follow up assessment concerned a clinical, laboratoristical and imaging-instrumental screening. Estimation of response and survival rates was conducted by Kaplan and Mayer analysis
Results: From 2001 to 2009, 117 patients were enrolled in the study. All patients completed therapeutic schedule and were included into the analysis. Median follow up was 86 months (11-135 months). CRR was 94% (109/117 patients achieved CR at the end of treatment and 8/12 patients had persistent/progressive disease). According to WHO Toxicity Grading System no grade 3-4 extra-hematological and hematological acute toxicity occurred. Five cases of pulmonary infection were diagnosed during the treatment, all successfully managed by antibiotics. 10-year DFS rate was 97% (4/109 had relapsed disease). All relapsed/refractory patients received salvage treatment and autologous stem cell transplantation. Grade 3-4 chronic toxicity profile of VEBEP plus radiotherapy regimen was very low. Only 2 patients had late cardiac toxicity (1%) and 2 patients developed restrictive respiratory disease (1%) during the follow-up. Three secondary neoplasms were diagnosed (2%) (1 Lymphoblastic Acute Leukemia, 1 Promyelocitic Acute Leukemia, 1 Nasopharyngeal cancer). 10-year OS was 96% (5/117 patients died: 3 for persistent disease and 2 for secondary leukemias).
Summary / Conclusion: VEBEP regimen plus IFRT could be considered an effective therapy for early unfavorable HL patients in order to its low toxicity and its efficacy.

P162

DEVELOPMENT OF A PROGNOSTIC SCORING SYSTEM FOR PRIMARY REFRACTORY HODGKIN'S LYMPHOMA TREATED WITH HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION

M David[1,*] R Mózes[2], E Horváth[2], Á Nagy[2], Sz Kosztolányi[2], G Kovács[2], R Csalódi[2], J Pammer[2], Á Szomor[2]
[1]Department of Haematology, Royal Shrewsbury Hospital, Shrewsbury, United Kingdom, [2]Department of Haematology, University of Pécs, Pécs, Hungary

Background: Management of primary refractory Hodgkin's lymphoma represents a major therapeutic challenge in malignant haematology. Several authors have identified prognostic factors in cohorts of patients with relapsed and/or refractory disease who have undergone subsequent salvage chemotherapy followed by conditioning therapy and autologous stem cell rescue (ASCT). In these publications relapsed and refractory Hodgkin's lymphoma patients have usually been analyzed together as one group but there are significant survival differences in previously responding and never responding patients.
Aims: Thirteen prognostic factors have been analyzed in 45 patients with primary refractory Hodgkin's lymphoma treated with salvage chemotherapy and subsequent high dose therapy and ASCT to create a prognostic scoring system specific for primary refractory Hodgkin's lymphoma.
Methods: The ASCTs were performed between January 2000 and April 2012. The sex distribution of the patients showed a slight male predominance (21 females, 24 males), their mean age at the time of their ASCT was 30.31 years (range: 17-60 years). The most common histological subtype was nodular sclerosis in 65% of patients. 56% of them could be categorized as having Ann Arbor stage III-IV disease with B symptoms in 70% and with bulky disease in 55%.
The analyzed prognostic factors were the following: Age, Sex, Ann Arbor stage, Histologic subtype, Presence of B symptoms, Bulky disease, Radiotherapy, Type of conditioning regimen, Number of previous treatment lines, Response before ASCT, Time interval between diagnosis and ASCT, LDH and Serum albumin. Statistical analysis: Univariate analysis has been performed according to Kaplan-Meier estimates, multivariate analysis according to Cox regression model. P<0.05 was considered as significant.
Results: The outcome of the ASCTs was the following: overall response rate 84% (complete response in 52%, partial response in 32%), stable disease in 7%, 9% of the patients turned out to be non-responders to ASCT. Overall survival according to Kaplan- Meier estimates at 3 years was 68%, at 5 years 28%. The ASCTs were well tolerated (non-relapse mortality (<100 days): 1 of 45 patients - 2.2%). Five adverse prognostic factors have been identified as significant (P<0.05) in both statistical analyses: 1. Ann Arbor stage (stage 4 disease), 2. Number of previous treatment lines (≤3, >3), 3. Response before ASCT (progression, stable disease, response), 4. Time interval between diagnosis and ASCT (≤18, >18 months), 5. Serum albumin (≤35, >35 g/L).
A prognostic scoring system has been constructed from these five significant prognostic factors: 0 or 1 adverse prognostic factor: 'low' risk group; 2 or 3 adverse prognostic factors: medium risk group; >3 adverse prognostic factors: 'ultra high' risk group. There was a highly significant difference (P=0.000) in the overall survival of patients belonged to the three different prognostic categories (Figure 1).
Summary / Conclusion: A new prognostic scoring system has been constructed specifically for primary refractory Hodgkin's lymphoma that can be useful in driving treatment decisions for patients within this desperate disease category. There were significant overall survival differences between the three prognostic categories (Figure 1) constructed on the bases of the five adverse prognostic factors that were significant with both statistical analyses. Our results should further be approved on a larger cohorts of patients with primary refractory Hodgkin's lymphoma.

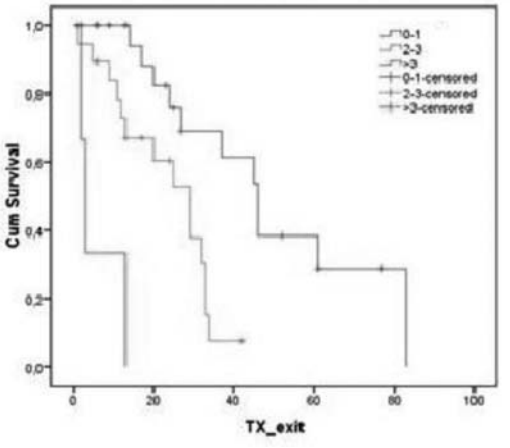

Figure 1. Kaplan-Meier estimate of OS according to risk categories (P=0.000).

P163

HETEROGENEOUS MANAGEMENT OF ADOLESCENTS AND YOUNG ADULTS WITH HODGKIN LYMPHOMA AND INCONSTANT CONFORMITY OF MEDICAL PRACTICE TO CLINICAL GUIDELINES: EXHAUSTIVE COHORT FROM RHÔNE-ALPES REGION

A Dony[1,*] Y Bertrand[1], C,Sebban[2], A Belhabri[2], P Cony-Makhoul[3], G Salles[4], M Rogasik[5], C Chassagne-Clément[6], I Ray-Coquard [7]
[1]Institut d'Onco-Hématologie Pédiatrique, [2]Hematology, Centre Léon Bérard, Lyon, [3]Hematology, Centre Hospitalier d'Annecy, Pringy, [4]Hematology, Center Hospitalier Lyon Sud, [5]EMS team, [6]Anatomopathology, [7]Cancerology, Centre Léon Bérard, Lyon, France

Background: Management of adolescents and young adults (AYAs) with cancer remains unsatisfying and carelessness, as indicated by data from the SEER registry. Overall outcome of Hodgkin lymphoma (HL), the most frequent cancer of AYAs, is favorable, but the question of the optimal treatment is far from being resolved, in particular for the impact of the therapeutic choice on the long-term secondary effects. In an attempt to measure quality of AYAs management, evaluation of physicians' decisions using conformity rate of successive procedures with clinical practice guidelines (CPG's) was observed.
Aims: The aim of this study was to describe the primary management of HL among AYAs and the compliance's rates with CPG's used at time of management.
Methods: All institutional patients' records of 13-25y AYAs with classical HL diagnosed in the Rhône-Alpes region between 2000 and 2005 were retrospectively analyzed. Data from diagnosis to last follow-up were collected until 2011. Five successive sequences were assessed: staging, histology, chemotherapy, radiotherapy and follow-up. The overall sequence of treatment was considered to be conform when each assessable part of the procedure was respected.
Results: One hundred and ninety eight patients were included, 148 (75%) managed in adult units (A) and 50 (25%) in pediatric units (P). Median age was 21y (range 13-25) in (A) and 14y (range 13-24) in (P). Thirty three patients (17%) were included in clinical trials, 13 (7%) were managed apart from any recommendation and 97 (49%) had their medical case reviewed in multidisciplinary staff. Treatment delay, once diagnosis made, was longer in (A) than in (P) (median 18 days (range 0-62) versus 9 days (range 1-33), P<0.01). All patients received initially chemotherapy; 63% in (A) received after radiotherapy, 100% in (P). Among irradiated patients, average dose received was lower in (P) than in (A) (23 Grays versus 34 for supradiaphragmatic, 21 Grays versus 31 for infradiaphragmatic irradiation). Differences were notified between (A) and (P) for chemotherapy protocols used: larger use of anthracyclins and bleomycin in (A), of corticosteroids and alkylants in (P). End of treatment evaluation for response was similar in both groups. At the last follow-up, staging was conform to CPG's in 88% for all patients (86% and 92% respectively for (A) and (P)), chemotherapy in 82% (78% and 94%), radiotherapy in 81% (79% and 88%), follow-up in 87% (90% and 78%), global conformity in 56% (55% and 60%). In the 15-18y subgroup (*n*=60, among whose 40 managed in (A), 20 in (P)), conformity was found to be significantly higher in (P) for global conformity (P=0.02) and for chemotherapy conformity (P=0.05). Ten patients (5%) died, 9 in (A) and 1 in (P), all from HL disease except 1 from treatment toxicity (managed in (A)). Six patients (3%) were lost to follow-up. Among the 182 alive patients (64 months median follow-up), 1 managed in (A) developed a thyroid carcinoma.
Summary / Conclusion: Our study emphasizes the heterogeneity of the management of AYAs with HL as well as the absence of standard of care. The too short follow-up does not allow to compare (A) and (P) management about long term toxicities, particularly for second malignancies occurrence. We encourage increased cooperation and communication between adult and pediatric oncologists to develop dedicated clinical trials for this population. Improving compliance with CPG's should lead to improve specific cares for AYAs, to induce more homogeneity in their management and to facilitate the development of new drugs.

Table1.

	Adult (*n*=148)	Pediatric (*n*=50)
	n= (%)	*n*= (%)
Ratio F/M	1,3	1,0

5-years PFS (95% CI)	87% (84-90)	76% (70-82)

P164

THERAPEUTIC STRATEGIES FOR RELAPSED OR REFRACTORY HODGKIN'S LYMPHOMA (RR-HL): A SINGLE CENTER FDG-PET-ADAPTED STRATEGY

C Mohr[1],* M Dilhuydy[1], S Vigouroux[1], P Dumas[1], M Sauvezie[1], N Milpied[1]
[1]Hematology, CHU Bordeaux, Pessac, France

Background: The current standard of care for relapse and refractory RR-HL consist of salvage chemotherapy (SLT) followed by high dose chemotherapy and autologous stem cell transplantation (HDT/ASCT).
Aims: FDG-PET scan has consistently been identified as a critical predictor of outcome. As a consequence, we have adopted at our center a PET-adapted strategy for the treatment of RR-HL. We report here the outcome of patients (pts) treated according to this strategy.
Methods: Pts < 65 years old with RR-HL were treated with 1 or 2 lines of SLT. The response was then evaluated by PET scan before a planned HDT/ASCT. Pts with a negative pretransplant PET scan (PETneg) underwent HDT/ASCT after a BEAM regimen. If the pretransplant PET remained positive (PETpos), patients underwent HDT/ASCT followed by an additional treatment consisting of tandem allogeneic stem cell transplant (Allo-SCT), a second HDT or radiotherapy (RT).
Results: From 2006 to 2012, 61 pts were included with a median time between end of first-line therapy and relapse of 6 months (range, 0,5-167,5 months). The median age was 38 years (range, 17-66 years). The first line chemotherapy was ABVD in 58 pts (95%) completed by RT in 16 pts. Our RR-HL cohort was defined as follow: 22 pts (36%) had primary-refractory (PR) disease defined as the persistence of active disease at the end of therapy or recurring within 3 months, while 23 (38%) and 16 (26%) have early (< 1 year) or late (> 1 year) relapse. Thirty-one pts (51%) were PETneg before HDT/ASCT: 6 had PR disease (out of 22, 27%); 16 had early relapse (out of 23, 70%); and 9 had a late relapse (out of 16, 56%). All PETneg patients underwent HDT/ASCT as planned. Thirty pts had PETpos before HDT/ASCT. We performed HDT/ASCT in 25 of these pts, among whom 12 subsequently underwent a reduced-intensity (RIC) allo-SCT, 1 a second HDT, and 7 a RT. Considering the entire cohort 11 pts died, 9 because of progression of disease and 2 of toxicity. With a median follow-up of 37 months (range, 4-88) the 5-y OS was 75% and EFS was 59%. Pretransplant PETscan a critical predictor of outcome: for PETneg pts, 5-y OS and EFS were 87% and 82 % respectively while it was 61% and 33% for PETpos pts (P=0.009 and P=0.0001 respectively). For PETpos pts3y-OS was 57% if they underwent tandem allo-SCT after HDT/ASCT versus 19% if they received a RT or no treatment (P=ns). For relapse pts 3-y EFS is 95% when TEP is negative and 65% when TEP is positive (P<0.00001) regardless of time of relapse (early or late). For PR pts, 3-y EFS is 37% when TEP is negative and 10% when TEP is positive. Otherwise, the 3-y OS is 32% for primary refractory pts with TEPpos while it is 100% for PR pts with TEPneg, 90% for relapsed pts with TEPpos and 95% for relapsed pts with TEPneg (P=0.002).
Summary / Conclusion: In our cohort, patients with a negative PET after SLT had a very good outcome as compared to pts with a positive PET. For these PETpos pts, alloSCT in tandem after HDT/ASCT seems to be a good therapeutic option even if our results have to be interpreted with caution because of the limited number of pts. Patients with a PR have poor EFS despite a negative PET before HDT/ASCT. However, despite a significant relapse rate for patients with PR disease, the salvage treatment after ASCT was effective enough to allow good survival especially for pts with TEPneg before HDT/ASCT. In sharp contrast, PR pts with a positive PET had a very poor outcome.

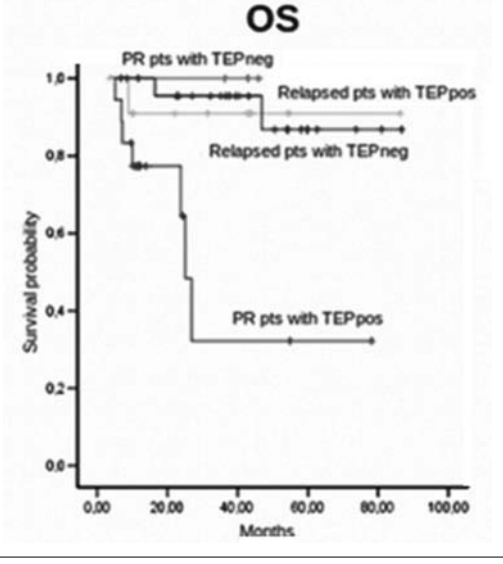

Figure 1.

P165

HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION FOR ADULTS WITH HODGKINS LYMPHOMA IN BELARUS: OUTCOME IN 214 PATIENTS OF A SINGLE CENTRE.

N Milanovich[1],* A Uss[1], A Marozava[1], A Dzuba[1], Y Strongin[1]
[1]department of bone marrow transplantation, Centre Hematology and bone marrow transplantation, city clinical hospital №9, Minsk, Belarus

Background: Relapsed or refractory Hodgkin lymphoma is a challenging problem for clinicians. Hodgkin's lymphoma has high rates of cure, but in 15% to 20% of general patients and between 35% and 40% of those in advanced stages, the disease will progress or will relapse after initial treatment. The standard management of these patients should include the use of salvage chemotherapy followed by autologous stem cell transplant (ASCT).
Aims: We retrospectively analyzed efficacy in 214 adult patients with relapsed and refractory Hodgkin's lymphoma who were consecutively submitted to high-dose chemotherapy followed by ASCT in a single centre between November 1996 and December 2010. Induction failure was defined as failure to achieve a partial remission (PR), complete remission (CR) after initial treatment with combination chemotherapy, using one or more regimens.
Methods: 109 (51%) patients were male and 105 (49%) were female, with a median age of 29,3 years. All patients received dexaBEAM and DHAP as salvage. Responses to salvage therapy were defined as PR in 38 (18%), CR in 146 (38%) and stable/minimally responsive disease (SD/MR) in 30 (14%). OS and PFS rates were determined , and prognostic factors were investigated using univariate analyses.
Results: Responses to high-dose therapy and ASCT were complete response 141 (66%), partial response 39 (18%), stable disease 19 (9%), progressive 10 (5%), and toxic death 4 (2%). Actuarial 5-year OS rates were 63% and 10-year OS rates were 46%; 5-year PFS rates were 53% and 10-year PFS rates were 32%, respectively. Univariate analysis shows that sensitivity to pre-transplant treatment (5-year OS 73% (CR) vs 67% (PR) vs 34% (SD), PFS 72% (CR) vs 12.
Summary / Conclusion: High-dose therapy and ASCT is an effective treatment strategy for patients with Hodgkin's disease for relapse and refractory Hodgkin's lymphoma for cases that were responsive to pre-transplant chemotherapy. Additionally, using radiotherapy before ASCT has a negative impact on the survival of patients after transplant.

Myelodysplastic syndromes and bone marrow failure syndromes incl. PNH - Biology

RECURRENT SETBP1 MUTATIONS IN ATYPICAL CHRONIC MYELOID LEUKEMIA

S Valletta[1,*] R Piazza[1], S Redaelli[1], N Winkelmann[2], R Spinelli[1], A Pirola[1], L Mologni[1], C Donadoni[1], E Papaemmanuil[3], S Schnittger[4], K Dong-Wook[5], J Boultwood[6], F Rossi[7], G Gaipa[8], G De Martini[1], P Francia di Celle[9], H Jang[10], V Fantin[11], G Bignell[3], V Magistroni[1], T Haferlach[4], E Pogliani[1], P Campbell[3], A Chase[12], W Tapper[12], N Cross[12], C Passerini[1]
[1]Dept Health Sciences, University Milano Bicocca, Monza, Italy, [2]Wessex Regional Genetics Laboratory, Salisbury District Hospital, Salisbury, [3]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [4]Munich Leukemia Laboratory, Munich, Germany, [5]The catholic university of Korea, Seoul, Korea, Republic Of, [6]Leukaemia & Lymphoma Research Molecular Hematology Unit, John Radcliffe Hospital, Oxford, United Kingdom, [7]San Gerardo Hospital, [8]Centro Ricerca Tettamanti, Monza, [9]CeRMS, Azienda Ospedaliera San Giovanni Battista di Torino, Torino, Italy, [10]Agios Pharmaceuticals, [11]Pfizer pharmaceutical, Cambridge, United States, [12]University of Southampton, Salisbury, United Kingdom

Background: Atypical Chronic Myeloid Leukemia (aCML) is a heterogeneous disorder which belongs to the group of myelodysplastic/myeloproliferative (MDS/MPN) syndromes. Since no specific recurrent genomic or karyotypic abnormalities have been identified in aCML, the molecular pathogenesis of this disease has remained elusive and the outcome dismal. This sharply contrasts with the outcome of CML, for which the prognosis has been dramatically improved by the development of imatinib.
Aims: To identify recurrent genetic lesions specifically present in aCML patients.
Methods: Analysis of exome and transcriptome was performed using Illumina Genome Analyzer IIx according to standard procedure for the preparation of the libraries.
Results: By applying whole-exome and transcriptome sequencing on aCML samples, we show for the first time the presence of recurrent somatic mutations of SETBP1 in approximately 25% of aCML cases. Surprisingly, the mutations identified in aCML, albeit somatic, are virtually identical to the germline variants identified in the Schinzel-Giedion syndrome (SGS), which suggests a common link between the two disorders. SGS is a rare genetic disease characterized by midface retraction, a prominent forehead and a higher incidence of tumors, which suggest a critical role for mutated SETBP1 in activating yet unknown pro-oncogenic pathways. Very little is known about the biological function of SETBP1, besides that it binds SET protein, a physiological inhibitor of protein phosphatase 2A (PP2A), protecting it from proteolytic cleavage. Interaction of SETBP1 with the HOXA9 and HOXA10 promoters has been also recently described. By screening the region where aCML and SGS mutations cluster (aa858-871) with the ELM server (http://elm.eu.org/), we identify a virtually perfect degron, containing the consensus binding region (DpSGXXpS/pT) for beta-TrCP1, the substrate recognition subunit of the E3 ubiquitin ligase (aa868-873). This degron lies inside a PEST domain (HSEETIPSDSGIGTDNNSTSDQAEK), a sequence associated with proteins that have a short intracellular half-life, suggesting that this region may be critical for ubiquitin binding and for subsequent protein degradation. This hypothesis was experimentally confirmed using biotinylated, phosphorylated peptides encompassing aa859-879: while the WT peptide could efficiently bind beta-TrCP1, no binding could be detected when peptides carrying mutations D868N, S869G and G870S, were used as a bait. In line with this model, we demonstrated that the mutated SETBP1 is overexpressed at protein but not at mRNA level, protecting SET from proteolytic cleavage and leading to SET accumulation, which causes phosphorylation of PP2A in Y307 (a well-known marker of PP2A inactivation), inhibition of PP2A phosphatase activity and increase in the proliferation rate
Summary / Conclusion: In summary, mutated SETBP1 represents a newly discovered oncogene recurrently present in aCML.

P167

A NEW RECURRENT CHROMOSOMAL ABERRATION OF MYELODYSPLASTIC SYNDROME WITH COMPLEX KARYOTYPE: T(5;17)(Q11~Q13;Q11~Q13)

B Vajen[1], P Greif[2], S Bohlander[2], M Edeling[1], K Thomay[1], D Steinemann[1], B Schlegelberger[1,*] G Göhring[1]
[1]Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover, [2]Department of Internal Medicine III, Ludwig-Maximilians-Universität (LMU) Munich, Munich, Germany

Background: A complex karyotype, detected in approximately 10%>15% of patients with myelodysplastic syndrome (MDS), is associated with a very short median survival and a high risk of transformation into AML. The most frequent chromosome aberrations in complex karyotypes are deletion of 5q (del(5q)) and deletion of 17p (del(17p)) harboring the tumor suppressor gene *TP53*. It is still unclear, how complex karyotypes develop.
Aims: We have identified an unbalanced translocation der(5)t(5;17)(q11~q13;q11~q13) in 20 patients with MDS or secondary AML after MDS. The cohort consists of 9 male and 11 female patients between 1 and 74 years of age (median age 68 years). It was our aim to better understand the underlying pathomechanism of this aberration and we have investigated these cases in greater detail.
Methods: For all patients, we performed cytogenetic banding analysis, fluorescence in-situ hybridization (FISH) and for 7 of the 20 patients multicolor-FISH.
Results: In all patients, a complex aberrant karyotype with a median of 10 aberrations was observed, indicating high chromosomal instability. In 8 patients, a clonal evolution was identified. To identify the breakpoints in 5q and 17q more precisely, array-CGH was performed in 7 of the 20 patients. The breakpoints in 5q and 17p were located between 5p15 and between 17q22, respectively, indicating that no fusion transcript evolved from the translocation. Notably, the breaking points were all very close to the centromeric region and heterochromatin. It is known that an altered methylation of heterochromatic regions plays an important role in tumor development. Therefore, alterations of DNA methylation or histone modifications may be involved in the generation of the unbalanced translocation t(5;17). By performing whole exome sequencing, we aimed to define the mutation spectrum of complex karyotypes with t(5;17). In one patient we were able to analyse bone marrow cells from different time points: complex karyotype at diagnosis – complete remission – relapse with complex karyotype again. As possible candidate genes for driver mutations we identified mutations in the genes *NF1*, *TEL* and *MLL3*. Especially the identification of a mutation in *NF1*, a negative regulator in the *RAS* pathway, is of great significance. *NF1* is encoded on 17q11.2. A possible underlying mechanism for the induction of a complex karyotype could be a downregulation of *NF1* by a mutation of one allele and by a deletion evolved from the unbalanced translocation t(5;17) of the second allele.
Summary / Conclusion: These data provide further evidence that the inactivation of *NF1* seems to play an important role in clonal evolution and leukemic progression.

P168

ABERRANT SPLICING DURING ERYTHROID DIFFERENTIATION IN SF3B1 MUTATED SIDEROBLASTIC ANEMIA

S Conte[1,*] L Vesterlund[2], S Katayama[2,3], M Karimi[1], P Unneberg[4], E Papaemmanuil[5], M Jansson[1], T Mortera-Blanco[1], M Dimitriou[1], B Sander[6], T Skoog[2], P Campbell[5], J Kere[2], E Hellström-Lindberg[1]
[1]Department of Medicine, Center for Hematology and Regenerative Medicine (HERM), Huddinge, [2]Department of Biosciences and Nutrition and Center for Biosciences, Karolinksa Institutet, [3]Science for Life Laboratory, Stockholm, Sweden, [4]Department of Biochemistry and Biophysics, Science for Life Laboratory, Stockholm, Sweden, [5]Cancer Genetics & Genomics, The Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom, [6]Department of Laboratory Medicine, Division of Pathology, Karolinksa University Hospital, Huddinge, Stockholm, Sweden

Background: Refractory anemia with ring sideroblasts (RARS) is a myelodysplastic syndrome (MDS) subgroup distinguished by anemia, erythroid apoptosis and mitochondrial ferritin accumulation in erythroblasts, which fail to mature into erythrocytes. It is poorly understood at which stage and by which mechanism erythroid failure occurs; hence possible targets for therapy are yet to be discovered. Recently, heterozygous mutations in SF3B1, a core component of the spliceosome, were identified in >70% of RARS cases. This discovery may provide clues to how the failure of terminal differentiation is executed, and how the hematopoietic stem cells (HSC) gain their clonal advantage.
Aims: To explore the molecular and cellular mechanisms behind the clonal expansion of immature progenitors and the defective erythroid maturation, we investigated transcriptome characteristics, splice patterns and SF3B1 allelic burden during erythroid differentiation in 11 RARS patients SF3B1 mutated, of which the majority also carried other driver mutations.
Methods: Initially, normal and RARS transcriptomes from two time points during early erythroid differentiation were analyzed and compared, and in a second phase, transcriptome findings were validated using Taqman Low Density Array (TLDA) analysis in an extended cohort.
Results: We observed the activation of genes involved in defense against oxidative stress in $CD34^+$ progenitors. By contrast, erythroblasts were characterized by a failure to up-regulate genes in the autophagy pathway, essential for terminal maturation to erythrocytes, and by a maintained expression over time of regulators of transcription, apoptosis and adhesion, indicating that transcription in general is not hampered by SF3B1 mutation. We also report marked alterations in gene expression during RARS differentiation (FDR <5%) and altered splicing of genes involved in hematopoiesis. The exon usage pattern was very heterogeneous within the RARS population, while showing limited variation in the NBM cohort. Finally, we demonstrated that SF3B1 mutation does not confer a growth disadvantage to the erythroid cells until final maturation to reticulocytes, the stage at which autophagy becomes essential for erythroid differentiation.

Summary / Conclusion: Our study suggests oxidative stress defense, potentially caused by mitochondrial iron accumulation, as an underlying mechanism for the clonal advantage of RARS stem and early progenitor cells and provides novel insights into the erythroid differentiation process. By showing that anemia develops during terminal maturation into erythrocytes, we provide important insights into how the severe anemia in RARS patients may be addressed.

P169

RESISTANCE TO APOPTOSIS IN HIGH-RISK MYELODYSPLASTIC SYNDROME CAN BE OVERCOME BY PRO-APOPTOTIC DRUG TREATMENT USING ABT-737

S Jilg[1,*] J König[1], U Höckendorf[1], J Schauwecker[2], C Huberle[1], C Müller-Thomas[1], B Schmidt[3], R Burgkart[2], H Kolb[1], KGötze[1], C Peschel[1], P Jost[1]
[1]III. Medizinische Klinik für Hämatologie und Onkologie, [2]Klinik für Orthopädie und Sportorthopädie, Klinikum rechts der Isar der Technischen Universität München, [3]Onkologie , Pasing, München, Germany

Background: Increased apoptosis in the bone marrow (BM) is an identifying feature of low/intermediate-risk myelodysplastic syndrome (MDS). Upon disease progression to high-risk MDS/sAML, bone marrow cells acquire a resistance to apoptosis and exhibit increased survival. These findings are consistent with an elevated expression of anti-apoptotic Bcl-2 family proteins relative to their pro-apoptotic family members in MDS cells. The lack of mitochondrial priming for cell death is an identifying feature of leukemic blasts and correlates with resistance to therapy. We therefore hypothesize that restoring the balance between pro- and anti-apoptotic Bcl-2 family members overcomes acquired apoptotic resistance in high-risk MDS, reduces the survival of the malignant clone and decreases the probability of transformation into sAML.
Aims: Pharmacologic inhibition of pro-survival Bcl-2 family members using specific BH3-mimetic compounds (e.g. ABT-737) potently induces apoptosis in hematopoietic cells *in vitro* and in clinical trials for hematologic malignancies including chronic lymphocytic leukemia *in vivo*. Using ABT-737, we want to induce apoptosis specifically in high-risk MDS/sAML and quantify the toxicity on healthy age-matched bone marrow controls.
Methods: We subjected primary bone marrow mononuclear cells (BMMNCs) from patients diagnosed with various MDS risk groups (WHO / WPSS) or sAML in the presence of protective cytokines to ABT-737 treatment. A large cohort of primary BMMNCs of healthy, age-matched donors was used as controls. Induction of apoptosis of cellular subpopulations including $CD34^+$ BMMNCs was measured by flow cytometry. Individual BMMNC samples were cultured with or without protection by stromal cells using the murine cell line EL08-1D2, which protects human hematopoietic $CD34^+$ cells.
Results: ABT-737 specifically killed MDS/sAML cells in a time and dose-dependent manner, whereas $CD34^+$ age-matched healthy control cells remained largely unaffected. Induction of apoptosis in low/intermediate-risk MDS cells was minimal, whereas high risk MDS/sAML underwent apoptosis very efficiently in the presence of ABT-737 (1 uM) (Figure 1; low-risk vs. high-risk (P=0,0042); low risk vs. sAML (P=0,001); intermediate-risk vs high-risk (P=0,001) and intermediate-risk vs. sAML (P<0,0001)). We found a clear correlation between accelerated induction of apoptosis by ABT-737 and increasing risk group of patients in MDS cells. In representative MDS BMMNCs cultured in the presence of stromal cells, induction of apoptosis was similar to BMMNcs without stromal cell support, indicating the potent cell death-inducing potential of ABT-737. FICOLL-purified BMMNC from primary bone marrow aspirate from 11 healthy donors and 2 patients with low-risk, 5 intermediate-risk, 7 high-risk or very high-risk MDS patients and 7 patients with sAML were treated with ABT-737 (1 μM) or vehicle control for 72h. Each circle represents the ratio between viable cells after ABT-737 treatment and viable cells after vehicle treatment. Cells were stained with an anti-CD34 antibody and Annexin V/7-AAD for viability and measured by flow cytometry.
Summary / Conclusion: These results support the notion that pharmacologic intervention with the pro-apoptotic compound ABT-737 potently induces apoptosis in high-risk MDS/sAML bone marrow cells. Therefore, ABT-737 may be a powerful tool to overcome resistance to apoptosis in high-risk MDS and sAML and delay progression into accelerated disease.

DNA METHYLATION PROFILING IN PATIENTS WITH MYELODYSPLASTIC SYNDROME TREATED WITH 5-AZACYTIDINE

M Belickova[1,*] A Jonasova[2], J Vesela[1], E Stara[1], A Mrhalkova[1], J Soukupova[1], J Cermak[1]
[1]Institute of Hematology and Blood Transfusion, [2]General University Hospital, Prague, Czech Republic

Background: Myelodysplasticsyndromes (MDS) are clonal disorders of hematopoietic stem cells characterized by ineffective hematopoiesis. Aberrant DNA methylation in MDS was documented in several studies. Hypermethylation in the promoter regions may reduce the expression of tumor suppressor genes, whereas hypomethylation may lead to an increased expression of oncogenes. The DNA-hypomethylating drug 5-azacytidine is in clinical use for the treatment of MDS.
Aims: To date, correlation between DNA methylation and the clinical response to hypomethylating agents has not been found.Therefore, we investigated whether DNA methylation status might predict response to azacytidine treatment.We also analyzed different methylation levels between patients and controls.
Methods: We assessed methylation status in 31 samples from MDSpatients before 5-azacytidine treatment using the Illumina Infinium HumanMethylation27 BeadChip, which interrogates 27,578 CpG sites, selected predominantly from the promoter regions of 14,000 annotated genes. DNA was isolated from CD34+ cells separated by magnetic bead from bone marrow. DNA was subsequently modified by sodium bisulfite. The nonparametric Mann-Whitney test was used for comparison of β-values between responders and nonresponders and between patients and control group.
Results: We found significant promoter hypermethylation in CD34+ cells in 10 genes with transcription regulator activity (e.g. *GATA4, WT1, EGR3, MAPK15, MYF6* and *PAX3*) *and* 10 genes involved in embryonic organ morphogenesis (e.g.*HOXA2, HOXA5, HOXB6* and *TCF21*) (P<0.001) in MDS patients compared to controls. The contrary, we detected promoter hypomethylation in genes participating in regulation of programmed cell death (*CASP3, IL3, MAPK, PRAME* and *TNFSF14*) and genes are involved in cellular response to stress (e.g. *DDB1, MBD4, MAPK1 and PARP3*) (P<0.005). To determine whether DNA methylation could predict response to 5-azacytidine treatment, we compared DNA methylation at baseline with clinical responses in 31 MDSpatients. Fourteen patients of 31 (45 %) achieved complete remission or partial remission, 10 had stable disease (32%), and 7 showed progression (23%). We found significant differences in methylation status in 45 genes (P<0.05) between groups of responders and nonresponders. The affected genes were functionally annotated with the David database. 20 genes (e.g. *HMP19, NOS, PDCD, 1LG21, VPS53* and *GPR92*) from these were integral to membrane.Furthermore, among the genes with the largest methylation difference between responders and nonresponders belonged *HSD17B4* (0.29 vs 0.75, p <0.001), *HMP19* (0.37 vs 0.77, P<0.01) and *DAAM2* (0.51 vs 0.15, P<0.001).
Summary / Conclusion: Our study shows aberrant promoter methylation in MDS patientscompared to controls and different levels of methylation between groups of patients with unlike response to therapy. We suppose that the success of 5-azacytidine therapy may depend on its transport into cells. Drug must be transported into cells before its incorporation into DNA and subsequently inactivates DNA methyltransferases. Cellular transport across membranes is crucial for uptake of this highly polar hydrophilic molecule. We detected significantly altered levels of methylation in large number of genes for proteins, which are integrated into the membrane in responders vs nonresponders. These changes of methylation level may influence the absorption of the active substance.

Background: Cohesin is a multimeric protein complex, which is involved in

cohesion of sister chromatids, post-replicative DNA repair and transcriptional regulation. Using high-throughput target resequencing and SNP array-based copy number analysis, we found that the core components of cohesin, including STAG2, RAD21, SMC1A and SMC3, were mutated or deleted in a variety of myeloid neoplasms, including AML, CMML, MDS and CML, in a mutually exclusive manner. However, the functional role of cohesin mutations in myeloid leukemogenesis is largely unknown.

Aims: The purpose of this study is to obtain an insight into the functional role of cohesin mutations in myeloid leukemogenesis.

Results: First, we investigated the possible impact of mutations on cohesin function. The expression of several cohesin components was examined in 17 myeloid leukemia cell lines with (N=4) or without (N=13) known cohesin mutations, as well as in the chromatin-bound fractions of 13 cell lines. Although a significant reduction in RAD21 was observed in Kasumi-1 harboring RAD21 p.K330PfsX6, P31FUJ, CMY and MOLM-7 were not accompanied by significant decreases in the corresponding proteins compared with the wild-type cell lines. In contrast, severely reduced expression of one or more cohesin components was observed in KG1 (STAG2) and MOLM-13 (STAG1/2 and RAD21) without any accompanying mutations in the relevant genes. No significant differences in protein expression of the cohesin components in cohesin-mutated and non-mutated cell lines were noted in whole cell lysates. However, several components of the cohesin in chromatin-bound fractions, including SMC1, SMC3, RAD21, and STAG2 were significantly reduced in cell lines with mutated or reduced cohesin components compared with the cell lines with no known cohesin mutations or abnormal cohesin expression. These data indicate that mutation or reduction of one or more cohesin components compromise the formation of integrated cohesin complex on chromatin. Next, we examined the effect of forced expression of wild-type cohesin component on cell proliferation of cohesin-defective cell lines. Forced expression of the wild-type RAD21, but not a truncated RAD21 allele, induced significant growth suppression of the Kasumi-1 cells harboring RAD21 p.K330PfsX6. No growth suppression was observed in K562 and TF1 cells harboring wild-type RAD21 alleles by forced expression of RAD21. We also observed that forced expression of RAD21 or STAG2 induced the growth suppression of MOLM-13 cell lines which showed severely reduced RAD21/STAG2 expression. These results support a leukemogenic role for compromised RAD21 and STAG2 functions. Expression microarray analysis of RAD21- and mock-transduced Kasumi-1 cells revealed that a total of 63 genes reproducibly and significantly showed more than 1.2 fold increase or decrease in gene expression, which was confirmed by quantitative PCR and RNA sequencing. We are now examining the relationship of cohesin localization and transcription by ChIP sequencing analysis using antibody against cohesin components.

Summary / Conclusion: A mutated cohesin component could induce compromised recruitment of the cohesin complex onto chromatin. Defective cohesin function is implicated in leukemic proliferation possibly through deregulated gene expression.

P172

CLINICAL AND BIOLOGICAL RELEVANCE OF SRSF2 MUTATION IN CHRONIC MYELOMONOCYTIC LEUKEMIA AND THEIR COOPERATION WITH ADDITIONAL GENE MUTATIONS IN THE PROGRESSION TO SECONDARY ACUTE MYELOID LEUKEMIA

M Kuo[1,*] Y Huang[2], C Lai[3], P Dunn[1], P Wang[3], J Wu[3], Y Shih[2], T Lin[2], D Liang[4], L Shih[1]

[1]Chang Gung Memorial Hospital and Chang Gung University, [2]Chang Gung University, [3]Chang Gung Memorial Hospital, Taoyuan, [4]Mackay Memorial Hospital, Taipei, Taiwan

Background: Gene mutations involving splicing machinery have recently been described in myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemia (CMML). *SRSF2* mutation is one of the most frequent spliceosome component mutations and occurred exclusively at Pro95. The role of *SRSF2* mutation in the progression of CMML to secondary acute myeloid leukemia (sAML) is not clear.

Aims: We aimed to investigate the clinical relevance of *SRSF2* mutation in CMML and its cooperation with other genetic alterations at initial diagnosis and during sAML progression.

Methods: Bone marrow cells from 103 CMML patients: 34 dysplastic form (CMML-MD) and 69 proliferative form (CMML-MP), were analyzed for *SRSF2* mutation, 36 of them had matched paired CMML/sAML samples available for comparative analysis. The mutation status and relative allelic frequency of *SRSF2* mutants were measured by pyrosequencing. Additional 20 known mutated genes associated with myeloid neoplasms were also analyzed in *SRSF2*-mutated patients by using PCR-based analysis followed by direct sequencing.

Results: Thirty-six (7 CMML-MD and 29 CMML-MP) of 103 patients (35%) with CMML had *SRSF2* mutations (22 P95H, 9 P95L, and 5 P95R, with one of P95H mutated patient combined with P95R102del) at initial diagnosis. CMML-MP patients had a significant higher frequency of *SRSF2* mutation than CMML-MD patients (42.0% vs. 20.6%, P=0.047). There was no correlation between the mutation status of *SRSF2* and age, gender, hemoglobin, platelet count, bone marrowblasts, cytogenetics, WHO subtype, or IPSS-R; whereas *SRSF2* mutation was significantly associated with higher WBC count (P=0.038). Forty-five patients progressed to sAML. *SRSF2* mutation had no impact on risk to sAML progression (P=0.678), overall survival (P=0.899) or sAML-free survival (P=0.840). All of the 36 *SRSF2* mutation-positive patients harbored at least one additional gene mutations at diagnosis (16 *TET2*, 14 *ASXL1,* 13 *RUNX1*, 8 *RAS*, 7 *C-CBL*, 5 *DNMT3A*, 3 *PTPN11*, 3 *IDH2*, 2 *FLT3*-ITD, 2 *FLT3*-TKD, 2 *CEBPa, 1 JAK2*V617F, and *1 EZH2*). Of the 36 paired CMML/sAML samples, 13 were positive for *SRSF2* mutation at both CMML/sAML phases, their relative allelic frequency of *SRSF2* mutants remained unchanged at both phases (40.1±12.4% vs. 41.0±11.2%, P=0.469). One *SRSF2* wild-type patient harboring *TET2, ASXL1* and *JAK2*V617F mutations at diagnosis of CMML acquired *SRSF2* and *RUNX1* mutations but lost *JAK2*V617F mutation at sAML phase. Together, progression to sAML was accompanied by evolution of a new clone in 5 patients (1 *CEBPα,* 1 *NPM1*, 1 *FLT3*-TKD, 1 *SRSF2* and *RUNX1*, and 1 *IDH2* with *FLT3*-ITD and *RUNX1*) during sAML transformation.

Summary / Conclusion: Our results showed that *SRSF2* mutation was frequently detected in CMML and inevitably cooperated with other gene mutations at initial diagnosis. Progression of *SRSF2*-mutated CMML to sAML was frequently accompanied by acquisition of additional genetic alterations.

A CASE OF TWO MONOZYGOTIC TWINS WITH CONCORDANT JUVENILE MYELOMONOCYTIC LEUKEMIA: INSIGHT IN THE COURSE OF THE DISEASE

S Bresolin[1,*] P De Filippi[2], C Cagioni[2], S Cesaro[3], A Di Meglio[4], A Leszl[1], C Frasson[4], C Cugno[5], M Zecca[5], C Danesino[2], G Basso[1], G te Kronnie[1]

[1]Department of Women's and Children's Health, University of Padova, Padova, [2]Department of Molecular Medicine, University of Pavia, Pavia, [3]Pediatric Oncohematology, Azienda Integrata of Verona, [4]Department of Women's and Children's Health , Fondazione Città della Speranza, Padova, [5]Pediatric Oncohematology, Fondazione IRCSS Policlinico San Matteo di Pavia, Pavia, Italy

Background: Juvenile myelomonocytic leukemia (JMML) is a rare early childhood disorder characterized by excessive proliferation of myelomonocytic cells, mutations in the RAS signaling pathway (85% of patients) and monosomy of chromosome 7 (25% of patients). The incidence of leukemia in monozygotic twins is high and this has been related to a common clonal origin of the disease; studies reporting cases of monozygotic twins with JMML have been also reported but they are lacking information concerning the chorionic/amniotic type and the presence of genomic aberrations

Aims: Taking advantages of the newest molecular biology technologies we investigated a pair of monoplacental monozygotic twins with concordant JMML, *PTPN11* mutation and abnormal chromosome 7 in order to better understand the origin of the disease.

Methods: *PTPN11* mutations were analyzed using 454 Roche Next Generation Sequencing and validated by Sanger sequencing in bone marrow (BM), peripheral blood (PB) fibroblast, oral swabs and hair bulbs. In the same samples abnormalities of chromosome 7 were analyzed using FISH, aCGH and STR. To detect mutations and chromosome 7 abnormalities in different BM and PB lineage, sorted cell populations were analyzed. Gene expression profiling (GEP) analysis at diagnosis of both twins was performed using Affymetrix HG U133 Plus 2.0 arrays.

Results: A common *PTPN11* mutation (E76G) was found in both twins in BM and PB. Both twins share the same abnormal chromosome 7. Moreover, STR analysis revealed loss of chromosome 7 material of maternal origin. The germline origin of the disease was excluded as no *PTPN11* mutations or loss of maternal chromosome 7 were detected in fibroblast, hair bulbs, mesenchymal cells and in the PB of patients' parents. *PTPN11* mutations and abnormal chromosome 7 in oral swabs were detected only in the active phase of the disease attributed to infiltration by mutated cells. To show that JMML is a clonal disease that originated from a pluripotent stem cells we screened *PTPN11* mutations and STR markers in different cell lineages of BM and PB. Notably, all cell lineages harbored different percentages of the mutation and the chromosome 7 abnormality.

Furthermore, GEP analysis of the twins identified two signatures: an AML-like signature in twin_01 and non AML-like signature in twin_02. The distinct GEP signatures predicted a different course of disease for the twins. Indeed, twin_01 presented a more aggressive disease, relapsed at 8 months after HSCT and died; whereas twin_02 had a less aggressive disease and is in remission after HSCT.

Summary / Conclusion: We showed that mutation of *PTPN11* and maternal der 7 occurred as two concurrent prenatal events and concordance of the leukemia in both monoplacental twins may be attributed to the high probability of vascular anastomoses within the common placenta. Remarkably, the different GEP signatures at diagnosis predicted the large divergence in the clinical course of the disease in twins sharing most biological features. Further studies are in course to discover possible second hits that may explain the large discordance in the clinical course of disease in the two twins.

P174

FAMILIAL, NON-ZINC FINGER REGION, GATA2 MUTATED MYELODYSPLASTIC SYNDROME; ASSOCIATED WITH SHORTENED TELOMERE LENGTHS, VIRAL WARTS, PROFOUND MONOCYTE/B/NK CELL DEFICIENCY

M Patnaik[1,*] A Jackson[1], R Abraham[2], V Rodriguez[1], M Howard[3], A Hsu[4], S Holland[4]
[1]Hematology, [2]Immunology, [3]Laboratory medicine and Pathology, MAYO CLINIC, Rochester, [4]Clinical Infectious Diseases, NIH, Bethesda, United States

Background: GATA-2 is a transcription factor vital for stem cell homeostasis. Haploinsufficiency of *GATA2* results in familial immunodeficiency and myelodysplastic syndromes (MDS)/ acute myeloid leukemia (AML). Some of the well characterized familial *GATA2* mutated phenotypes include: MonoMAC syndrome (monocytopenia with *Mycobacterium avium* complex infections), DCML (dendritic cell, monocyte, B and NK lymphoid deficiency) and Emberger syndrome (primary lymphedema with or without deafness and risk for AML). The GATA-2 protein contains two highly conserved zinc finger domains mediating protein-DNA and protein-protein interactions. Mutations affecting these regions produce clinical syndromes as described above.
Aims: To characterize the genetic defect in a family that presented with an extensive history of MDS/AML, viral warts, and B/NK lymphoid immunodeficiency.
Methods: The propositus is a 37 year old male who was diagnosed with AML-MRC (myelodysplastic related changes) with trisomy 8. He had an extensive history of HPV driven warts, and reported a family history with multiple maternal relatives with warts, cytopenias and formal diagnoses of MDS/AML (2 maternal aunts, 1 maternal uncle and 1 maternal nephew who died of MDS/AML). He received standard induction chemotherapy with idarubicin and cytarabine and developed profound bone marrow (BM) aplasia. His course was complicated with an *Absidia* invasive fungal infection. He was given 12 granulocyte transfusions along with antifungal therapy and underwent extensive sinus debridement. At D+70 BM was hyoplastic and demonstrated recurrent disease. Due to the lack of a sibling donor, a matched unrelated donor was identified, salvage chemotherapy was administered, and the patient is currently undergoing a reduced intensity conditioning allogeneic stem cell transplant. At day 70, after due IRB approval and patient consent, blood samples, including DNA, were obtained. Tests performed included quantitative and qualitative, B/T/NK lymphoid cell assessment, gene sequencing for *GATA-2* (National Institute of Health), *RUNX-1*, *CEBPA*, *JAK2*, *CXCR4* mutations and flow-FISH for telomere length (TL) [Repeat Diagnostics, Vancouver, Canada]. His 16 year old daughter, who has multiple warts, underwent a BM biopsy that demonstrated MDS with diploid cytogenetics. His 9 year old son, who also has extensive warts and unilateral lymphedema was found to have a markedly hypoplastic BM without dysplasia. Both children had severe monocytopenia and profound monocyte/B/NK lymphoid deficiency.
Results: Gene sequencing identified a heterozygous *GATA2* mutation; c1339A>C, p.S447R. This mutation is located outside the second zinc finger and is predicted to be deleterious. Telomere length assessment revealed reduced TL among the granulocyte (< 1st percentile) and NK cell population (< 10th percentile). Among the lymphocytes, there were two populations of distinct TL. 35% had TL < 1st percentile while 65% had normal TL. These results are confounded by the recent exposure to chemotherapy (70 days) and TL results on the children are awaited. Total number of B cells and NK cells were reduced at 0 and 2% respectively and NK cytotoxicity was low at 1%. Neither the propositus, nor affected family members had MAC infections or defects involving T lymphocytes.
Summary / Conclusion: We describe a *GATA-2* mutation located outside the zinc finger region, associated with familial MDS/AML with high penetrance. Affected members have palmoplantar warts, reduced monocyte, NK and B lymphoid numbers and function. None of the affected patients had MAC infections. Based on preliminary reports there could be an association with shortened telomere lengths, resulting in extended cytopenias from standard chemotherapy and possible bone marrow failure. The final results will be available before presentation at the meeting.

MDS and bone marrow failure syndromes incl. PNH - Biology

EVALUATION OF PRO-SURVIVAL PATHWAYS, INCLUDED AUTOPHAGY, IN HIGH-RISK MDS BONE MARROW AFTER TREATMENT WITH 5-AZACITIDINE TO RESTORE NORMAL HEMATOPOIESIS

A Romano[1,*] C Giallongo[1], P La Cava[1], D Tibullo[1], N Parrinello[1], C Vetro[1], G Palumbo[1], F Di Raimondo[1]
[1]Division of Hematology, Ospedale Ferrarotto, Catania, Italy

Background: Myelodysplastic Syndromes (MDS) are clonal diseases due to an uncoupling of proliferation and differentiation at the level of the hemopoietic stem cell with consequent ineffective hematopoiesis, peripheral cytopenias and variable risk of transformation to acute leukemia. Recently, 5-azacytidine (AZA) has been used to improve clinical outcomes, but despite an initial response obtained within first nine months of treatment, many patients progress to leukaemia and die within two years from the therapy start.
Aims: Evaluation of autophagy as a pro-survival compensatory pathway induced by long-term exposure to AZA in-vivo.
Methods: By reverse-phase protein microarray (RPMA), we analyzed bone marrow mononuclear cells (BMC) from 19 patients affected of high risk MDS, treated for 4 months with 5-azacytidine (median age 71 years, M/F=12/5). Treatment consisted of 4 cycles of 100mg flat dose for 7 days+21 days of wash-out. In 7 cases the sample after 4 cycles of therapy was matched to the sample collected before the therapy start. RPMA was used to quantitatively map 45 cell signaling pathway endpoints, including survival, proliferation, drug resistance, apoptosis, and autophagy. In additional 4 patients, BMC have been exposed to AZA 5uM every 24 hours for three days, then washed and treated with 1-2.5-5uM chloroquine (CQ, an autophagy inhibitor) for 12-24 hours to evaluate cell viability using a luminescence assay, changes in protein expression and cell-cycle by flow cytometry. Dose-response curve was generated for each drug and each condition, including pre-treatment and wash of each investigated drug; combination index was detected using the Chou`s method.
Results: All patients were evaluable for response one month after the 4th cycle. Three patients were refractory, progressing to AML under treatment and 1 was a late responder (documented response after 7cycles). All other patients experienced hematologic improvement. Autophagy was induced independently form the clinical response observed: ATG5, Beclin 1 and LC3B were significantly elevated after treatment (p values respectively <0.0001, 0.0056 and 0.0124), at downstream of mTOR, since mTORSer2448, AktSer473, AktThr308, ERKThr202Tyr204 (and in general proliferation markers) were not affected. After three days of 5uM AZA, CQ inhibited cell growth in a dosage and time-dependent manner, via G1 *cell cycle* arrest. Combination index of AZA and CQ was found to be >1, thereby indicating antagonistic drug interaction, sustained by AZA-mediated autophagy induction.
Summary / Conclusion: Taken together our data confirm the ability of AZA to activate pro-survival pathways after long term exposure.

P176

IDENTIFICATION OF CAMPATH-1 (CD52) AS A DRUG TARGET IN NEOPLASTIC STEM CELLS IN 5Q- PATIENTS WITH MDS OR AML

K Blatt[1,*] H Herrmann[1,2], M Willmann[3], S Cerny-Reiterer[1,2], I Sadovnik[1], S Herndlhofer[1], B Streubel[4], W Rabitsch[5], W Sperr[1,2], T Rülicke[6], P Valent[1,2]
[1]Department of Internal Medicine I, Division of Hematology & Hemostaseology, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [3]Department for Companion Animals and Horses, Clinic for Internal Medicine and Infectious Diseases, University of Veterinary Medicine Vienna, [4]Department of Obstetrics and Gynecology, [5]Department of Internal Medicine I, Bone Marrow Transplantation Unit, Medical University of Vienna, [6]Institute of Laboratory Animal Science, University of Veterinary Medicine Vienna, Vienna, Austria

Background: The anti-CD52 antibody alemtuzumab (MabCampath) induces major responses in a group of patients with myelodysplastic syndromes (MDS). The mechanisms underlying this drug effect remain unknown.
Aims: In the present study, we asked whether CD34+/CD38− neoplastic stem cells (NSC) express CD52 in patients with MDS (n=29) or acute myeloid leukemia (AML, n=62).
Results: As assessed by flow cytometry, CD52 was expressed on NSC in 7/10 patients with MDS and isolated 5q-. In most other patients with MDS, CD52 was weakly expressed or not detectable on NSC. In AML, NSC displayed CD52 in 23/62 patients, namely 4 with complex karyotype including 5q-, one with 5q- and t(1;17;X), 2 with inv(3), 2 with t(8;21), one with inv(16), one with isolated del(13q), 3 with trisomy 8, one with monosomy7, and 8 with normal karyotype. In highly enriched NSC of 5q- patients, qPCR confirmed expression of CD52 mRNA, and clonality of NSC/LSC was confirmed by FISH. Consecutive studies revealed that CD52-expression correlates with EVI1 mRNA-expression-levels in NSC, but not with expression of CD300a mRNA expression. The CD52 antibody alemtuzumab induced complement-dependent lysis of CD34+/CD38−/CD52+ NSC/LSC in all patients examined, but did not induce lysis in CD52− NSC/LSC. Finally, alemtuzumab inhibited AML-formation in NOD-SCID-IL-2Rg$^{-/-}$ (NSG) mice.
Summary / Conclusion: In conclusion, our data show that the target-antigen CD52 is expressed abundantly in NSC/LSC in a group of patients with MDS and AML, including 5q- patients. These observations may have clinical implications and may explain clinical effects seen with alemtuzumab in these patients.

Background: So far , three different types of PNH have been described, based upon the evidence of bone marrow failure (BMF) and hemolysis: a) florid PNH (hemolysis+/BMF-), b) PNH within a BMF syndrome (hemolysis+/BMF+), c) subclinical PNH (hemolysis-/BMF+). In any case, the presence of a PNH clone detected by Flow Cytometry is a prerequisite for PNH diagnosis. In 2010, an Italian archive of FCM-detected PNH clones (HYPERLINK "http://int.clonepnh.com/" http://int.clonepnh.com/) was created on a multi-laboratory basis.
Aims: We had two main goals: a) to provide a large dictionary of Italian PNH clones; b) based upon stringent rules regarding the compilation of records, to obtain an auto-educational effect on participating laboratories.
Methods: Ninety-one laboratories participated in the project. We analyzed data from *Clone*PNH Archive to evaluate: a) how many PNH clones have been identified so far and how they are classifiable on the basis of the Reason for Testing (RFT) reported in clinical request; b) how many clones received more than one FCM determinations; c) among these, which was the initial RFT as well as the fate of the clone. Data refer to analysis registered in *Clone*PNH Archive up to 02/20/2013.
Results: Here, we describe the cellular composition and the clonal evolution of 350 type III (complete defect of GPI-linked proteins) PNH clones identified during the study. Forty-nine of these clones (16.6%) were accompanied by a PNH-II clone (partial defect of GPI-linked proteins). Hemoglobinuria was the most frequent (45.4%) reason for testing (RFT), followed by aplastic anemia (AA, 17.7%), MDS (11.1%), unexplained cytopenia (UC, 8%), hemolytic anemia (5.7%), , BMF (4.6%), atypical venous thrombosis (3.1%), other (8%). Fluorescent Aerolysin (FLAER) was used since 2007, with an increasing % of utilization, from 4% to 60% of cases. CD24 utilization also progressively increased. CD59 was the most used antigen for RBC typing. The most used gating strategies were based upon physical parameters for RBC, CD45 and/or CD33 *vs* side scatter for granulocytes and monocytes. The 350 clones were categorized into 3 classes according to their size, determined as the percent of PNH cells in peripheral granulocytes: 0.01-10% (134 clones, or 38.3%, defined as "small"), 10.1%>70% (74 clones, or 21.1%, defined as "intermediate"), 70.1%>100% (131 clones, or 37.4%, defined as "large"). This distribution was significantly different from that expected on the basis of a random distribution within the three classes (*i.e.* 10%, 60% and 30%): *chi* square was 51 with a p value <0.0001. Ninety-six clones were sequentially studied (with a follow up ranging from 3 to 74 months): Twenty-nine of them (30%) showed a change in category (19 increased and 10 decreased). Just 5 clones jumped from "smallest" to "biggest" category or *vice versa* (three increased ant 2 decreased).
Summary / Conclusion: This is the first multi-laboratory relational database of FCM-detected PNH clones described so far. An auto-educational goal was reached, since general sensitivity increased progressively and reagent choice significantly changed, leading to a stable FCM protocol, consisting of FLAER and CD24 for granulocytes, FLAER and CD14 for monocytes, CD59 for erythrocytes. As regards clonal evolution, the rarity of migration between extreme categories suggests that the belonging to these ones could be sustained by different backgrounds and pressures, as suggested by different association with HLA genotypes.

P178

CYTOGENETIC CHARACTERIZATION OF CD34+ HEMATOPOIETIC PROGENITOR CELLS AND MESENCHYMAL STROMAL CELLS IN MYELODYSPLASTIC SYNDROME (MDS)

Maria Pimenova[1],* Elena Parovichnikova[1], Alina Kokhno[1], Elena Domracheva[2], Tatyana Manakova[3], Ruben Saribekyan[4], Irina Galtseva[4], Valeriy Savchenko[5]
[1]Chemotherapy of hemoblastoses and BMT, [2]Karyology laboratory, [3]Physiology Laboratory, [4]Research Center of Hematology, Moscow, Russian Federation, [5]General director, Research Center of Hematology, Moscow, Russian Federation

Background: Chromosomal abnormalities play an important role in understanding biology of the disease, predicting prognosis and choosing therapeutical approach to MDS patients. It is known that MDS is caused by clonal impairment of hematopoietic stem cell. Moreover dysfunction of bone marrow stroma could also contribute the pathogenesis of the disease.
Aims: To investigate and compare cytogenetic changes in bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic progenitor cells and mesenchymal stromal cells (MSC) in MDS.
Methods: The study comprised 42 patients: 35 MDS (RA-4, RCMD-15, RARS-2, RAEB-11, 5q-syndrome-3), 7 transformed to acute myeloid leukemia (AML) and 7 healthy individuals. Male/female-19/23. Age median was 60 (range 19-77). Cytogenetic analysis was performed by G-banding and FISH.
Results: BM karyotype was abnormal in 21 (50%) out of 42 pts. We confirmed the presence of the same abnormalities in magnetically separated BM and PB CD34+ cells using FISH DNA probes LSI(5q33-q34), LSI(7q31)/CEP7, CEP8, LSI AML1/ETO, CEPX/CEPY, LSI(20q12) (Vysis, USA), EVI t(3;3),inv(3)(3q26) Break (Kreatech Diagnostics, Netherlands). The percentage of abnormal BM cells, BM CD34+ and PB CD34+ cells had no statistical difference (means 62.7%, 69.2% and 70.5% respectively). However, in 3 pts we detected significant difference between clone sizes in BM cells and CD34+ cells. In 2 pts with isolated del(5q) (27% clone) and -21 (25% clone) the percentage of abnormal nuclei in BM cells was much lower than in CD34+ cells, in which it constituted 75% and 85% respectively, and in 1 pt with -7 clone=60% in BM there was only 26% abnormal CD34+ cells. We didn't reveal any cytogenetic abnormality in CD34+ cells from pts with normal BM karyotype. We performed flow cytometry (FACS Canto II, BD) to calculate the percentage of CD34 cells in BM and PB in 8 pts (RCMD-1, RAEB-6, AML-1) using monoclonal antibodies CD34-FITS and CD45-PE (BD, USA). According to ISHAGE protocol 100,000 events were counted. In all pts CD34+ cells showed an abnormal granularity and a large proportion of non-viable cells (mean 6.7%). The mean percentage of BM CD34+ cells was 4.65% in RAEB pts. There were 0.9% of BM CD34+ cells in patient with RCMD and 15% in AML patient. The mean percentage of PB CD34+ cells was 0.4% in RAEB pts. We didn't detect PB CD34+ cells in RCMD and AML pts. MSC karyotype was carried out in 26 pts (22 MDS and 4 AML). We didn't obtain the growth of MSC culture in 38% pts (16 out of 42) due to a low proliferation ability of these cells. MSC karyotype from AML pts was normal. There were structural abnormalities in 2 (9%) out of 22 MDS pts: in one pt with constitutional inv(9)(p13q21) we detected non-clonal translocation-46XY,t(2;22)(p10;q11),inv(9)(p13q21)[1]/46XY,inv(9)(p13q21)[19] and in the other pt–clonal abnormality 46XY,add(2q)[7]/46XY[13]. The 1st pt had only constitutional inv(9) in BM cells and the 2nd one had a complex karyotype. We performed FISH in MSC from 12 pts with cytogenetic abnormalities in BM with appropriate DNA probes, which didn't show any of those abnormalities in MSC. MCS karyotype from all healthy individuals was normal.
Summary / Conclusion: Hematopoietic and mesenchymal progenitor cells in MDS have different cytogenetic changes. CD34+ cells from BM and PB display the same abnormalities as whole population of BM cells. Cytogenetic analysis in MSC revealed structural clonal and non-clonal aberrations in MDS pts, which were different from BM and CD34+ cells abnormalities in these patients. We didn't obtain any cytogenetic abnormality in MSC from AML pts. Our results suggest that the stroma in MDS is not a part of the malignant clone, but it shows genetic instability and may play an important role in the pathogenesis of MDS.

P179

POLYMORPHISMS IN GENES INVOLVED IN DNA REPAIR AND FOLATE PATHWAY SIGNIFICANTLY IMPACT ON SURVIVAL IN LOW-RISK, UNTREATED MYELODYSPLASIA

G Visani[1,*] A Ruzzo[2], F Loscocco[1], F Graziano[1], S Barulli[1], E Canestrari[2], A Volpe[3], D Magro[4], T Ricciardi[1], P Picardi[1], E Giacomini[2], M Rocchi[5], M Magnani[2], A Isidori[1]

[1]AORMN , Hematology and Stem Cell Transplant Center, Pesaro, [2]Department of Biomolecular Sciences, Section of Biochemistry and Molecular Biology, University of Urbino, Urbino, [3]S.G. Moscati Hospital, Hematology and Transplant Center, Avellino, [4]Pugliese-Ciacco Hospital, Hematology, Catanzaro, [5]Insitute of Biomathematics, University of Urbino, Urbino, Italy

Background: the analysis of polymorphisms in DNA repair genes and folate pathway could help to identify patients with possible different prognosis and survival. Single nucleotide polymorphisms (SNPs) and insertion/deletion polymorphisms have been described in association with prevalence, progression-free (PFS) and overall survival (OS) in both solid and hematological cancers. However, up to now, correlations between polymorphisms of genes involved in DNA repair and folate pathways have not been demonstrated in patients with myelodisplastic syndromes (MDS) and low or intermediate-1 IPSS.

Aims: to prospectively evaluate the frequencies of the studied polymorphisms (XRCC1, XRCC3, TS, MTHFR and APE1), not previously evaluated in MDS; to investigate the impact of the studied polymorphisms on survival of patients with low/Int-1 IPSS MDS.

Methods: We prospectively genotyped 54 MDS patients (median age 75 years) with IPSS low (n=23) or intermediate-1 (n=31) treated with best supportive care only. Genomic DNA was isolated from 1ml of peripheral blood by means of commercially available kits. Polymorphisms were determined by PCR-HRM (High Resolution Melting) assay and restriction digests of PCR products. All samples were analyzed for the following polymorphisms: XRCC1 194 (rs1799782 C/T, Arg/Trp) and 399 (rs25487 G/A, Arg/Gln), XRCC3 241 (rs861539 C/T, Thr/Met), TS 5'-UTR (2R/3R and rs183205964 G/C) and 3'-UTR Ins/Del (rs11280056 6bp+/6bp-), MTHFR 677 (rs1801133 C/T, Ala/Val) and 1298 (rs801131 A/C, Gln/Ala), APE1 148 (rs1130409 T/G, Asp/Glu). The characteristics and laboratory features of MDS patients with each polymorphisms were compared using X^2(chi square)-test and Mann-Whitney test.

Results: The frequencies of genotypes of studied gene polymorphism in patients with low/Int-1 risk were as follows: Arg/Arg 91%, Arg/Trp 9% for XRCC1 194; Gln/Gln 11%, Arg/Gln 43%, Arg/Arg 46% for XRCC1 399; Met/Met 41%, Thr/Met 23%, Met/Thr 23%, Thr/Thr 13% for XRCC3 241; 2R/3G, 3C/3G and 3G/3G 50%, 2R/2R, 2R/3C and 3C/3C 50% for TS5'-UTR; Ins/Ins 26%, Ins/Del 50%, Del/Del 24% for TS3'-UTR; Ala/Ala 30%, Ala/Val 46%, Val/Val 24% for MTHFR 677; Ala/Ala 48%, Gln/Ala 52% for MTHFR 1298 and Glu/Glu 13%, Glu/Asp 50%, Asp/Asp 37% for APE1 148. No significant associations between polymorphisms and demographic, clinical or prognostic characteristics were observed. When comparing all the allele and genotype frequencies according to OS, the groups of patients with XRCC1 399 Arg/Arg, TS5'-UTR 2R/3G, 3C/3G, 3G/3G, TS3'-UTR Del/Del and MTHFR 677 Val/Val genotypes showed longer OS (XRCC1 399 Arg/Arg vs non- Arg/Arg P=0.015; TS5'-UTR 2R/3G, 3C/3G, 3G/3G vs 2R/2R, 2R/3C, 3C/3C P=0.03; TS3'-UTR Del/Del vs non-Del/Del P=0.04 and MTHFR 677 Val/Val vs non-Val/Val P<0.001). On the other hand, no statistically significant association between XRCC1 Arg194Trp, XRCC3 Thr241Met, MTHFR Gln1298Ala polymorphisms and OS was found. In multivariate analysis XRCC1 399 Arg/Arg (P=0.007), TS5'-UTR 2R/3G, 3C/3G, 3G/3G (P=0.038), TS3'-UTR Del/Del (P=0.041) and MTHFR 677 Val/Val (P=0.001) genotypes were independent prognostic factors, significantly associated with longer survival.

Summary / Conclusion: BER gene and folate pathway gene polymorphisms may affect the prognosis and survival of patients with low-Int-1 myelodisplastic syndrome treated with best supportive care only. If confirmed in larger series, these polymorphisms could help to identify a subset of patients with short survival, who could benefit from an early treatment with hypometilating agents which are, at present, not indicated for the treatment of patients with MDS and low/Int-1 IPSS.

HIGHER LEVELS OF CIRCULATING MYELOID DERIVED SUPPRESSOR CELLS (MDSC) IN MYELOID DYSPLASTIC SYNDROMES (MDS)

A Kittang[1,2,*] S Kordasti[3], O Bruserud[1,2], G Mufti[4]

[1]Institute of Medicine, University of Bergen, [2]Section for Hematology, Department of Medicine, Haukeland University Hospital, Bergen, Norway, [3]Department of Haematological Medicine, Kings College London, Rayne Institute, [4]Department of Haematological Medicine, Kings College London, London, United Kingdom

Background: MDSC is a group of immature cells that can differentiate into dendritic cells (DC), granulocytes or macrophages. An expansion of these cells has been described in many cancers and in autoimmune diseases. Arginase-1- and ROS-activity, Interleukin (IL)-10 and Transforming Growth Factor (TGF)-β, take part in direct and indirect inhibition of T cells.

Aims: Our hypothesis is that immunosuppressive effects of MDSC participate in MDS immunopathogenesis. Chemokine receptors direct leukocyte migration, and we therefore investigated the levels of CX3CR1, CXCR3 and CXCR4 on MDSC from MDS patients, to see if this expression could be involved in MDSC accumulation in MDS bone marrow.

Methods: We investigated the percentages of MDSC in fresh peripheral blood (PB) from 24 MDS patients and fresh bone marrow (BM) samples from 12 MDS patients from the out-patient clinic at Haukeland University Hospital. 17 of the patients had either RA, RARS or RCMD, 7 patients had MDS with excess of blasts. We also analysed fresh peripheral blood samples from 5 age-matched healthy controls. Flow cytometry of PB and BM was performed after red cell-lysis using the following markers: Live/dead, Lineage (CD3, CD16, CD19, CD20, CD34, CD56, HLA-DR), CD33, CD11b, CD15, CD66b, CD14, IL-10, TGF-beta, CX3CR1, CXCR3 and CXCR4. Internal staining was performed with and without stimulation with IL-6 and IL-1beta.

Results: We found that cells with MDSC phenotype exist in PB of MDS patients in higher percentages than in healthy controls, both when comparing healthy controls (N=5, median 0.7 % (0.4-1.6%) and MDS with less than 5 % blasts (N=17, median 1.75 % (0.3-3.9%) P=0.031), and when comparing the same healthy controls with patients with MDS RAEB-1 and RAEB-2 (N=7, median 2.6 % (2.1-17.9%) P=0.003). There was also a significant difference when comparing MDS RA, RARS, RCMD and RAEB-1 and -2 (P=0.031). We found a significant correlation between MDSC and blasts in RAEB (Pearsons correlation significant at the 0.01 level, R^2 Linear 0.837). There was no correlation between MDSC percentages and bone marrow blast percentages in RA, RARS and RCMD. No correlation was found between subsets of granulocytic and monocytic MDSC and levels of neutrophils or monocytes in blood for neither group. In peripheral blood CX3CR1 was expressed on a higher level on M-MDSC than G-MDSC P=0.08. There was higher expression of CXCR3 on G-MDSCs than M-MDSC (P=0.046), but CXCR4 was higher expressed on M-MDSC than G-MDSC (P=0.011). In bone marrow, levels of G-MDSC were significantly higher than of M-MDSC (N=12, P=0.002), and the same chemokine receptor pattern was observed as in peripheral blood MDSC; CX3CR1 and CXCR4 significantly higher on M-MDSC (N=10, P=0.013and N=9, P=0.007, respectively).

Summary / Conclusion: Circulating MDSCs are increased in peripheral blood of MDS patients, indicating a possible role for these cells in MDS immunopathogenesis. Higher expression of chemokine receptors in subtypes of MDSCs may lead to redistribution of these cells to the bone marrow.

P181

DOWNREGLULATION OF BNIP3 AND NIX, TARGETS OF HIF-1 ALPHA, IN HIGH-RISK MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

M Lazarini[1],* A Duarte[1], J Machado-Neto[1], P de Melo Campos[1], F Pericole[1], F Traina[1], S Saad[1]
[1]Hematology and Hemotherapy Center, University of Campinas, Campinas, Brazil

Background: HIF-1 alpha is a key component of hypoxia-responsive regulatory pathways and is a transcription factor that regulates several signaling pathways involved in cell differentiation, angiogenesis, apoptosis and autophagy. Expression of HIF-1 alpha protein levels has already been correlated with poor overall survival and disease progression in myelodysplatic syndromes (MDS). Among other proteins, BNIP3, NIX and GLUT-1 are targets of HIF-1 alpha. *BNIP3* and *NIX* are two members of the Bcl-2 family of proteins and regulate both apoptotic and autophagic pathways. The glucose transporter GLUT-1 participates in the control of cell energy metabolism and its activation has been related to the energy imbalance found in several malignancies.
Aims: We aimed to characterize the expression of *BNIP3, NIX, GLUT-1* and *HIF-1 alpha* in bone marrow samples from healthy controls and in patients with MDS and AML.
Methods: We studied total bone marrow cells from 24 healthy controls, 47 patients at diagnosis of MDS and 41 patients at diagnosis of AML. MDS patients were grouped in low-risk and high-risk according to WHO (RAUD/RCMD/del5q/=34; RAEB1/RAEB2=13) and IPSS (low/INT1=41; INT2/high=6). *BNIP3*, *NIX*, *GLUT-1,* and *HIF-1 alpha* expression were evaluated by quantitative PCR. Appropriated statistical analysis was performed and the data were showed as median.
Results: *BNIP3* and *NIX* expression were significantly decreased in high-risk MDS and AML patients compared to healthy controls (BNIP3: 5.42 *vs.* 0.67 *vs.* 2.8 and NIX: 1.95 *vs.* 1.03 *vs.* 0.89 for controls, high risk MDS and AML [WHO], respectively; P<0.05). When MDS patients were stratified by IPSS, similar results were found. *HIF-1 alpha* expression trended to decrease in high risk MDS and AML compared to healthy controls, although the differences were not statistically significant (*HIF-1 alpha*: 0.37 *vs.* 0.15 *vs.* 0.24 for controls, high risk MDS and AML [WHO], respectively; *P*>0.05). *GLUT-1* expression was not modulated between normal, MDS and AML samples. Interestingly, a positive correlation was observed between *NIX* and *HIF-1 alpha* expression (P=0.0001; r=0.46). No correlation was observed between *HIF-1 aplha* and *BNIP3* or *GLUT-1* expression.
Summary / Conclusion: We demonstrated that *BNIP3* and *NIX* expression are significantly decreased in bone marrow samples from high-risk MDS and AML patients, and a positive correlation between *NIX* and *HIF-1 alpha*. It is well know that HIF-1 alpha protein levels are controlled by oxygen availability resulting in the regulation of numerous targeting genes. We then provide evidence that *HIF-1 alpha* mRNA levels may be important for the control of *NIX* expression. These data point out to a possible role of HIF-1 alpha, NIX and BNIP3 in MDS pathophysiology.
Supported by FAPESP, CNPq and INCT do Sangue.

EVALUATION OF A HIGH THROUGHPUT MUTATION-SCREENING STRATEGY IN MYELODYSPLASTIC SYNDROME PATIENTS AND ACUTE MYELOID LEUKEMIA USING TARGETED-GENE ENRICHMENT TECHNOLOGY

M Karimi[1],* M Dimitriou[1], C Nilsson[1], M Jansson[1], H Matsson[2], P Unneberg[3], S Lehmann[1], J Kere[2], E Hellstrom-Lindberg[1]
[1]Dept. Medicine Huddinge, [2]Department of Biosciences and Nutrition, [3]Science for Life Laboratory, Karolinska Instutet, Stockholm, Sweden

Background: A number of recurrent mutations are implicated in the disease biology of myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). Clinically, there is a continuum between *de novo*, therapy-related and secondary AML (t/sAML), and MDS of the various risk categories, but the molecular characteristics of these conditions have not been compared.
Aims: By applying targeted sequencing of a selection of candidate genes with relevance for both MDS and AML we hypothesized that we would be able to identify molecular patterns with relevance for the diagnostic and prognostic process.Sequencing data was validated using the Sequenom methodology, which potentially could develop into an inexpensive and quick clinical tool.
Methods: We analyzed 200 MDS and AML patients diagnosed according to the WHO classifications for MDS, MDS/MPN and AML. The cohort included 100 MDS and 100 AML patients and were grouped as follows; 23 RARS/RCMD-RS/RARS-T, 19 lower-risk MDS with del (5q), 19 RAEB-1 / RCMD, 24 RAEB-2, 15 CMML, 25 AML following MDS, 11 AML following MPN, 17 therapy related AML, and 47 *de novo* AML.Diagnostic samples were investigated for mutations in 22 genes using Halogenomics™ targeted-gene enrichment technology followed by high-throughput sequencing using a pooling strategy of 10 samples per pool.
Results: Analysis of sequencing data relieved 223 single nucleotide variations affecting protein sequences. All mutations found by Halogenomics enrichment, as well as 9 hot spot mutations in SF3B1, SRSF2 and U2AF35 genes, were validated in individual patients by the Sequenom™ genotyping system. Sequenom analysis confirmed 100 SNVs, of which 23 were SNPs (according to 1000 Genome) and 77 were defined as mutations. Based on Sequenom data 61/100 (61%) of MDS and 51/100 (51%) of AML samples carried mutations at least in one gene while 22% and 16% showed more than one mutation, respectively. *TET2*, *SRSF2*, *SF3B1*, *U2AF35* and *IDH2* were the most mutated genes while no mutation was detected in 7 genes *ETV6*, *KDM6A*, *KIT*, *MPL*, *NPM1*, *SH2B3*, and *WT1*. The most common mutated genes in the respective subgroups are shown in Table 1. Gene function analysis revealed that gene mutations in MDS patients was mainly in Splicing machinary and Epigenetics factors while in AML patints gene mutations occured more in cell signaling and Oncogenes.
Summary / Conclusion: We conclude that next generation sequencing of candidate genes may help to understand the spectrum of disorders on the boarder between MDS and AML. Moreover, genotyping by Sequenom may, in the future, develop into a rapid and cost-effective method for clinical detection of hot spot mutations in a high troughput manner.

Table 1. Most frequent mutated genes in each subgroup of patients.

Subgroups	No. Patients	Gene 1 (%)	Gene 2 (%)
RARS	23	SF3B1 (61%)	TET2 (17%)
Del 5q	19	TET2 (11%)	SRSF2, ASXL1 (5%)
RAEBI +RCMD	19	IDH1 (21%)	U2AF35 (21%)
RAEBII	24	SRSF2 (21%)	IDH2 (17%)
CMML	15	TET2 (60%)	SRSF2 (40%)
MDS-AML	25	U2AF35 (21%)	TET2 (17%)
MPN-AML	11	ASXL1 (27%)	TP53 (18%)
t-AML	17	SRSF2 (18%)	DNMT3A (18%)
De novo AML	47	DNMT3A (33%)	IDH1, SRSF2 (33%)

IMPACT OF 5Q BREAKPOINTS ON CLINICAL OUTCOMES IN PATIENTS WITH IPSS LOW-/INT-1-RISK MYELODYSPLASTIC SYNDROMES (MDS) AND ISOLATED DEL(5Q) TREATED WITH LENALIDOMIDE IN THE MDS-004 STUDY

G Göhring[1,*] A Giagounidis[2], A List[3], E Hellström-Lindberg[4], M Sekeres[5], G Mufti[6], B Schlegelberger[1], J Morrill[7], C Wu[7], B Skikne[7], P Fenaux[8]
[1]Institute of Cell and Molecular Pathology, Hannover Medical School, Hannover , [2]St Johannes Hospital, Duisburg, Germany, [3]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, United States, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Cleveland Clinic, Cleveland, OH, United States, [6]King's College Hospital, London, United Kingdom, [7]Celgene Corporation, Summit, NJ, United States, [8]Avicenne Hospital, Bobigny, France

Background: Deletions of the long arm of chromosome 5 [del(5q)] are the most frequent abnormalities observed in MDS (Solé F, *et al*. Br J Haematol. 2000;108:346-56). Proximal and distal del(5q) breakpoints can vary considerably. Breakpoints at the proximal and distal extremes of 5q may result in a more aggressive disease phenotype (Jerez A, *et al*. J Clin Oncol. 2012;30:1343-9). The exact clinical impact of affected 5q regions on overall survival (OS), acute myeloid leukemia (AML) progression, and response remain largely undefined.
Aims: This retrospective study analyzed OS, AML progression, and the rate of RBC-transfusion independence (TI) ≥26 weeks according to the 5q breakpoints in lower-risk MDS patients with isolated del(5q) treated with lenalidomide, in an attempt to ascertain if the proximal level of the breakpoints influences OS, AML progression, or the RBC-TI response.
Methods: Of 205 MDS patients with International Prognostic Scoring System (IPSS) Low-/Int-1-risk del(5q) included in a multicenter phase 3 study (MDS-004; Fenaux P, *et al*. Blood. 2011;118:3765-76), 137 had isolated del(5q) with available data on the proximal and distal breakpoints and were included in the current analysis. Fluorescence R banding cytogenetics were used to determine 5q breakpoints by central cytogenetics review. OS, time to AML progression, and rate of RBC-TI ≥ 26 weeks were analyzed according to the most commonly occurring 5q breakpoints in patients who received lenalidomide from study start (n=91); i.e. excluding those who were randomized to placebo.
Results: Overall, the identified 5q breakpoints were q13q34 (6.6%), q14q34 (64.2%), q15q34 (2.2%), q21q34 to q31q34 (26.3%), and q31q35 (0.7%). Clinical outcomes were analyzed according to the most frequent q14q34 breakpoint versus all other 5q breakpoints. Among lenalidomide-treated patients with breakpoints at q14q34, baseline characteristics such as age, hemoglobin and platelet levels, absolute neutrophil counts, and time from diagnosis were similar to those patients with other breakpoints. OS was similar for patients with breakpoints at q14q34 (n=59) versus other positions (n=32) (logrank test P=0.6533); median OS was 3.8 years (95% confidence interval [CI]: 2.5–not evaluable [NE]) and 4.4 years (95% CI: 2.3–NE), respectively. Time to AML progression was comparable for patients with q14q34 versus other breakpoints (logrank test P=0.2662); 5-year rates were 37.3% (95% CI: 23.7–50.9%) and 34.5% (95% CI: 13.6–55.3%), respectively. Results for time to AML progression remained similar when analyzed with death as competing risk (Gray's test P=0.1442). Rates of RBC-TI ≥ 26 weeks were similar across patients with q14q34 versus other breakpoints (P=0.830).
Summary / Conclusion: The 5q breakpoint q14q34 was the most frequent breakpoint among patients with IPSS Low-/Int-1-risk MDS with isolated del(5q), and was not associated with altered probabilities for AML progression and OS, or altered rates for RBC-TI ≥ 26 weeks compared with breakpoints occurring at other positions. These findings suggest that there are unlikely to be any genes involved in the very proximal portions of the isolated deletion 5q chromosome that may influence response, OS, or progression to AML.

P185

PROGNOSTIC IMPACT OF DER(1;7) IN MDS IS DIFFERENT FROM DEL(7Q)

C Ganster[1], C Haferlach[2], P Vandenberghe[3], S Raynaud[4], F Solé[5], N Kröger[6], U Platzbecker[7], D Haase[1], J Schanz[1,*]
[1]Hematology and Oncology, University Medicine of Goettingen, Goettingen, [2]Munich Leukemia Lab (MLL), Munich, Germany, [3]Human Genetics, KU Leuven, Leuven, Belgium, [4]Laboratory of Hematology, University of Nice, Nice, France, [5]Institut de Recerca contra la Leucèmia Josep Carreras, Badalona, Spain, [6]Clinic for Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, [7]Hematology and Oncology, University of Dresden, Dresden, Germany

Background: Der (1;7) (p10;q10) is a rare abnormality in MDS, occurring in less than 1% of patients with primary MDS (Schanz *et al*. JCO 2012). The unbalanced translocation results in a deletion of 7q and a trisomy of 1q. As chromosome 7 is involved in this aberration, der(1;7) was suspected to be associated with an adverse prognosis. However, less is known about the real prognostic impact of der(1;7) in MDS.
Aims: The present study was performed to analyze the prognostic impact of der(1;7) as compared to a partial or total monosomy 7 in a multicentric cohort of patients with MDS.
Methods: In total, 35 patients with der(1;7) were coalesced from 8 European centers and retrospectively analyzed. The patients were dervived from the Munich leukemia Lab (n=20), the University of Leuven (n=5), the University of Nice (n=3), the Institut de Recerca contra la Leucèmia Josep Carreras (n=3), the University of Goettingen (n=2), the University of Hamburg (n=1) and the University of Dresden (n=1). Additionally, 107 patients with del(7q) (n=45) and -7 (n=62), originating from a monosomy 7 database (Schanz *et al*., EHA 2012) were analyzed. Time-to event analyses were performed by the method of Kaplan and Meier.
Results: Among the 142 patients with der(1;7), del(7q) and -7, 129 patients (90.8%) showed a primary MDS. A disease-modifying treatment was applied in 7 (5%) of all patients. In the group of der(1;7), 31 patients (88.6%) showed the abnormality as an isolated aberration and 4 (11.4%) had one additional abnormality. As compared to del(7q)/-7, a significantly lower (P=0.01) mean hemoglobin level was observed (der(1;7): 9.6 g/dl; del(7q)/-7: 10.3 g/dl). Furthermore, the lactate dehydrogenase (LDH) was significantly lower in these patients (251 U/l in der(1;7); 741 U/l in del(7q)/-7, P<0.001). The bone marrow blast count, platelet count and ANC count did not show a significant difference. The median survival was 53.4 months in der(1;7), 23.5 months in del(7q) and 13.8 months in -7 (P<0.01) and the AML-free survival was not reached in der(1;7), 9.6 months in del(7q) and 6.3 months in -7.
Summary / Conclusion: The prognosis of der(1;7) is better as compared to del(7q) and patients with der(1;7) show a very low risk of transformation to AML. Hence, der(1;7)(q10;p10) needs to be prognostically classified independently from the deletion of 7q that results from this unbalanced translocation.

P186

CLINICAL SIGNIFICANCE OF ASXL1 MUTATION IN PATIENTS WITH PRIMARY MYELODYSPLASTIC SYNDROME AND ITS STABILITY DURING DISEASE PROGRESSION

T Chen[1,*] H Hou [1], C Chen[1], W Chou[1,2], J Tang,[1], M Yao[1], S Huang[1], B Ko[1], M Tseng[1], S Wu[1], W Tsay[1], Y Chen[1,2], C Huang[1], Y Lai[1], Y Chiang[1], F Lee[3], M Liu[3], C Liu[3], H Tien[1]
[1]Division of Hematology, Department of Internal Medicine, [2]Departments of Laboratory Medicine, [3]Department of pathology , National Taiwan University Hospital Taipei, Taiwan , Taipei City, Taiwan

Background: Mutations of the additional sex comb-like 1 (*ASXL1*) gene were recently identified in a substantial portion of patients with myelodysplastic syndrome (MDS), but the interaction of this mutation with other genetic alterations and the stability of this mutation during disease progression remain to be determined.
Aims: We correlated the *ASXL1* mutation with clinical characteristics and other genetic alterations in 455 *de novo* MDS patients. Paired samples during disease progression were also analyzed in 108 patients to evaluate the stability of *ASXL1* mutation.
Methods: According to French-American-British (FAB) classificationfour hundred and fifty fiveadult MDS patients with adequate cryopreserved bone marrow cells for study were recruited for gene mutation analyses. The *ASXL1* exon 12 until the stop codon was amplified by 3 pairs of primers and sequenced by another 6 internal primers. Detection of mutations in other genes, including *IDH1/2*, *JAK2*, *MLL*-PTD, *AML1/RUNX1*, *FLT3*-ITD, *WT1*, *NRAS*, *KRAS*, *EZH2*, and *DNMT3A* was performed.
Results: *ASXL1* mutations were identified in 106 (23.3%) of the 455 patients with primary MDS based on the FAB classification and 63 (17.9%) of the 351 patients based on the 2008 WHO classification. *ASXL1* mutation was closely associated with male sex, older age, normal karyotype, chronic myelomonocytic leukemia and refractory anemia with excess blasts. The patients with *ASXL1* mutation had significantly higher incidences of concurrent *AML1/RUNX1* mutation (32.2% *versus*. 7.8%, P<0.001), *EZH2* mutation (23.6% *versus*. 0.9%, P<0.001), *IDH* mutation (11.4% *versus.* 2.3%, P<0.001), *NRAS* mutation (8.6% *versus*. 3.2%, P=0.028), and *JAK2 mutation (4.4% versus*. 0%, P=0.019) than those with wild type *ASXL1*. With a median follow-up of 58.2 months, there was a significant correlation between *ASXL1* mutations and acute leukemia transformation (36.3% *versus.* 17.9%; P<0.001). Patients with *ASXL1* mutation had a significantly poorer overall survival than those without the mutation (median, 18.7 months *versus.* 32.5 months, P<0.001). *ASXL1* mutation was an independent poor prognostic factor in all MDS patients (HR=1.496, CI 95%, 1.040-2.153, P=0.030) and those with normal karyotype (HR=2.217, CI 95%, 1.253-3.925, P=0.006). To investigate the role of *ASXL1* mutation in disease progression, sequential analysis of the gene mutation was performed in 299 samples from 108 patients, including 32 patients with *ASXL1* mutation and 76 patients without the mutation at the beginning. Among the 32 *ASXL1*-mutated patients,two patientslost the original *ASXL1* mutation following transplantation; all of the remaining 30 *ASXL1*-mutated patients retained

the same mutation during follow-ups, including 17 with acute leukemic transformation. Among the 76 *ASXL1*-wild patients who were sequentially studied, only one patient acquired *ASXL1* mutation when the disease progressed to acute myeloid leukemia. Using a more sensitive TA cloning technique, no *ASXL1* mutation could be detected in the initial sample of this patient.
Summary / Conclusion: In conclusion, *ASXL1* mutations were associated with distinct clinical-biologic characteristics and correlated with shorter survival in MDS patients. Further, sequential analysis showed that *ASXL1* mutations were in general stable during disease progression, but may contribute to disease progression in few patients.

P187

A LONGITUDINAL OBSERVATIONAL STUDY ON THE HEALTH-RELATED QUALITY OF LIFE IN IPSS LOW-RISK MDS - IMPACT OF TIME COURSE AND TRANSFUSION NEED

Background: The EuropeanLeukemiaNet has initiated a prospective, multicenter European Registry (EUMDS) for newly diagnosed IPSS low and intermediate-1 MDS. In MDS health-related quality of life (HR-QoL) represents an important parameter in patient reported outcome as well as in individualized therapy planning. Thus, the EQ-5D (European quality group 5 dimensions) descriptive system was used in this registry to evaluate HR-QoL at initial diagnosis and at follow-up visits every six months.
Aims: To describe the time course as well as the impact of blood transfusions and hemoglobin (Hb)-levels on HR-QoL in this cohort of MDS-patients.
Methods: Results from EQ-5D Visual analog scale (VAS) were analyzed. A multiple linear regression model incorporating random effects (allowing both the baseline score and the rate of change over time to vary between patients) was performed. Adjusting factors included in the model are age at diagnosis, sex, WHO-subgroup, country and haemoglobin measured at each follow-up visit. The effect of transfusions was assessed in two ways: First, all patients that received any transfusion during follow-up were compared to all patients who received no transfusions. Second, the transfusion intensity (defined as the average number of units received per month) recorded for the previous six months at each visit was included. Interactions between the trend in VAS over time and the other factors were analysed.
Results: Median age among the first 1000 patients in the registry is 74.2 years (range 18.7-95.3) with 60.3% male patients and a median follow-up of two years. 936 patients with a definable follow-up period were eligible for this analysis. The mean VAS at the first visit was 69 (±20 SD). In both regression models, in the absence of any interacting effects, there was a moderate average decrease in VAS of approximately 0.2 units per month (95% CI: -0.28, -0.15) identified. Analyses of the random effects indicated that the baseline VAS varied between patients as did the rate of decrease over time. Older patients had a lower average VAS score (0.46 lower per life year; [-0.56; - 0.35] 95% CI; P<0.001). There was no evidence of difference in VAS between men and women (-2.23 lower among women; [-4.51; 0.04] 95% CI; P=0.055). VAS varied between the diagnostic groups and varied between countries. VAS was varied by WHO-subtype with RAEB-2 displaying the lowest levels and 5q-syndrome the highest (P=0.045). Marked differences between different countries were also observed (P<0.0001) and there was some evidence that the rate of decrease in VAS over time varied by country. VAS was positively associated with Hb values over time: VAS increased by 1.6 for each 1 g/dL increase in Hb ([1.2; 2.01] 95% CI; P<0.001). These effects were consistent regardless of which of the regression models were examined. Transfused patients had, on average, lower VAS scores (3.06 units lower [-5.52; -0.59] 95% CI; P=0.015) than untransfused patients. In addition, there was evidence that the rate of change in VAS over time was different for transfused and untransfused patients: no significant change over time among untransfused patients (-0.09 units/months; 95%CI: -0.19, 0.01) but a decline of 0.32 units/month (95% CI: -0.41, -0.23) in transfused patients. When transfusion intensity that varies over time is incorporated into the model, higher rates of transfusion are associated with lower VAS scores (-1.64 lower VAS for each additional unit transfused per month, 95% CI: -2.84, -0.44). There was no interaction detected between this effect and the change in VAS over time.
Summary / Conclusion: HR-QoL in MDS is associated with diagnostic subgroups, Hb-values and transfusion need. Analyses of time course reveal a faster decrease in VAS over time in transfused as compared to untransfused patients. Moreover, high rates of transfusions are associated with lower HR-QoL VAS. Prevention of transfusion need might sustain and improve the QoL in MDS patients.

P188

HIGH DOSES OF ELTROMBOPAG ARE WELL-TOLERATED IN CONJUNCTION WITH AZACITIDINE AND THE COMBINATION DEMONSTRATES ENCOURAGING ACTIVITY IN PATIENTS WITH MDS AND AML.

M Dickinson[1,2,*] K Herbert[1], C Sardjono[3], T Le[3], E Link[3], D Zannino[3], S Ruell[4], J Seymour[5,6], M Kenealy[7], H Prince[5,6]
[1]Haematology Department, Peter MacCallum Cancer Centre, East Melbourne, [2]Department of Medicine, University of Melbourne, [3]Biostatistics and Clinical Trials Unit, [4]Clinical Trials Unit, [5]Haematology Department, Peter MacCallum Cancer Centre, [6]Sir Peter MacCallum Department of Oncology, University of Melbourne, [7]Cabrini Medical Centre, Melbourne, Australia

Background: Pre-existing thrombocytopenia in MDS/AML is exacerbated during the initial cycles of azacitidine (AZA) therapy, resulting in bleeding risk and possible platelet transfusion. Eltrombopag is an oral TPO-receptor agonist. *In vitro*, it has anti-proliferative effects on AML blasts. Hence, it may have clinical utility in MDS/AML as a treatment for thrombocytopenia as well as the leukemic process.
Aims: We wished to assess the safety and initial signal of efficacy of the combination of azacitidine and high doses of eltrombopag in MDS/AML.
Methods: This is a phase-II, single arm, dual-centre, open-label study of escalating doses of eltrombopag with AZA. Inclusion required: a diagnosis of relapsed or *de-novo* MDS/CMML/AML with marrow blasts 5-30%; or symptomatic cytopenia; or blasts 31-50% if either ≥65 years *or* previously-treated disease; and platelets ≤150x10^9/L. The primary endpoint was the rate of grade III/IV non-haematological events related to therapy. Secondary endpoints were AE rates, overall response rates, and survival. Eltrombopag 50 mg/day continuously was begun with AZA 75 mg/m^2 d1-5, & 8-9 on a 28d cycle. For patients with platelets ≤100 there was a 14d pre-treatment with eltrombopag monotherapy. Intrapatient dose-escalation of eltrombopag to 100 mg, 200 mg and 300mg fortnightly occurred in those with cycle start platelet counts <75 or nadir ≤50. Eltrombopag was ceased after 6 months but could be restarted for severe thrombocytopenia at investigator discretion.
Results: 17 of a planned 25 patients have been recruited; 6 had received prior therapy for MDS/AML, 11 had baseline marrow blasts ≥10%. Median baseline platelet count was 37.5 (range 17-127). A median of 8 (2-18) cycles of AZA and 5(1-11) cycles of eltrombopag have been delivered.
One patient developed grade-III eltrombopag-related LFT abnormalities (resolved). There were no other grade III/IV AEs attributable to the combination. Thrombocytosis resulting in eltrombopag cessation occurred in 4 patients (at 50, 50, 150 and 200mg), without complications. 10 patients experienced reversible skin yellowing. Activity was seen in 76%: 4CR, 3CR-marrow, 3 HI-P (2 unconfirmed), 1 HI-E (unconfirmed), 2 with >50% blast reduction from >20% (1 also with Hi-P unconfirmed). 2 patients with previously-treated AML progressed at cycle 2 and one with untreated AML progressed at cycle 10. Platelet improvement was seen in 53% (8/15) of patients with baseline platelets <100 at median (range) at 63d (21-106) following commencement of AZA. One patient (7%) had an improvement in platelets following the monotherapy phase.
Summary / Conclusion: A strategy of intra-patient dose escalation of eltrombopag from 50-300mg with AZA has promising response rates, is well-tolerated and has an acceptable rate of AE. However, the 14d 50mg eltrombopag monotherapy pre-phase was insufficient to lead to consistent haematological improvement.

P189

OUTCOMES OF INTERMEDIATE OR HIGH RISK MYELODYSPLASTIC SYNDROMES (MDS) PATIENTS POST AZACITIDINE AND/OR DECITABINE TREATMENT FAILURES WITH SGI-110, A NOVEL SECOND GENERATION HYPOMETHYLATING AGENT (HMA)

C O'Connell[1,*] R Tibes[2], K Walsh[3], D Rizzieri[4], K Yee[5], W Stock[6], H Kantarjian[7], M Savona[8], E Griffiths[9], P Kropf[10], J Issa[10], S Naim[11], Y Hao[11], L Bui[11], G Choy[11], M Azab[11], G Roboz[12]
[1]University of Southern California, USC Keck School of Medicine, Los Angeles, [2]Mayo Clinic Arizona, Scottsdale, [3]The Ohio State University, Columbus, [4]Duke University Medical Center, Durham, United States, [5]Princess Margaret Hospital, Toronto, Canada, [6]University of Chicago Medical Center, Chicago, [7]University of Texas, MD Anderson Cancer Center, Houston, [8]Sarah Cannon Research Institute, Center for Blood Cancers, Nashville, [9]Roswell Park Cancer Institute, Buffalo, [10]Fels Institute, Temple University, Philadelphia, [11]Astex

Pharmaceuticals Inc., Dublin, [12]Weill Cornell Medical College, New York, United States

Background: SGI-110 is second generation HMA formulated as a dinucleotide of decitabine (DAC) and deoxyguanosine delivered as a low volume and pharmaceutically stable subcutaneous injection allowing longer half-life and more extended decitabine exposure than DAC intravenous infusion. As previously reported, the differentiated pharmacokinetic profile offers the potential of improved biological and clinical activity and safety over currently available HMAs (Kantarjain *et al*. ASH, 2012).
Aims: Determine the maximum tolerated dose (MTD), biological effective dose (BED), the overall safety profile and preliminary efficacy of SGI-110 in relapsed/refractory MDS patients.
Methods: We report here the clinical characteristics of MDS patients treated in a randomized Phase 1 Dose Escalation study with two different regimens of SGI-110 (QDx5 or QWx3). Responses were based on the International Working Group 2006 MDS Criteria and adverse events were based on CTCAE v4. Biological activity was assessed by SGI-110 effects on LINE1 methylation in blood.
Results: Fifteen patients with Intermediate-1 (3), Intermediate-2 (5), High Risk (6) MDS and 1 with CMML, median age 74 years (range, 46–82), ECOG PS 0/1/2 in 5/8/2 patients respectively, with a median number of prior regimens of 2 (range, 2–6) were enrolled (9 and 6 patients in the QDx5 and QWx3, respectively). All patients enrolled (100%) had prior treatment with decitabine and/or azacitidine; 87% had prior azacitidine, 53% had prior decitabine, and 40% had both azacitidine and decitabine as prior treatment. Patients were treated with doses ranging from 3-125 mg/m^2. The BED was determined as 60 mg/m^2 QDx5. Responses were observed in 5 patients for an overall response rate of 33% with reported response duration of 28–224 days. Details of each of the 5 responders are shown in Table 1. The median bone marrow blast count at baseline for the responders was 16.5% while the non-responders were 5%. Median LINE1 demethylation in responders showed a decrease by -19.3% compared to -12.0% in non-responders. Marrow CRs were reported in 2 of 8 patients who demonstrated LINE1 demethylation ≥10%. Treatment was well tolerated with the most common reported non-hematological adverse events being injection site pain and diarrhea mostly Grade1, and anticipated hematological adverse events of neutropenia/febrile neutropenia, thrombocytopenia, and anemia. The MTD was determined at 90 mg/m^2 QDx5. Currently the trial is enrolling treatment naïve MDS patients in the Phase 2 Dose Expansion Segment randomized to either 60 or 90 mg/m^2 QDx5. Updated results from the Phase 2 will be presented.
Summary / Conclusion: SGI-110 given as subcutaneous injection was well tolerated and clinical responses were observed in heavily-pretreated MDS patients, particularly High Risk patients, who had received prior treatment with decitabine and/or azacitidine.

Table 1. SGI-110 dose and regimen for MDS patient response outcomes.

Patient # (Risk category)	SGI-110 Dose (mg/m^2)	Response Status	Duration of Response (days)	Prior Treatments
QD x 5				
120 (HR)	18	mCR/HI-E	224	azacitidine, decitabine, lenalidomide/decitabine
188 (HR)	125	mCR	28	azacitidine, lenalidomide, arsenic trioxide/decitabine, hydroxyurea
QW x 3				
108 (HR)	6	HI-E/HI-N	100	azacitidine, decitabine
158 (HR)	90	HI-E	84	azacitidine/entinostat, azacitidine
160 (Int-1)	90	HI-P	126	azacytidine, ezatiostat HCL (TLK-199)

P190

MULTICENTER STUDY EVALUATING THE IMPACT OF HYPOMETHYLATING AGENTS AS BRIDGING THERAPY TO HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MYELODYSPLASTIC SYNDROMES

Y Kim[1,*] J Jang[1], J Lee[2], I Kim[3], J Jang[4], H Kim[5], S Kim[1], Y Min[1]
[1]Internal Medicine, Yonsei University Severance hospital, [2]Internal Medicine, University of Ulsan College of Medicine, [3]Internal Medicine, Seoul National University College of Medicine, [4]Internal Medicine, Sungkyunkwan University School of Medicine, Seoul, [5]Internal Medicine, Chonnam National University Medical School, Jeonnam, Korea, Republic Of

Background: Allogeneic hematopoietic stem cell transplantation (alloHSCT) is the only curative modality for myelodysplastic syndromes (MDS). Recently, treatment paradigm has changed since the introduction of hypomethylating agent (HMA) to treatment of MDS. There is little known about effect of HMA to transplant outcome and appropriate dose and schedule when used as bridging therapy to alloHCT.
Aims: Therefore this retrospective multicenter study aimed to assess the effect of pre-transplant HMA on transplant outcome and aimed to determinate the patient who would benefit from pre-transplant HMA therapy.
Methods: Medical record of 113 patients (male n=69; female n=44) were reviewed. Patients who received HSCT from 2007 to 2010 were enrolled regardless of pre-transplant HMA therapy. Five institutions participated. Primary endpoint event-free survival (EFS) after HSCT. Second endpoint was engraftment after HSCT. Analysis was done by HMA versus non-HMA.
Results: Eighty-five of the 113 patients were treated with HMA before HSCT (51 with Azacitidine (AZA), 30 with Decitabine (DCT) and 4 with both alternatively). Twenty-eight patients received HSCT without HMA bridging. The median age 47 (range 20-69) for HMA group and 42 (range 17-64) for non-HMA group (P=0.035). Distribution of WHO classification group and IPSS score were similar criteria (P=0.230 and P=0.328), For HMA group, median number of HMA administration was 5 cycles (range 1~20). Among HMA treated patients, 21 (18.5 %) achieved CR or marrow CR (mCR) and 4 (3.5 %) achieved PR. For all patients, median EFS was 29±2 months. IPSS score at diagnosis (Low/Intermediate (INT)-1 vs. INT-2/ High) affected OS after HSCT (32±3 vs. 25±4 months, respectively; P=0.020). Pre-transplant HMA didn't affect OS (P=0.771) and there was also no difference between AZA and DEC (P=0.60). However, for patient with high blast count (>5% of bone marrow at diagnosis) pre-transplant HMA therapy had a benefit of 1-yr EFS (16.7 % for non-HMA vs. 67.9 % for HMA, P=0.126) Median time to neutrophil engraftment was 28 (range, 2~380 days) for HMA and 12 (range, 7~18 days) for non-HMA (P=0.031). Median time for platelet engraftment was 35 for HMA group and 19 for non-HMA group (P=0.052). Effect of HMA to GVHD or graft failure was uncertain.
Summary / Conclusion: Benefit of bridging therapy of HMA before HSCT was not definite by this retrospective study. However for a proportion of patients with high leukemic burden, HMA tended to have benefit for post-HSCT EFS. There was considerable delay of engraftment among HMA treated patients. Therefore, pre-HSCT bridging HMA therapy may not be appropriate for all MDS patients. Prospective trial is required to confirm the benefit and effect of HMA bridging therapy to HSCT.

P191

AZACITIDINE PRETREATMENT FOLLOWED BY NON-MYELOABLATIVE STEM CELL TRANSPLATION IN PATIENTS WITH HIGH RISK MYELODYSPLASTIC SYNDROME : PROSPECTIVE, OPEN LABEL, MULTICENTER, PHASE II TRIAL

J Ahn[1,*] H Kim[1], Y Kim[1], Y Min[2], J Kim[2], J Jang[3], C Jung[3], I Kim[4], H Yoon[5], H Lee[6], S Song[7], J Moon[7], H Kim[8], Y Kim[9], J Won[10], J Chung[11], Y Mun[12]

Background: Hypomethylating agents(HMA) are commonly used as " bridging" therapy to facilitate allogeneic stem cell transplanataion (allo-SCT) preventing progression during the period while donor is identified and the patients undergoes pre-transplant screening. However, it is largely unknown whether treatment with HMA before allo-SCT will affect the results of the transplant and no prospective data are available.
Aims: In phase II study, we explored the efficacy and safety of azacitidine in patients with transplant eligible high risk MDS and we analyzed the data to identify the predictor of survival.
Methods: Patients were enrolled from all participating institutions prospectively. Subjects could have an IPSS score of intermediate- 2 (1.5-2.0) or high (≥2.5), the age was < 65-year and performance status was 0-2 without serious comorbid disease. Response was assessed using 2006 IWG MDS response criteria after 4 cycles of therapy.
Results: A total of 30 subjects were enrolled at the 13 centers from Feb. 2008 to Dec, 2010 and 27 patients could be collected clinical data at analysis. Six out of 27 patients were excluded because they were diagnosed as intermediate-1. Among 21 patients, median age was 50 years (range 18-63) and median follow-up was 25.4 months (range, 21.7-52.9). IPSS categories included intermediate-2 (11) and high (10). The overall response rate of azacitidine pretreatment was 62%: 2 CR, 1 PR and 10 hematologic improvement. During azacitidine therapy, three (14.3%) patient showed the disease progression (2: leukemic conversion, 1: died of infection). Fourteen (66.7%) out of 21 patients received planed non-myeloablative SCT (7: sibling, 7: unrelated) and donor was not available in 4 (19%) patient. After transplantation, two (9.5%) patients died as a result of GVHD and colitis, respectively. Disease progression was observed in 8/14 (57%) transplant patients and 6 of them died of disease progression. Five patients were alive at last follow-up. The two-year overall survival and progression free survival was 47.6±10.9% and 32.5±10.8%, respec-

tively. In univariate analysis, the karyotype and WPSS at diagnosis is the only predictable factor for overall survival in intention to treat analysis (P=0.016, 0.030).
Summary / Conclusion: Even though high risk MDS patients received azacitidine pretreatment followed by allo-SCT, the most common cause of treatment failure is the disease progression especially in high risk karyotype. So, more intensive consolidative treatment after transplantation may be considered in high risk patient.

P192

CLINICAL SPECTRUM AND OUTCOMES OF PATIENTS WITH INHERITED BONE MARROW FAILURE SYNDROMES: A MAYO CLINIC SERIES OF 55 PATIENTS

S Kenderian[1],* M Litzow[1], D Gastineau[1], L Letendre[1], V Rodriguez[2], J Gourde[2], S Khan[2], W Hogan[1], R Abraham[3], M Patnaik[1]
[1]Hematology, [2]Pediatric Hematology, [3]Laboratory Medicine and Pathology, MAYO CLINIC, Rochester, Minnesota, United States

Background: Bone marrow failure syndromes (BMFS) are clonal, heterogenous, stem cell disorders, characterized by progressive cytopenias and hypocellular bone marrows. While most cases are acquired, resulting from myelodysplastic syndromes (MDS) and aplastic anemia (AA), there are a spectrum of Inherited BMFS (IBMFS) associated with multi system abnormalities, immunodeficiency and an inherent predisposition for clonal evolution to MDS and acute myeloid leukemia (AML). Early recognition and multi-disciplinary evaluations are critical for optimal outcomes.
Aims: To identify and describe the spectrum of inherited BMFS at our institution, with special focus on demographics, clinical characteristics, treatment strategies and over all outcomes.
Methods: After an approval by the Institutional Review Board, the Mayo Clinic BMFS database (1990-2012) was evaluated to identify all patients with inherited BMFS. Clinical data was retrospectively abstracted and pathological data was reviewed. Information analyzed included; presenting features, genetic aberrations, telomere lengths, presence and magnitude of PNH clone sizes, details on clonal evolution, treatment strategies and overall outcomes.

Table 1. Clinical characteristics, treatment and outcomes of patients with IBMFS.

IBMFS	#	Med Age	Sex (Male)	CE	SCT	Solid tumors	Death	Cause	Other Features
FA	12	13 0-32	5 (42%)	3 (25%)	7 58.3%	Vulvar 25%, BCC 8%, HNSCC 8%, Anal 8%, Cervix 8%	2 (17%)	AML, vulvar Ca	Skeletal abnormalities 30%, CHD 8%, Infertility 8%, Single kidney 8%, Undescended testes 8%
DC	14	16 2-61	8 (57%)	N	4 28.5%	N	3 (21%)	Pul Fibrosis, NRM	Nail 64%, Deafness 14%, Pulmonary fibrosis 21%, Cirrhosis 14%, Esophageal strictures 14%
DBA	12	0 0-2	6 (50%)	1 (8%)	2 16.7%	N	1 (8%)	TRM	Fe overload 100%, Growth retardation 67%, Skeletal abnormalities 25%, FSGS 8%
SDA	3	0 0-1	3 100%	N	N	N	0%		Malabsorption 100%, Growth retardation 100%, Hepatitis 33%
TAR	4	0	2(50%)	N	N	N	0%		Growth retardation 50%
CAMT	5	1	1(20%)	N	2(40%)	N	0%		
Pearson syndrome	1	1	1 (100%)	N	N	N	1 (100%)	Sepsis	CHD, recurrent pancreatitis, ataxia, malabsorption, Fanconi Syndrome
IBMFS NOS	4	20 16-38	1 (25%)	1 (25%)	N	Vulvar ca 25%	1 25%	Vulvar Ca	Polycystic ovaries 25%
Total	**55**		**27 (49%)**	**5 (9%)**			**8 (15%)**		

IBMFS=inherited bone marrow failure syndromes, CE=clonal evolution, SCT=allogeneic stem cell transplantation, FA=Fanconi Anemia, DC=Dyskeratosis Congenital, DBA= Diamond-Blackfan Anemia, SDA=Shwachman-Diamond Anemia, TAR=Thrombocytopenia with Absent Radii, CAMT=Congenital Amegakaryocytic Thrombocytopenia, CDA=Congenital Dyserythropoietic Anemia, NOS=not otherwise specified, BCC=basal cell carcinoma, HNSCC=head and neck squamous cell carcinoma, AML=acute myeloid leukemia, TRM=transplant related mortality, CHD=congenital heart disease, FSGS=focal segmented glomerulosclerosis, NRM = non-relapse mortality

Results: Three hundred and seventy five patients were diagnosed with an IBMFS or Severe AA between 1990 and 2012. Of these, 55 (15%) had an inherited BMFS, with the median age of presentation being 13 years (range, 0-61 years). The specific diagnostic categories included; Fanconi Anemia (FA) in 12 (21.8%), Dyskeratosis Congenita (DC) in 14 (25.4%), Diamond Blackfan Anemia (DBA) in 12 (21.8%), Shwachman Diamond Anemia (SDA) in 3 (5.5%), Thrombocytopenia with Absent Radii (TAR) in 4 (7.3%), Congenital Amegakaryocytic Thrombocytopenia (CAMT) in 5 (9.1%), and Pearson syndrome in 1(1.8%). Four patients (7.3%) had a familial BMFS, without a formal diagnostic categorization [IBMFS, not otherwise specified (nos)]. Twenty-seven (49%) were males. All patients had genetic defects and multi-system abnormalities as outlined in Table 1. While the majority presented during the first decade of life, 16 (29%) patients were diagnosed with an IBMFS in adulthood [5 with FA (31.3%), 7 with DC (43.7%), and 4 with IBMFS-nos (25%)]. Fifteen (27%) patients underwent reduced intensity conditioning (RIC) allogeneic stem cell transplantation (allo-SCT); 7 with FA, 4 with DC, 2 with DBA, and 2 with CAMT. Stem cell sources included; 6 (38 %) matched sibling donors, 7 (47%) matched unrelated donors and 2 (13%) umbilical cord blood units. The 100 day and 5 year, non-relapse mortality rates were 13% and 16% respectively. There was one patient with DC, who in spite of receiving a RIC conditioning, died from progressive pulmonary fibrosis. Five patients (9%) had clonal evolution to MDS or AML. Of these, 3 had FA, one had DBA and one had IBMFS-nos. Cytogenetic alterations at time of evolution included trisomy 8, complex karyotype, 20q deletion, and monosomy 7. Three of these 5 patients underwent allo-SCT, while the other two were transplant ineligible (concomitant metastatic vulvar cancer and active infections). The 5 year overall mortality in the entire cohort of patients with IBMFS was 15%.
Summary / Conclusion: Approximately 30% of IBMFS can present in adulthood, indicating that this is not a disease restricted to the pediatric age group. Early identification, followed by a multidisciplinary diagnostic and therapeutic approach, does result in good outcomes. RIC Allo transplant is associated with low non relapse mortality rates (5 year NRM 16%) and excellent overall and disease free survivals.

P193

IMPROVED FATIGUE AND QUALITY-OF-LIFE IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA DURING TREATMENT WITH ECULIZUMAB: DATA FROM THE GLOBAL PNH REGISTRY

Petra Muus[1],* H Schrezenmeier [2], G Socié[3], J P Maciejewski [4], J Szer[5], RA Brodsky[6], A Urbano-Ispizua[7], M Bessler[8], Y Kanakura [9], W Rosse[10], G Khursigara [11], C L Bedrosian [11], P Hillmen[12]

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, progressive, life-threatening disease characterized by chronic intravascular hemolysis caused by uncontrolled complement activation. PNH can present in all ages; the median age is approximately 34 yrs. Patients have a highly increased risk of thrombosis and mortality with approximately 35% of patients dying within 5 yrs, despite best supportive care. PNH symptoms and sequelae of vascular events decrease patient's quality of life (QOL) with fatigue as one of the most common and burdensome problems. The terminal complement inhibitor eculizumab has been shown to provide a rapid, sustained, and clinically meaningful reduction in intravascular hemolysis and thrombotic events, alleviate common PNH-related symptoms, and improve survival.
Aims: Assessment of changes in patient-reported QOL and fatigue after 6 and 12 months of treatment with eculizumab.
Methods: As of January 2013, 2013 patients were entered into PNH Registry, of whom 144 had started eculizumab treatment on or after entry into the Registry. Completed pretreatment and follow-up study questionnaires were available for 62 patients with a median age of 41 (10-86) yrs. The questionnaires were based on Functional Assessment of Chronic Illness Therapy (FACIT) fatigue evaluations and the European Organization for Research and Treatment of Cancer (EORTC) QOL and symptom assessments. Mean changes from baseline were assessed at 6- and 12-month follow-up intervals. Two-sided paired t-tests were used to assess statistical significance. All patients provided written informed consent prior to enrollment in the registry.
Results: At baseline patients had a median granulocyte PNH clone size of 86.3%, with median LDH level 5× the upper limit of normal. Median time from diagnosis to start of treatment was 4 years. After 6 months of treatment, statistically significant improvements over baseline were reported for FACIT-Fatigue (+6.8, P<0.001) and EORTC assessments of global health/QOL (+12.0, P=0.002), role (+24.0, P<0.001), social (+17.0, P<0.001), and physical functioning (+11.9, P<0.001), fatigue (-14.7, P<0.001), dyspnea (-15.6, P=0.004), pain (-8.8, P=0.019), and nausea/vomiting (-6.3, P=0.029). At 12 months these improvements were maintained, with the majority of assessments showing further improvement, with significant changes over baseline also seen in emotional functioning (+12.9, P=0.003) and insomnia (-16.3, P=0.015). At both 6- and 12-months >60% of patients had a ≥3-point improvement in FACIT-Fatigue score and, with the exception of cognitive functioning, the majority of patients had a ≥5-point improvement in EORTC functioning scores. At least 40% of patients had a ≥10-point improvement in all EORTC functioning scores and symptom assessments of fatigue, pain, and dyspnea at 6 and 12 months with a ≥10-point improvement in insomnia reported for >40% of patients at 12 months.
Summary / Conclusion: PNH patients in the Global Registry on eculizumab

reported a significant improvement in fatigue and other PNH-related symptoms following commencement of eculizumab therapy. These improvements were associated with a significant increase in patient reported global health and QOL. All effects were maintained over the 12 months of assessment. Alleviation of symptoms, such as pain and dyspnea, is consistent with the reduction of hemolysis and maintenance of circulating nitric oxide levels. Improvements in fatigue and QOL are very important additional effects of eculizumab in patients with PNH.

P194

APPLICABILITY OF A REPRODUCIBLE FLOW CYTOMETRY SCORING SYSTEM IN THE DIAGNOSIS OF REFRACTORY CYTOPENIA OF CHILDHOOD

A Aalbers[1,2,*] M van den Heuvel-Eibrink[1], V Haas[3], J. te Marvelde[2], A de Jong[3], M van der Burg[2], M Dworzak[4], H Hasle[5], F Locatelli[6], B De Moerloose[7], M Schmugge-Liner[8], J Stary[9], M Zecca[10], C Zwaan[1], A van de Loosdrecht[11], J van Dongen[2], C Niemeyer[12], V van der Velden[2]

Background: Refractory cytopenia of childhood (RCC), defined as myelodysplasia without an increased blast count, is the most common subtype of childhood myelodysplastic syndrome (MDS). Karyotype is normal in the majority of patients with RCC, and, in contrast to adults with MDS-refractory anemia (RA), about 80% of children have a hypocellular bone marrow. Although morphologic criteria for diagnosing RCC are strictly defined, differentiating RCC from the immune mediated bone marrow failure syndrome aplastic anemia can be challenging. Flow cytometry immunophenotyping has been suggested to be a valuable addition to morphology in the diagnosis of MDS in adults. Recently, a reproducible flow cytometry scoring system has been described as diagnostic tool by Ogata and others in adult low-grade MDS, with a sensitivity of 70% and a specificity of 93% (Ogata *et al*. Haematologica 2009 and Della Porta *et al*. Haematologica 2012).
Aims: We investigated whether the flow cytometry scoring system described by Ogata and others is applicable in childhood MDS, with emphasis on RCC.

Table 1.

	0	1	2	3	4	Cases positive (%)
Children						
RCC	29	14	3	1	0	4 of 47 (8.5)
RAEB	2	0	3	3	2	8 of 10 (80)
Cytopenic controls						
FA/ITP/TEC	2	3	0	0	0	0 of 5 (0)
(v)SAA	3	0	0	0	0	0 of 3 (0)
Adults						
Low-grade MDS	1	0	5	1	1	7 of 8 (88)
Cytopenic controls	20	6	2	0	0	2 of 28 (7.1)
Healthy controls	9	0	0	0	0	0 of 9 (0)

Methods: Bone marrow samples, obtained from 82 previously untreated primary RCC patients, who were included in the prospective studies EWOG-MDS 2006 and EWOG-MDS RC06 and diagnosed between June 2005 and December 2011, were analyzed by flow cytometry. Diagnosis of RCC was based on WHO criteria for pediatric MDS and confirmed by central review of bone marrow morphology and histology. Pediatric MDS-RAEB or RAEB-t patients, low-grade adult MDS patients, healthy individuals, and cytopenic non-MDS adult and pediatric patients were used as controls. Samples were evaluated based on the published criteria and cut-offs: CD34+ myeloid blast cells (parameter 1) ≥2%, CD34+ B-cell progenitors within CD34+ blast cells (parameter 2) ≤5%, lymphocyte/myeloid blast cell CD45 MFI ratio (parameter 3) ≤4 or ≥7.5, granulocyte/lymphocyte SSC peak channel ratio (parameter 4) ≤6. Patients scored 1 point for each fulfilled criteria; patients scoring 2 or more points were considered likely to have MDS.
Results: The median age of included RCC patients was 10.5 years (range: 1-18 years). Bone marrow was hypocellular in 81% of patients; cytogenetic analysis was normal in 76% of patients, monosomy 7 was present in 6%, and other cytogenetic aberrations in 6%. In 35 of 82 patients (43%), insufficient blast cells and/or granulocytes were present for reliable analysis of all four parameters. Of the patients who could be evaluated completely, 4 of 47 patients (8.5%) scored ≥2 points, and were thus likely to have MDS according to the previously published criteria. The patients who scored positive were slightly older than the total RCC cohort (median age at diagnosis: 13 years); 2 patients carried a monosomy7, and in 2 patients no cytogenetic result was obtained due to insufficient metaphases. Results obtained in evaluable RCC patients and controls are summarized in Table 1.
Summary / Conclusion: The scoring system proposed by Ogata and others is not usefully applicable in RCC due to a limited number of patients that can be evaluated for all four parameters, and due to a low sensitivity in those patients that can be evaluated. To evaluate whether other immunophenotypic abnormalities are present and might aid in diagnosing RCC, more detailed analyses of myeloid maturation patterns are currently underway.

P195

IMPROVED PREDICTIVE PROGNOSTIC POWER OF REVISED-IPSS (IPSS-R) IN A SERIES OF 301 PATIENTS WITH MYELODYSPLASTIC SYNDROME FROM A SINGLE CENTER.

H Pomares[1,*] M Arnan[2], E Alonso[3], J Grau[4], V Navarro-Perez[5], L Abenoza[2], I Sánchez-Ortega[2], A de Sevilla[2], R Duarte[6]
[1]Hematology Department, Institut Català d'Oncologia. Hospital Duran i Reynals., [2]Hematology Department, Institut Català d'Oncologia. Hospital Duran i Reynals, [3]Patology Department, Hospital Universitari de Bellvitge, L'Hospitalet, [4]Institut Català d'Oncologia. Institut Josep Carreras. Hospital Germans Trias i Pujol, Badalona, [5]Clinical Research Unit, Institut Català d'Oncologia. Hospital Duran i Reynals, [6]Hematology Department, Institut Català d'Oncologia. L'Hospitalet, L'Hospitalet, Spain

Background: Background: The International Prognostic Scoring System (IPSS) (Greenberg *et al*, 1997) has recently been revised (IPSS-R) (Greenberg *et al*, 2012) in order to better define the prognostic impact on overall survival (OS) and risk of transformation to acute leukemia (PFS) in patients diagnosed with MDS. The variables considered are the same but include five cytogenetic categories (Schanz *et al*, JCO,2011), new cut off values for cytopenias and bone marrow blasts and different weighing of these parameters.
Aims: Aims: The purpose of this study was to validate the prognostic value of IPSS-R respect to IPSS, in a series of 682 patients with MDS.
Methods: Material and Methods: Between 1987 and 2012, 682 patients with MDS were identified in our database. Among the 682 MDS patients registered, cytogenetic analysis at diagnosis was available in 301 patients (47%). We evaluated the prognostic power of IPSS-R respect to IPSS by Harrell's C and Somers' D statistics, analyzing as endpoints overall survival (OS) and leukemia-free survival (LFS).

Table 1.

		IPSS-R					
		Very Low	Low	Intermediate	High	Very High	TOTAL
IPSS	Low	83	73	3	0	0	159
	Intermediate-1	2	63	36	7	0	108
	Intermediate-2	0	3	10	10	5	28
	High	0	0	0	1	5	6
	TOTAL	85	139	49	18	10	301

Results: Median age at diagnosis was 71 years (range 29-101). 209 (69%) were male. WHO diagnosis was: 1% CRDU, 7% RA, 35% RCMD, 20% RAEB-1, 10% RAEB-2, 25% CMML, the remaining 2% were MDS-U and isolated 5q deletion. Median follow up was 46.8 months (1.2-213.84). Classification of the 301 patients by IPSS versus IPSS-R is shown in the table. In this comparative classification, IPSS-R refined the MDS in five prognostic risk groups. Patients with low-risk IPSS remained on groups of very low (52%) and low risk (46%) of IPSS-R, while all high risk IPSS spread between high (16%) and very high risk (84%). However, those classified in Int-1 and Int-2 IPSS categories are reclassified in the IPSS-R in very low (2% / 0%), low (58% / 10%), intermediate (34% / 36%), high (6% / 36%) and very high risk (0/36%) respectively. Kendall's tau was 0.68 showing a good correlation between IPSS-R and IPSS. The 71% (5/7) of patients with IPSS INT-1 who were reclassified as high risk in the IPSS-R had an OS ≤ 30 months, 43% progressed to acute leukemia and 86% of them were transfusion-dependent. OS from 66% (2/3) of IPSS INT-2 group patients who were reclassified as low risk in IPSS-R index was about 60 months, the other patient died for a cause not related with MDS. OS and LFS were estimated using the Kaplan-Meier method. Both prognostic scores systems allowed the identification of curves with statistically significant differences

among the different risk categories (All P<0.001). Harrel's C and Somers' D statistics analysis demonstrated that IPSS-R exhibit a better predictive power and discriminated prognostic risk more effectively than IPSS (C= 0.656 vs 0.624; D=0.312 vs 0.247).
Summary / Conclusion: Conclusion: In our series, the IPSS-R score demonstrated a strong prognostic value for OS and LFS and a greater prognostic power compared to IPSS. As the decisions on therapy are based on this initial prognostic risk assessment, the improvement in the definition of risk categories will directly impact on therapeutic approach.

P196

PREDICTIVE ROLE OF WT1 AND RPS14 EXPRESSION IN PATIENTS AFFECTED BY MYELODYSPLASTIC SYNDROMES RECEIVING AZACITIDINE

S Galimberti[1],* M Rocco[1], T Mingrone[1], S Grassi[1], E Ciabatti[1], A Azzarà[1], M Petrini[1]
[1]Clinical and Experimental Medicine - Hematology, University of Pisa, Pisa, Italy

Background: Demetylating agents, including azacitidine, represent a valid therapeutic approach for patients affected by intermediate-2/high risk myelodysplastic syndromes (MDS). Different groups previously reported that WT1 expression levels at diagnosis and during follow-up could significantly condition the prognosis of high-risk MDS patients. Moreover, in the recent years, many efforts have been spent in order to understand the pathogenesis of the 5q- syndrome; low levels of RPS14 were previously reported also in MDS intermediate-1 patients without 5q- aberration, thus supporting the hypothesis that the defective ribosomal biogenesis could represent a more general pathogenetic mechanism.
Aims: 1) to evaluate the WT1 expression levels at diagnosis and during follow-up of high-risk MDS patients treated by azacitidine; 2) to evaluate the RPS14 expression at diagnosis and its modulation during demethylating therapy; 3) to correlate these molecular findings with clinical outcome (quality of response, PFS, OS).
Methods: WT1 and RPS14 mRNA levels have been measured by quantitative real-time PCR on bone marrow from 33 high-risk MDS patients at diagnosis, and then after 8, 12, 16, and 24 weeks of azacitidine treatment. Bone marrow samples from 8 healthy donors (patients who underwent femur surgery) were used as controls; the stratification in 2 categories (low and high) was defined according to the median value measured in the healthy donors. Patients' characteristics (age, sex, IPSS, WPSS, blast count) did not differ between cases with high or low RPS14 and WT1 levels. At the start of treatment, WPSS was high or very high in 77% of cases and 49% of patients were transfusion-dependent. When mRNA expression was monitored during the follow-up, increases ≥2.5 folds or decreases ≥0.5 folds were considered as significant.
Results: For the entire series, 2-year overall survival (OS) was 63,2% and 2-year leukemia-free-survival (LFS) 53,7%. In univariate analysis, LFS was significantly affected by the quality of response after 24 weeks (P=0.001) and by the persistence of erythroid transfusion dependence at 24 weeks (P=0.03). OS was significantly affected by quality of response at 24 weeks of treatment (P=0.001) and by the erythroid transfusion dependence at 24 weeks (P=0.002). For patients with low RPS14 levels, 2-year LFS was significantly shorter (39% for cases with low RPS14 versus 100%; P=0.018). Also the OS appeared negatively affected by low RPS14 levels (2-year OS of 51% for cases with low RPS14 expression versus 100% for cases with high levels), but without statistical significance (P=0.08). At diagnosis, WT1 was over-expressed in 63% of cases; its quantitative expression before treatment did not significantly influence the quality of response or the long-term outcome. After 16 weeks of therapy, 49% of cases showed a partial or complete response, and only 18% did not respond at all. At that time-point, WT1 was reduced in the 74% of cases (percentage comparable to that of responding cases), with a significant impact on the 2-year PFS: indeed, 56% of patients with WT1 decreased levels remained progression-free versus 21% of cases with stable/increased WT1 levels. On the contrary, 66% of cases had stable, 21% decreased, and 13% increased RPS14 levels. RPS14 levels during the follow-up did not correlate with clinical response or outcome, predicting the disease status in less than half of patients.
Summary / Conclusion: This study shows that RPS14 and WT1 would be useful molecular markers in the management of high-risk MDS patients receiving azacitidine. Nevertheless, their role could be different in the different phases of the disease: RPS14 could further stratify patients at diagnosis, whereas WT1 would be more useful during the follow-up. On this basis, a patient-tailored approach could be designed: 1) cases with low RPS14 expression at diagnosis or with increasing WT1 levels during treatment could be probably treated for longer periods or, when possible, considered for alternative treatments (allogeneic transplantation, lenalidomide).

P197

HIGH LEVELS OF CEREBLON MESSENGER RNA ARE THE CHARACTERISTIC FEATURE OF LOWER RISK MYELODYSPLASTIC SYNDROMES WITH 5Q DELETION AND ARE CONNECTED WITH THE EFFICACY OF LENALIDOMIDE

O Fuchs[1],* J Polak[1], M Vostry[1], A Kostecka[1], R Neuwirtova[2], M Siskova[2], M Caniga[3], D Sponerova[3], J Cermak[3], J Brezinova[4], K Michalova[5], A Jonasova[2]
[1]Department of Molecular Genetics, Institute of Hematology and Blood Transfusion, [2]Department of Hematology, General University Hospital, [3]Clinical Department, [4]Center of Oncocytogenetics, Institute of Hematology and Blood Transfusion, [5]Center of Oncocytogenetics, General University Hospital, Prague2, Czech Republic

Background: Cereblon (CRBN) was named according to its putative role in cerebral development, especially in memory and learning. CRBN forms an E3 ubiquitin ligase complex with damaged DNA binding protein 1 (DDB1), cullin-4 (CUL4) and regulator of cullin 1 (ROC1). This complex regulates DNA repair, DNA replication and transcription. CRBN is a primary target of thalidomide teratogenicity (Ito *et al*., *Science* 2010; 327:1345-1350). The binding of immunomodulatory drugs (IMiDs), including lenalidomide, to CRBN is associated with cytotoxicity of IMiDs and is used to treat multiple myeloma, myelodysplastic syndromes (MDS) and lymphomas. Down-regulation of the *CRBN* expression is associated with the development of marked IMiDs resistance in human multiple myeloma cells (Zhu *et al*., *Blood* 2011; 118: 4771-4779; Lopez Girona *et al*., *Leukemia* 2012; 26: 2326-2335). Therefore, the *CRBN* expression is required for the antimyeloma activity of IMiDs.
Aims: To gain insight into the role of CRBN in lower risk MDS with 5q deletion or with normal chromosome 5 and into the mechanisms of lenalidomide action, we studied the *CRBN* expression in these two groups of lower risk MDS patients and in healthy controls.
Methods: Informed consent was obtained from all patients and healthy controls. Mononuclear cells were isolated from bone marrow [19 MDS patients with 5q- syndrome, 28 patients with low-risk MDS with normal chromosome 5 (non5q-) and 15 healthy controls] and from peripheral blood [23 MDS patients with 5q- syndrome, 19 non5q-patients and 11 healthy controls] by Ficoll-Paque PLUS gradient separation, washed with phosphate-buffered saline and rest red cells were lysed. Total RNA was isolated using RNA isolation solvent and complementary DNA was synthesized from total RNA using SuperScript II reverse transcriptase. Relative levels of the CRBN mRNA were determined by Taq-Man-based quantitative real-time PCR and by calculation to the level of housekeeping glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA. The experiments were performed in duplicate. Evaluation of 2^{-ddCt} indicates the fold change in gene expression relative to the control.
Results: The median of CRBN mRNA levels was the highest (3.6) in total RNA isolated from peripheral blood mononuclear cells of lower risk myelodysplastic syndromes with 5q deletion, the lower (2.2) in non5q- MDS and the lowest (1.0) in healthy controls. The similar results were obtained in bone marrow blood mononuclear cells (medians 3.2 in 5q- syndrome, 2.2 in non5q- and 1.2 in healthy controls). The differences between all groups were statistically significant (P<0.05, Mann-Whitney test). We analysed CRBN mRNA levels before and in the course of the treatment of 5q- syndrome with lenalidomide. High level of CRBN mRNA before and during the treatment correlated with sustained response to lenalidomide. In one 5q- syndrome patient who relapsed after the discontinuation of successful treatment the level of CRBN mRNA sharply decreased. This patient did not respond to the second course of lenalidomide and progressed to RAEB II.
Summary / Conclusion: Low risk MDS patients with 5q deletion have the highest levels of CRBN mRNA in comparison to lower risk MDS with normal chromosome 5 or healthy controls. High levels of CRBN mRNA in 5q- syndrome are necessary for the efficacy of treatment by lenalidomide. Great decrease of CRBN levels during the treatment by lenalidomide is connected with the absence of response and the disease progression.

ECULIZUMAB PROTECTS AGAINST TE AND PROLONGS SURVIVAL IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: AN INTERNATIONAL PNH REGISTRY STUDY

G Socie[1],* H Schrezenmeier[2], P Muus[3], J Szer[4], A Urbano-Ispizua[5], J P Maciejewski[6], R Brodsky[7], M Bessler[8], Y Kanakura[9], W Rosse[10], G Khursigara[11], C L Bedrosian[11], P Hillmen[12]
[1]Department of Hematology/Transplantation, Hôpital Saint-Louis and Institut National de la Santé et de la Recherche Médicale (INSERM), Paris, France, [2]Institute of Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service and Institute of Transfusion Medicine, University of Ulm, Ulm, Germany, [3]Radboud University Nijmegen Medical Centre, Nijmegen , Netherlands, [4]Clinical Haematology & Bone Marrow Transplant Service, Royal Melbourne, Hospital, Parkville, Australia, [5]Hospital Clinic Barcelona, University of Barcelona, José Carreras Institute of Research, Barcelona, Spain, [6]Taussig Cancer Center, Cleveland Clinic, Cleveland, [7]Johns Hopkins University School of Medicine, Baltimore, [8]Department of Hematology,

University of Pennsylvania School of Medicine, The Children's Hospital of Philadelphia, Philadelphia, United States, [9]Osaka University Graduate School of Medicine, Osaka, Japan, [10]Duke University Medical Center, Durham, [11]Alexion Pharmaceuticals, Inc., Cheshire, United States, [12]Department of Haematology, St James' University Hospital, Leeds, United Kingdom

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a chronic and life-threatening hematopoietic stem-cell disorder characterized by uncontrolled complement-mediated hemolysis. Thromboembolism (TE) is one of the leading causes of mortality in PNH, in large part due to chronic hemolysis and platelet hyperactivation. Eculizumab, a monoclonal antibody that inhibits terminal complement activation, has been shown in clinical trials to reduce hemolysis and the incidence of TE.
Aims: To assess characteristics associated with TE and mortality and the effectiveness of eculizumab in reducing the occurrence of these outcomes in PNH patients enrolled in the International PNH Registry.
Methods: Patients are eligible for the Registry if they have a detectable PNH clone, regardless of disease severity or treatment status. The cumulative incidence of TE was determined using competing risks (to account for bone marrow transplantation [BMT] and death), while Kaplan-Meier methods were used for the cumulative incidence of mortality. Characteristics associated with TE and mortality were explored using a Cox proportional hazards model with stepwise selection. Variables examined included: demographics, medical history, symptoms, Karnofsky performance score, granulocyte clone size, lactate dehydrogenase (LDH), red blood cell (RBC) transfusions in the 6 months prior to enrollment, anticoagulant use, BMT (for mortality model), and use of eculizumab during follow-up as a time-varying covariate.
Results: As of June 30, 2011, 1047 patients were evaluable: mean age 45 years, 51% were female. Anticoagulants (heparin/warfarin) were used by 28% of patients and eculizumab was used by 51% during follow-up (18% used both). During a mean follow-up of 22.5 months, there were 16 patients with TE and 51 deaths. Patients treated with eculizumab during follow-up had a cumulative incidence of TE at 2 years of 1.35%, while those not treated with eculizumab had TE incidence of 2.61% at 2 years. In the multivariate Cox model, the greatest associations with TE were recent RBC transfusion (adjusted hazard ratio [HR]=8.42, 95% CI 2.38-29.79), history of impaired hepatic function (HR=5.22, 95% CI 1.17-23.34), and headache (HR=2.72, 95% CI 0.98-7.51). While controlling for these variables, eculizumab had a protective effect (HR=0.52, 95% CI=0.18-1.51). The cumulative incidence of mortality in eculizumab-treated patients was 4.21% at 2 years, while in untreated patients it was 7.01%. The top 5 reported causes of death (accounting for 68% of cases) were aplastic anemia, cardiovascular disease, PNH, BMT, and AML. In the multivariate Cox model of mortality, the greatest associations were age 60+ years (HR=6.32, 95% CI 2.35-17.00), BMT (HR=5.43, 95% CI 2.06-14.32), and Karnofsky score <80 (HR=2.47, 95% CI 1.24-4.92). While controlling for these variables, eculizumab had a protective effect (HR=0.40, 95% CI=0.21-0.77).
Summary / Conclusion: This analysis of a large international cohort of 'real world' PNH patients receiving a variety of treatments (or no treatment) showed that eculizumab is associated with a reduced risk of TE and mortality, consistent with prior research. Recent RBC transfusion, a surrogate marker for hemolysis, was associated with increased risk of TE. As might be expected, older age, lower performance status, and BMT were associated with mortality. These data are limited due to small number of TE and mortality outcomes and should be interpreted in the context of a contemporary cohort of PNH patients who may or may not be treated (with either eculizumab and/or anticoagulation).

P199

MORTALITY BURDEN OF TRANSFUSION DEPENDENCY AND IRON OVERLOAD IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES.

M Arnan[1,*] H Pomares[2], L Esteban[3], E Alonso[4], L Pareja[5], I Sánchez-Ortega[6], A Fernández de Sevilla[7], J Ribes[8], R Duarte[1]
[1]Hematology Department, Institut Català d'Oncologia, [2]Hematology Department, Institut Català d'Oncology. Hospital Duran i Reynals, [3]Catalan Registry of Cancer., Institut Català d'Oncologia., [4]PAtology Department, Hospital Universitari de Bellvitge, [5]Catalan Registry of Cancer, Institut Català d'Oncologia, [6]Hematology Department, Institut Català d'Oncologia. Hospital Duran i Reynals, [7]Hematology Department, Institut Catlà d'Oncologia. Hospital Duran i Reynals, [8]Catalan Registry of Cancer, Institut Catlà d'Oncologia, L'Hospitalet, Spain

Background: Transfusion dependency (TD) is associated with iron overload (IO) and a decreased probability of overall survival (OS) in patients with MDS (*Malcovati L et al. J Clin Oncol 2007 25:3505*).
Aims: The purpose of this study was to validate the prognostic value of TD and IO and their impact on life expectancy in our single-centre series of 635 MDS patients.
Results: Median age at diagnosis 71y (27-101); 411 male; median follow-up 60 months (0-228). Karyotype available at diagnosis in 263 patients (41%) in whom IPSS-R could be assessed (26% very low risk, 47% low, 17% intermediate, 7% high and 3% very high. 31% were TD, as defined by the WPSS, requiring a median of 4 packed red blood cell (PRBC) monthly transfusions. Our results confirm that patient age, gender, FAB and WHO subtype, karyotype risk according to IPSS and IPSS-R, percentage of BM blasts at diagnosis, number of cytopenias, IPSS, IPSS-R, WPSS, IO at diagnosis and TD were all associated with overall survival (OS) in this series (P< 0.001 in all cases). Furthermore, TD and the intensity of TD translated into a strong reduction of the life expectancy of TD-MDS cases compared to non-TD counterparts. A significant higher standardized mortality ratio (SMR) had been shown in our series in comparison with the mortality of the general Catalan population, TD vs Non TD patients (Table 1); SMR 5.3 vs 2.6 in men, and 5.7 vs 2.2 in women. Data also seen with the intensity of transfusion >2 PRBC vs ≤2 PRBC monthly 6.7 vs 3.8 and >3 PRBC vs ≤3 PRBC; 9.1 vs 4 and IO as serum ferritin ≥ 1000 ng/ml vs <1000 ng/mL SMR was 6.3 vs 2.9. The negative impact of TD, intensity of TD and IO was also seen in patients>65. We estimated years of life lost (YLL) attributable to TD, intensity of TD and IO. Large differences in YLL were observed by gender (Table 2).
Summary / Conclusion: Our results confirm in our single-center experience the negative impact of TD, intensity of transfusion requirements and IO on life expectancy of patients with MDS and indicates that strategies to reduce this factors may provide a gain of years of life in all MDS population.

Table 1. Transfusion dependency-SMR.

		TRASNFUSION DEPENDENCY		NON-TRANSFUSION DEPENDENCY	
	YEARS	SMR	95% CI	SMR	95% CI
MALES	<65	22,9	15,1-33,3	4,0	2,4-6,4
	65-79	6,2	4,7-8,1	2,5	2,0-3,1
	>80	2,3	1,4-3,5	2,4	1,7-3,4
FEMALES	<65	28,1	12,1-55,3	6,6	2,9-13,1

NOVEL 3Q26 DELETION BONE MARROW FAILURE SYNDROME IN A NEWBORN RESULTING IN DOMINANT NEGATIVE INTERFERENCE OF HEMATOPOIESIS BY TRUNCATED EVI1/MECOM

L Van Der Veken[1,*] M Bierings[2], M Maiburg[1], F Groenendaal[3], A Bloem[4], N Knoers[1], A Buijs[1]
[1]Dept. of Medical Genetics, [2]Dept. of Pediatric Oncology, [3]Dept. of Neonatology, [4]Dept. of Immunology, University Medical Center Utrecht, UTRECHT, Netherlands

Background: We report on a patient born with severe congenital abnormalities including macrocephaly, brain MRI abnormalities, bilateral clubfeet, and bone marrow failure with pancytopenia presenting with none but T-lymphocytes in the peripheral blood.
Aims: Characterization of the underlying genetic aberration explaining the severe clinical phenotype of the patient.
Results: A 824 kb to 868 kb heterozygous deletion on chromosome 3q26.2 was identified by array-CGH on peripheral blood using an Agilent 180k oligo array (Amadid 023363). The deletion truncated the 3' part of *EVI1/MECOM* and extended into microRNA 551b (*MIR551B*). The 3' *MECOM* deletion was confirmed by FISH using a *MECOM* specific probe on uncultured peripheral blood cells in 10 investigated metaphases and 200 interphase nuclei. To assess whether the deletion was constitutional, FISH analysis was performed on buccal swaps and cultured skin fibroblasts. Loss of one *MECOM* signal was observed in 200 interphases, and 10 metaphases of cells derived from buccal mucosa and skin fibroblasts, respectively, demonstrating the constitutional nature of the *3' MECOM* deletion. Karyotyping and FISH analysis of both parents did not reveal a structural or numerical abnormality of 3q26.2 *MECOM*, indicating the deletion to be *de novo*. EVI1/ MECOM is a transcriptional regulator essential for maintaining embryonic and adult hematopoietic stem cells by directly regulating transcription of *GATA2*. In mouse models, homozygous disruption of *MECOM* results in embryonic lethality, with hypocellular bone marrow, reduced body size, small or absent limb buds, abnormal development of the nervous system and heart and massive hemorrhaging. Furthermore,

MECOM heterozygosity leads to a marked impairment of the self-renewal capacity of hematopoietic stem cells. In our case the heterozygous deletion results in 3' terminal truncated *MECOM* lacking the C-terminal acidic amino acid cluster domain (AD) encoding sequences. The AD of MECOM is important for activation of *GATA2* transcription *in vitro*. This supports the notion that dominant negative interference of normal EVI1/MECOM expression by truncated amino terminal EVI1/MECOM causes severe bone marrow failure, supposedly by deregulating GATA2 mediated control of hematopoietic stem cell homeostasis.

Summary / Conclusion: We will discuss our data in relation to two cases with a milder phenotype likely to be caused by haploinsufficiency of *EVI1/MECOM*. In conclusion, we report on a novel 3q26 *EVI1/MECOM* deletion syndrome with multiple severe congenital abnormalities and bone marrow failure due to a dominant negative effect on *EVI1/ MECOM* regulated hematopoiesis.

P201

SPANISH PNH REGISTRY: PNH CLONE SIZE, LDH AND THROMBOSIS EVOLUTION

A Villegas[1,2,3,*] Á Urbano[4], E Ojeda[5], A González[3], M Roncero[6], M Cuevas[7], R Córdoba[8], A Gaya[4], I Jarque[9], R Nuñez[10], B Arrizabalaga[11]
[1]on behalf of PNH Registry, [2]Medicina, Universidad Complutense de Madrid, [3]Hematology, Hospital Clínico San Carlos, Madrid, [4]Hematology, Hospital Clínic de Barcelona, Barcelona, [5]Hematology, Hospital Puerta de Hierro de Majadahonda, Madrid, [6]Hematology, Hospital Virgen de la Salud, Toledo, [7]Hematology, Hospital General de Burgos, Burgos, [8]Hematology, Hospital Infanta Sofía, Madrid, [9]Hematology, Hospital La Fe, Valencia, [10]Hematology, Hospital Virgen del Rocío, Sevilla, [11]Hematology, Hospital de Cruces de Barakaldo, Bilbao, Spain

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a hematopoietic stem cell disorder caused by a PIG-A gene mutation.
Aims: To analyze epidemiological data obtained from patients enrolled in the National PNH Registry as well as clone size, LDH and thrombotic status evolution at enrollment, 6 and 12 months.
Methods: We analyzed 111 patients (45 female and 66 male) from 26 sites classified according to Parker in three groups: classic/hemolytic PNH (group I; n=54), PNH with another bone marrow disorder (group II; n=32) and subclinical PNH (group III; n=25). We compared in these populations demographic data, clone size, LDH levels and incidence of thrombosis at enrollment, 6 and 12 months.
Results: Median age at disease onset was 35 y with no statistical differences among groups. The median age from disease onset to enrollment was 7.7 yrs (11.6 (0.5-41.2) in group I, 4.1 (0.6-33.8) in group II and 4.7 (0.3-41.8) in group III, P=0.0084). Previous history of thrombosis was present in 19 patients (17.1%), 5 of them in group II, 11 were male (57.9%) and 8 women (42.1%), (P=0.0397). Those patients had 41 thrombotic events in total: 8 (one event), 5 (two events) and 5 (four events). Thrombosis is more common in venous thrombosis, but there were some arterial thrombosis. Median granulocytes clone size at enrollment (n=88) was 60% (0.9-99), 86.5% (20-99.9) in group I, 59% (10-98.9) in group II and 3.2% (0-20) in group III. Median LDH at enrollment (n=105) was 643 U/L (135-6000), 1119 U/L (188-6000) in group I (n=52), 866 U/L (135-2685) in group II (n=28), and 312 U/L (167-752) in group III (n=25), P<0.0001. 10 patients in group II had LDH>1000 U/L and clone size >50% at baseline, so probably, were not well classified at enrollment. A total of 46 patients are treated with eculizumab: 36 being classical and 10 in group II. 14 patients started eculizumab on or after enrollment, 65 have never been on eculizumab, and 5 were treated with eculizumab prior to enrollment but did not continue for different reasons (pregnancy, ending trial, government criteria, etc). No patient on eculizumab has presented a new thrombotic event. One patient not treated (in group I) has presented with thrombosis at 6 months. At 6 months, clone size is 87.3% (24.5-100) in group I (n=21), 45.4% (5.0-98.9) in group II (n=12) and 2% (0.0-15) in group III (n=13), P<0.0001. At 12 months, clone size is 82.4% (18.1-99.2) in group I (n=11), 84.0% (31.6-99.5) in group II (n=7) and 2% (0.0-6.5) in group III (n=7), P<0.0007. Median LDH at 6 months (n=72) is 501 U/L (112-4467), 492 U/L (160-4467) in group I (n=36), 739 U/L (153-2317) in group II (n=22), and 391 U/L (112-778) in group III (n=14), P=0.0013. At 12 months, the median is 396 (205-5509) in group I (n=26), 525 (214-2701) in group II (n=14) and 379 (189-655) in group III (n=9), P= 0.2999. LDH ratio (patient value/ULN) is also significant at enrollment (P<0.0001) at 6 months (P<0.0001) and at 12 months (P=0.0316).
Summary / Conclusion: 17.1 % of patients presented with history of thrombosis at enrollment, but most of them had a history of several thrombotic events. Patients treated with eculizumab have never had a new thrombotic event. One patient present venous thrombosis at 6 months and still is without treatment. LDH levels and LDH ratio are significantly higher in patients with classical PNH, lowering with eculizumab treatment at 6 and 12 months. Granulocyte clone size is statistically significant higher among patients with classical PNH with hemolysis at enrollment, 6 and 12 months and does not change in groups I and II although it appears to increase in group II. The data showed that PNH is an evolving disease with some cases from group II moving to group I over time.

P202

EUROPEAN PATTERN AND IMPACT OF THE USE ERYTHROPOIETIC AGENTS (ESAS)IN LOW AND INT-1 RISK MDS WITH PROPENSITY SCORING TECHNIQUES IN OBSERVATIONAL LONGITUDINAL STUDIES.

Background: The EU MDS Registry is a non-interventional, observational longitudinal study enrolling patients with lower-risk MDS <3 months from diagnosis. Between 2008 and 2011 1000 patients were recruited from 14 countries and 118 sites, with a follow-up every 6 months.
Aims: This substudy aims to describe the usage of erythropoietic agents (ESAs), and the impact of treatment on overall survival and transfusion patterns in anemic patients.
Methods: Two cohorts were investigated; all patients for distribution of ESA usage, and patients with hemoglobin levels <10 g/dL at registration for the evaluation of outcome. The effect of ESA treatment on survival and other outcomes was assessed using a proportional hazards model. To account for the non-randomised use of ESA within the cohort, a propensity score for receiving ESA treatment was derived using logistic regression and included in the proportional hazards modeling.

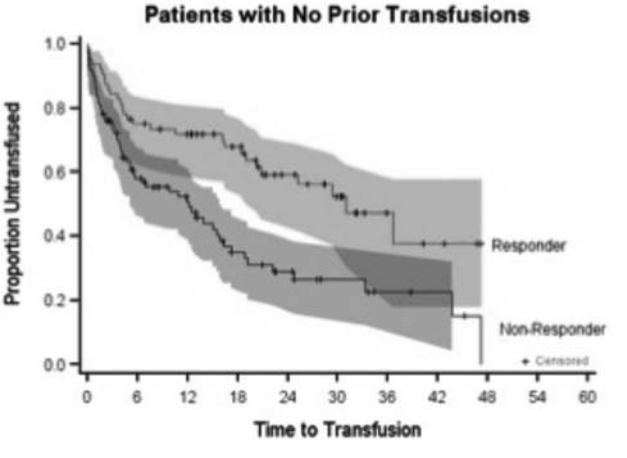

Figure 1. Time to first transfusion in ESA-responders vs ESA nn-responders P=0.0011.

Results: The ESA use varies by country, varying from 16.7% in Poland to 61.1% of the patients in Denmark, as did the pre-treatment Hb levels (range: 4.6-14.9 g/dL). Of the first 1000 patients (median age 74.6 years, range=18.7-95.3), 487 patients (median age 75.8, range: 42-95) were ESA-treated. The median duration of treatment was 8.1 months (0-48 months). The majority of patients started ESA within 6 months after their first visit. In a multivariable

logistic regression model, the strongest predictors of receiving ESA were country, WHO diagnosis subtype, baseline hemoglobin, the percentage of bone marrow blasts and age at diagnosis. The outcome cohort consisted of 419 patients; 260 received ESA and 159 were untreated before their second visit. For a treated patient to be classed as a responder there had to be at least 28 days between the start of ESA treatment and their second visit, with an increased Hb to >10 g/dL or an increase of at least 1.5 g/dL. A patient with transfusions prior to receiving ESA was considered a responder if the transfusion need was abrogated for at least 56 days. Responders appear to have a longer time to first post-ESA transfusion. (P<0.0011) (Figure 1) Median time to transfusion in patients transfused before start of ESA was 5 months (IQR: 2.8-30 months) compared to 15 months (IQR: 3.9-47 months) in patients with no prior transfusions (P=0.0064). The proportional hazards model shows a (non-significant) decreased risk of death (HR=0.74, 95% CI:0.51-1.08, P=0.11) associated with ESA treatment.
Summary / Conclusion: There are marked variations in the patterns of ESA usage across Europe. Treatment with ESA is associated with a tendency to improved survival. Patients starting ESA treatment before receiving transfusions experienced a longer delay in the onset of a regular transfusion need, with ESA–responders having a significant longer time to transfusion after starting ESA compared to non-responders.

P203

HYPOMETHYLATING AGENTS DOES NOT IMPROVE OVERALL SURVIVAL IN PATIENTS DIAGNOSED WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) COMPARED TO HISTORICAL DATA
D Alfakara[1], C Hanson[2], A Swedeh[1], M Elliott[1], S Hashmi[1], A Wolanskyj[1], W Hogan[1], M Litzow[1], A Al-Kali[1,*]
[1]Hematology, [2]Hematopathology, Mayo Clinic, Rochester, United States

Background: CMML is a clonal hematopoietic disorder that is characterized by a mix of myelodysplastic and myeloproliferative features where its pathologic process is not fully understood and its natural course is variable. Hypomethylating agents (HA) (azacitidine and decitabine) have been approved for the treatment of myelodysplastic syndromes (MDS) and CMML. However, previous studies have included small numbers of patients (pts) who received azacitidine (AZA) and decitabine (DAC) as a treatment for CMML.
Aims: To study the overall response (OR) rates and median overall survival (mOS) in pts who received HA for the treatment of CMML.
Methods: A retrospective chart review of pts diagnosed with CMML at Mayo Clinic Rochester between 1994-2011 was done. All information including hematological labs, bone marrow biopsies results, treatments and responses were obtained from medical records. OR was defined as complete remission (CR), partial remission (PR), marrow remission (MR) and hematological improvement (HI), based on modified International Working group (IWG) criteria in MDS (Cheson B *et al* Blood 2006). IRB approval was obtained in accordance with Helsinki declaration. Comparison between two groups was done using Wilcoxon test, while mOS were calculated using Kaplan-Meier estimates via JMP software V.9.
Results: We found 269 pts diagnosed with CMML, 67% of which were males with a median age of 72 years. Median hemoglobin (Hgb) was 10 mg/dL, white blood cells (WBC) $12x10^9$/L, platelets $88x10^9$/L, and peripheral blood (PB) blasts 0, bone marrow (BM) blasts 4%. Cytogenetics was diploid in 62% (168 pts). Only 25 pts (9%) were considered CMML-2 per WHO criteria. Median overall survival was 515 days. A total of 36 (13%) out of 269 pts received HA (group 1) while 233 (87%) did not receive HA (group 2); of the HA treated patients, 29 (81%) pts received DAC and 7 (19%) pts received AZA. In group2, 69 (30%) pts were treated with other therapies including hydroxyurea, imatinib, prednisone, intensive chemotherapy, or multiple other treatments. No statistical difference was found when comparing both groups where group 1 had median Hgb was 11 mg/dl, WBC $12x10^9$/L, platelets $58x10^9$/L, and PB blasts 0, BM blasts 4%, compared to group 2 of 10, 12, 93, 0,4, respectively. Median OS was not statistically significant between the 2 groups (group 1 of 569 vs group 2 of 513, P=0.39). On multivariate analysis, age, Hgb, platelets, and BM blasts were significant for mOS, but not WBC, PB blasts or HA treatment (P=0.22). Even with subgrouping pts to BM blasts ≥5% or CMML2 (per WHO definition), no statistical significance was found between both groups (P=0.65, P=0.07, respectively). In HA group, 6/32 (19%) pts achieved CR, 5 pts (16%) MR, 3 pts (9%) HI, with a total OR of 44% (in the DAC arm, CR/MR rate was 42%). Median OS for responders (CR/MR) was not statistically significant from non-responders (1083 days vs 409 days, P=0.25). Leukemic transformation into AML was seen in 9/36 (25%) pts in group 1 compared to 11% in group 2 (P=0.028).
Summary / Conclusion: HA are effective therapies in treating pts diagnosed with CMML. HA responders did have better mOS than non-responders but did not reach statistical significance. When compared to historical data of pts who never received HA, HA did not have a improve mOS; both in univariate and multivariate analysis. Our results were limited by small number of pts and being retrospective, therefore more prospective and larger studies are needed to elucidate the effect of HA on CMML pts.

Multiple myeloma: Biology 1

P204

ANTI-MYELOMA ACTIVITY OF A NOVEL ALKYLATING AGENT MELPHALAN-FLUFENAMIDE
D Chauhan[1,*] A Ray[1], KViktorsson[2], J Spira[3], C Paba-Prada[1], P Richardson[1], R Lewensohn[2], K Anderson[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [2]Department of Oncology, [3]Oncopeptides, AB, Karolinska Institutet, Stockholm, Sweden

Background: Despite several recent advances with novel biological agents, multiple myeloma (MM) remains incurable due to the development of relapsed/refractory disease in the majority of patients. The alkylating agent melphalan in combination with prednisone is a standard MM treatment in the non-transplant candidates. High-dose melphalan (HDM) together with autologous stem cell transplantation (ASCT) has enhanced progression-free and overall survival in transplant candidates. Addition of novel therapies such as bortezomib, thalidomide, or lenalidomide into the transplant paradigm as induction, consolidation, and maintenance has further improved patient outcome. Recent research efforts, in Sweden, focused on the development of melphalan prodrug to enhance the therapeutic potential of melphalan. Melphalan-flufenamide (Mel-flufen) is an aminopeptidase N-activated prodrug of melphalan, which enables a more rapid and greater intracellular delivery of melphalan. Mel-flufen has undergone phase-I/IIa clinical trials in solid tumors. Here, we examined the anti-MM activity of mel-flufen using various MM cell lines and patient MM cells, as well as murine models of human MM.
Aims: To study the effects of a mel-flufen on MM cell growth and survival in the bone marrow microenvironment *in vitro* and in xenograft models of human MM. To determine whether the combination of a mel-flufen with other anti-MM agents triggers synergistic or additive anti-MM activity.
Methods: MM cell lines, patient MM cells, and the human MM xenograft animal model were utilized to study the antitumor activity of mel-flufen. *In vitro* assays included measurement of intracellular melphalan, cell viability and apoptosis, Transient transfections, aminopeptidase N activity, and capillary-like tube structure formation assays. Statistical significance was derived using the Student's *t* test. Synergistic anti-MM activity of mel-flufen was obtained with isobologram analysis.
Results: Treatment of MM cells with low doses of mel-flufen induces a more rapid and higher intracellular concentrations of melphalan than is achievable by free melphalan. Analysis of mel-flufen cytotoxicity showed significantly lower IC_{50} of mel-flufen than melphalan; and importantly, mel-flufen triggers apoptosis in melphalan-, and bortezomib-resistant MM cells. Low concentrations of mel-flufen (0.5 micromolar) are able to trigger more potent and greater DNA damage than is observed in cells treated with higher concentrations (3 micromolar) of melphalan.Aminopeptidase N, one of the peptidases mediating melflufen hydrolysis to melphalan, is highly expressed in MM cells; and knockdown of aminopeptidase N with siRNA attenuated mel-flufen induced cytotoxicity. Furthermore, mel-flufen-triggered apoptosis in MM cells was associated with activation of caspases and PARP cleavage, as well as induction of DNA damage, p53, and p21. Using knockdown and knockout cell models, we show that blockade of p21 abrogates mel-flufen-induced cytotoxicity. Moreover, melflu-fen inhibits MM cell migration and tumor-associated angiogenesis. A head-to-head efficacy analysis using our human MM xenograft model showed a more potent inhibition of tumor growth and prolonged survival in mice treated with melflufen than mice receiving equimolar doses of melphalan. Finally, combining mel-flufen with lenalidomide, bortezomib, or dexamethasone triggers synergistic anti-MM activity.
Summary / Conclusion: Our preclinical study supports clinical evaluation of mel-flufen to enhance therapeutic potential of melphalan, overcome drug-resistance, and improve MM patient outcome.

P205

METABOLOMIC PROFILING IDENTIFIES MECHANISMS REGULATING HYPOXIA-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA.
P Maiso[1,*] Y Aljawai[1], A Sacco[1], S Breitkopf[2], M Moschetta[1], Y Mishima[1], J Asara[2], A Roccaro[1], I Ghobrial[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, [2]Division of Signal Transduction/Mass Spectromety Core, Beth Israel Deaconess Medical Center, Boston, United States

Background: Multiple Myeloma (MM) is the second most prevalent hematological malignancy and remains incurable, with a median survival of 3-7 years. However, despite the success of the new treatments, most patients still succumb to their disease. In about 20-25% of high-risk patients, MM progresses rapidly and does not respond to conventional therapies leading to rapid extramedullary disease and demise of these patients. One such regulator of dissemination and drug resistance is the dynamic process of oxygen depriva-

tion or hypoxia. A number of studies show that hypoxia promotes neo-angiogenesis, cancer progression, epithelial-mesenchymal transition (EMT), acquisition of metastasis potential and stem-cell features, as well as resistance to therapy by activating adaptive transcriptional programs. Targeting hypoxia, and the metabolic pathways regulated by hypoxia in the tumor cells, could lead to novel opportunities for cancer therapy. Rapidly proliferating hypoxic cancer cells undergo a "metabolic switch" to anaerobic glycolysis. This altered energy metabolism has been shown to be associated with activated oncogenes and mutant tumor suppressors, which are more prevalent in patients with high-risk MM.

Aims: Examine the role of HIF1A and HIF2A in regulating drug resistance *in vitro* and *in vivo*. Identify specific hypoxia-regulated genes and regulators of energy metabolism leading drug resistance in MM.

Methods: The effect of hypoxia was analyzed in different MM cell lines (MM1S, RPMI8226, U266 and H929) in basal conditions and after the treatment with bortezomib, dexamethasone or melphalan. The cytotoxicity was analyzed by means of MTT assay. Cell cycle and apoptosis studies were performed by flow cytometry. Proteomic changes induced after treatment were analyzed under normoxic and hypoxic conditions by western-blotting. Gene expression profile of MM1S cells treated with bortezomib was compared in normoxia vs hypoxia using D-chip software. Genes with expression changes greater or lower than 2 fold in either direction were selected. HIF1A and HIF2A knockdowns were performed in MM1S using lentiviral vectors. For metabolite collection, samples were re-suspended using HPLC grade water for mass spectrometry and analyzed using a 5500 QTRAP hybrid triple quadrupole mass spectrometer (AB/SCIEX) coupled to a Prominence UFLC HPLC system (Shimadzu). A total of 254 endogenous water soluble metabolites were analyzed.

Results: We observed that hypoxic conditions (12 hours at 0.7% of oxygen levels) suppressed the effect of melphalan and more significantly the effect of bortezomib. At the transcriptional level and protein level, we observed that cells treated with bortezomib in hypoxic conditions affected a large number of genes/proteins involved in cell cycle, cell death, glucose metabolism and the Wnt signaling pathway. Hypoxia blocked cell cycle progression, which was accompanied by p21, p53 and p57 up-regulation. In addition, apoptosis pathways were inhibited after exposure to hypoxia including inactivation of caspases3, 8 and 9 and PARP cleavage. HIF1A and HIF2A knockdowns restore the effect of bortezomib in MM1S and increased the percentage of apoptosis in cells treated with bortezomib under hypoxic conditions. To further explore the role of hypoxia in the regulation of tumor metabolism, metabolomic studies were performed to characterize metabolic alterations following bortezomib treatment. This analysis revealed that hypoxic tumor cells treated with bortezomib show significant metabolic changes involving multiple pathways, the most significant of which are intermediates in glucose and, sucrose metabolism. Bortezomib treatment under hypoxic conditions was accompanied by a significant decrease in UDP-D-glucose, UDP-D-glucuronate, and glutathione disulfide.

Summary / Conclusion: Hypoxic conditions are essential for drug resistance and glucose utilization. These data provide new therapeutic targets and associated biomarkers for the treatment of Multiple Myeloma.

P206

GENOMIC CHARACTERIZATION OF THE PUTATIVE MULTIPLE MYELOMA STEM CELLS CLONE REVEALS COPY NUMBER ALTERATIONS (CNAS) POSSIBLY CORRELATED WITH THE ORIGIN OF DISEASE

M Martello[1,*] C Terragna[1], G Martinelli[1], E Borsi[1], E Zamagni[1], L Pantani[1], P Tacchetti[1], B Zannetti[1], K Mancuso[1], F Dico[1], M Cavo[1]
[1]Department of Experimental Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy

Background: Although the advances in Multiple Myeloma (MM) therapy and the introduction of novel-agent-based regimens, the disease remains incurable. The existence of Myeloma Propagating Cells (MPCs) is supposed to be one of the major causes of MM drug-resistance, leading to relapse. However, very little is known about the molecular characteristics of MPCs, even if some studies suggested that these cells have phenotypic characteristics resembling the memory B cells that reside in the CD138- compartment.

Aims: To molecularly characterize the CD138+ neoplastic clone and the memory B cells located both in BM and in PBL.

Methods: We collected the CD138+ and CD138-19+27+ cell fractions from bone marrow (BM) and peripheral blood (PBL) of 50 newly diagnosed MM patients (pts), 7 MGUS pts and 15 relapsed pts. For several pts we collected buccal swab sample as a negative control. The complete set of genomic aberrations was evaluated by SNP Array 6.0 (Affymetrix) and the identification of copy number alterations was performed with Genotyping Console and Partek Genomics softwares.

Results: Both BM and PBL CD138+ cell fractions showed exactly the same genomic macro-alterations. In contrast, in the CD138-19+27+ cell fractions from BM and PBL any macro-alteration was detected, whereas several micro-alterations (range: 1-834 Kb) unique of the memory B cells clone, were highlighted. We observed that these micro-alterations are located out of any genomic variants region (Database of Genomic Variants, DGV) and, therefore, presumably associated to the MM pathogenesis. In particular, these micro-alterations involved the following genes: *HMGCLL1*, *DLGAP2* and *RCOR3*, *PRR16*, *TSC1*, *ETS1*, *RBFOX1* , identified in CD138-19+27+ derived from PBL and BM, respectively. These genes are involved in pathways related to the cholesterol metabolism, the embryonic development and the transcriptional regulation. Interestingly, three focal micro-deletions (involving *SKT*, *CES1P1*, *MIR650*) were shared both by the PBL and the BM memory B cells clones. In particular, the *MIR650* gene is located on chr22 in the immunoglobulin lambda gene locus, thus directly controlling its expression and also targeting the expression of several cell cycle genes; indeed, its physiological function allows the inhibition of the cell cycle progression by regulating p16INK4-mediated pathway. By applying a more stringent analysis, the CD138-19+27+ cell fraction obtained from all pts analyzed showed a unique micro-deletion (410 Kb) on chr14, involving *JAG2*, *BRF1*, *PACS2*, *NUDT4* and *BTBD6*. This deletion has been already described as involved in a pediatric *syndrome of chr.14q*, and its presence is correlated to a variety of developmental disorders and mental retardation.

Summary / Conclusion: Reported data suggest that the MM CD138+ clone might resume the end of the complex process of tumorigenesis, proven by the presence of numerous macro-alterations, which might be probably due to an established genomic instability. In contrast, the memory B cells, which lack these macro-alterations, have some intriguing micro-alterations, supporting the idea that these post germinal center cells might be involved in the transforming event that originate the neoplastic clone. Results need to be confirmed in a higher number of pts;additional data will be presented during the meeting.

P207

MULTIDIMENSIONAL FLOW CYTOMETRY FOR SENSITIVE EVALUATION OF PATIENTS WITH IGM MGUS OR WALDENSTROM'S MACROGLOBULINEMIA AND DIFFERENTIAL DIAGNOSIS WITH OTHER LYMPHOMAS

B Paiva[1,*] R Garcia-Sanz[1], E Ocio[1], C Jimenez[1], I Aires[1], F Escalante[2], N de las Heras[2], J Hernandez[3], A Garcia-Mateo[3], A Garcia de Coca[4], R Cuello[4], T Gonzalez-Lopez[5], M Sierra[6], M Montes[6], J Galende[7], A Garcia[8], J Alonso[9], E Pardal[10], M Vidriales[1], J San Miguel[1]
[1]Hospital Universitario Salamanca, Salamanca, [2]Complejo Hospitalario Leon, Leon, [3]Hospital General Segovia, Segovia, [4]Hospital Clinico Universitario Valladolid, Valladolid, [5]Hospital General Yague, Burgos, [6]Hopital Virgen de la Concha, Zamora, [7]Hopital Comarcal del Bierzo, Ponferrada, [8]Hospital Nuestra Sra Sonsoles, Avila, [9]Hospital Rio Carrio, Palencia, [10]Hospital Virgen del Puerto, Plasencia, Spain

Background: Although that MYD88 L265P mutation has recently become a genetic hallmark of Waldenström's Macroglobulinemia (WM), approximately 10% of WM patients still lack the mutation, while it can also be present in some cases with B-CLL or Marginal Zone lymphoma (MZL).

Aims: Here, we hypothesized that novel multidimensional flow cytometry (MFC) integrating a total of 16 antigens into a principal component analysis (PCA), after previous merging and calculation of flow cytometric data, would increase the sensitivity to detect the Waldenström's B-cell and plasma cell (PC) clone, as well as contribute towards an automatized-computer-generated differential diagnosis between WM and B-CLL or MZL.

Methods: Bone marrow (BM) samples from newly diagnosed IgM MGUS (n=35), smoldering (n=35) and symptomatic WM (n=21) patients, as well as from MZL (n=7) and B-CLL (n=6) patients were studied by MFC immunophenotyping.

Results: Phenotypically aberrant clonal B-cells were detectable in 77%, 97% and 100% of IgM MGUS, smoldering and symptomatic WM patients, while clonal PCs in 71%, 89% and 100%, respectively. 16-color MFC-derived PCA revealed a complete phenotypic overlap between the Waldenstrom's B-cell and PC clones representative of the three entities, thereby suggesting that the malignant transformation in WM relies mostly in a numeric expansion rather than an evolving phenotype. Clonal B-cells were typically characterized by $CD22^{dim}$, $CD25^{hi}$, $CD79b^{hi}$, $CD81^{hi}$ and $smIgM^{hi}$ expression; bimodal staining for CD27, CD38 and CD200; and absence of CD5, CD10, CD11c and CD103. Clonal PCs were identified by $smIgM^{hi}$ or $CD79b^{hi}$ positive staining. Phenotypically aberrant B-cells and PCs were simultaneously assessed by cytoplasmic kappa and lambda expression to confirm the clonal nature of the selected cell populations. We then investigated if the phenotypic profile of the Waldenström's B-cell clone differed from mutated (n=38) versus wild type (n=4) MYD88, but no significant differences were observed. As expected, in all cases with MYD88 L265P clonal B-cells were detected by MFC; conversely, in 3 out of the 4 cases with wild type MYD88 clonal B-cells were also detectable by MFC. Moreover, ASO-PCR on FACS purified clonal B-cells from these 3 cases confirmed the wild type MYD88, indicating that the absence of MYD88 L265P mutation was not related to a sensitivity limit but a truly non-mutated variant. Finally, automatized-computer-generated PCA between the Waldenström's B-cell clone and clonal B-cells from patients with MZL and B-CLL showed that all cases belonging to the latter group were accurately differentiated within 2 standard deviations (SD), with CD79b, smIgM and CD5 being the most significant markers. Similarly, 5 out of the 7 cases with MZL patients were accurately differentiated from IgM MGUS and/or WM cases within 1SD (with LAIR1, smIgM and CD79b pattern of expression contributing the most). Interestingly, the two cases misclassified were from extranodal MZL of MALT, whereas all 5 cases with nodal

MZL were correctly identified.
Summary / Conclusion: We show here that novel multidimensional flow cytometry is a complementary diagnostic tool for the screening and identification of IgM MGUS and WM patients, as well as to potentially standardize the differential diagnosis between these and other entities potentially concurring with an IgM M-component or MYD88 mutation such as B-CLL and MZL.

P208

IDENTIFICATION OF SERUM MICRORNA PROFILE IN MULTIPLE MYELOMA ASSOCIATED WITH COMPLETE REMISSION AND PROGRESSION AFTER AUTOLOGOUS STEM-CELL TRANSPLANTATION

C Fernández De Larrea[1,*] A Navarro[2], N Tovar[1], F Pedrosa[1], R Tejero[2], Mª Cibeira[1], T Díaz[2], L Magnano[1], L Rosiñol[1], M Monzó[2], J Bladé[1]
[1]Amyloidosis and Myeloma Unit, Department of Hematology. Hospital Cínic de Barcelona. IDIBAPS, [2]Molecular Oncology and Embriology Laboratory, Human Anatomy Unit. School of Medicine. University of Barcelona, Barcelona, Spain

Background: MicroRNAs (miRNAs) are small non-coding RNAs that mainly regulate mRNA translation of specific target mRNAs. MiRNAs are deregulated in myeloma cells, and their pattern of expression in MM seems to be associated with specific genetic abnormalities. These molecules can be detected in biological fluids, such as serum, and tumor-associated microRNA profiles can provide potential utility as biomarkers of tumor mass, remission and/or progression.
Aims: To ascertain the expression of miRNA in paired serum samples from patients with multiple myeloma (MM) at diagnosis and at complete remission (CR) after autologous stem-cell transplantation (ASCT), versus sera from healthy donors and those with stable monoclonal gammopathy of undetermined significance (MGUS), and to identify miRNAs related to relapse.

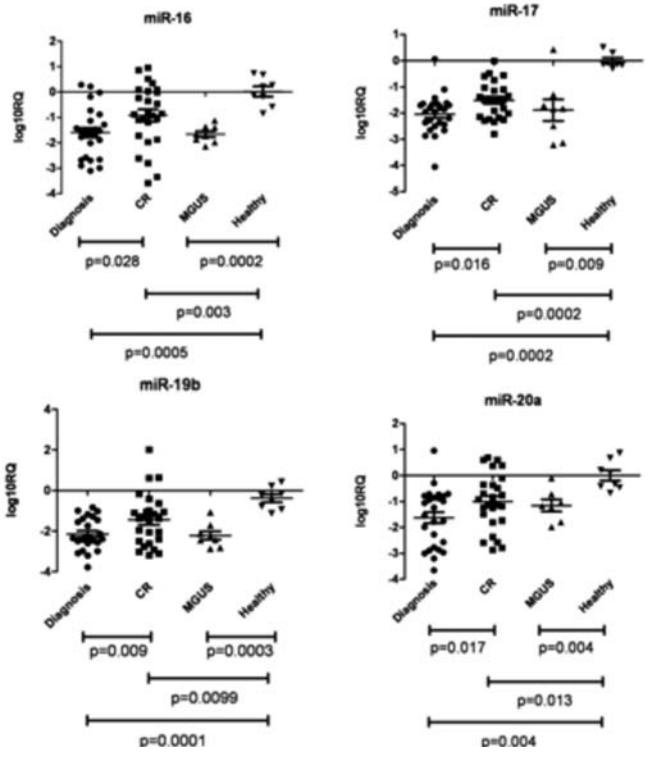

Figure 1. Differential serum levels of four miRNA (miR-16, miR19b, miR-17 and miR-20a in patients with multiple myeloma at diagnosis and complete remission (CR) in comparison with monoclonal gammopathy of undetermined significance (MGUS) and healthy donors.

Methods: First, fifteen MM patients with paired serum samples at diagnostic and at CR after melphalan-based ASCT were studied as screening group. RNA was extracted from frozen serum samples using miRNeasy Mini Kit (Qiagen) and 380 miRNAs and controls were profiled using TaqMan Human MicroRNA Arrays (Array A; Applied Biosystems) using pre-amplification. Expression levels were calculated by 2^{-DDCt} using mir-483-5p as endogenous control, due to the smallest standard deviation among samples, without statistical differences between patients and healthy donors, and the median of 4 serum healthy controls as calibrator. miRNA differentially expressed between diagnosis and CR were selected for validation by single Real Time TaqMan® MicroRNA Assays (without pre-amplification) in a series of 28 patients with paired diagnosis/CR samples after ASCT as first line treatment, plus 8 additional patients with samples in CR, 8 healthy controls and 8 stable MGUS for more than 5 years. Progression-free survival (PFS) after ASCT was recorded in the 36 patients in CR. All PCR reactions were performed using an ABI 7900 HT sequence detection system. Statistical analysis was performed with BRB Array Tools (screening analysis) and GraphPad Prism and PASW Statistics 18 (validation analysis).
Results: Supervised analysis by significance analysis of Microarrays (SAM) and t-test based on multiplex permutations (class comparisons analysis; P<0.001) of the first 15 patients revealed underexpression of 14 miRNAs in sera at diagnosis in comparison with paired samples in CR. The validation in 28 patients with paired samples of this series has shown that this statistical significance remained for miR-16 (P=0.028), miR-19b (P=0.009), miR-17 (P=0.016), miR-20a (P=0.017) (Figure 1), miR-25 (P=0.043) and miR-660 (P=0.048), with a trend for miR-152 (P=0.073). Patients achieving CR showed a partial recovery of the normal serum levels, while MGUS patients had levels very close to patients with MM in CR but lower than normal sera (Figure 1). Trying to explain why all these miRNAs were upregulated in patients in remission, we found that patients with oligoclonal bands had a significantly higher level of miR-25 (P=0.002), suggesting than the cellular origin of at least this miRNA could also be found in non-malignant plasma cells. In the prognostic analysis, patients that had relapsed after ASCT showed a significantly lower levels of miR-19b when in CR (P=0.001). Higher vs. lower levels of serum miR-19b (median PFS 6 vs. 1.8 years; P=0.0001) and miR-331 (median PFS 8.6 vs. 2.9 years; P=0.001) were associated with longer PFS after ASCT.
Summary / Conclusion: In our series of patients with MM after ASCT, measurement of expression levels of several miRNAs in serum showed a underexpression of several miRNA (miR-16, miR-19b, miR-25, miR-17, miR-660 and miR-20a) when compared with normal sera. These results encouraged the potential value of miRNA as serum biomarkers in MM, and even as prognostic factors in patients in CR. Underexpression of some of them in patients with active disease suggested that the origin of these miRNA should be other than malignant plasma cells, such as bone marrow microenvironment. Further studies on this last subject are necessary.

P209

IMPROVED ACCURACY OF DISCRIMINATION BETWEEN IGM MULTIPLE MYELOMA (MM) AND WALDENSTROEM'S MACROGLOBULINAEMIA (WM) BY TESTING FOR MYD88 L265P MUTATIONS

W Willenbacher[1,*] E Willenbacher[1], A Brunner[2], C Manzl[2]
[1]Intenal Medicine V - Haematology & Oncology, [2]Department of Pathology, Division of General Pathology, Innsbruck Medical University, Innsbruck, Austria

Background: IgM myelomas account for < 0.5% of all myelomas and are responsible for only a very small proportion of all IgM paraproteinaemias (pp) estimated not to exceed 0.2%. They have been implicated to be frequently associated with an immunophenotype negative for CD20, CD56 and CD117, the occurrence of a translocation t(11;14) and an aggressive clinical course with bad prognosis in the biggest series published of 10 pts., although the universality of these findings have been challenged. WM, which accounts for the waste majority of all IgM pp's , on the other side has recently been shown to be associated with the *MYD88* L265P exon 5 mutation, that triggers IRAK mediated NF-κB signaling**,** in over 90% of cases. The analysis of the frequency of *MYD88* mutations in WM related lymphoid neoplasms showed a positive mutational status in only 16/93 non-WM pts., as well as in only 44/213 pts. in a 2nd published series but included only 3 cases of IgM MM.
Aims: To clarify whether *MYD88* mutational analysis could help to make the clinically critical distinction between IgM MM and WM we analysed 5 further cases of IgM MM with appropriate control samples and extended the analysis to exon 3 and exon 4 of the *MYD88* gene.
Methods: Patients with IgM Myeloma were identified by a search of the Austrian Myeloma Registry (AMR) database (www.myeloma.at), as well as an alignment within the local pathology repository for sample availability. Clinical charts were reviewed for plausibility of the diagnosis (e.g. confirmation of lytic bone disease), as well as an analysis of the cytogenetic and immunophenotypic profil of the neoplasms for myeloma characteristics. Control samples with an established diagnosis of WM were taken from clinical routine diagnostics. DNA from 5 patients (pts.) with IgM MM and 7 pts. with WM was extracted from formalin-fixed paraffin-embedded samples using QIAGEN DNA easy kit (Qiagen, Hilden/Germany). For Sanger sequencing of relevant exons primers were used described elsewhere. Amplified PCR products were isolated by High Pure PCR-Product Purification kit (Roche,Vienna/Austria). For sequencing of the amplified fragments Big Dye Terminator v1.1 ready reaction cycle sequencing kit was used as recommended by the manufacturer (Applied Biosystems, Vienna/Austria). We analysed 5 cases of IgM MM and 6 control cases of active WM, by PCR amplification and Sanger sequencing for MYD88 exon3, 4 and 5 mutations.
Results: We analysed 5 cases of IgM MM and 6 control cases of active WM, by PCR amplification and Sanger sequencing for MYD88 exon3, 4 and 5 muta-

tions. 4/4 IgM MM were found to be unmutated, while 6/7 WM were mutated. No mutations in exons 3 and 4 were found. The clinically important but sometimes difficult discrimination of these two entities can be made with higher precision by MYD88 mutational screening.
Summary / Conclusion: Our results might contradict a role for *MYD88* exon 3 and exon 4 mutations in both WM and IgM MM , but to confirm this findings a higher number of patients needs to be investigated. Furthermore we added another 5 *MYD88* unmutated IgM MM cases to the 3 cases described by (Xu *et al*. 2013). This distinct genetic trait could be exploited to discriminate these entities earlier on and with more precision to allow for a more rationale therapy allocation to the best of our patients.

ABT-199 IS HIGHLY EFFECTIVE AGAINST MULTIPLE MYELOMA AND PLASMA CELL LEUKEMIA HARBORING T(11;14) TRANSLOCATION
C Touzeau[1,2],* C Dousset[1,2], S Le Gouill[1,2], S Maiga[2], D Sampath[3], J Leverson[4], A Souers[4], M Bene[5], P Moreau[1,2], C Pellat-Deceunynck[2,6], M Amiot[2,6]
[1]Hematology, University Hospital, [2]INSERM U892, University, Nantes, France, [3]Genentech, San Francisco, [4]Abbvie, North Chicago, United States, [5]Laboratory of Hematology, University Hospital, [6]UMR 6299, CNRS, Nantes, France

Background: Despite recent advances in the treatment of multiple myeloma (MM) patients invariably relapse and innovative treatment strategies are urgently needed. The development of Bcl-2 inhibitors brings new hope for cancer therapy. We recently demonstrated that the Bcl-2 and Bcl-xL BH3-mimetic ABT-737 induces apoptotic cell death in a sub-group of MM identified by its high Bcl-2/Mcl-1 gene expression ratio. The clinical development of ABT-263 the orally active analog of ABT-737 is impaired due to thrombocytopenia dose-limiting toxicity related to Bcl-x_L inhibition. To overcome this hematologic toxicity, ABT-199, the first-in-class orally bioavailable Bcl-2-selective BH3 mimetic has been developed.
Aims: In the present study, the apoptotic efficiency of ABT-199 was evaluated in both human myeloma cell lines (HMCL) and primary myeloma cells.
Methods: Sensitivity to ABT-199 was assessed by flow cytometry on a panel of HMCLs (n=25) representative of MM heterogeneity and on primary cells from 15 consecutive MM patients. Expression of Bcl-2 and Mcl-1 transcripts by real time quantitative PCR was determined and analyzed in relation to ABT 199 sensitivity.
Results: Among our panel of HMCLs representative of MM heterogeneity, high sensitivity to ABT-199 was restricted to CCND1 subgroup while MMSET HMCLs are always the most resistant subgroup. Indeed, six out eight CCND1 cell lines are efficiently killed by ABT-199 (LD_{50} values ranging from 5 nM to 80 nM). Efficiency of ABT-199 was always superior to the one of ABT-737 as indicated by a decrease of LD_{50} values with ABT-199. Five of sensitive CCND1 cell lines harbors an abnormal p53, indicating that cell death induction is independent of p53 status. Sensitivity to ABT-199 was associated to a higher expression of Bcl-2 (P=.008) and to a lower expression of Mcl-1 (P=.09). The Bcl-2/Mcl-1 ratio defined by Q-PCR was the most powerful biomarker to discriminate ABT-199 sensitive from resistant cell lines (P=.002). Indeed, the median ratio was 6.06 (range 4.47-121) and 1 (range 0.18-3) for sensitive and resistant cell lines respectively. To confirm the role of Mcl-1 in ABT-199 resistance, siRNA against Mcl-1 were transfected in LP1 cells leading to a complete down-regulation of Mcl-1. Mcl-1 silencing highly sensitized these cells to low doses of ABT-199 indicating that Mcl-1 levels are mainly responsible for ABT-199 resistance like it was previously demonstrated for ABT-737. Sensitivity of primary myeloma cell to ABT-199 from 15 consecutive patients was evaluated. A considerable variability in sensitivity to ABT-199 among patient samples was observed. Four patient samples (*de novo* MM, n=2; primary plasma cell leukemia (pPCL), n=1; relapsed MM, n=1) were found highly sensitive to ABT 199 with a LD_{50}<100nM. A FISH analysis of t(11;14), t(4;14) and 17p deletion was analyzed. Of major interest, four ABT-199 sensitive patients bear CCND1 translocation showing that ABT-199 sensitivity is related to genetic subtypes.
Summary / Conclusion: Our data show that ABT-199 lethality is restricted to the specific t(11;14) myeloma subtype. The t(11;14) translocation is found in up to 40% of pPCL which represent a very aggressive form of MM. ABT-199 therapy could represent a very interesting opportunity for targeted therapy for MM and pPLC harboring t(11;14).

P211

BRUTON TYROSINE KINASE EXPRESSION IN MULTIPLE MYELOMA
L Elias[1],* J Buggy[1]
[1]Research, Pharmacyclics, Sunnyvale, United States

Background: Bruton Tyrosine Kinase (BTK) is expressed in normal B and myelo-monocytic lineage cells, where it functions in several signal transduction pathways including the B cell receptor (BCR), the CXCL12 (SDF-1α/β) receptor CXCR4, Toll-like receptors, FcRε, and GpIb. BTK is prominently expressed in normal and malignant B cells and is now an important molecular target for treatment of CLL/SLL, MCL, DLBCL and other malignancies with the oral BTK inhibitor ibrutinib. BTK expression is not detected upon B cell differentiation into plasma cells, however significant BTK expression has been reported in MM patient samples and some MM cells lines. Although over-expression may not necessarily be directly correlated with sensitivity to ibrutinib, tumor types identified as having high levels of BTK expression would merit further investigation.
Aims: Determine the patterns of BTK expression in clinical and molecular subgroupings of MM, characterize the role of BTK in the pathophysiology of MM, and identify subgroups of interest for clinical investigation.
Methods: BTK mRNA expression was analyzed in relation to clinical and molecular variables in gene expression databases, accessed through Compendia Oncomine, which includes 2196 MM clinical accessions from multiple public databases. BTK over-expression was defined as >4-fold average mRNA expression. Results are presented descriptively below.
Results: BTK mRNA was over-expressed in most MM patient samples (74.1%), which was similar to CLL (79.2%), or B cell lymphomas (91-100%), and to a much greater extent than seen in any solid tumor grouping. In comparison with MM, trends towards a higher level of expression were observed in cases of MGUS subtype (92.7%, N= 57) and in plasma cell leukemia (91.7%, N=12). Previously treated patient samples had a slightly greater incidence of over-expression (82.8%, N=842). No differences however were identified between patients with ISS stages I, II or III, patients with or without hyper-diploid cytogenetics, or in patients with light chain myeloma vs IgA/IgG myeloma. BTK was broadly expressed across molecular and cytogenetic subgroupings, however patients with gains of chromosome 11 or CCND1 amplification tended to have higher levels of BTK expression, whereas samples from patients in the MS (Zhan *et al*, Blood 2006;108:2020-2028) or TC 4 (Agnelli *et al*, J Clin Oncol 2005;23:7296-7306) molecular subgroups (generally associated with t(4;14) and related abnormalities) had lower BTK expression, as compared to other subgroups. BTK over-expression was similarly seen to correlate inversely with FGFR3 expression (characteristic of t(4;14)). BTK further showed some degree of co-expression with BCR associated B cell determinants such as CD79a, CD79b, and SYK; a correlation with CXCR4 was also noted.
Summary / Conclusion: BTK is widely expressed in MM, including previously treated patients. Over-expression is frequent however in some molecular and cytogenetic subgroups (e.g. CCND1 amplification, chromosome 11 abnormalities) characterized by high CCND1 expression. This pattern overlaps t(11;14) which has features in common with MCL, a disease known to be sensitive to treatment with ibrutinib. Whether these differences correspond to differences at the protein level and sensitivity to agents such as ibrutinib, or could be the basis of a predictive biomarker, will require further study. BTK co-expression with CXCR4 in MM suggests a prominent functional role of BTK in chemotaxis independently of possible BCR signaling.

P212

PROGRESSING THROMBOTIC MICROANGIOPATHY IN ATYPICAL HAEMOLYTIC URAEMIC SYNDROME PATIENTS: LONG TERM IMPROVEMENTS IN OUTCOMES WITH ECULIZUMAB
K Douglas[1],* N Sheerin[2], C Legendre[3], L Greenbaum[4], R Furman[5], D Cohen[6], C Bedrosian[7], C Loirat[8]
[1]Beatson West Scotland Cancer Centre, Glasgow, [2]Newcastle University, Newcastle upon Tyne, United Kingdom, [3]Université Paris Descartes & Hôpital Necker, Paris, France, [4]Emory University, Atlanta, GA, [5]Weill Cornell Medical College, [6]Columbia University Medical Center, New York, [7]Alexion Pharmaceuticals Inc, Cheshire, CT, United States, [8]Hôpital Debré, Paris, France

Background: Thrombotic microangiopathy (TMA) is associated with a number of life-threatening conditions with poor outcomes without appropriate treatment. Establishing its etiology before treatment is therefore important. Atypical hemolytic uremic syndrome (aHUS) arises from chronic uncontrolled complement activation. Thrombotic thrombocytopenic purpura (TTP) is another disease of systemic TMA characterized by severe deficiency of ADAMTS-13 (<5% activity). Eculizumab (ECU) has been approved for the treatment of aHUS. In the absence of rapid testing, presenting platelet levels >30×10^9/L or serum creatinine levels 150-200 mmol/L can be used to identify patients (pts) with a higher likelihood of aHUS compared to TTP (Coppo P *et al*, PLoS ONE 2010;5(4):e10208).
Aims: To evaluate long-term follow-up data from a clinical trial of ECU, a terminal complement inhibitor, in pts with aHUS and active TMA despite plasma exchange or infusion (PE/PI). TTP was excluded by >5% ADAMTS-13 activity levels in all pts.
Methods: This was an open-label, single-arm, phase 2 trial with a long-term extension. Pts aged ≥12 y with aHUS and progressing TMA were treated with ECU 900 mg/wk for 4 wks, 1200 mg at wk 5 and 1200 mg q2 weeks thereafter. The primary endpoint was change in platelet count from baseline.
Results: 17 pts entered the trial; at baseline (not presentation), mean (SD) values were 109 (32)×10^9/L for platelets, 352 (214) mmol/L for creatinine, 89.1 (13) g/L for hemoglobin, 0.47 (0.37) g/L for haptoglobin and 93.5 (15)% for ADAMTS-13 activity. 16/17 pts had been receiving PE/PI prior to inclusion. Four pts (24%) had no identified complement mutations or complement factor

H (CFH) antibodies. Two pts discontinued at wks 1 and 6 due to a protocol violation and an unrelated adverse event (AE), respectively; 13 pts continued ECU treatment in the long-term extension. Platelet normalization (>150×10^9/L) was achieved by 26 wks in 13/15 pts with low platelets at baseline, and was maintained through 2 y in 12 pts. Hemoglobin improved, likely reflecting control of aHUS-related hemolysis, since study pts were maintained on a constant EPO dose and median number of transfused red cell units per pt was 0 (range 0-16). Improvements in renal parameters were also seen and were sustained through 2 y (Table 1). ECU eliminated the need for dialysis in 4/5 pts receiving dialysis at baseline. Rates of treatment-related AEs remained the same or declined with ongoing treatment.
Summary / Conclusion: Baseline platelet and creatinine levels of study pts were consistent with ongoing active aHUS at the time of study entry and confirmed by ADAMTS-13 levels >5%. Identification of a complement mutation is not required for diagnosis of aHUS (24% in cohort had no identified complement mutation). Long-term ECU therapy in these pts, who had progressing TMA, was associated with significant and continuous improvements in outcomes at a median duration of 2 y (Table 1). Although aHUS carries a poor prognosis, all pts receiving chronic ECU therapy remain alive.

Table 1.

Key outcomes with ECU	26 wks	2 y[a]
Platelet count change, mean, ×10^9/L (SD)	96.7 (80.9) p=0.0004	93.9[b,c] (55.5) p=0.001
Hemoglobin g/L (SD)	125 (18)	128 (22)
Hematological normalization,[d] n (%)	13 (76)	15 (88)
TMA-event-free status,[e] n (%)	15 (88)	15 (88)
eGFR increase ≥15 mL/min/1.73m^2, n (%)	9 (53)	10 (59)
eGFR change from baseline,[f] mL/min/1.73m^2, mean (95% CI)	32.0 (14.5-49.4) p=0.001	35.2[b] (17.3-53.1) p=0.0005

For all parameters, improvement was seen in ≥2 consecutive measurements over 4 wks. Baseline mean eGFR 22.9 mL/min/1.73m^2 (SD, 14.5).
[a]At data cutoff (median 100 wks), unless otherwise noted.
[b]104 wks.
[c]Change from baseline based on sample size at each time point.
[d]Normal platelet count (>150 x 10^9/L) and LDH levels for ≥2 consecutive measurements, ≥4wks apart.
[e]≥12 consecutive wks with no platelet count change >25% + no PE/PI + no new dialysis.
[f]Based on ANOVA.

P213

ACTIVATION OF THE MTOR PATHWAY AND LOCALIZATION OF THE MTOR PROTEIN IN PRIMARY MYELOMA CELLS AND MULTIPLE MYELOMA CELL LINES: ROLE OF POMALIDOMIDE

T Guglielmelli[1,*] E Giugliano[1], V Brunetto[1], S Rrodhe[1], G Saglio[1]
[1]Department of Clinical and Biological Sciences, S Luigi Hospital, Orbassano, Italy

Background: mTOR is a protein kinase that plays a central role in regulating critical cellular processes. Consistent with its primary target being the translation machinery, mTOR is predominantly localized in the cytoplasm. However, a nuclear localization of mTOR has been found in rhabdomyosarcomas and HCT8 colon carcinoma cells. Furthermore, mTOR becomes nuclear in HEK293 cells treated with leptomycin B, a specific inhibitor of nuclear export receptor Crm1 suggesting that mTOR may be a shuttling protein.
Aims: to evaluate: activation of the mTOR pathway in multiple myeloma (MM), cellular localization of mTOR protein in MM cell lines and primary myeloma cells, the role of pomalidomide in regulating mTOR.
Methods: immunohistochemistry with antibody against p-mTOR was performed on bone marrow sections of 92 MM patients. Antibody against p-AKT, p-P70S6K and p-4EBP-1 was also used on bone marrow sections of the 57 newly diagnosed MM patients. Proliferation was evaluated by MTT assays in RPMI8226 and OPM2 cells following incubation with pomalidomide. Apoptosis was evaluated by flow cytometry for the detection of annexin V-positive cells in MM cell lines and in plasmacells from 3 MM patients. Cellular localization of mTOR was evaluated with confocal microscopy in RPMI8226 and OPM2 cells and in plasmacells from 4 MM patients in basal condition and after pomalidomide treatment. MM cell lines untreated or treated with the drug were fractionated and both cytoplasmic and nuclear fraction were analysed by western blotting with antibodies against mTOR and p-mTOR.
Results: overall, cytoplasmic p-mTOR stained positive in 46 out 92 (50%) cases by immunohistochemistry. A nuclear p-mTOR staining was also detected in 11 cases (12%). In the 57 newly diagnosed MM patients, p-mTOR expression significantly correlated with p-AKT (r=0.32, P=0.012), p-P70S6K (r=0.48, P=0.0001), and p-4E-BP1 (r=0.47, P=0.0001). In this population, strong mTOR expression (HSCORE >60) significantly correlated with high β2microglobulin-serum levels (>3.5 mg/L). Pomalidomide 1μM at 48h inhibited proliferation of OPM-2 and RPMI-8226 cells with 50% and 40% decrease in cell numbers by MTT assays. Pomalidomide 1μM was also effective in plasmacells from 3 MM patients at 24h with 23%, 33% and 26% annexin-V positive cells (versus 11%,18% and 3% of controls). Immunofluorescence assays demonstrated that mTOR protein is distributed throughout the cytoplasm and the nucleus at baseline in both MM cell lines and in plasmacells of 3 out 4 MM patients. A clearly increase of the nuclear mTOR protein was detected after pomalidomide treatment in RPMI-8226 and OPM-2 cells (10 μM at 48h) and in plasmacells from 3 MM patients (1 μM at 24h) (2 with nuclear mTOR localization at baseline and 1 without it). Cytoplasmic and nuclear distribution of mTOR and p-mTOR was also evidenced by Western blotting in RPMI-8226 and OPM-2 cells. As expected, the mTOR and p-mTOR protein levels were significantly higher in the cytoplasm when compared to the nucleus. Treatment with pomalidomide 10μM at 48h increased nuclear mTOR and p-mTOR expression levels in the nucleus with a concomitant decrease of cytoplasmic p-mTOR protein amount.
Summary / Conclusion: the AKT/mTOR pathway is activated in a subset of MM patients. In MM cell lines and in a fraction of primary MM cells, mTOR is distributed throughout the cell cytoplasm and in some nucleus. The anti-myeloma activity of pomalidomide may be mediated by the downregulation of the mTOR pathway with a nuclear shuttling of mTOR protein and a reduction of the cytoplasmic p-mTOR.

P214

MULTIDIMENSIONAL FLOW CYTOMETRY IMMUNOPHENOTYPIC QUANTIFICATION AND CHARACTERIZATION OF IN VIVO MESENCHYMAL STEM CELLS IN MGUS AND MULTIPLE MYELOMA

R Leite[1,*] B Paiva[2], T Carvalheiro[3], A Paiva[3], P Rocha[4], M Pereira[5], C Geraldes[6], S Ramos[6], A Teixeira[6], H Trindade[3]
[1]College of Health Technology of Coimbra, Coimbra, Portugal, [2]University of Salamanca, Salamanca, Spain, [3]Flow Cytometry Lab - Blood and Transplantation Center of Coimbra | Portuguese Institute of Blood and Transplantation, IP, Coimbra, [4]Clinical Hematology Department- Hospital Center of Tondela-Viseu, Viseu, [5]Medicine Department - Distrital Hospital of Figueira da Foz, [6]Clinical Hematology - University Hospital Center of Coimbra, Coimbra, Portugal

Background: The interaction between clonal plasma cells (PCs) and bone marrow (BM) stromal cells plays a crucial role in multiple myeloma (MM), accounting for unbalanced bone remodeling and activation of pleiotropic signaling cascades which can promote chemoresistance. Interestingly though, the mesenchymal stem cell (MSC) - precursor of stromal cells - have only been modestly investigated, recurring to *ex vivo* expansion and mostly in active MM.
Aims: Identify, quantify and characterize the minor BM compartment of MSC in patients with MGUS and MM, using sensitive multidimensional flow cytometry (MFC).
Methods: A total of 61 newly diagnosed patients with a PC dyscrasia are the focus of this study, 32 being diagnosed as MGUS, 5 as smoldering and 24 as symptomatic MM. Ten age-matched normal individuals were used as control. MSC were identified in BM samples according to positive staining for CD73, CD90 and CD105, without expression of CD34 and CD45; the mean intensity of fluorescence (MFI) for CD11b, CD13, CD24, CD29, CD49e, CD73, CD106 and NGFR was specifically assessed on the surface membrane of MSC.
Results: Upon normalization by removing clonal PCs from the differential, the mean frequency of BM MSC was found to be similar between normal individuals (0.03%) versus MGUS (0.03%) and SMM (0.02%) patients (P>.05). By contrast, significantly increased numbers of BM MSC (0.14%) were noted in symptomatic MM patients as compared to MGUS patients (P=.03), with a trend also recorded versus SMM cases (P=.05) and normal individuals (P=.08). Among symptomatic MM patients, a progressive increment in the number of MSC was found between ISS I, II and III (0.01%, 0.07% and 0.23%, respectively; P>.05). Moreover, a significantly inverse correlation between the percentage of BM MSC and hemoglobin values was noted (r=0.51; P=.006); conversely, increasing numbers of MSC were followed by higher BM plasmacytosis (r=0.54; P=.008). We then compared the specific phenotypic profile of MSC from patients with the benign (MGUS and SMM) versus malignant (MM) form of the disease. From a total of 8 markers under analysis, significantly differences between symptomatic MM versus MGUS and SMM patients were found exclusively for the adhesion molecule CD49e (P=.01) and CD90 (P=.02), which was significantly increased in symptomatic MM.
Summary / Conclusion: Our results show a significant increment in the frequency of BM MSC from MGUS and SMM to symptomatic patients, thereby suggesting that in addition to support chemoresistance in the active form of the disease, MSC may be potentially implicated in its malignant transformation. The fact that MSC from symptomatic MM patients show increased expression of adhesion molecules deserves further investigations, as it may facilitate its interaction and support clonal PCs. Accordingly, symptomatic MM patients with advanced disease stage showed increased number of BM MSC.

P215

HUMAN VDELTA1 T CELLS REPRESENT A DOMINANT GAMMA-DELTA T CELL SUBSET IN PATIENTS WITH MULTIPLE MYELOMA

A Knight[1,2,*] L Rihova[2], T Varmuzova[2], P Zarbochova[2], M Piskacek[2], F Kryukov[2], S Mackinnon[3], R Hajek[2]
[1]Dpt of Haematology, University College London, London, United Kingdom, [2]Masaryk University, Brno, Czech Republic, [3]Dpt. of Haematology, University College London, London, United Kingdom

Background: Human γδ T cells are potent effector lymphocytes of innate immunity involved in anti-tumor immune surveillance. However, the role of Vδ1 γδ subset in patients progressing from monoclonal gammopathy of undetermined significance (MGUS) to Multiple Myeloma (MM) in this process is unknown. We have recently shown that Vδ1 lymphocytes isolated from myeloma patients exert specific cytotoxicity against primary CD38+CD138+ bone marrow derived plasma cells (Knight *et al*., Cytotherapy 2012).
Aims: We aimed to determine the frequencies and phenotypes of Vδ1 and Vδ2 γδ T cell populations in MGUS patients, newly diagnosed myeloma patients, and treated myeloma patients. We hypothesized that the innate immune responses are gradually deregulated in patients progressing from MGUS to MM and this leads to changes in T cell distribution.
Methods: Fresh whole bone marrow samples were used from MGUS (n=25), newly diagnosed myeloma (n=41) and treated myeloma patients (n=7). We used multicolor flow cytometric analysis to determine the naïve/memory/effector phenotypes in patient cohorts and to compare the data with healthy donors.
Results: In MGUS patients, the median levels of Vδ1 and Vδ2 cells were 2.19 (range 0.55-8.05) and 0.63 (0.04-10.2) of CD3+ T cells respectively. Interestingly, largely elevated Vδ1 cells compared to healthy donors were predominantly of naïve phenotype CD27+CD45RA+ in these patients. In contrast, Vδ1 cells in newly diagnosed MM patients and patients after treatment showed effector memory CD27+CD45RA- and terminally differentiated phenotype of CD27-CD45RA+ expression. More importantly, we detected continuously expanded frequencies of Vδ1 cells in both cohorts of MM patients, (range 0.19-17.50 and 1.35-7.50 respectively). The Vδ2 cell subset was also expanded in MM patient cohorts, however the medians were overall reduced compared to the Vδ1 population. The Vδ2 cells were mostly of memory phenotype with CD27+CD45RA- expression in all patient cohorts.
Summary / Conclusion: Our results show significantly elevated frequencies of Vδ1 γδT cell subset in patients progressing from MGUS to MM indicating a possible compensation for defects in specific T-cell immunity. Given that the Vδ1 subset shows a very restricted TCR repertoire compared to the Vδ2 subset, the overall capacity of γδ T cells to recognise and respond to antigens in the bone marrow microenvironment might be significantly enhanced by the interactions with other cell types. The role of large expansions of Vδ1 cells and factors leading to myeloma progression remain to be elucidated. Nevertheless, this is the first report analyzing the Vδ1 cells in patients with monoclonal gammopathy. The project has been funded by the Royal Free Charity, and IGA NT 11145-4, IGA 12130-4, MSMT 0021622434, P304/10/1395 grants.

P216

AN EGFP IMAGING BASED *IN VIVO* MODEL FOR STUDYING THE BIOLOGY AND TREATMENT OF MULTIPLE MYELOMA

L Ai[1,*] C Sun[1], T Guo[1], Y Wang[1], L Zhang[1], Y Hu[1]
[1]Tongji Medical College, Huazhong University of Science & Technology, Wuhan, China, Institute of Hematology, Union Hospital, Wuhan, China

Background: Multiple myeloma (MM) is a B-cell malignancy characterized by the accumulation of abnormal plasma cells in the bone marrow (BM) and the development of progressive bone destruction. New treatments targeting the interactions between MM cells and their host BM microenvironment, may improve the survival of MM patients. Therefore, it is necessary to develop an appropriate model presenting the detail interactions and enables real-time monitoring of tumor burden, for assessment of *in vivo* activity of novel anti-MM therapeutics.
Aims: Here we sought to explore such a model in severe combined immunodeficient (SCID) mice, by utilizing whole-body non-invasive fluorescence imaging.
Methods: RPMI8226 and ARH-77 cell lines were stably transduced with an enhanced green fluorescence protein (eGFP) gene. Then these cells were injected into rabbit bone chips previously inoculated into SCID mice (SCID-rab mice), to induce myelomatous tumor growth and bone disease. Tumor burden was then monitored by real-time whole-body fluorescence imaging and serum human immunoglobulin (Ig) detection. Radiographs of mice were taken weekly by X ray. Changes in rabbit bone mineral density (BMD) were recorded. At the end of the experiment, rabbit bone sections were stained with hematoxylin and eosin (H&E) staining. Then SCID-rab-RPMI8226 mice were treated with bortezomib to further clarify the effects of this model for assessment of novel anti-MM therapeutics.
Results: We showed that both cell lines (RPMI8226 and ARH-77) progressed as myeloma-like tumors predominantly in the rabbit bone marrow. Increased tumor burden and decreased survival were detected in SCID-rab mice inoculated with MM cells (P<0.05). In addition, in our model, the sensitivity of fluorescence imaging technique appeared superior to human Ig for tumor growth monitoring. Moreover, rabbit bones harboring myeloma cells were severely resorbed and BMD was significantly decreased when compared with control (P<0.01). Furthermore, mice treated with bortezomib were preserved, exhibited no radiologically identifiable osteolytic lesions and, unlike the controls treated with PBS, lived longer and showed reduced tumor burden (P<0.05).

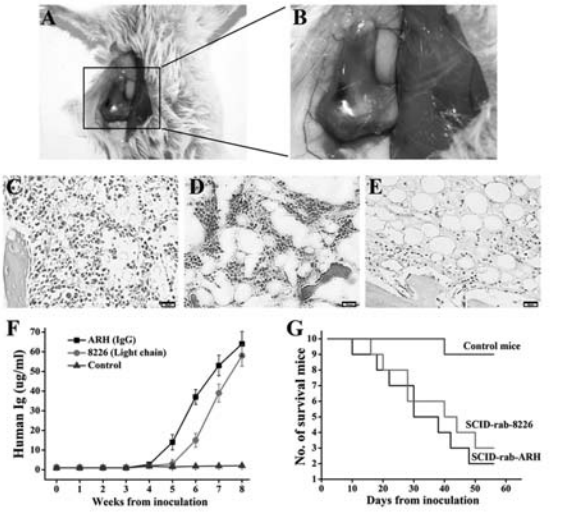

Figure 1.

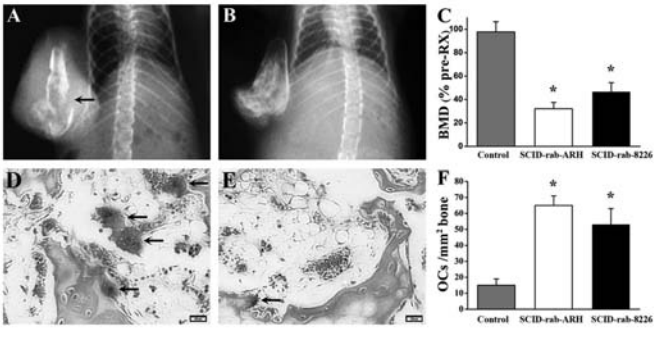

Figure 2.

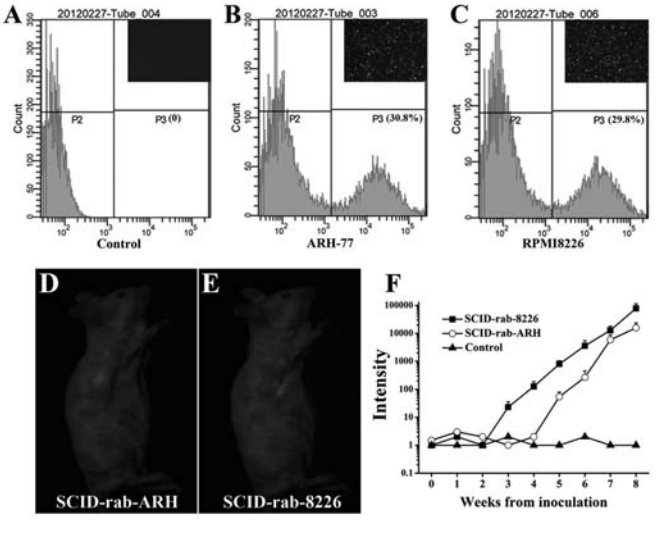

Figure 3.

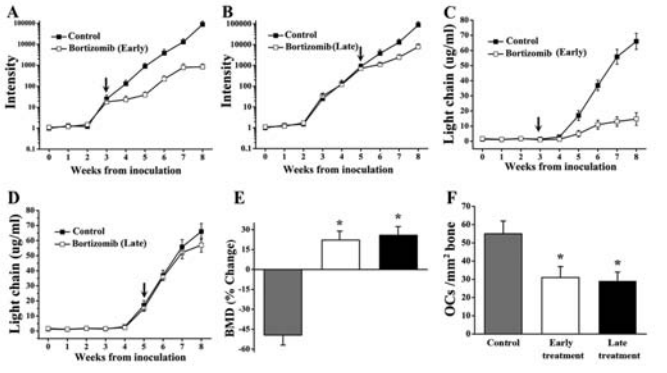

Figure 4.

Summary / Conclusion: This *in vivo* system both exhibits the interaction of MM cells with BM milieu *in vivo* and allows for sensitive real-time monitoring of tumor burden. Therefore, it provides a valuable and sensitive model for the comprehensive preclinical evaluation of anti-MM therapeutics.

P217

IDENTIFICATION OF POTENTIAL DRUG TARGETS WITHIN THE UBIQUITIN PROTEASOME SYSTEM IN MULTIPLE MYELOMA

L Crawford[1,*] B Walker[2], M Drake[3], A Irvine[1]
[1]Centre for Cancer Research and Cell Biology, [2]Pharmacy, Queen's University Belfast, [3]Haematology, Belfast City Hospital, Belfast, United Kingdom

Background: One of the most significant therapeutic advances in Multiple Myeloma (MM) has been the disruption of the ubiquitin proteasome system (UPS) through the use of proteasome inhibitors. Bortezomib, the first-in-class proteasome inhibitor, is now a widely used component of MM therapy. Despite its success a number of patients develop drug resistance and dose-limiting side-effects such as peripheral neuropathy. As knowledge of the UPS has increased, it has become evident that there may be other potentially druggable targets within this system which would confer greater specificity. E3 ligases and de-ubiquitinating enzymes (DUBs) in particular present an ideal therapeutic candidate as they play key roles in substrate selection and may enable direct targeting of an aberrant signalling pathway.
Aims: To identify aberrantly expressed genes within the ubiquitin proteasome system in Multiple Myeloma.
Methods: We carried out comparative gene expression profiling of MM cell lines (U266 and OPM-2) and normal bone marrow (NBM) using microarrays specifically focused on UPS-associated genes (Piqor, Miltenyi). Gene expression levels of select UPS enzymes were validated in MM cell lines (U266, OPM-2, KMS-18) and CD138+ cells from 4 MM patient samples and 3 healthy donors by real-time PCR.
Results: Initial microarray analysis found that 132 genes were significantly differentially expressed in MM cell lines compared to NBM (2 sided 't' test with equal variance using normalised log2-ratio). On the basis of these results, consolidated with publically available data sets comparing healthy donor CD138+ cells with CD138+ cells isolated from MM patients (GSE6691 and GSE6477), 25 E3 ligases/DUBs were found to be consistently differentially expressed in MM and brought forward for further validation. 7 E3 ligases and 2 DUBs demonstrated at least 2-fold higher expression across cell lines and primary MM cells compared to NBM CD138+ cells. One of the UPS enzymes identified though this analysis has recently been demonstrated to be an effective therapeutic target in pre-clinical models of MM, which serves to support the validity of this research strategy.
Summary / Conclusion: The proteasome is already established as a valid therapeutic target in MM and it is becoming increasingly clear that the UPS offers many opportunities for more targeted anti-cancer therapy. The 9 upregulated E3 ligases/DUBs identified in this study will be further investigated to explore their potential as therapeutic targets in MM.

P218

MULTIPARAMETER FLOW CYTOMETRY DETECTION OF CLONAL PLASMA CELLS IN THE BONE MARROW OF PATIENTS WITH SOLITARY PLASMACYTOMA DETERMINES THE RISK OF PROGRESSION TO ACTIVE MYELOMA

B Paiva[1,*] M Chandia[1], M Vidriales[1], J Perez[1], N Puig[1], L Lopez-Corral[1], E Ocio[1], R Garcia-Sanz[1], N Gutierrez[1], M Mateos[1], J San Miguel[1]
[1]Hospital Universitario Salamanca, Spain

Background: Although solitary plasmacytoma (SP) represents only 5% of all plasma cell (PC) dyscrasias this is nonetheless a heterogeneous group of patients; half or more develop treatment-requiring myeloma (MM) in 2-3 years, while others remain disease-free at 10 years. Since the diagnosis of SP requires absence of bone marrow (BM) plasmacytosis, no additional lytic lesions (by any imaging modality) or other CRAB, the identification of patients at risk of developing MM is challenging. Albeit patients with SP and an abnormal serum FLC ratio have a shorter time to progression (TTP) to MM, approximately 20% of cases with normal FLCs also develop MM at 5 years.
Aims: Here, we hypothesized that sensitive bone marrow (BM) evaluation of patients with SP through multiparameter 4-color flow cytometry (MFC) would unravel the presence of clonal PCs in otherwise disease-free BM according to conventional techniques, and that BM clonality could identify those patients at higher risk of developing MM.
Methods: Twenty patients with histological confirmation of a solitary plasmacytoma of bone (n=12) or soft tissue (n=8), without BM involvement and absence of PC-related CRAB symptoms are the focus of this study. Clonal PCs were investigated by MFC immunophenotyping based on differential expression of CD38, CD19, CD45, and CD56, and light scatter characteristics, using a single 4-color MoAb combination.
Results: Among the 20 patients with SP, 8 (40%) cases showed phenotypically aberrant PCs in BM (median of 0.04%: 0.004 - 0.9%). In 6 of these 8 patients an MRI was also performed but no BM involvement was noted. After radiotherapy, patients with clonal PCs showed a median TTP to treatment-requiring MM of 36 months versus not reached for those with undetectable clonal PCs (P=.003). Accordingly, 50% of patients with clonal PCs have progressed; by contrast, only 1 of the 12 cases (9%) without BM involvement showed disease transformation (occurring in this case 12.5 years after diagnosis of SP and with multiple skin plasmacytomas but no evidence of BM disease). At the time of diagnosis of SP, 9 out of the 20 patients had an M-protein, with no significant differences in the median TTP to MM between these vs. those cases with undetectable M-protein (P=.97).
Summary / Conclusion: Our results highlight the importance of MFC immunophenotypic studies for a sensitive evaluation of BM samples from patients with SP, and an accurate prediction of their risk of developing treatment-requiring MM.

P219

CAN IMMUNOPHENOTYPIC CR BE ALSO ACHIEVED IN RELAPSED MULTIPLE MYELOMA PATIENTS?

B Paiva[1,*] M Chandia[1], M Vidriales[1], J Perez[1], N Puig[1], L Lopez-Corral[1], E Ocio[1], R Garcia-Sanz[1], N Gutierrez[1], M Mateos[1], J San Miguel[1]
[1]HOSPITAL UNIVERSITARIO SALAMANCA, Salamanca, Spain

Background: Although the introduction of IMiDs and proteasome inhibitors has significantly improved response rates and outcome in relapse multiple myeloma (MM), the management of these patients remains challenging and prognostic biomarkers to identify those at different risk are scarce.
Aims: Here, we hypothesized that in parallel to the front-line setting, novel therapeutic options and autologous or allogeneic stem cell transplantation (SCT) may induce minimal residual disease (MRD) clearance and that this may translate into extended survival in the relapse setting.
Methods: Thirty patients achieving CR after rescue therapy were referred for MRD investigation by multiparameter flow cytometry (MFC) and are the focus of the study. Rescue therapy immediately preceding CR was usually based on novel agent combinations (90%), followed by alloSCT in 37% of cases and autoSCT in 23%. The remaining 40% were not transplanted. Patients were defined to be in immunophenotypic CR when less than one phenotypically aberrant plasma cell was detected among 10^5 cells analyzed.
Results: From the 30 patients in CR, 14 (47%) also achieved immunophenotypic CR whereas the remaining 16 (53%) were MRD+. MRD clearance was most likely achieved in patients submitted to SCT vs. those who were not (61% vs. 25%; P=.05). Only 2 out of the 14 (14%) MRD- cases experienced subsequent relapse as compared to 94% in MRD+ cases (P<.001); median time to progression not reached (NR) vs. 13 months (P=.007), respectively. Median overall survival was NR vs. 38 months (P=.14), respectively. It should be noted that only 2 of the14 MRD- patients have died (both from GVHD without MM progression) in contrast to 10 of the16 MRD+ cases (P=.01). Further sub analysis focusing exclusively on patients submitted to SCT showed that persistent MRD also predicted for significantly inferior TTP (median 11 months vs. NR; P=.018); conversely, no relapses occurred among patients not submitted to

SCT but achieving an immunophenotypic CR (0% vs. 100% of cases MRD+; P=.005).
Summary / Conclusion: We show that achieving immunophenotypic CR is possible in a subset of relapse MM patients particularly after SCT, and identifies a subset of cases with long term relapse free survival.

P220

MYELOMA PLASMA CELLS ALTER THE BONE MICROENVIRONMENT BY STIMULATING AN INCREASE IN MESENCHYMAL STEM CELLS: A COMPARATIVE STUDY OF MYELOMA PATIENT- AND MURINE MODEL-DERIVED MESENCHYME

J Noll[1,2,*] S Williams[2], C Tong[2], H Wang[2], L Purton[3,4], A Farrugia[2], L To[5], S Gronthos[6], A Zannettino[1,2]
[1]School of Medical Sciences, University of Adelaide, [2]Myeloma Research Laboratory, Department of Haematology, SA Pathology, Adelaide, [3]Stem Cell Regulation Unit, St. Vincent's Institute, [4]Medicine, St. Vincent's Hospital, Fitzroy, [5]Haematology, SA Pathology, [6]Mesenchymal Stem Cell Laboratory, School of Medical Sciences, University of Adelaide, Adelaide, Australia

Background: Multiple myeloma (MM) is an incurable haematological cancer characterised by the clonal proliferation of plasma cells within the bone marrow (BM). Numerous studies suggest that the myeloma plasma cells occupy and alter the stromal tissue of the bone marrow as a means of enhancing their survival and growth. However, the nature and magnitude of the changes to the stromal cell tissue remain to be determined.
Aims: To identify changes in stromal tissue in response to myeloma plasma cells.
Methods: In this study, we used mesenchymal stromal cell (MSC) and osteoblast (OB)-related cell surface marker expression and flow cytometry to enumerate MSC and OB numbers in diagnostic BM recovered from myeloma patients and C57BL/KaLwRij mice bearing myeloma disease.
Results: Using this approach, we identified an increase in the number of STRO-1 positive colony forming MSC and a concomitant decrease in alkaline phophatase positive OB. Notably, this increase in MSC numbers correlated closely with plasma cell burden at the time of diagnosis. Additionally, in comparison with the OB population, the STRO-1+ MSC population was found to express higher levels of plasma cell- and osteoclast- activating factors, including RANKL, CXCL12 and IL-6, providing a mechanism by which an increase in MSC may promote and aid the progression of myeloma. Importantly, these findings were faithfully replicated in the C57BL/KaLwRij murine model of myeloma.
Summary / Conclusion: Myeloma plasma cells alter the bone microenvironment by stimulating an increase in mesenchymal stem cells. In addition, the C57BL/KaLwRij murine model presents a clinically relevant system in which to identify and therapeutically modulate the bone microenvironment and in turn, alter the progression of myeloma disease.

Multiple myeloma - Translational and clinical studies 1

EFFICACY AND SAFETY OF 3 LENALIDOMIDE-BASED COMBINATIONS IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: RESULTS FROM THE PHASE 3 COMMUNITY BASED EMN01 TRIAL

F Gay[1,*] S Bringhen[1], M Offidani[2], A Liberati[2], C Cellini[2], V Magarotto[1], G Benevolo[2], G Aitoro[2], F Patriarca[2], P Omede[1], C Conticello[2], Vi Montefusco[2], D Rossi[2], C Palladino[1], L Pour[3], A Allegra[2], G Pietrantuono[2], A Falcone[2], A Rocci[1], R Zambello[2], A Ledda[2], S Gentili[2], P Musto[2], M Boccadoro[1], R Hajek[4], A Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Dep. Of Internal Medicine, Hematology and Oncology, University Hospital Brno and School of Medicine MU, Brno, [4]School of Medicine, University of Ostrava, Institute of Clinical Haematology, University Hospital , Ostrava, Czech Republic

Background: Lenalidomide plus low-dose dexamethasone (Rd) and melphalan-prednisone-lenalidomide (MPR) followed by lenalidomide maintenance showed to be effective and safe in elderly newly diagnosed multiple myeloma(MM) patients (pts). Cyclophosphamide represents a valid alkylant alternative in combination with steroids and novel agents. No formal comparison between these combinations has been performed until now.
Aims: To assess the efficacy and safety of the lenalidomide plus low dose dexamethasone (Rd) vs Melphalan-Prednisone-Lenalidomide (MPR) and Cyclophosphamide-Prednisone-Lenalidomide (CPR) in a community-based setting of MM pts ≥65 years old or not eligible to autologous stem cell transplantation.
Methods: Pts with symptomatic MM were randomized (1:1:1) to receive 9 28-day cycles of Rd, MPR or CPR. Upfront dose reductions of dexamethasone, melphalan and cyclophosphamide were performed, according to pt age (Rd: lenalidomide 25 mg/day for 21 days; dexamethasone 40 mg on days1, 8, 15 and 22 in pts 65-75 years old and 20 mg in those >75 years; MPR: lenalidomide 10 mg/day for 21 days; melphalan orally 0.18 mg/Kg for 4 days in pts 65-75 years old and 0.13 mg/Kg in >75 years pts; prednisone 1.5 mg/Kg for 4 days; CPR: lenalidomide 25 mg/day for 21 days; cyclophosphamide orally 50 mg/day for 21 days in pts 65-75 years old and 50 mg every other day (eod) in >75 years pts; prednisone 25 mg eod). After induction, pts were randomized to receive maintenance with lenalidomide (10 mg/day on day 1-21 every 28) alone or in combination with prednisone (25 mg eod), until disease progression. The primary endpoint was progression-free survival (PFS).

Table 1.

Frail						
Yes (ECOG≥2 or Charlson≥2 or age>75)	124	56%	140	65%	143	65%

Results: Between October 2009 and October 2012, 663 pts were enrolled (Rd:222, MPR:218; CPR: 223). Patient characteristics were well balanced in the

three groups. Median age was 73 years in each arm; 37%, 40% and 36% of pts respectively in Rd, MPR and CPR arms were >75 years. Frail pts were 65% in the Rd arm, 65% in the MPR arm and 56% in CPR arm. (Table 1). At data cut-off all pts had completed the 9 induction cycles. Median follow-up was 19 months. Partial response (PR) rate was similar in the 3 arms: 74%, 74% and 75% respectively in Rd, MPR and CPR group, including 35% very good partial response in Rd, 29% in MPR and 26% in CPR. A trend towards a higher complete response (CR) rate was noticed in the MPR group (12%), similar CR rate was reported in Rd (5%) and CPR (7%). At least 1 grade ≥3 hematological adverse event (AE) was reported in 28% Rd pts, 62% MPR pts and 29% CPR pts. The main hematological AE was neutropenia (Rd: 24%; MPR: 59%; CPR: 26%). At least 1 grade ≥3 non-hematological AE was observed in 25% of Rd pts, 29% of MPR pts and 22% of CPR pts. The most common grade ≥3 non-hematological AEs were infections (Rd: 6%, MPR: 9%, CPR:4%) and dermatological toxicities (Rd: 4%, MPR: 4%, CPR: 7%). Treatment discontinuations for toxicity were 7% in Rd, 12% in MPR and 12% in CPR. The main reason for treatment discontinuation was non-hematological toxicity in Rd (6%) and CPR (11%). Only 1% of pts stopped treatment for hematological AEs in Rd and CPR. In the MPR arm 7% of pts stopped treatment for hematological AEs and 5% for non-hematological AEs. Rate of toxic deaths was similar in the 3 arms (4% Rd, 4% MPR and 5% CPR).

Summary / Conclusion: Rd, MPR and CPR produced similar RR in elderly MM patients. The main AEs were hematological, with a higher incidence in MPR in comparison with Rd and CPR. Non-hematological AEs were similar in the 3 groups.

P222

MELPHALAN/PREDNISONE/LENALIDOMIDE (MPR) VERSUS HIGH-DOSE MELPHALAN AND AUTOLOGOUS TRANSPLANTATION (MEL200) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS

A Palumbo[1],* F Cavallo[1], F Gay[1], T di Toritto[2], M Cavalli[2], D Ben Yehuda[3], P Finsinger[2], G Rossi[2], A Rocci[1], A Siniscalchi[2], L Barbarano[2], A Carella[2], L Catalano[2], P Musto[2], C Cerrato[4], M Marcatti[2], M Cavo[2], F Patriarca[2], M Genuardi[1], V Redoglia[1], F Rossini[2], P Corradini[2], A Nagler [5], F Di Raimondo[2], I Hardan [6], M Boccadoro[1]

[1]Myeloma Unit, Division of Hematology, University of Turin, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Hematology Division, Hadassah Medical Center, Jerusalem, Israel, [4]Myeloma Unit, Division of Hematology, Italian Multiple Myeloma Network, Torino, Italy, [5]Hematology Division, BMT and Cord Blood Bank, Chaim Sheba Medical Center, Tel hashomer, [6]Hematology Division, Meir Medical Center, Kfar-Saba, Israel

Background: The incorporation of new drugs into induction, consolidation and maintenance therapy is changing the treatment paradigm of MM but their role is not well defined.

Aims: To compare in a prospective randomized trial (MM-RV-PI209) conventional chemotherapy plus novel agents [melphalan-prednisone plus lenalidomide (MPR)] with tandem high-dose melphalan (melphalan 200 mg/m2 with stem-cell support; MEL200), both followed by maintenance with lenalidomide or no maintenance.

Methods: A 2x2 factorial randomized trial was designed to assess the role of adding lenalidomide to melphalan/prednisone at induction and as maintenance therapy.The primary end point was PFS on the intent to treat population. An enrolment of 170 pts/arm was required to demonstrate a15% improvement of PFS at 2 years (2-sides a= 0.05, 1- β=80%). At diagnosis, 402 pts (≤ 65 years) were randomly assigned to receive MPR (six cycles of melphalan-prednisone-lenalidomide, N=202) or tandem MEL200 (N=200). After MPR or MEL200, pts were further randomized, within each group, for no maintenance (N=204) or lenalidomide maintenance (10 mg, days 1-21, N=198).

Results: Patients characteristics were well balanced, including median age (58 years in both groups), ISS and FISH abnormalities [presence of t(4;14) or t(14;16) or del17p]. Response rates were similar after consolidation (MPR vs MEL200), with very good partial response (VGPR) or better of 60% vs. 58% (P=0.24) and complete response (CR) rate of 20% vs. 25% (P=0.49). The median duration of maintenance was 26.28 months. Lenalidomide maintenance did not significantly increase response rate: CR rate was 20% after MPR and 25% after maintenance, while it was 25% after MEL200 and 32% after maintenance. After a median follow-up of 45 mos from diagnosis, the median PFS was 25 mos with MPR and 39 mos with MEL200 (corresponding to a PFS of 50% vs 68% at 2 years, HR=1.66; 95%CI 1.27-2.18, P=.0002). Median PFS were 37.5 mos for maintenance and 25.7 mos for no maintenance (HR=0.63, 95%CI 0.48-0.83, P=.0008). The 4-year OS from diagnosis was similar: 71% with MPR and 72% with MEL200 (HR 1.08, 95%CI 0.72-1.63, P=0.71), 76% for maintenance and 68% for no maintenance (HR 0.68, 95%CI 0.45-1.04, P=.08). After a median follow-up of 32 mos from start of maintenance, the median PFS was for 41 mos for maintenance and 18 mos for no maintenance (HR=0.50, 95%CI 0.36-0.68, P<.0001). The 3-year OS from start of maintenance was 81% for maintenance and 72% for no maintenance (HR 0.60, 95%CI 0.37-0.97, P=.04). No meaningful interaction was detected between MPR/MEL200 and maintenance/observation effects.

Summary / Conclusion: MPR at diagnosis was clearly inferior to MEL200 when PFS is used as the main endpoint. Lenalidomide maintenance significantly reduced the risk of progression independently from the previous treatment. At present, OS is similar between MPR and MEL200, with a trend for an improved OS in pts receiving lenalidomide as maintenance therapy.

Table 1.

	First randomization			Second randomization		
	MPR	MEL200	HR (95%CI;p value)	MAINT	No MAINT	HR (95%CI;p value)

BORTEZOMIB-THALIDOMIDE-DEXAMETHASONE VERSUS THALIDOMIDE-DEXAMETHASONE PLUS AUTOTRANSPLANTATION FOR MULTIPLE MYELOMA: UPDATED FOLLOW-UP AND OUTCOMES AFTER RELAPSE IN THE PHASE 3 GIMEMA-MMY-3006 TRIAL

P Tacchetti[1],* M Galli[2], L Pantani[1], F Di Raimondo[2], C Crippa[2], M Offidani[2], E Zamagni[1], V Montefusco[2], F Narni[2], A Pezzi[1], A Spadano[2], N Pescosta[2], L Baldini[2], A Ledda[2], C Cellini[2], T Caravita[2], A Falcone[2], C Nozzoli[2], R Zambello[2], L Masini[2], M Boccadoro[2], M Cavo[1]

[1]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, [2]GIMEMA Italian Myeloma Network, Roma, Italy

Background: The phase 3 GIMEMA trial of thalidomide-dexamethasone (TD) versus bortezomib-thalidomide-dexamethasone (VTD) as induction therapy before, and consolidation therapy after double autologous stem-cell transplantation for newly diagnosed multiple myeloma (MM), demonstrated that VTD significantly improves rate of CR/nCR and extends PFS.

Aims: We report an updated follow-up of the GIMEMA trial with a detailed analysis of outcomes after relapse or progression (R/P), an important issue for patients (pts) treated up-front with a triplet or doublet novel agent-based therapy incorporated into ASCT.

Methods: Overall, 474 patients (236 randomized to VTD and 238 to TD) were enrolled in the trial. With a median follow-up of 52 months (mos) 226 pts (48%) relapsed or progressed. 182/226 pts resulted analyzable for outcomes after R/P.

Results: Median PFS for pts randomized to the VTD arm was 56 mos vs 42 mos for those assigned to TD (HR=0.64, P=0.0006). Similarly, median TTP for pts in the VTD group was longer than in the TD group (57 vs 45 mos, HR=0.63, P=0.0006), reflecting a 37% reduction in the risk of R/P with VTD. The probabilities of R/P in the VTD and TD arms were 41% vs 55% (P=0.002). After relapse, in comparison with the VTD-treated group a higher percentage of pts in the TD arm required the immediate start of salvage therapy for symptomatic R/P (67% vs 82.5%, P=0.016). Median time to salvage therapy (TTST) was significantly longer for pts who experienced R/P in the VTD arm than in the TD-treated group (35 vs 29 mos, P=0.018) and the associated salvage therapy-free interval (STFI) was 22.5 mos and 15 mos, respectively (P=0.009). Both bortezomib and lenalidomide were the most frequently used agents at the time of R/P (82% of all cases), while only 18% of pts were treated with conventional cytotoxic drugs. As expected, the majority of pts in the TD arm received a second-line therapy that included bortezomib (68%), while lenalidomide-dexamethasone was received by 12% of pts. By the opposite, in the VTD arm both bortezomib- and lenalidomide-based salvage therapies were equally distributed (40% vs 40%). The probability to achieve at least a partial response after second-line therapy including bortezomib was 60% for pts with prior exposure to VTD vs 63% for those randomized to TD. No difference in post-R/P OS was demonstrated between VTD-treated and TD-treated subgroups of pts who received bortezomib-based salvage therapy after R/P (2-yr estimates: 48% vs 53%, P=0.59). In the overall population, a trend toward longer post-R/P OS was observed for pts who received salvage therapy with novel agents, including bortezomib or lenalidomide (2-yr estimates: 52% and 53%, respectively), in comparison with pts treated with conventional cytotoxic drugs (2-yr estimate: 41%)(P=0.088).

Summary / Conclusion: With an extended follow up of 52 months, VTD incorporated into front-line ASCT was superior in comparison with TD plus ASCT in terms of TTP, PFS, TTST e STFI.VTD-treated pts had a higher probability than TD-treated pts to experience long-lasting asymptomatic R/P not requiring second-line therapy. VTD-treated and TD-treated pts who subsequently received bortezomib-based salvage therapies had similar rates of response and post-R/P OS; this finding suggests that short-term exposure to VTD did not favor the selection of bortezomib-resistant clones at the time of relapse.

P224

CMP-CARFILZOMIB (CFZ) PLUS MELPHALAN-PREDNISONE (MP)-IN ELDERLY PATIENTS (PTS) WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): RESULTS OF A PHASE (PH) I/II TRIAL

P Moreau[1,*] B Kolb[2], C Hulin[3], D Caillot[4], L Benboubker[5], M Tiab[6], C Touzeau[1], X Leleu[7], M Roussel[8], C Chaleteix[9], M Attal[8], T Facon [7]

[1]Department of hematology, university hospital, Nantes, [2]Department of hematology, university hospital, Reims, [3]Department of hematology, university hospital, Nancy, [4]Department of hematology, university hospital, Dijon, [5]Department of hematology, university hospital, Tours, [6]Department of hematology, university hospital, la Roche-sur-yon, [7]Department of hematology, university hospital, Lille, [8]Department of hematology, university hospital, Toulouse, [9]Department of hematology, university hospital, Clermont-ferrand, France

Background: MP+thalidomide (MPT) and MP+bortezomib (MPV) have shown significant progression-free survival and overall survival (OS) benefits in NDMM pts > 65 years (y) but are associated with peripheral neuropathy (PN). CFZ, a novel proteasome inhibitor, has shown promising activity and a favorable toxicity profile with low PN rates.
Aims: This PhI/II study in NDMM >65y was designed to determine maximum tolerated dose (MTD) of CMP and assess safety and efficacy.
Methods: In PhI, CFZ was started at 20 mg/m^2, then escalated to 27, 36, and 45 mg/m^2, given IV in 42-day (D) cycles (C) on D1/2/8/9/22/23/29/30 for 9C. Melphalan 9 mg/m² and prednisone 60mg/m² were given PO D1–4 of every 45-day cycle. MTD was based on dose-limiting toxicity (DLT) in C1 defined as any grade (G) 4 hematologic adverse event (AE), any hematologic AE preventing aministration of ≥ 2 C1 CFZ doses except G4 thrombocytopenia without bleeding or G4 neutropenia ≤7D, ≥G3 febrile neutropenia, or any ≥G3 nonhematologic AE.
Results: As of February 26, 2013, 24 pts have been enrolled in PhI: 6 for each dose level. There were 2 DLTs at 45mg/m^2 (fever, hypotension) resulting in a MTD of 36 mg/m². In PhII, 45 additional pts received CMP at 36 mg/m² CFZ for N=69 total PhI/II pts (median age 74y). ORR was 89% with 51% ≥VGPR. With median follow-up of 12 mo, the projected 2y OS was 89.9%. CMP was well tolerated without PN ≥G2. These results compare favorably to those of MPV, MPT, MP+lenalidomide (R), and R+dex in similar pts (ORR 71% San Miguel NEnglJMed2008, 76% Facon Lancet2007, 80% Palumbo JClinOncol2007 and 85% Rajkumar LancetOncol2010, respectively).
Summary / Conclusion: CFZ 36 mg/m^2 +MP is tolerable and effective in elderly NDMM pts. Treatment is ongoing. Final safety and efficacy data will be presented during the meeting.

P225

RANDOMIZED, OPEN-LABEL, PHASE 2 STUDY OF SILTUXIMAB (AN ANTI-IL-6 MAB) AND BORTEZOMIB-MELPHALAN-PREDNISONE VERSUS BORTEZOMIB-MELPHALAN-PREDNISONE IN PATIENTS WITH PREVIOUSLY UNTREATED MULTIPLE MYELOMA

Background: For patients newly diagnosed with symptomatic multiple myeloma (MM) and ineligible for autologous stem cell transplantation (ASCT), bortezomib (VELCADE)-melphalan-prednisone (VMP) is a standard treatment regimen. Interleukin (IL)-6 enhances proliferation, differentiation, and survival of malignant plasma cells in MM. Therefore, anti-IL-6-directed treatment could further enhance VMP activity. Siltuximab (S; formerly CNTO 328) is a chimeric, anti-IL-6 monoclonal antibody that has been shown in preclinical experiments to enhance the anti-myeloma activity of VELCADE, melphalan, and corticosteroids.
Aims: To evaluate if the combination of S+VMP demonstrates improved efficacy compared with VMP alone, as assessed by complete response (CR) rate using the European Group for Blood and Marrow Transplantation (EBMT) criteria.
Methods: Newly diagnosed MM patients with measurable secretory disease who were not candidates for high-dose chemotherapy with ASCT received S+VMP for up to 9 cycles in the Part 1 safety run-in of a two-part, phase2, multicenter study. The safety profile of S+VMP was deemed acceptable, and the study proceeded to Part2, in which patients were randomly assigned to receive S+VMP or VMP alone for up to 9 cycles during the treatment period. V 1.3 mg/m^2 was given IV twice weekly at weeks1,2,4, 5 for four 6-week cycles, then weekly for five 6-week cycles with M 9 mg/m^2 once daily and P 60 mg/m^2 once daily on days 1−4 of every cycle. S was given as a 1-hour IV infusion at 11 mg/kg every 3 weeks with VMP. Patients with at least partial response (PR) on the S arm could enter an 18-month maintenance period with S alone. The primary endpoint was safety for Part 1 and CR rate according to EBMT criteria for Part 2.
Results: From June 2009 to May 2011, 12 patients were recruited in Part1, and 106 patients were randomized in Part 2: 52 to S+VMP and 54 to VMP. Data presented here are from the randomized Part 2. Baseline demographics and disease characteristics were well balanced between S+VMP and VMP, except for IgA subtype (40% in S+VMP and 19% in VMP). High-risk cytogenetic abnormalities (ie, t(4;14), t(14;16), and 17p deletion) were present in 17% in S+VMP and 10% in VMP, including 17p deletion in 15% in S+VMP and 4% in VMP. Median treatment duration during Cycles 1−9 was 12.5 months for S+VMP and 12.9 months for VMP alone. Twenty-one patients received maintenance S with a median treatment duration of 6.2 months. The median follow-up was 21.7 months at the current analysis. With S+VMP and VMP, CR was 27% vs. 22%, near CR was 31% vs. 14%, and overall response rate (CR+PR) was 88% vs. 80%, respectively (table). At least very good PR (VGPR) by International Myeloma Working Group (IMWG) assessment was observed in 71% with S+VMP and in 51% with VMP (P=0.0382). Median progression-free survival (PFS) was 17 months with S+VMP and 17 months with VMP. Overall survival (OS) rate with S+VMP and VMP was 88% and 88% at 1 year. During Cycles 1−9, Grade ≥3 adverse events were reported in 92% of patients with S+VMP and in 81% of patients with VMP alone. Common Grade ≥3 adverse events in the S+VMP and VMP arms were neutropenia (62% vs. 43%), thrombocytopenia (44% vs. 25%), and bronchopneumonia/pneumonia (17% vs. 17%). Serious adverse events were reported with S+VMP and VMP in 58% vs. 51% of patients, respectively. The most frequently reported serious adverse events were infections (23% with S+VMP and 17% with VMP). Five patients on S+VMP and 4 patients on VMP died due to an adverse event; 1 death on VMP was considered drug-related.
Summary / Conclusion: The addition of siltuximab to VELCADE-melphalan-prednisone resulted in a numerical increase in CR rates (from 22% to 27%) and at least VGPR rates (from 51% to 71%) and added moderate additional toxicity. No improvements in longer-term outcomes have been observed.

Table 1.

	VMP	S+VMP
Evaluable patients in Part 2	49	49

MM-005: A PHASE 1 TRIAL OF POMALIDOMIDE, BORTEZOMIB, AND LOW-DOSE DEXAMETHASONE (PVD) IN RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (RRMM)

P Richardson[1,*] C Hofmeister[2], D Siegel[3], S Lonial[4], J Laubach[1], Y Efebera[2], D Vesole[3], A Nooka[4], J Rosenblatt[5], N Raje[6], M Zaki[7], Y Hua[7], S Shah[7], J Wang[7], K Anderson[1]

[1]Medical Oncology, Jerome Lipper Multiple Myeloma Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, [2]Internal Medicine, Hematology, The Ohio State University, Columbus, OH, [3]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, [4]Division of Bone Marrow Transplant, Emory University, Winship Cancer Institute-Hematology and Medical Oncology, Atlanta, GA, [5]Beth Israel Deaconess Medical Center, Harvard Medical School, [6]Massachusetts General Hospital, Boston, MA, [7]Celgene Corporation, Summit, NJ, United States

Background: Combinations of lenalidomide (LEN), bortezomib (BORT), and dexamethasone (DEX) have demonstrated preclinical and clinical activity in

patients with multiple myeloma (Kumar S, *et al*. *Blood.* 2012; Richardson PG, *et al*. *Blood*. 2010). POM was recently approved by the US Food and Drug Administration for the treatment of RRMM patients who have received at least 2 prior therapies, including LEN and BORT. POM with low-dose DEX (LoDEX) has demonstrated efficacy in RRMM patients treated with prior LEN and BORT (Leleu X, *et al*. *Blood*. 2013; Lacy MQ, *et al*. *Blood.* 2011). MM-005 was designed to identify the optimal dose of PVD for a phase 3 trial comparing PVD vs. BORT + LoDEX (VD) in patients with RRMM (MM-007).

Aims: Identify the maximum tolerated dose (MTD) of POM in combination with VD.

Methods: Eligible patients had RRMM with 1-4 prior lines of therapy including 2 or more consecutive cycles of LEN and a proteasome inhibitor. Patients must have been refractory to LEN (progressive disease [PD] during or within 60 days of LEN treatment), but not refractory to BORT (at 1.3 mg/m^2 twice weekly). The MTD was determined using a 3 + 3 design in 5 cohorts. Each cohort received 21-day cycles of POM 1-4 mg/day on D1-14; BORT 1-1.3 mg/m^2 on D1,4, 8, and 11; and LoDEX 20 mg/day on D1-2, 4-5, 8-9, and 11-12. All patients received thromboprophylaxis with aspirin or low-molecular-weight heparin. An expansion cohort was enrolled at the MTD. Treatment was continued until PD or unacceptable toxicity. Dose-limiting toxicities (DLTs) were assessed during cycle 1. The primary endpoint was MTD; secondary endpoints included safety, overall response rate (ORR; ≥ partial response), duration of response, and time to response (TTR).

Results: As of December 31, 2012, twenty-one patients were enrolled (3 patients per escalating dose cohort; 6 in the expansion cohort). The median age was 57 years (range, 36-75 years). All patients were LEN refractory and had received prior BORT. Patients had received a median of 2 prior lines of therapy (range 1-4 prior lines). No DLTs have been observed at any dose level. Confirmation of the tolerability of the highest dose level (POM 4 mg, BORT 1.3 mg/m^2, LoDEX 20 mg) is ongoing. The most common grade 3-4 adverse events (AEs) were neutropenia (37%) and thrombocytopenia (21%). With thromboprophylaxis, no deep vein thrombosis was observed and no significant PN (≥ grade 3) has been seen to date. Importantly, none of the patients discontinued treatment due to AEs and 17 patients remain on study. Thus far, the ORR was 73% (n=15 evaluable), including 27% very good partial response. Responses are ongoing and were also observed in patients with adverse cytogenetics. Furthermore, PVD rapidly induced responses with a median TTR of 2 cycles (6 weeks). Updated data will be presented at the meeting.

Summary / Conclusion: PVD was generally well tolerated in RRMM with no DLTs and no discontinuations due to AEs to date. This combination had promising activity in this LEN-refractory population with an ORR of 73%. The maximum planned dose of POM 4 mg/day on D1-14; BORT 1.3 mg/m^2 on D1,4, 8, and 11; and LoDEX 20 mg on D1-2, 4-5, 8-9, and 11-12 of a 21-day cycle has been incorporated into the ongoing MM-007 randomized, prospective phase 3 trial comparing PVD with VD in RRMM patients (n=782).

P227

TANDEM AUTOLOGOUS/ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATIONS IN FIRST LINE HIGH RISK MULTIPLE MYELOMA PATIENTS: EVOLVING STRATEGIES WITH THE IMMUNOMODULATING DRUGS

M Michallet[1,*] M Sobh[1], J El-Cheikh[2], S Morisset[1], A Sirvent[3], O Reman[4], J Cornillon[5], R Tabrizi[6], N Milpied[6], J Harousseau[7], H Labussière[1], F Nicolini[1], M Mohty[7], D Blaise[2], M Attal[8], H Avet-loiseau[8]

[1]Hematology, Centre Hospitalier Lyon Sud, Pierre Bénite, [2]Hematology, Institut Paoli Calmettes, Marseille, [3]Hematology, Hôpital de l'ARCHET, Nice, [4]Hematology, CHU de Caen, Caen, [5]Hematology, Institut de Cancérologie de la Loire, Saint Etienne, [6]Hematology, CHU de Bordeaux, Bordeaux, [7]Hematology, CHU de Nantes, Nantes, [8]Hematology, CHU de Toulouse, Toulouse, France

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only available potentially curative treatment for patients with hematological malignancies particularly those with high risk factors; its use in multiple myeloma as a first line treatment is still controversial especially not only with discordant results from different studies with different treatment and conditioning modalities but also with different patient/donor characteristics

Aims: We evaluated the efficacy and toxicity of tandem auto-HSCT strategy followed by RIC and allo-HSCT with the post-allo-HSCT use of bortezomib and DLI in high risk (β2 microglobulin level >3 mg/L, del13, t(4;14) or del17p) multiple myeloma patients (Group1). We compared our results to those observed after traditional tandem auto-RIC-allo-HSCT without bortezomib (Group2). Groups 1 and 2 were compared to matched patients not receiving allo-HSCT from the IFM studies.

Methods: Conditioning regimen combined fludarabine 30 mg/m²/d (d-5→d-1), busilvex IV 3.2 mg/kg/d (d-4,d-3) and ATG 2.5 mg/kg/d (d-2,d-1). In group1, by day 90 post-allo-HSCT, patients not in CR received 4 cycles of bortezomib 1.3 mg/kg; if the CR not achieved, increasing doses of DLI were administered. Allo-HSCT groups included 25 patients (12 in group1 and 13 in group2), 18 males and 7 females with a median age of 51 years [28-67]; 14 (56%) patients had del13, 7 (28%) del17 and 17 (68%) had β2 microglobulin level >3 mg/L. The stem cell source was PBSC in 22 (88%) of cases from 16 identical siblings and 9 HLA (10/10) matched unrelated donors. At allo-HSCT, one patient was in CR, 4 in VGPR and 20 in PR. The matched population included 36 controls for group1 and 39 for group2.

Results: At Day 90 after allo-HSCT, all patients engrafted, 10 patients were in CR and 15 patients were in less than CR. Nine patients in group1 received bortezomib, 3 reached a CR while the 6 others were still in PR and received increasing doses of DLI. There were 8 acute GVHD [7 grade II (3 in group1) and 1 grade III in group1] and 11 chronic GVHD [3 lim. (all in group1) and 8 ext. (1 in group 1)]. At the last follow-up, 14 patients are alive (9 in group1 and 5 in group2), 10 were in durable CR1 and 4 in PR after DLI; 11 patients died (3 in group1: all from progression; 8 in group2: 5 from progression and 3 from TRM). After a median follow-up of 55 months [3-142], the median OS was not reached in group1 vs. 65 months (51-NR) in its matched patients (P=0.027); and it was 96 months (49-NR) in group2 vs. 91 months (32-NR) in its matched patients (P=0.77). The median PFS was 49 months (29-NA) in group1 vs. 25 months (21-35) in its matched patients (P=0.004); it was 31 months (22-NR) in group2 vs. 28 months (21-40) in its matched patients (P=0.077).

Summary / Conclusion: The encouraging results in group1 are due to the use of IV busilvex and better ATG administration schedule in addition to the immunomodulating role of bortezomib in the elimination of the residual disease. The use of tandem auto-RIC-allo-HSCT including new agent combinations and immunomodulation after transplantation should be reconsidered in the context of first line treatment for MM especially for patients with poor prognostic factors.

P228

PHASE II CLINICAL AND CORRELATIVE STUDY OF CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE FOLLOWED BY LENALIDOMIDE EXTENDED DOSING (CRD-R) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS

N Korde[1,*] A Zingone[1], M Kwok[2], E Manasanch[1], P Wu[1], N Tageja[1], M Bhutani[1], A Flanders[2], R Costello[1], M Mulquin[1], D Zuchlinski[1], M Roschewski[1], I Maric[3], K Calvo[3], R Braylan[3], C Yuan[4], M Stetler-Stevenson[4], D Arthur[4], L Xi[5], M Raffeld[5], M Lindenberg[6], P Choyke[6], K Kurdziel[6], S Steinberg[7], M Lee[8], J Trepel[8], O Landgren[1]

[1]NCI, NIH, [2]Hematology/Oncology, Walter Reed National Military Medical Center, [3]Hematology Service, DLM, [4]Lab of Pathology, NCI, [5]Molecular Diagnostics Core Lab, NCI, [6]Molecular Imaging Program, NCI, [7]Biostatistics and Data Management Section, NCI, [8]Molecular Oncology Branch, NCI, CCR, NIH, Bethesda, United States

Background: As modern MM treatments induce deeper responses, there is an increasing demand to characterize remissions with sensitive techniques. Flow cytometry and functional imaging techniques are emerging tools that measure minimal residual disease (MRD). Carfilzomib (CFZ) is an irreversible proteasome inhibitor with potent anti-MM effects that induces rapid and deep responses when combined with lenalidomide (LEN) and dexamethasone (DEX).

Aims: In this single arm phase II trial using CRd therapy, we report the results of the first n=28/45 patients. The primary endpoint is the incidence of ≥ grade 3 neuropathy. Secondary endpoints include response rate, profiling CFZ activity to biological endpoints, and impact of MRD studies on clinical outcomes.

Methods: Eligible patients included both transplant and non-transplant newly diagnosed MM patients. Each cycle is 28-days: CFZ IV 20/36 mg/m^2 on days1,2, 8, 9, 15, 16; LEN oral 25 mg days 1-21; and DEX IV/oral 20/10 mg on days1,2, 8, 9, 15, 16, 22, 23. Patients younger than 70-75 years underwent stem cell harvest after 4 cycles of CRd and continue therapy. After 8 cycles of CRd, all patients with SD or better clinical outcome received cycles 9-20 of LEN extended dosing 10 mg days 1-21. MRD assessments with multi-parametric flow cytometry and FDG-PET CT were performed on achievement of CR/end of cycle (during cycles 1-8).

Results: A total of 31 patients meeting eligibility criteria have been enrolled (15 female, 16 male; median age 60; range 40-88). Among enrolled patients, mean baseline M-protein was 3.0 g/dL (range 1.0-7.1) and isotypes included 7 IgA, 19 IgG, 4 kappa, and 1 lambda. 28 patients were evaluable for toxicity and response with a median of 8 cycles of therapy completed (2-17). As no patients reported ≥ grade 3 neuropathy, the primary endpoint of this study was met. The mean M-protein decline after completing one cycle of therapy was 67.2%. Highlighting the rapid rate of response, patients obtaining ≥ VGPR went from 42% after 2 cycles of therapy to 85% after 4 cycles of therapy. Best responses after median of 8 cycles of therapy included 11 – sCR/7-nCR (64.3%), 4 – VGPR (14.3%), 5 – PR (17.9%), and 1 – SD (3.6%). Median time to sCR was 6.9 cycles. One patient had progressive disease (PD) based on biochemical progression and not clinical symptoms. Toxicities were consistent with that previously reported. The most common G3/4 toxicities: non-hematologic - rash, electrolyte disturbance, and LFT elevation; hematologic - lymphopenia and anemia. Among 10 sCR and 4 nCR who underwent MRD assessment, all were negative. Among 1 VGPR, 1 PR and 1 PD patients, there was evidence of immunophenotypically abnormal plasma cells defined by multi-parametric flow cytometry after 8 cycles of CRd. All 11 patients with baseline FDG avid lesions or extramedullary disease showed decrease or resolution of FDG avidity at

MRD assessment time points.
Summary / Conclusion: Combination CRd therapy followed by extended LEN dosing in newly diagnosed MM patients show deep response rates corroborated by MRD assays and tolerable side effects.

Table 1.

	2 cycles n/N (%)	4 cycles n/N (%)	8 cycles n/N (%)
ORR (≥PR)	27/28 (96.4)	20/21 (95.2)	14/15 (93.3)
≥VGPR	12/28 (42.9)	18/21 (85.7)	13/15 (86.7)
sCR	2/28 (7.1)	5/21(23.8)	7/15 (46.7)
nCR	4/28 (14.3)	6/21 (28.6)	4/15(26.7)

P229

PROLONGED OVERALL SURVIVAL WITH POMALIDOMIDE AND DEXAMETHASONE IN END STAGE MYELOMA

X Leleu[1,*] M Roussel[2], B Arnulf[3], P Moreau[4], C Traulle[5], G Marit[6], M MICHALLET[7], C Mathiot[8], M Petillon[9], M Macro[10], B Pegourie[11], B KOLB[12], A Stoppa[13], S Brechiniac[8], L Garderet[8], B Royer[14], C Hulin[14], L benboubker[15], O Decaux[16], D Caillot[17], M Escoffre[16], H LOISEAU[18], M ATTAL[19], J FERNAND[20], T FACON[9]
[1]Hopital Huriez, Lille, [2]Hopital Purpan, Toulouse, [3]Paris, Hopital, paris, [4]Hopital, Nantes, [5]lyon, Hopital, Lyon, [6]hopital, bordeaux, [7]CH, Lyon, [8]Hopital, Paris, [9]Hopital Claude Huriez, Lille cedex, [10]CHU, Caen, [11]CHU, Grenoble, [12]CHU, Reims, [13]CH, Marseille, [14]CHU, Amiens, [15]CHU, Tours, [16]CHU, Rennes, [17]CHU, Dijon, [18]CHU, Nantes, [19]CHU, Toulouse, [20]CHU, Paris, France

Background: MM remains incurable and patients will ultimately acquire resistance to novel agents. Kumar *et al*. have shown that the expected median PFS and OS for patients relapsed or were refractory to bortezomib and an IMiDs (double refractory) was 5 months and 9 months, respectively. Several studies have shown that the combination of pomalidomide plus dexamethasone was active and well tolerated in double refractory MM, with a response rate (PR and greater) of approximately 25% to 35%.
Aims: In this final analysis, we aimed to further demonstrate that treatment with pomalidomide and dexamethasone translated into prolonged survival.
Methods: The IFM2009-02 phase 2 (Leleu *et al*, ASH 2011) randomized study was designed to determine the impact of pomalidomide; given orally either 4 mg daily on days 1–21 of a 28-day cycle (arm 21/28) or continuously on days 1–28 of a 28-day cycle (arm 28/28); in combination with dexamethasone (oral 40 mg weekly). This study included MM patients who did not achieve a response (≤ SD) as per IMWG criteria with the last course of bortezomib and the last course of lenalidomide, or who were refractory to both bortezomib and lenalidomide. The primary objective was ORR, assessed centrally and reviewed by an independent committee. The analysis is performed on the ITT population and combines data from the 2 arms.
Results: Overall, 84 patients (57 male and 27 female)were enrolled, with a median age of 60 years (range 42-83). The median time from diagnosis to enrolment was 70.5 months (range 9-277). The median number of prior lines of therapy was 5 (range 1-13), and 100% of the patients had received prior bortezomib and lenalidomide as per protocol. Additionally, 84.5% were refractory to their last prior line of therapy and 77% were refractory to their last prior lines of both lenalidomide and bortezomib. With a median follow up of 22.8 months, the median (95%CI) PFS and TTP was 4.6 months (4-7) and 5.4 months (CI 4-8), with a median duration of response of 7.3 months (5-15). 28% of patients were free of progression and 44% responded, at 1 year respectively. The most common reason for treatment discontinuation was disease progressions (84%). 95% of deaths wereconsidered to be disease related. Importantly, 10 patients (12%) remain on treatment after 36 months. The median OS was 14.9 months (11-20) with 57% and 44% of patients surviving at 12 and 18 months respectively. We noticed that OS was significantly prolonged in responders when compared to patients with SD. The median OS has not been reached in responders, (18.4;-); and was 13 (8; 20) months in patients with SD, (HR [95% CI) 0.45 [0.2, 0.9], P=0.018). Noteworthy, 83% of responders and 50% of patients with SD were still alive after 12 months of treatment, and 69% and 36% were still alive at 18 months, respectively. Future studies may consider studying response rate and survival improvement on pomalidomide by adding a third agent to Pomalidomide plus dexamethasone regimen.
Summary / Conclusion: The IFM2009-02 study thus pointed out the survival difference in responders as compared to patients with stable disease related to a prolonged duration of response. Pomalidomide and dexamethasone is effective and generally well tolerated in heavily pre-treated MM patients. The combination of pomalidomide and dexamethasone compared very favourably to the expected median OS reported in the historical control study in end stage MM. This study provides further evidence that pomalidomide can provide benefit for patients who have relapsed after other novel therapies.

P230

A NEW SCORING SYSTEM TO IDENTIFY PATIENTS AT HIGH-RISK OF EARLY DEATH IN THE CONTEXT OF NOVEL AGENT-BASED INTENSIVE THERAPY

P Moreau[1,*] M Cavo[2], P Sonneveld[3], I Rosinol[4], G Marit[5], A Pezzi[2], H Goldschmidt[6], J Blade[4], M Attal[7], J Mary[8]
[1]department of hematology, University Hospital, Nantes, France, nantes, France, [2]department of hematology, University Hospital, bologna, Italy, [3]department of hematology, university hospital, amsterdam, Netherlands, [4]department of hematology, university hospital, barcelona, Spain, [5]department of hematology, university hospital, bordeaux, France, [6]department of hematology, university hospital, heidelberg, Germany, [7]department of hematology, university hospital, toulouse, [8]department of hematology, university hospital saint-louis, paris, France

Background: Several biological parameters or indexes including cytogenetics and/or International Staging System (ISS) have been identified to define patients with multiple myeloma with high-risk of progression, but none of them are defined in order to select a subgroup of patients at high risk of early death from progression, especially in the context of frontline therapy using novel-agents based induction and autologous stem cell transplantation.
Aims: We investigated prognostic parameters of patients enrolled in the IFM2005-01 trial comparing bortezomib-dexamethasone versus VAD induction followed by ASCT (Harousseau *et al*, J Clin Oncol 2010;28:4621-4629).
Methods: The risk of death within the first 2 years from the start of therapy from progressive disease (and not toxicity) (42 cases out of 482 patients) was related to 3 independent adverse initial characteristics in a multivariate logistic regression analysis: high LDH > normal value (P=0.0014), ISS 3 (P=0.0097) and cytogenetic abnormalities defined by the presence of either t(4;14) or 17p deletion (P=0.0002). These 3 variables enabled the identification of a simple 0 to 3 scoring system predicting for overall survival (OS). Score 0 was defined by the absence of adverse factor (neither high LDH, nor ISS3, nor t(4;14) and /or 17p); in this group of patients representing 57% of the overall population, the 4-year OS rate was 84%. Score 1 was defined by the presence of only 1 adverse factor (either high LDH or ISS3 or t(4;14) and/or 17p); in this group of patients representing 32% of the overall population, the 4-year OS rate was 73%. Score 2 was defined by the presence of high LDH plus ISS3, without t(4;14) and /or 17p; in this group of patients representing 6% of the overall population, the 4-year OS rate was 68%; Score 3 was defined by the presence of t(4;14) and/or 17p in addition with either ISS3 or high LDH; in this group of patients representing 5% of the overall population, the median OS was only 19 months.
Results: This score was subsequently applied to a larger population of patients enrolled in 4 phase 3 studies independently conducted by HOVON/GMMG (Sonneveld *et al*, JClinOncol 2012), IFM (Harousseau *et al*, J Clin Oncol 2010), PETHEMA (Rosinol *et al*, Blood 2012) and GIMEMA (Cavo *et al*, Lancet 2010) cooperative groups comparing bortezomib-based versus no bortezomib-based inductions prior to single or tandem ASCT. Out of 2169 patients enrolled in these 4 trials, 1601 had data available to use the new scoring system. 903 (56%) had a score of 0, 515 (32%) a score of$_1$, 68 (4%) a score of$_2$, and 115 (7%) a score of$_3$, respectively. 2-year OS was significantly different according to the score: 93% for a score of 0, 85% for a score of$_1$, 67% for a score of$_2$, and 55% for a score of 3 (P<0.0001). This score was also very effective in defining cases with dramatic outcome in the population of 850 patients treated in these 4 trials into the bortezomib-based induction regimens (2-year OS of 52% in patients with score 3).
Summary / Conclusion: We have defined a new and simple scoring system that allows the identification of a small group of patients at very high-risk disease and shortened survival, despite the use of the most recent intensive novel-agent based therapy. The subgroup of patients with a score of 3 associated with a dramatic outcome might be candidate for innovative therapeutic approaches.

P231

BENDAMUSTINE, BORTEZOMIB AND DEXAMETHASONE (BVD) IN ELDERLY MM PROGRESSIVE AFTER 1ST LINE THERAPY (IFM 2009-01 TRIAL): PREDICTIVE FACTORS OF DEFAVOURABLE OUTCOME

Background: Prognosis of relapse is severe in elderly multiple myeloma (MM). In recent studies, median survival at progression after 1st line therapy was between 9 and 13 months (T. Facon, Lancet 2007; C. Hulin, J Clin Oncol 2009). Bortezomib (V) plus dexamethasone (D) is a major regimen in the treatment of relapses. Bendamustine (B) demonstrated to be highly active in advanced MM. The IFM 2009-01 trial evaluated the combination of B, V and D in elderly patients with progressive MM on or after 1stline treatment.
Aims: The present analysis aimed to determine predictors of defavourable outcome at 6 months.
Methods: IFM 2009-01 trial was dedicated to pts > 65 years in 1st relapse or refractory to 1st line therapy. Inclusion criteria were measurable disease, PS ECOG 0-2, ANC > 1.5x10^9/L, platelets > 100x10^9/L, serum creatinine level <250 mcmol/l, AST and ALT < 3xULN. Pts with prior exposure to bortezomib were excluded. Treatment regimen was 6 28 days cycles of B 70 mg/m^2 D1-8, V 1.3 mg/m2 D1-8-15-22 and D 20 mg D1-8-15-22. Responders were assigned to receive maintenance treatment with 6 additional cycles given 1 month out of 2. Pts with favourable outcome at 6 months were defined as achieving sustained PR or better and beginning maintenance treatment without major toxicity or unrelated event.
Results: From 03/2010 to 07/2011, 73 pts were included. Median age was 75.8 years (range 66-86). Median time from diagnosis to inclusion was 29 months. All pts received only 1 prior line of therapy: melphalan-prednisone (MP) in 12, MP-Thalidomide in 44, Lenalidomide-Dexamethasone (LD) in 14, other IMiD-based regimen in 3. 49 pts (67.1%) achieved at least partial response [best response CR: 9 pts (12.3%), VGPR: 12 pts (16.5%), PR: 28 pts (38.3%), MR: 6 pts (8.2%), SD: 4 pts (5.5%), progression: 13 pts (17.8%), early discontinuation: 1 pt (1.3%)]. At 6 months, PFS was 67.1% and OS 80.8%. Defavourable outcome was observed in 36 pts (49.3%): failure to achieve sustained PR in 24, treatment toxicity in6, unrelated adverse event in4, patient refusal or lost to follow-up 1 each. Predictive factors of a defavourable outcome were beta 2 microglobulin (B2M) level > 3.5 mg/L (P=0.0029), 17p deletion (P=0.025) and male sex (P=0.04).
Summary / Conclusion: In the IFM 2009-01 trial, elevated serum B2M level, presence of deletion 17p and male sex correlated with defavourable outcome

Background: Several studies have demonstrated the impact of VTd on response rates and PFS either as induction or consolidation regimen upfront in Myeloma (MM). However there are limitations to these studies, especially that no data is available regarding the role of VTd consolidation in the context of bortezomib-triple based VTd induction regimen followed by a single autologous transplantation (auto). The CR rate, relapse rate and median PFS were 29%, 53% and 26 months in the VTd arm of the IFM2007-02 trial with no consolidation. Cavo *et al*. reported 61% CR rate, 39% 3-year progression and 62% estimated 5-year PFS with VTd consolidation after double auto in the GIMEMA study (Cavo *et al*, Lancet 2010).
Aims: We aimed to assess the efficacy and safety of VTd as consolidation therapy in the context of VTd as induction regimen followed by a single auto (VTd-auto-VTd regimen).
Methods: This retrospective multicentre study has included newly diagnosed MM patients eligible for ASCT upfront and aged less than 65 in 2 cohorts across 9 IFM centers. The patients must have completed the procedure. The first group (VTd-auto-VTd) included 121 MM treated with VTd-auto-VTd regimen. The regimen consisted of 4 induction cycles and 2 consolidation cycles of VTd [bortezomib I.V. 1.3 mg/m² on days1,4, 8, and 11, thalidomide 100 mg/day administered orally, and dexamethasone 40mg weekly administered orally]. All patients underwent ASCT with high dose melphalan 200mg/m² as conditioning regimen. The second cohort (VTd-auto) included 96 MM that completed the same VTd-auto regimen but without consolidation. None of the patients had received a maintenance therapy across cohorts.
Results: ORR was identical at completion of therapy across cohorts, nevertheless the CR rate was greater in the cohort VTd-auto-VTd, 52% vs. 30% (P=0.001), while identical across cohorts after induction and autotransplantation. With 30 months median follow-up, the relapse rate was lower in VTd-auto-VTd, 21% vs. 45% (P=0.001) and the median TTP not reached and 25 months in either cohort, respectively (P=0.005). The expected 4-years TTP was 62% and 29% in either cohort respectively. The safety profile of the cohort VTd-auto-VTd was superimposable to that of VTd-auto without consolidation.
Summary / Conclusion: This study further demonstrated the importance of the VTd consolidation to improve clinical outcomes with an acceptable toxicity profile, in the context of VTd as induction and a single ASCT upfront in MM. This study showed an impressive CR rate in relation to the consolidation that translated into a lower relapse rate and a prolonged TTP. This study demonstrated that the VTd regimen, used both as induction and consolidation, in the context of a single ASCT upfront significantly contributed to improve clinical outcomes with an acceptable toxicity profile in MM. VTd-auto-VTd compared very favorably to the other upfront protocols, and may become in the near future a standard of care in newly diagnosed patients with Myeloma.

P233

CLINICAL PROFILE OF ONCE-DAILY, MODIFIED-RELEASE OPROZOMIB TABLETS IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES: RESULTS OF A PHASE 1B/2 TRIAL

J Kaufman[1],* D Siegel[2], R Vij[3], I Ghobrial[4], A Badros[5], L Neuman[6], J Anderl[6], M Savona [7]
[1]Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, [2]John Theurer Cancer Center, Hackensack, [3]Washington University School of Medicine, St. Louis, [4]Dana-Farber Cancer Institute, Boston, [5]M & S Greenebaum Cancer Center, Baltimore, [6]Onyx Pharmaceuticals, Inc., South San Francisco, [7]Sarah Cannon Research Institute, Nashville, United States

Background: Oprozomib, a structural analog of carfilzomib, is an orally bioavailable proteasome inhibitor that binds selectively and irreversibly to its target. We have previously shown that oprozomib split-dose powder-in-capsule demonstrated promising clinical activity in patients with hematologic malignancies (Savona MR, *et al*. ASH 2012. Abstract 203). In an effort to improve gastrointestinal tolerability, a once-daily modified-release tablet was introduced into the ongoing phase 1b/2 dose escalation study, the preliminary findings of which were presented at the 14th International Myeloma Workshop (Seigel DS, *et al*. IMW 2013. P-225). More mature data with oprozomib once-daily, modified-release tablets are now available, the results of which are presented herein.
Aims: To determine the maximum tolerated dose (MTD) and the safety and tolerability profile of once-daily, modified-release oprozomib tablets. Secondary endpoints include response according to relevant criteria (eg, International Myeloma Working Group Uniform Response, Third International Workshop on Waldenström's Macroglobulinemia) and pharmacodynamics.
Methods: This is an ongoing, multicenter, phase 1b/2 dose-escalation study (NCT01416428) taking place in 7 centers in the United States in patients with hematologic malignancies. Dose escalation is underway. Two dosing schedules are being investigated: oprozomib once-daily, modified-release tablets have been administered to patients on days1,2, 8, and 9 of a 14-day cycle (QD×2) or on days 1–5 of a 14-day cycle (QD×5). Dose escalation began at 150 mg/d for each schedule and is being increased in 30-mg increments using a 3+3 study design. There is no maximum planned dose for this study.
Results: As of February 2013, 21 patients have enrolled in the study following introduction of oprozomib once-daily modified-release tablets. To date, the patients (16 with multiple myeloma [MM]; 5 with Waldenström's macroglobulinemia) have been enrolled in 6 cohorts (Table 1). No dose-limiting toxicities

(DLT) have been observed for patients who received tablets QD×2. One DLT (acute renal failure) was reported at 180 mg/d from the QD×5 dosing schedule (n=3 patients). This cohort was expanded. For both dosing regimens, no Grade 4 adverse events have been reported, while the most common adverse events have been gastrointestinal disorders that are typically Grade 1/2 in severity. The MTD has not been reached for the QD×2 or the QD×5 dosing regimen. Preliminary response data demonstrated promising activity; updated response data will be presented. Rapid and potent proteasome inhibition in whole blood was observed after administration of oprozomib tablets on Cycle1, Day 1. Proteasome inhibition was >75% at 4 hours postdose for both the 150- and 180-mg cohorts of the QD×2 regimen and for the 150-mg cohort of the QD×5 regimen. This inhibition was sustained and surpassed 95% by Cycle 2.

Summary / Conclusion: Although these data are preliminary, oprozomib once-daily, modified-release tablets have an acceptable safety and tolerability profile with a trend toward lower grades of gastrointestinal adverse events and use of fewer antiemetic medications compared to the previously investigated split-dose powder-in-capsule. Early pharmacodynamic data demonstrate significant proteasome inhibition at lower doses. Dose escalation will continue until the MTD is reached, followed by cohort expansion in patients with MM and Waldenström's macroglobulinemia. Updated safety, tolerability, and efficacy data will be presented at the meeting.

AN ASSAY FOR SIMULTANEOUS DIAGNOSIS OF T(4;14), T(11;14), T(14;16)/T(14;20), DEL1P, ADD1Q, DEL13Q, DEL17P, MS/MF EXPRESSION CLUSTERS, AND THE SKY-92 HIGH RISK SIGNATURE IN MULTIPLE MYELOMA PATIENTS

M Van Vliet[1,*] R Kuiper[2], A Broijl[2], Y de Knegt[2], W Hoos[1], L de Best[1], M van Duin[2], E Van Beers[1], P Sonneveld[2]
[1]Skyline Diagnostics BV, [2]Department of Hematology, ErasmusMC, Rotterdam, Netherlands

Background: Multiple Myeloma (MM) is a heterogeneous disease, with several recurring chromosomal aberrations including t(4;14), t(11;14), t(14;16)/t(14;20), del1p, add1q, del13q, and del17p. Gene expression profiling studies have revealed clusters of patients with distinct expression patterns including a signature that identifies high-risk patients (SKY-92) [1]. However, methodologies for assessing these markers have not been standardized yet. Lack of standardization hampers marker interpretation across cohorts, and limits the emerging strategies that combine these markers towards patient stratification and personalized medicine.

Aims: To develop a standardized assay for the detection of SKY-92, t(4;14), t(11;14), t(14;16)/t(14;20), del1p, add1q, del13q, and del17p.

Methods: The MMprofiler assay uses standardized plasma cell purification, RNA and DNA extraction and proprietary sample labeling process for use with Affymetrix HG-U133 Plus2 and a Cytoscan HD chip and proprietary data preprocessing and analysis software. The assay includes ten markers, namely translocations t(4;14), and t(11;14), chromosomal copy number aberrations, del1p, add1q, del13q, and del17p, the MS, and MF gene expression clusters, and the SKY-92 high risk signature. A total of 329 patients from the HOVON-65/GMMG-HD4 trial were used to train nearest mean classifiers for the translocation markers by means of a double loop cross validation protocol.

Results: The SKY-92 signature identifies high risk MM patients, and was previously shown to be a strong independent prognostic risk factor across multiple datasets, that outperforms signatures developed by others for the same goal [1]. The translocations t(4;14), and t(11;14) are associated with strong gene expression profiles, also reflected in their correlation with the clusters. Classifiers with high sensitivity and specificity were developed, as shown in Table 1. Classifiers for the prognostic MS and MF gene expression clusters were also developed. However, as there is no alternative method to compare against (e.g. no FISH etc.) their performance must be assessed by evaluation of their prognostic value in independent cohorts. Gene expression based classifiers performed reasonablefor the chromosomal aberrations add1q, and del13q, and performed poorly for the del17p. Since clinical implementation of these gene expression profiles is suboptimal we decided to detect clinically relevant variants of del1p, add1q, del13q, and del17p using the Cytoscan HD platform, at 99% sensitivity and specificity. An overview of all performances is provided in Table 1.

Summary / Conclusion: We report the development of a research use only assay for evaluation of ten different markers relevant for MM, which can ultimately be applied by qualified laboratories. The assay will be employed for further evaluation along the EMN-02/HOVON-95 clinical trial.

A COMPARISON BETWEEN NEXT-GENERATION SEQUENCING AND ASO-QPCR FOR MINIMAL RESIDUAL DISEASE DETECTION IN MULTIPLE MYELOMA

H Takamatsu[1], R Murata[2], J Zheng[3], M Moorhead[3], Y Terasaki[4], T Yoshida[5], M Faham[3,*] S Nakao[1]
[1]Kanazawa University Graduate School of Medical Science, [2]NTT WEST Kanazawa Hospital, Kanazawa, Japan, [3]Sequenta, Inc., South San Francisco, United States, [4]Toyama City Hospital, [5]Toyama Red Cross Blood Center, Toyama, Japan

Background: Although molecular complete remission (mCR) in multiple myeloma (MM) can be assessed by allele-specific oligonucleotide (ASO)-PCR, this technique requires preparation of clonotype-specific primers for each individual which is laborious and time-consuming. We utilized a sequencing method, termed LymphoSIGHT™, which employs consensus primers and high-throughput sequencing to amplify and sequence all rearranged immunoglobulin gene segments present in a myeloma clone. The sequencing method is quantitative at frequencies above 10^{-5} and the lower limit of detection is below 10^{-6}. Usage of the sequencing method for minimal residual disease (MRD) detection in MM may provide increased sensitivity and specificity, while overcoming the challenges associated with ASO-PCR.

Aims: We compared the LymphoSIGHT method with ASO-qPCR for MRD detection in autografts in the autologous peripheral blood stem cell transplantation (ASCT) setting.

Methods: Seventeen Japanese patients with newly diagnosed MM who received various induction regimens prior to ASCT were retrospectively analyzed. All patients had achieved a partial response (PR) or complete response (CR) after ASCT. Bone marrow (BM) slides from 13 MM patients and fresh BM cells from 4 MM patients at diagnosis as well as autografts were obtained for DNA extraction. IGH-based ASO-PCR was performed as described previously (van der Velden *et al*. Methods Mol Biol 2009). In addition, we used the LymphoSIGHT platform, which employs universal primer sets to amplify *IGH* variable (V), diversity (D), and joining (J) gene segments, *IGH-DJ*, and *IGK* from genomic DNA (Faham *et al*. Blood 2012). Amplified products were subjected to deep sequencing using next-generation sequencing (NGS). Reads were analyzed using standardized algorithms for clonotype determination. Myeloma-specific clonotypes were identified for each patient based on their high frequency in BM samples. The presence of the myeloma clonotype was then assessed in follow-up samples.

Results: MRD in autografts was detected in 6 of 17 (35%) by ASO-qPCR and

13 of 17 (76%) by NGS (Figure 1A). When MRD was assessed by NGS, 6 MRD (+) cases received post-ASCT therapy while 4 MRD (-) cases and 7 MRD (+) cases were followed without post-ASCT therapy. The MRD (-) cases tended to show a better PFS than the MRD (+) cases with post-ASCT therapy (P=0.26) and those without post-ASCT therapy (P=0.09) (Figure 1B) although overall survival rates were comparable among the three groups. There was no difference in PFS between MRD (-) and MRD (+) cases when MRD was assessed by ASO-qPCR (P=0.6). These studies will be extended in 30 additional MM patients, and results will be presented.

Summary / Conclusion: MRD-negativity in autografts revealed by NGS may be more closely associated with durable remission of MM than that revealed by ASO-qPCR.

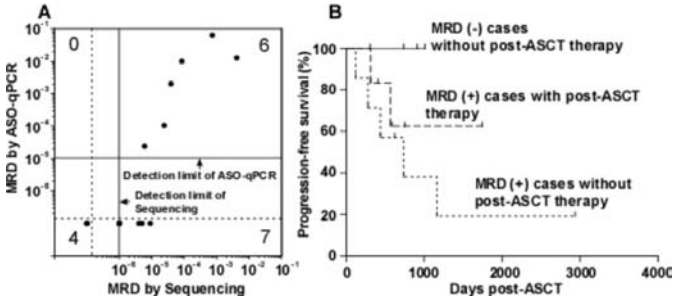

Figure 1. Minimal residual disease detection in autografts by next-generation sequincing.

WEEKLY ORAL INVESTIGATIONAL PROTEASOME INHIBITOR MLN9708 PLUS LENALIDOMIDE-DEXAMETHASONE IN ELDERLY PATIENTS (PTS) WITH PREVIOUSLY UNTREATED MULTIPLE MYELOMA (MM): SUBSET ANALYSIS OF A PHASE 1/2 STUDY

P Richardson[1,*] J Berdeja[2], R Niesvizky[3], S Lonial[4], M Hamadani[5], A Stewart[6], P Hari[7], R Vescio[8], V Roy[9], D Berg[10], J Lin[11], A Hui[10], S Kumar[12]

Background: Novel and active combination regimens that are well tolerated as long-term therapy are required for elderly MM pts who are ineligible for ASCT. The investigational agent MLN9708 (ixazomib citrate) is the first oral proteasome inhibitor in the boronate peptide class with reported clinical activity in MM. This phase 1/2 study investigated oral MLN9708 plus lenalidomide-Dex in both transplant-eligible and -ineligible pts with previously untreated MM (NCT01217957).

Aims: Phase 1 objectives included evaluation of safety, tolerability, the MTD, and recommended phase 2 dose (RP2D). The phase 2 primary objective was CR+VGPR rate. Secondary objectives included ORR and PFS. The aims of this subset analysis were to evaluate efficacy and safety in elderly vs younger pts. This analysis includes data up to Jan 23, 2013 (median follow-up 8.5 mos).

Methods: Pts received oral MLN9708 on days1, 8, 15, lenalidomide 25 mg on days 1-21, and Dex 40 mg on days1, 8, 15, 22, in 28-day cycles. After 12 cycles, pts received MLN9708, on the same weekly schedule, as maintenance therapy until progression or unacceptable toxicity. Transplant-eligible pts could undergo stem cell collection after 3 and ASCT after 6 cycles. In phase1, MLN9708 dose escalation proceeded from 1.68 to 3.95 mg/m^2 based on cycle 1 DLTs. The MTD was 2.97 mg/m^2; RP2D was 2.23 mg/m^2 (converted to a fixed dose of 4.0 mg based on population PK findings).

Results: 65 pts (15 phase1, 50 phase 2) were enrolled, including 31 aged <65 yrs and 34 aged ≥65 yrs, of whom 12 were aged ≥75 yrs; 25, 28, and 10 pts, respectively, were treated at the RP2D. Disease characteristics were similar among the age groups, including the proportion of pts with ISS stage II/III MM (55%, 56%, and 67% in pts aged <65, ≥65, and ≥75 yrs, respectively). Data on treatment exposure, disposition, and common AEs at the RP2D are shown in the table. Constipation occurred less frequently, while diarrhea occurred more frequently in older pts (≥65, ≥75 yrs) compared to the <65 yrs group. The incidences of grade ≥3 AEs and serious AEs were similar across the age groups. Peripheral neuropathy (PN), which was primarily grade1, was seen in 24%, 29%, and 40% of pts at the RP2D in the <65, ≥65, and ≥75 yrs groups, respectively; grade 3 PN was reported in only 2 pts, both ≥65 yrs (1 ≥75 yrs). There were 2 on-study deaths, 1 due to cardio-respiratory arrest after abdominal surgery in a pt aged 86 yrs (considered unrelated by the investigator) and 1 due to drug-related RSV pneumonia in a pt aged 68 yrs. The acceptable safety profile of MLN9708-lenalidomide-Dex induction enabled non-transplant-eligible pts to proceed to the maintenance phase. MLN9708 maintenance was generally well tolerated, with no evidence of cumulative toxicities. Preliminary response data showed clinical activity across the age groups, with a CR+VGPR rate in pts aged <65, ≥65, and ≥75 yrs of 42%, 70%, and 73%, respectively (including 29%, 24%, 18% CR, and 13%, 45%, 55% VGPR), and an ORR of 94%, 91%, and 82%, respectively. A total of 3 pts had disease progression, including 0,3, and 2 pts aged <65, ≥65, and ≥75 yrs, respectively.

Summary / Conclusion: These data suggest the all-oral combination of MLN9708 plus lenalidomide-Dex is associated with reversible and manageable toxicities, with limited PN, regardless of age. Preliminary data also suggest encouraging antitumor activity across the age groups analyzed, with CR+VGPR rates of 42–73%, including CR rates of 18–29%. Small pt numbers limit the power of this analysis; however, data support further studies, including phase 3 investigations.

PROGNOSTIC VALUE OF DEEP SEQUENCING METHOD FOR MINIMAL RESIDUAL DISEASE DETECTION IN MULTIPLE MYELOMA

J Martinez-Lopez[1,*] R Ayala[1], R Garcia-Sanz[2], F Pepin[3], M Montalban[1], B Paiva[2], L Weng[3], S Barrio[1], L Montejano[1], I Rapado[1], R Martinez[4], M Blanchard[5], P Sanchez-Godoy[6], J Blade[7], J San Miguel[2], M Faham[3], J Lahuerta[1]
[1]Hospital Universitario 12 de Octubre, Madrid, [2]Hospital Clinico Universitario de Salamanca, Salamanca, Spain, [3]Sequenta, Inc., South San Francisco, United States, [4]Hospital Clinico de Madrid, [5]Hospital Ramon y Cajal, [6]Hospital Severo Ochoa de Leganes, Madrid, [7]Hospital Clinic de Barcelona, Barcelona, Spain

Background: In multiple myeloma (MM), the prognostic significance of achieving complete remission (CR) using the European Group for Blood and Marrow Transplantation (EBMT) criteria has been widely validated (Ladetto *et al*, JCO 2010). Nevertheless, most MM patients will relapse due to persistence of residual tumor cells, or minimal residual disease (MRD) (Paiva *et al*, JCO 2011). As a result, and also due to the introduction of new, more effective treatments, there is a need to evaluate the clinical relevance of achieving deeper levels of cytoreduction, which may be associated with improved prognosis. We developed the LymphoSIGHT™ platform, a high-throughput sequencing method with a sensitivity of 10^{-6}, which universally amplifies immune receptor gene segments and can identify all myeloma-specific sequences at diagnosis, allowing monitoring of disease progression during therapy (Faham *et al*, Blood 2012).

Aims: We compared the prognostic value of traditional response criteria and MRD measurement by the sequencing-based method and multiparameter flow cytometry (MFC) in a cohort of 56 uniformly-treated MM patients from the Spanish Myeloma Group trials.

Methods: Bone marrow samples were obtained from 56 patients at diagnostic and post-treatment time points on GEM clinical trials (GEM00 and GEM05). All patients were in CR or VGPR at the post-treatment time point. The LymphoSIGHT platform was used to amplify IGH variable (V), diversity (D), and joining (J) gene segments, IGH-DJ, and IGK from genomic DNA. Amplified products were sequenced deeply, and reads were analyzed using standardized algorithms for clonotype determination. Myeloma-specific clonotypes were

identified for each patient based on their high frequency in BM samples. We assessed MRD in follow-up samples, analyzed concordance between sequencing and MFC MRD results, and compared the prognostic value of each method with traditional response criteria.
Results: We observed high correlation between MFC and sequencing MRD results (r^2=0.86). 45 patients were positive by sequencing at MRD levels of 10^{-5} or higher and 11 were MRD negative. There was significantly improved overall survival (OS) in the MRD negative group versus the MRD positive group (median not reached vs. 86 mos, P=0.026). Similar differences were found in progression free survival. When limiting the analysis to the 35 patients in conventional CR, 25 of 35 patients were positive by sequencing at MRD levels at 10^{-5} and higher and 10 were MRD negative. There was significantly improved OS in the MRD negative group versus the MRD positive group (median not reached vs. 80.92 mos, P=0.041).
Summary / Conclusion: Our data shows high correlation between MFC and sequencing MRD levels in MM patients. For patients in CR by traditional response criteria, the presence or absence of MRD by sequencing delineated 2 groups of patients with significantly different OS. MRD negativity by sequencing may be a better prognostic indicator than CR by traditional response criteria.

PHASE 1B DOSE ESCALATION STUDY OF ORAL QUISINOSTAT, A HISTONE DEACETYLASE INHIBITOR, IN COMBINATION WITH VELCADE (BORTEZOMIB) AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED MULTIPLE MYELOMA

P Moreau[1,*] T Facon[2], L Benboubker[3], C Touzeau[1], M Delain[3], N Fourneau[4], C Phelps[5], A Forslund[4], P Hellemans[4], H Smit[4], J Badamo-Dotzis[6], X Leleu[2]
[1]Service d'Hématologie, Hôpital Hôtel Dieu, CHU Nantes, Nantes, [2]Service des Maladies du Sang, 5ème EST, Hôpital Claude Huriez, CHRU de Lille, Lille, [3]Service Hématologie, CHRU Bretonneau, Centre H. Kaplan, Tours, France, [4]Janssen Research & Development, Beerse, Belgium, [5]Janssen Research & Development, LLC, Raritan, United States, [6]providing services on behalf of Janssen Research & Development, division of Janssen-Cilag, Quintiles, Issy-Les-Moulineaux, France

Background: Aggresome formation is a mechanism of resistance to agents (e.g., bortezomib) which block proteasome activity. Histone deacetylase inhibitor (e.g., quisinostat) prevents aggresome formation by deacetylation of tubulin that allows the transport of unfolded proteins to lysosomes for degradation.
Aims: We therefore investigated the safety and efficacy of the combination of the histone deacetylase inhibitor Quisinostat with the proteosome inhibitor Velcade in relapsed multiple myeloma.
Methods: Patients received quisinostat (Q) at escalated doses (6, 8, 10 and 12 mg) on days1,3, and 5 weekly, subcutaneous VELCADE (V) at 1.3 mg/m^2 on days1,4, 8, and 11 of a 3-week cycle, and oral dexamethasone (D) at 20 mg on the day of and the day after VELCADE dosing. The primary endpoint was the maximum tolerated dose (MTD) of Q in the combination (Q+V+D). The secondary endpoints included safety, overall response rate, and pharmacodynamic biomarkers.
Results: Eighteen patients (3,3, 6, and 6 in increasing Q doses) were enrolled: 56% male; median age 69 (range 50-82) years; multiple myeloma stage: IA = 11% and IIIA = 89%; prior lines of therapy: 1 = 100%, 2 = 55.6%, and 3 = 11.1%; prior VELCADE treatment = 50%. At the highest dose (12 mg) 2 patients had dose-limiting toxicity, 1 with QTc prolongation and 1 with atrial fibrillation. The MTD was established at the 10 mg Q for the Q+V+D regimen. The most common adverse events (≥10% of patients) were diarrhea (39%), asthenia (33%), peripheral oedema (22%), nausea (17%), thrombocytopenia (17%), alopecia (11%), constipation (11%), and vomiting (11%); most were grade 2 or lower in toxicity. To date, 13 patients have discontinued treatment, of which 5 completed 11 cycles of treatment. The overall response rate was 87.5% (14/16, 95% CI: 61.7% to 98.5%), including 1 complete response, 2 very good partial responses, and 11 partial responses. Most patients (9/11) showed a decrease in number of circulating multiple myeloma cells after 1 cycle. Two of 5 patients showed an increase in acetylated histone 3 from baseline as measured in peripheral blood mononuclear cells.
Summary / Conclusion: The maximum tolerated dose is 10 mg quisinostat in combination with VELCADE and dexamethasone. The combination is active in the treatment of relapsed multiple myeloma and has an acceptable safety profile.

P241

IMPACT OF HISTORY OF AUTOIMMUNE DISEASE ON SURVIVAL IN MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

E Lindqvist[1,*] O Landgren[1,2], S Helga Lund[3], I Turesson[4], L Goldin[5], M Björkholm[1], S Kristinsson[1]
[1]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Center for Cancer Research, NCI, NIH, Bethesda, United States, [3]Department of Public Health, University of Iceland, Reykjavik, Iceland, [4]Department of Hematology, Skåne University Hospital, Malmö, Sweden, [5]Division of Cancer Epidemiology and Genetics, National Cancer Institute (NCI), National Institutes of Health (NIH), Bethesda, United States

Background: The risk of monoclonal gammopathy of undetermined significance (MGUS) is increased in individuals with a personal and a family history of autoimmune disease (AI), and a personal history of several specific AIs increases the risk of multiple myeloma (MM). These previous findings suggest that immune-related conditions or the treatment of them may play a role in the etiology of MM and MGUS. History of AI is a negative predictor of survival in the general population, however, how AI affects survival in MM and MGUS is unknown.
Aims: The aim of the study was to determine whether a personal history of AI has an impact on survival in MM and MGUS.
Methods: Using national Swedish registries we identified2,765 patients with MM (diagnosed 2000-2006) and4,432 patients with MGUS (diagnosed 1988-2006), as well as 28,119 matched control subjects. The Swedish in- and outpatient registries were used to obtain information on AI in patients and controls, diagnosed prior to MM or MGUS diagnosis. MM and MGUS patients with AI diagnosed less than one year previous to diagnosis of MM or MGUS were excluded to avoid detection bias. We used the Kaplan-Meier method with log-rank test and Cox proportional hazards model to compare outcome among patients and controls with and without AI. We calculated hazard ratios (HR) and 95% confidence intervals (CI).
Results: A history of AI was found in 383 MGUS patients and 1,008 MGUS controls, and in 157 MM patients and 605 MM controls. In analyses restricted to MGUS patients, AI was associated with a 1.4-fold increased risk of death in males (HR=1.4; 95% CI 1.1-1.8) and 2.1-fold in females (95% CI 1.7-2.6). Compared to male controls without prior AI, male MGUS patients with a prior AI had a significantly 2.6-fold increased risk of death (95% CI 2.1-3.2), male controls with prior AI 2.1-fold (95% CI 1.9-2.3), and male MGUS patients without AI 1.9-fold (95% CI 1.8-2.1) risk of death. The corresponding numbers for female patients were HR=4.1 (95 % CI 3.5-5.0), HR=2.1 (95% CI 2.2-2.8), and HR=2.0 (95% CI 1.8-2.1; Figure 1). The interaction between AI and MGUS was significant in males but not in female individuals.

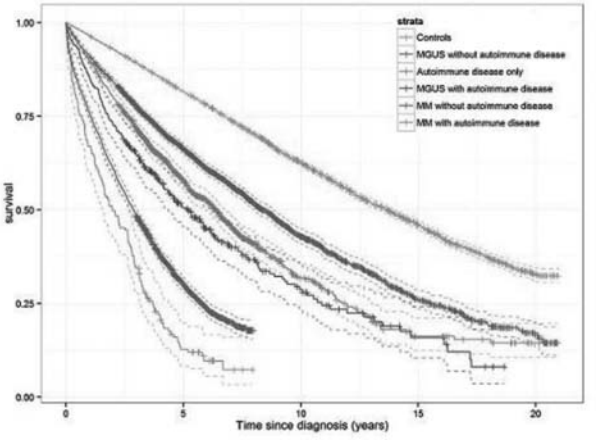

Figure 1.

In patients with MM and a prior history of AI, the risk of death was significantly increased 1.7 fold in females (95% CI 1.2-2.2), but was not significantly increased in males (HR=1.3, 95% CI 0.9-1.7). Compared to male controls without prior AI, male MM patients with prior AI had a significantly 9-fold increased risk of death (95% CI 7.0-11.7), male MM patients without AI 7.1-fold (95% CI 6.5-7.7), and male controls with AI 2.3-fold (95% CI 2.0-2.8) risk of death. The corresponding numbers for females were HR=12.6 (95% CI 9.9-16.0), HR=7.6 (95% CI 6.9-8.3), and HR=2.1 (95% CI 1.7-2.6; Figure 1). The interaction between AI and MM was significant in males and females.
Summary / Conclusion: In this large population-based study that included almost3,000 MM patients, more than4,000 MGUS patients, and their close to 30,000 matched control subjects, we found that a history of AI was linked to

decreased survival in MGUS patients and in female MM patients. AI was a stronger predictor of survival in individuals without MM or MGUS. Our findings suggest that although a history of AI is a poor prognostic factor in the general population, its impact on survival in patients with MGUS and MM is poor but not of similar magnitude. Underlying chronic diseases, such as AI, need to be taken into account when managing patients with MM and MGUS.

P242

LOW RATE OF SECONDARY PRIMARY MALIGNANCIES (SPMS) IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS TREATED WITH LENALIDOMIDE: FIRST RESULTS FROM THE MRC MM XI TRIAL

A Brioli[1,2,*] F Davies[1], W Gregory[3], S Hinsley[3], S Marshall[3], C Pawlyn[1], M Cavo[2], G Jackson[4], N Russell[5], G Morgan[1]
[1]Haemato-Oncology Research Unit, Institute of Cancer Research, London, United Kingdom, [2]Seragnoli Institute of Hematology, Bologna University School of Medicine, Bologna, Italy, [3]Clinical Trials Research Unit, University of Leeds, Leeds, [4]Department of Haematology, University of Newcastle, Newcastle Upon Tyne, [5]Clinical Haematology, Nottingham City Hospital, Nottingham, United Kingdom

Background: Long term therapy with Lenalidomide (Len) has been associated with an increased risk of developing SPMs.[1-3]
Aims: We are conducting a large phase III study to evaluate Len as induction and/or as maintenance therapy in newly diagnosed MM.
Methods: Patients are treated following an intensive or a non intensive pathway based on their eligibility for stem cell transplantation (ASCT) and are randomised to receive induction therapy with cyclophosphamide and dexamethasone combined with either Len (CRD) or Thalidomide (CTD). Patients failing to achieve an optimal response are randomised to receive additional therapy with cyclophosphamide, dexamethasone and bortezomib (CVD) or no extra therapy. A randomization between Len maintenance and no maintenance is also performed.
Results: We have enrolled 1882 patients, with 1879 having undergone the induction randomisation, and 581 patients having entered the maintenance randomization. The median follow up from initiation of the study is 1.3 years and from maintenance randomization is 1 year. Data on the occurrence of SPMs are being routinely collected as part of safety assessment during all protocol phases and follow up. So far 10 SPMs have been reported (0.5% of the randomised population); three additional patients, reported as having a SPM, were excluded, after central review of the data, either due to a previous history of malignancy or because of the evidence of a neoplasia other that MM at the time of study entry. The median time from trial entry to development of SPMs is 8 months (range 2.1-15.4). Seven out of 10 SPMs developed either during maintenance treatment or follow up. Three cases were diagnosed during induction. The SPMs reported during Len maintenance developed early in the course of treatment, 2.0, 3.3 and 5.9 months after starting maintenance (Figure 1).

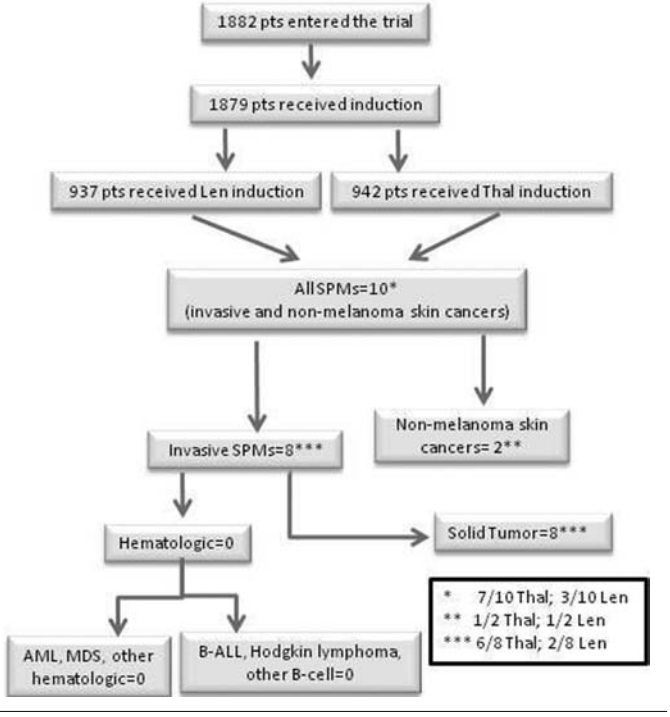

Figure 1.

The median age of patients developing SPM is 72 years (range 61-85), with 8/10 patients having been treated on the non intensive pathway; interestingly 7/10 of the cases received thalidomide induction. One patient, developing a squamous cell carcinoma of the nose received both Len induction and maintenance. Interestingly no hematologic SPM has been reported.
Summary / Conclusion: Our data clearly show a low incidence of SPMs, both overall and in patients treated with ASCT and Len maintenance. With almost 1900 patients enrolled, the cumulative incidence of SPMs reported so far has been 0.5%, with a cumulative rate of 0.1% for non-invasive SPMS and 0.4% for invasive SPMs. The incidence rate of all SPMs (invasive and non invasive) at one year is 0.74% (95% CI 0.39%>1.4%) and at two years is 0.91% (95% CI 0.48%>1.7%).Our data do not confirm previous findings of an excess risk of SPMs in association with the use of Len and melphalan in presenting patients, with only 2/1054 patients enrolled within the intensive pathway developing a SPM (ITT population). Longer follow up together with morphological, cytogenetic and molecular analysis is needed to elucidate the risk of Len associated SPMs.

THERAPY FOLLOWING RELAPSE ON MELPHALAN-PREDNISONE-LENALIDOMIDE (LEN) FOLLOWED BY LEN MAINTENANCE IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: EFFICACY AND SAFETY OF SECOND LINE LEN IN MM-015

M Dimopoulos[1,*] M Petrucci[2], R Foa[3], J Catalano[4], M Kropff[5], Z Yu[6], L Herbein[6], L Grote[6], C Jacques[6], A Palumbo [7]
[1]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece, [2]Division of Hematology, University La Sapienza, [3]Department of Cellular Biotechnology and Hematology, Division of Hematology, University La Sapienza, Rome, Italy, [4]Frankston Hospital and Department of Clinical Haematology, Monash University, Melbourne, Australia, [5]University of Muenster, Muenster, Germany, [6]Celgene Corporation, Summit, NJ, United States, [7]Division of Hematology, University of Turin, Turin, Italy

Background: The use of novel agents has dramatically changed the treatment paradigm of multiple myeloma (MM) leading to considerably improved patient (pt) outcomes. However, all pts eventually relapse, requiring subsequent therapy (Tx) to maintain disease remission. The pivotal, randomized, double-blind, placebo-controlled MM-015 phase 3 trial in elderly newly diagnosed MM pts demonstrated unprecedented increase in progression-free survival (PFS) with melphalan-prednisone-LEN followed by LEN maintenance (MPR-R) vs. fixed-cycle MPR or MP (31 vs. 14 and 13 mos, respectively; both P<0.001) (Palumbo A, *et al*. N Engl J Med. 2012;366:1759-69)
Aims: We present the longer term results of a post-hoc analysis assessing the impact of 1st line and 2nd line therapies on post-progression outcomes and safety in pts who went on to receive 2nd line Tx.
Methods: At progression, pts in the MM-015 study could enroll in an open-label extension phase (OLEP) to receive LEN 25 mg (D1–21/28 day cycle)±dexamethasone (DEX; 40 mg on days (D1–4, 9–12, and 17–20), or receive any other antimyeloma treatment outside of the protocol at investigator's discretion. This analysis includes data up to July 31, 2012 (median follow-up: 53 mos). 2nd line time-to-progression (TTP) was defined as time from 2nd to 3rd line Tx. Safety data were assessed only for pts enrolled in the OLEP (MPR-R, n=21; MPR, n=53; MP, n=79).
Results: A total of 459 pts were enrolled in MM-015; MPR-R(152); MPR (153); and MP (154). Fewer pts (53%) received 2nd line Tx in the MPR-R arm vs. the MPR (77%) and MP (82%) arms, consistent with the superior PFS of MPR-R. The median time from 2nd to 3rd line Tx was comparable across the arms (14, 16, and 15 mos for MPR-R, MPR, and MP, respectively; Figure A), suggesting that the addition of LEN did not induce resistant relapses. A total of 185 (57%) pts received LEN-based 2nd line Tx across the arms: 30% (MPR-R), 59% (MPR), and 72% (MP); 49%, 27%, and 21% of pts received bortezomib (BORT); and 21%, 15%, and 7% of pts received other 2nd line Tx, respectively. Pts receiving 2nd line LEN Tx had longer TTP from 2nd to 3rd line Tx (18, 23, and 18 mos for MPR-R, MPR, and MP, respectively) vs pts receiving BORT (14, 16, and 12 mos) or other Tx (6,4, and 6 mos; Figure B). Newly occurred or worsening grade 3–4 adverse events (AEs) reported in ≥ 5% of pts receiving LEN±DEX (n=153) in the OLEP were neutropenia (17%), thrombocytopenia (9%), and anemia and leukopenia (both 5%). Grade 3–4 deep-vein thrombosis and peripheral neuropathy occurred in 3% and 1% of pts, respectively. No cases of febrile neutropenia were reported. Updated data will be presented at the meeting.
Summary / Conclusion: 2nd line Tx is effective in pts who received prior LEN maintenance in the frontline setting indicating that LEN maintenance does not

appear to induce resistant relapses. Results with 2nd line LEN-based Tx compared favorably to outcomes with other Tx and further support the efficacy of LEN as 2nd line Tx for MM consistent with its improved indication. LEN as a 2nd line Tx was generally well tolerated with manageable AEs.

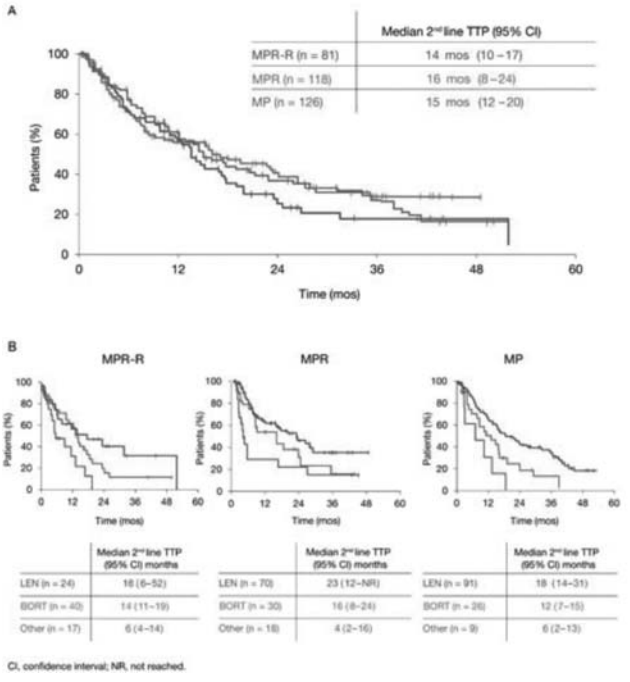

Figure 1. Median time from: (A) 2nd to 3nd line Tx in MM-D15; (B) 2nd to 3nd line Tx according to the type of 2nd line Tx.

Background: Renal failure is a common complication for patients with multiple myeloma (MM) and is the second leading cause of death in this disease (Korbet SM, *et al*. *J Am Soc Nephrol*. 2006). The incidence of renal failure increases during the course of the disease (Eleutherakis-Papaikovou V, *et al*. *Leuk Lymphoma*. 2007) and is particularly relevant in advanced MM. Patients who have exhausted treatment (Tx) options such as bortezomib (BORT) and lenalidomide (LEN) have limited durability of responses and shorter overall survival (OS) (Kumar S, *et al*. *Leukemia*. 2012). POM was recently approved by the US Food and Drug Administration for Tx of RRMM patients who have received at least 2 prior therapies, including BORT and LEN. POM + LoDEX was efficacious with favorable tolerability in RRMM patients with prior BORT and LEN, including those with renal impairment (RI) (Siegel DG, *et al*. ASH. 2012). MM-003 is an open-label, multicenter, phase 3 randomized trial comparing POM + LoDEX vs. HiDEX in RRMM patients who have failed BORT and LEN and progressed on their last therapy.

Aims: This prospective analysis examined RRMM patients with or without moderate RI (creatinine clearance [CrCl] <60 vs. ≥60mL/min).

Methods: Patients must have failed BORT and LEN after ≥ 2 consecutive cycles of each (alone or in combination) and must have been refractory to their last prior therapy (progressive disease [PD] during Tx or within 60 days). Patients with CrCl < 45 mL/min were excluded. Patients were randomized 2:1 to POM 4 mg D1-21 + LoDEX 40 mg (20 mg for patients aged > 75 years) weekly; or HiDEX 40 mg (20 mg for patients aged > 75 years) D1-4, 9-12, and 17-20 (28-D cycles). Tx continued until PD or unacceptable adverse event (AE). Thromboprophylaxis with low-dose aspirin, low molecular weight heparin, or equivalent was required for all patients receiving POM and those at high risk for thromboembolic events. AEs were graded according to the National Cancer Institute Common Terminology Criteria for AEs (v 4.0). Tx was withheld and started at a lower dose in subsequent cycles for any grade 4 hematologic or ≥ grade 3 non-hematologic AE. Supportive care in the form of bisphosphonates, hematopoietic growth factors, erythropoietin, and platelet or red blood cell transfusions was allowed. The primary endpoint of the trial was progression-free survival (PFS), and the secondary endpoints included OS, overall response rate (ORR; ≥ partial response [PR]), duration of response (DOR), and AEs.

Results: A total of 302 patients received POM + LoDEX; 153 patients received HiDEX. Within each group, 94 (31%) and 59 (39%) patients had moderate RI (CrCl < 60 mL/min), respectively. Patients with moderate RI vs. normal renal function were more likely to be older (64% vs. 36% aged > 65 years). Median PFS and OS were significantly longer with POM + LoDEX vs. HiDEX regardless of RI (Table; P<.001) with a median follow-up of 4 months. Similar rates of AEs for both POM + LoDEX and HiDEX Tx were seen in patients with and without moderate RI (Table). Discontinuations due to AE were: 5% vs. 7% (normal renal function) and 11% vs. 5% (moderate RI). Updated data to be presented at the meeting.

Summary / Conclusion: POM has shown activity in patients refractory to LEN and BORT. POM + LoDEX significantly extended PFS and OS compared with HiDEX in RRMM patients with or without moderate RI. The tolerability of POM + LoDEX was acceptable and comparable across subgroups, with few discontinuations due to AE.

Background: Multiple myeloma patients who relapse or are refractory after novel agents have a poor prognosis. The median event-free survival is 5 months and overall survival is 9 months (Kumar SK *et al*, Leukemia (2012) 26, 149-157). Pomalidomide is an effective option for patients relapsed or refractory after lenalidomide and bortezomib. In a phase 1/2 study pomalidomide-cyclophosphamide-prednisone (PCP) has demonstrated favorable tolerability and promising activity in myeloma patients relapsed or relapsed/refractory to lenalidomide.
Aims: We evaluated outcomes of patients treated with PCP according to prior treatment exposure.
Methods: Pomalidomide was administered at doses ranging from 1 to 2.5 mg/d, cyclophosphamide at 50 mg every other day, and prednisone at 50 mg every other day, for six 28-day cycles, followed by maintenance therapy with pomalidomide-prednisone. Thromboprophylaxis with aspirin 100 mg/day or low-molecular weight heparin was recommended at physician's discretion.
Results: Fifty-five patients enrolled at the maximum tolerated dose of 2.5 mg were evaluated after completing at least 1 cycle. Patients had previously been exposed to lenalidomide (100%), bortezomib (84%), thalidomide (20%), stem cell transplant (49%). The majority of patients (58%) had received 3 prior therapies (range, 1-3). Fifty-three percent of patients had received lenalidomide, 27% bortezomib, 5% thalidomide, 11% stem cell transplantation, and 4% conventional chemotherapy in their most recent prior line of therapy before enrolment. Median follow-up was 14.8 months. The overall response rate (ORR) was 45% after the last line of previous therapy and 46% after previous lenalidomide. The ORR with PCP was 51%, including 6% of patients attaining complete response, 18% very good partial response and 27% partial response. The ORR with PCP was 61% in patients who had received 1-2 prior therapies and 44% in patients who had received 3 prior therapies. Median progression-free survival (PFS) with PCP (10.4 months) was comparable to that obtained with the last anti-myeloma regimen before study entry (9 months) and with the previous lenalidomide therapy (10 months). Grade 3-4 adverse events included anemia (9%), thrombocytopenia (11%), neutropenia (42%), neurologic (7%), dermatologic (7%), thromboembolism (2%). Grade 3-5 infections occurred in 5 patients (9%). Five patients (9%) discontinued treatment for toxicity.
Summary / Conclusion: Pomalidomide-cyclophosphamide-prednisone is an effective salvage therapy that induced high response rates and prolonged PFS in relapsed/refractory multiple myeloma patients. The outcome achieved with PCP is comparable to that obtained with previous treatments including lenalidomide or bortezomib.

Table 1.

	Previous therapy		PCP		
	Lenalidomide (N=55)	Last line of therapy (N=55)	All Patients (N=55)	1-2 Prior therapies (N=23)	3 Prior therapies (N=32)

P246

EXPRESSION OF THE TRANSCRIPTION FACTOR NF-E2 IS REGULATED VIA THE NOVEL EPIGENETIC JAK2/H3Y41PH/HP1A PATHWAY

T Seeger[1,*] D Schanne[1], H Pahl[1]
[1]Section of Molecular Hematology, University Medical Center Freiburg, Freiburg, Germany

Background: Despite the recent description of an activating point mutation in the Janus Kinase 2 ($JAK2^{V617F}$) in the majority of MPN patients, the molecular etiology of these diseases remains poorly understood. We have shown that the hematopoietic transcription factor Nuclear Factor Erythroid 2 (NF-E2) is overexpressed in the vast majority of MPN patients and that the JAK2 allele burden is positively correlated with NF-E2 expression. However, we were unable to detect STAT5 binding sites in the NF-E2 promoter. Recently, a novel STAT-independent pathway of JAK2 transcriptional regulation was described. Nuclear JAK2 phosphorylates histone 3 on tyrosine 41 (H3Y41). In the phosphorylated state, H3Y41 no longer binds the repressive heterochromatin protein 1α (HP1α). Therefore, H3Y41 phosphorylation leads to transcriptional activation.
Aims: We tested the hypothesis that NF-E2 is regulated by JAK2 via the novel epigenetic JAK2/H3Y41ph/HP1α pathway.
Methods: To mimic the physiological down-regulation of NF-E2 during myeloid maturation we used HEL cells as we have demonstrated that the demethylating agent 5-aza-2'-deoxycytidine (DAC, decitabine) decreases NF-E2 levels in this model. Untreated HEL cells or cells treated with decitabine were submitted to Western Blot and ChIP analysis using antibodies to $H3K9me^2$, HP1α, H3Y41ph and SHP-1. In addition, granulocytes from healthy controls and PV patients were analyzed for protein expression and chromatin occupancy of $H3K9me^2$, HP1α and H3Y41ph.
Results: In order to assess whether decitabine treatment decreases NF-E2 expression by acting directly on the NF-E2 gene we examined the methylation status of the NF-E2 promoter using pyrosequencing. The NF-E2 promoter is unmethylated in untreated HEL cells as well as in peripheral blood granylocytes of healthy controls and PV patients and remains unchanged by decitabine. Rather, following decitabine treatment we observed an increase in the repressive histone mark $H3K9me^2$ on the NF-E2 promoter. Likewise, in primary mature granulocytes the NF-E2 promoter carries the repressive $H3K9me^2$ mark only in healthy controls, where the gene is physiologically silenced. Conversely, this mark is absent in PV patients which retain unphysiologically high levels of NF-E2. In addition, following decitabine treatment, we observe a decrease in H3Y41ph on the NF-E2 promoter and a concomitant increase in HP1α binding, suggesting that the demethylating agent suppresses JAK2 activity. In support of this model, direct inhibition of JAK2 by TG101348 likewise decreases NF-E2 levels in HEL cells. In order to determine the mechanism by which decitabine treatment reduces NF-E2 levels, we assayed expression of the phosphatase SHP-1, which represses JAK2 activity. Demethylation of the SHP-1 promoter by decitabine has previously been shown. SHP-1 levels were indeed upregulated in HEL cells following decitabine treatment. We therefore propose that the demethylating agent decitabine down-regulates NF-E2 expression via increasing SHP-1 levels, leading to a decrease of $JAK2^{V617F}$ activity, with a subsequent reduction in H3Y41 phosphorylation and increased HP1α binding on the NF-E2 promoter. A separate or interrelated mechanism leads to a concomitant decrease in the $H3K9me^2$ mark on the NF-E2 promoter.
Summary / Conclusion: Our data therefore demonstrate for the first time that NF-E2 expression is regulated by the novel JAK2/H3Y41ph/HP1α pathway and we propose that this epigenetic deregulation contributes to the observed NF-E2 overexpression in MPN patients. These observations strengthen the rationale for using epigenetically active agents, such as decitabine, in the treatment of MPN. Several such trials have recently been initiated.

P247

CHARACTERIZATION OF JMJD1C AND JMJD2C AS NOVEL NF-E2 TARGET GENES

J Peeken[1,*] J Wehrle[1], M Gothwal[1], T Seeger[1], H Pahl[1]
[1]Section of Molecular Hematology, University Medical Center Freiburg, Freiburg, Germany

Background: We have recently shown that expression of the transcription factor and epigenetic modulator "Nuclear Factor Erythroid-2" (NF-E2) is aberrantly elevated in patients with Myeloproliferative Neoplasms (MPN) and that NF-E2 overexpression in a murine model causes a MPN phenotype. As few NF-E2 target genes are known, the pathways by which this transcription factor exerts its effects remain unknown. We used lentivirally driven NF-E2 overexpression and shRNA mediated NF-E2 silencing in CD34-positive cells as well as *in silico* probing of NF-E2 ChIP Seq data to identify novel NF-E2 targets.
Here, we characterize the histone demethylases JMJD1C and JMJD2C as novel NF-E2 target genes. Both proteins demethylate lysine 9 on histone 3

thereby leading to transcriptional activation of target genes. SNPs in JMJD1C are positively correlated with platelet numbers. JMJD2C is overexpressed in several cancer entities and plays a role in oncogenesis, proliferation, pluripotency and stem cell self renewal. Moreover, it is a known downstream target of JAK2.
Aims: To test the hypothesis that JMJD1C and JMJD2C constitute novel NF-E2 target genes, which contribute to MPN pathophysiology.
Methods: NF-E2 binding to the JMJD1C and JMJD2C loci was analyzed by chromatin immunoprecipitation (ChIP). Functionality of the NF-E2 binding sites in the promoter regions of both demethylases was tested by luciferase reporter gene assays. We used short hairpin RNA (shRNA) mediated knock down of NF-E2 in HEL cells and introduction of the NF-E2 cDNA into CB3 cells to ask whether the transcription factor is required for and/or sufficient to induce target gene expression. Subsequently, we analyzed JMJD1C and 2C expression levels in PV patients and healthy controls as well as in our NF-E2 tg mouse model. Finally, we determined global histone 3 lysine 9 methylation levels in PV patients and healthy controls.
Results: By *in silico* analysis, the JMJD1C locus contains three potential NF-E2 binding sites, whereas the JMJD2C locus contains one. In ChIP assays, we were able to confirm *in vivo* NF-E2 binding to these sites. Luciferase reporter gene assays using NF-E2 binding site containing fragments of the JMJD1C and JMJD2C loci demonstrated NF-E2 driven activation of both promoters. Site directed mutagenesis confirmed the specificity of the NF-E2 effect.
Following shRNA mediated NF-E2 knock down in HEL cells a significant decrease in JMJD1C protein was observed, demonstrating that the transcription factor is absolutely required for JMJD1C expression. Conversely, upon viral reintroduction of NF-E2 into CB3 cells - a cell line that does not express NF-E2 - an upregulation of JMJD1C and 2C mRNA expression was observed. Likewise, NF-E2 transgenic mice demonstrate a significant increase in JMJD1C and 2C mRNA levels compared to wt control littermates, establishing the demethylases as novel NF-E2 targets. JMJD1C and 2C protein levels are statistically significantly elevated in patients with polycythemia vera (PV) compared to healthy controls. As JMJD1C and 2C proteins mediate the demethylation of histone H3K9, increased demethylase activity is expected to result in decreased steady state levels of mono and dimethylated H3K9 in PV patients. Indeed, we observed significantly decreased levels of H3K9me and H3K9me^2 in PV patients compared to healthy controls.
Summary / Conclusion: Here, we describe the histone demethylases JMJD1C and JMJD2C as novel NF-E2 target genes and propose that elevated NF-E2 levels in MPN patients contribute to disease pathophysiology in part by altering histone demethylation. These data provide a rationale for investigating novel JMJD-demethylase inhibitors, currently being developed, in the treatment of MPN patients.

P248

A MOUSE MODEL FOR HUMAN MYELOFIBROSIS
I Triviai[1,2,3,*] T Stübig[1], B Niebuhr[2], K Hussein[4], A Tsiftsoglou[3], B Fehse[1], C Stocking[2], N Kröger[1]
[1]Clinic of Stem Cell Transplantation, [2]Heinrich Pette Institute, Leibniz Institute for Molecular Virology, UKE, Hamburg, Germany, [3]Pharmacology, Department of Pharmaceutical Sciences, AUTH, Thessaloniki, Greece, [4]Institute of Pathology, Medical School Hannover, Hannover, Germany

Background: Primary Myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) characterized by bone marrow fibrosis, abnormal megakaryopoiesis and erythropoiesis, extramedullary hematopoiesis and with a high risk of transformation to Acute Myeloid Leukemia (AML). The disease is thought to be a clonal stem cell disorder, however, stem cells that actually drive the disease in xenotransplantation models have not been identified.
Aims: The aim of his study we assess the CD133+CD34+ stem cell compartment of PMF patients for its potential to reproduce the disease phenotype *in vivo*.
Methods: Patient peripheral blood was characterized for stem cell populations expressing CD133+ and/or CD34+ cells. All patients examined carried JAK2V617F mutations. Isolated CD133+ cells were transplanted in immunocompromised mice. Flow cytometry, immuno-histochemistry, *in situ* hybridization and qPCR were used for the detection of human cells and determination of their mutational burden with time.
Results: PMF patient-derived CD133+ stem cells engrafted for more than 6 months in an immuno-compromised mouse model and differentiated into myeloid and endothelial-like JAK2V617F+ progenitors. We observed the constant presence of human, atypical, JAK2V617F+ megakaryocytes in bone marrow and spleen. Anemia, splenomegaly and splenic fibrosis were observed in transplanted mice, mirroring the gradual development of PMF. Strikingly, the transition to AML was observed 9 months post-transplantation of patient cells in mice. Leukemic cells lacked JAK2V617F mutations, which has also been as reported for 20-25% of patients with PMF that transform into a blast crisis.
Summary / Conclusion: We have identified a stem cell population that can drive both chronic and acute phases of PMF. Our mouse model forms the basis to decipher the characteristics of the malignant clones in PMF and to introduce new therapeutic targets for MPN.

P249

DEREGULATED MIRNAS IN JAK2V617F-NEGATIVE ESSENTIAL THROMBOCYTHEMIA PATIENTS TARGET SOCS FAMILY MEMBERS
A Navarro[1,*] S Pairet[2], A Pons[3], G Ferrer[4], R Longarón[2], A Álvarez-Larrán[5], L Martínez-Avilés[6], C Fernández-Rodríguez[3], M Monzó[7], C Besses[5], B Bellosillo[2]

Background: The biological basis for essential thrombocythemia (ET) patients lacking the JAK2V617F mutation is still unknown. MicroRNAs (miRNAs) act as negative regulators of expression of important genes that participate in cellular proliferation, apoptosis and/or carcinogenesis and have been involved in both solid and hematological tumors. The potential role of miRNAs in JAK2V617F-negative ET remains to be elucidated.
Aims: To characterize the expression pattern of miRNA in JAK2V617F-negative ET.
Methods: Total RNA was extracted from platelets from 19 ET patients (10 were JAK2V617F+) and 10 healthy control samples. The expression of 670 mature miRNAs was analyzed using TaqMan Human MicroRNA Arrays v2.0 (Applied Biosystems) in an ABI 7900 HT real time PCR system. miRNA expression data was analyzed by the $2^{-\Delta\Delta Ct}$ method, using RNU48 as endogenous control. Statistical analyses were performed with TiGR MultiExperiment Viewer and R software. To identify molecular pathways potentially altered by the expression of multiple miRNAs we used Diana-mirPath, which performs an enrichment analysis of multiple miRNA target genes, comparing each set of miRNA targets to all known KEGG pathways. After that, mRNA expression of putative selected targets was analyzed by TaqMan gene expression assays (Applied Biosystems). The genes, whose expression was negatively correlated with miRNAs, were selected for further target validation by Renilla Luciferase assay. For Renilla-luciferase assay 100nM pre-miRNAs where transfected in K562 together with 1 μM of modified psicheck2 vector containing the 3'UTR region to be validated and Renilla luciferase levels were measured at 24h.
Results: The unsupervised hierarchical clustering of miRNA expression showed two well-separated clusters between patients and controls indicating that ET platelets had a characteristic miRNA signature (P<0.0001). Supervised analysis by means of significant analysis of microarrays (SAM) analysis showed a distinctive 101-miRNA signature, where most miRNAs (n=99) were downregulated in ET patients compared to controls. Interestingly, SAM analysis identified a 40-microRNA signature differentially expressed between JAK2V617F-positive and JAK2V617F-negative ET patients. Using the 40-miRNA signature we searched for potentially altered targets and pathways using Diana-mirPath. Among the pathways potentially altered, 11 miRNAs had putative targets affecting the JAK-STAT pathway. We quantified the mRNA expression of 8 of these putative targets and correlated it with miRNA levels. An inverse correlation was found between *SOCS1* and miR-221 (r^2=-0.719, P=0.001), *SOCS3* and miR-221 (r^2=-0.644, P=0.005), *SOCS3* and miR-203 (r^2=-0.447, P=0.072) and *PTPN11* and miR-23a (r^2=-0.494, P=0.044). These 3 miRNAs were upregulated in the JAK2V617F-negative ET patients. With these miRNAs we proceeded to target validation by Renilla Luciferase assay at the protein level. Transfection of K562 cells with pre-miRNAs or control pre-miRNA and the modified psicheck2 vector containing the 3'UTR binding sites of the selected miRNAs, resulted in target validation of SOCS1 for miR-221 (28.9% Renilla luciferase protein reduction, P=0.002) and SOCS3 for miR-203 (19.6% Renilla luciferase protein reduction, P=0.04). No significant modifications were observed for PTPN11.
Summary / Conclusion: ET shows a characteristic platelet miRNA-signature with downregulation of most miRNAs in comparison with healthy controls. JAK2V617F-negative ET cases harbor a 40-miRNA signature, differentially expressed from JAK2V617F-positive patients that target regulators of the JAK-STAT pathway, including members of the SOCS family.

A DIFFERENTIAL CENTROSOME LOCALIZZATION OF WILD TYPE (WT) AND JAK2V617F PROTEIN IN HUMAN LEUKEMIA CELL LINES
B De Angelis[1,2,*] C Quintarelli[1,2], S Errichiello[1], S Caruso[1], D Sarnataro[1], M Palma[1], N Pugliese[2], M Cosenza[3], V Martinelli[2], F Pane[2]
[1]Ceinge - Biotecnologie Avanzate , [2]Dipartimento di Medicina Clinica e Chirurgica, University of Naples Federico II, Italy, University of Naples Federico II, [3]Dipartimento di Medicina Clinica e Chirurgica, University of Naples Federico II, Italy, Ceinge - Biotecnologie Avanzate , Naples, Italy

Background: The JAK2^{V617F} mutation is frequently observed in myeloprolif-

erative neoplasm (MPN). Vainchenker's group recently reported that the strong activation of $JAK2^{V617F}$ stimulates homologous recombination, centrosome and ploidy abnormalities. The centrosome ensures symmetry and bipolarity of the cell division process, which is essential for accurate chromosome segregation and cell-cycle progression into mitosis. The centrosome amplification occurs frequently in both solid tumors and hematological malignancies and it is thought to contribute to the development of chromosomal abnormalities in these disorders. The level of centrosome tyrosine phosphorylation is a surrogate marker for activation of centrosomal downstream signaling pathways; constitutive phosphorylation at this site may perturbate centrosome function and cell cycle.

Aims: Main aim of our research is to probe the role of the centrosome in genomic stability, cell polarity and tumor formation. Then, we evaluate if JAK2 status is related to centrosome malfunction and malignant transformation.

Methods: To determine if JAK2 is a centrosomal partner, we performed co-immunoprecipitation and the co-immunofluorescence (CIF) assays between JAK2 and a centrosome marker gamma-tubulin on several cancer cell lines, expressing $JAK2^{WT}$ (K562 and BV173, derived from CML patients; and human bone marrow stromal cell line HS5) or carrying $JAK2^{V617F}$ (SET-2 and HEL cell lines). Furthermore, we also evaluated the JAK2 centrosomal localization in CD34+ cells isolated from MPN patients. Finally we evaluated if centrosome phosphorylation may be modulated by treatment with the JAK tyrosine kinase inhibitor.

Results: CIF assay shows a neat co-localization of JAK2 and gamma-tubulin in K562, BV173 and HS5 cell lines as well as in CD34+ cells isolated from MPN patients with JAK2WT (in more the 90% ±5% of cells) in a cell cycle independent manner. Moreover, we observed that JAK2 centrosomal interaction is strictly dependent on the intact microtubule network, since nocodazole treatment, inducing depolymerization of the microtubule network, was able to reverse JAK2 centrosomal localization. By contrast, in leukemia cell lines carrying $JAK2^{V617F}$ in hemizygosis (SET) or in homozygosis (HEL), we observe colocalization of JAK2 and gamma-tubulin in only 40%±5% and 10±3% of the cells, respectively. In BM CD34+ cells isolated from MPN patients with $JAK2^{V617F}$ mutation, we also observe a partial JAK2 co-localization on centrosome. Notably, in 90% of HEL cells, lacking of JAK2-gamma-Tubulin co-localization, we identified high percentage (61%) structural and/or numeric centrosome abnormalities. Interestingly, we observed that the exogenous expression of $JAK2^{V617F}$ in K562 cell line increased significantly the numbers of centrosome abnormalities. This strongly suggests that JAK2 protein interacts with centrosome structure and that $JAK2^{V617F}$ is associated with centrosome malfunction and transformation.

Summary / Conclusion: Our preliminary data suggest a functional interaction between JAK2 and centrosome in $JAK2^{V617F}$ cell lines and in patients affected by MPN; this interaction may result in a genetic instability of neoplastic cells.

P251

EVALUATION OF THROMBIN GENERATION POTENTIAL IN POLYCYTHEMIA VERA PATIENTS ENROLLED IN THE CYTO-PV ITALIAN CLINICAL TRIAL

C Gargantini[1],* M Marchetti[1], C Verzeroli[1], L Russo[1], A Vignoli[1], T Barbui[2], A Rambaldi[3], G Finazzi[3], D Rapezzi[4], P Musto[5], G Gaidano[6], C Musolino[7], R Cacciola[8], S Santini[9], A Falanga[1]

Policlinico Universitario 'G. Martino', Messina, [8]Division of Hematology, Ospedale Ferrarotto, Catania, [9]Unit of Hematology, Ospedale Misericordia e Dolce, Prato, Italy

Background: Polycythemia Vera (PV) is a chronic myeloproliferative neoplasm characterized by a clonal uncontrolled proliferation of bone marrow stem cells. PV typically presents with a hemostatic imbalance featuring an increased risk of both thrombotic and hemorrhagic events. Some studies show that in PV patients an elevated hematocrit (HCT) increments the thrombotic risk. Current guidelines for PV management advise to maintain HCT below 45% in males and 42% in females through phlebotomies and/or the use of cytoreductive drugs. Recently, the results of CYTO-PV clinical trial showed that PV patients with a HCT target <45% have a significantly lower rate of cardiovascular death and major thrombosis than those with a HCT in the range 45-50% (Marchioli *et al*, NEJM 2013).

Aims: In the setting of the CYTO-PV trial, we planned a biological sub-study to assess: 1) thrombin generation (TG) potential according to HCT levels, and 2) TG predictive value for bleeding and/or thrombosis.

Methods: One hundred twenty-four PV patients (HCT<45%: n=66, HCT 45-50%: n=58; age 42-87 years) were enrolled in the biological sub-study. Blood samples were collected at randomization and then after every 6 months for 5 years. TG was determined by the calibrated automated thrombogram assay (CAT assay, Stago), in platelet-poor plasma spiked with 5pM tissue factor (TF). TG results were expressed as endogenous thrombin potential (ETP) and as maximum quantity of thrombin produced (Peak). TG was also performed in the presence of activated Protein C (APC) to evaluate APC resistance, and results expressed as normalized APC sensitivity ratio (nAPCsr). Fifty-one healthy subjects acted as the control group.

Results: At baseline, HCT levels were not different between patients randomized at HCT<45% (46.4%) vs HCT 45-50% (47.9%). A significant correlation was observed between HCT values and TG parameters [ETP (R=0.501) and Peak (R=0.329)]. At baseline we also observed that APC markedly inhibited ETP and Peak of TG in both PV patients and controls; however, patients were more resistant to the anticoagulant action of APC compared to controls, resulting in significantly higher plasma nAPCsr. During follow-up, in patients randomized at HCT <45%, nAPCsr showed an overall decrease over time towards control values, while it remained higher than controls in the HCT 45-50%. The low rate of thromboses (n=9) and major hemorrhages (n=2) in the tested group did not allow us to assess the predictive values of TG for the thrombohemorrhagic events.

Summary / Conclusion: Our data show that in PV patients a correlation exists between HCT levels and TG potential, and a more resistant to APC phenotype occurs compared to healthy controls. The more aggressive cytoreductive regimen, i.e. HCT <45% as target, appeared to be associated to a less APC resistant features.

P252

A DECREASE IN JAK2 SIGNALLING COULD INDUCE A PARADOXICAL INCREASE IN MEGAKARYOPOIESIS

R Besancenot[1],* H Abdelouahab[1], C Tonetti[2], D Roos-Weil[1], F Pasquier[1], W Vainchenker[1], E Solary[1], S Giraudier[1,3]

[1]U1009, Inserm, VILLEJUIF, [2]Laboratoire d'Hématologie, AP-HP, Université Paris XII, Hopital Henri Mondor, [3]Laboratoire d'Hématologie, AP-HP, Hopital Henri Mondor, CRETEIL, France

Background: Megakaryopoiesis is the hematopoietic process leading from hematopoietic stem cells (HSC) to platelets production. In broad outline, it can be divided into a proliferative stage that generates megakaryocyte progenitors and a maturation stage in which differentiating megakaryocytes no more proliferate. These two stages can be driven by a single cytokine, namely thrombopoietin (TPO), which exerts both proliferative and anti-proliferative effects. Since MPL, the receptor of TPO, is devoid of kinase activity, the receptor associates with intracytoplasmic tyrosine kinases, in particular JAK2, for signal transduction. JAK2 is not only essential for TPO-induced signal transduction, but also for MPL stability and cell surface expression. A preferential amplification of the megakaryocytic lineage is observed in two myeloproliferative neoplasms (MPN), essential thrombocytemia (ET) and primary myelofibrosis (PMF). MPL is down-regulated in megakaryocytes and platelets from MPN patients, although this result is controversial in ET. A JAK2V617F mutation is detected in ~60% of PMF and ET whereas a mutation in MPL is detected in 2-8% of these diseases. A common feature of PMF and ET is the abnormal proliferation of megakaryocytes, suggesting that maturing megakaryocytes could escape the differentiation-associated induction of proliferation arrest by TPO.

Aims: The aim of our study was to demonstrate that a decrease in MPL or JAK2 expression or in JAK2 signalling could induce an increase in megakaryocytes production.

Methods: We derived clones from the human megakaryoblastic UT7-MPL cell line to explore the mechanisms allowing cells to escape the antiproliferative action of TPO. We confirmed our results by an RNA-interference strategy (shRNA anti-JAK2). We studied MPL and JAK2 expression, at the mRNA and protein levels, during the human CD34+ megakaryocytic differentiation process from cells cultured in presence of TPO. We then determined MPL/JAK2 expression in platelets from patients diagnosed with MPN. Finally, we studied the effects of a chemical JAK2 inhibitor on megakaryocytes production.

Results: In the present study, we show that TPO-induced cellular response depends on MPL and JAK2 protein levels. When one of these proteins is expressed at low level, the cytokine induces a weak signal that promotes cell proliferation. At higher MPL and JAK2 expression levels, TPO promotes cell cycle arrest and megakaryocytic differentiation. In our cell line model, a decrease in JAK2 expression can be sufficient to escape the antiproliferative action of TPO. We show that MPL and JAK2 expressions increase in a progressive and regular way during normal megakaryopoiesis and observed a decrease in MPL or JAK2 protein expression in platelets from MPN patients, correlated with the presence of a MPL or JAK2 mutation. We show that in some conditions a JAK2 inhibitor could paradoxically increase the production of megakaryocytes.

Summary / Conclusion: We propose that the modulation of MPL and JAK2 expression levels accounts for the two steps of normal megakaryopoiesis (ie proliferation versus proliferation arrest and differentiation) and that an MPL or JAK2 down-regulation may play a role in the abnormal proliferation of megakaryocytes in various MPN. Our results suggest that in some conditions, the clinical use of JAK2 inhibitors could paradoxically increase megakaryocytes production and result in an increase in the platelets number.

P253

A TRANSLOCATION T(3 ;13)(Q13 ;Q12) FUSES FLT3 TO A NOVEL PARTNER GENE, GOLGB1, IN A MYELOID/LYMPHOID NEOPLASM WITH EOSINOPHILIA.

E Troadec[1,*] S Dobbelstein[2], F Trimoreau[3], M Touati[4], D Bordessoule[4], B Philippe[5], J Feuillard[3], C Bastard[5], N Gachard[3]
[1]Laboratoire d'Hématologie, Hôpital Dupuytren, Limoges, [2]Laboratoire d'hématologie, Hôpital Necker-Enfants-Malades, Paris, [3]Laboratoire d'Hématologie, [4]Service Hématologie Clinique, CHU Dupuytren, Limoges, [5]Laboratoire de Génétique Oncologique, Centre Henri Becquerel, Rouen, France

Background: The "Myeloid and lymphoid neoplasms with eosinophilia and abnormalities of PDGFRA, PDGFRB or FGFR1." category has been added to the 2008 WHO classification. This group, characterized by constitutive activation of tyrosine kinase, often associated a myeloid neoplasm to a high grade lymphoma (most frequently of T-cell phenotype), and eosinophilia. FLT3 is a class III receptor tyrosine kinase (TK) that can be constitutively activated by mutations in the juxtamembrane or the tyrosine kinase domains. Fusion genes involving this TK have already been described. FLT3 has been found to be fused to ETV6 in two myeloid/lymphoid neoplasms with eosinophilia cases.
We report here the case of a patient with a myeloid/lymphoid neoplasm with eosinophilia harbouring a new t(3;13)(p13;p12) translocation.
Aims: The aim of this study was to determine genes involved in this chromosomal rearrangement and identify the product of this translocation.
Methods: The patient was a 70-year old woman who was referred to our institution for asthenia with elevated leukocytes and neutrophils, presence of myelocytes, hypereosinophilia and increased monocytes, revealed by examination of peripheral blood. LDH level was elevated without tumour syndrome. Bone marrow was hypercellular with granular hyperplasia, no excess of blast and no dysplasia. Lately, the patient developed lymph node enlargement and hepatosplenomegaly with degradation of general status. Histology and phenotypic analysis of lymph node revealed a T-cell lymphoblastic lymphoma. Conventional cytogenetic analysis on bone marrow and lymph node cells revealed a t(3;13)(q13;q12) translocation, highlighting the hypothesis of a lymphoid/myeloid disorder. The patient rapidly died in despite of CHOP chemotherapy initiation. Final diagnosis was a 8p11-like myeloid/lymphoid neoplasm with hypereosiniphilia and with a new translocation t(3;13).
Results: First, FISH analysis and RT-PCR experiments permit to exclude involvement of FGFR1 gene on 8p11. Then, in order to refine the breakpoint in chromosome 3 and 13, a series of BACs was hybridized on 3q13 and 13q12. Finally, the use of fosmid probes permits to identified GOLGB1 and FLT3 as gene candidate in chromosome 3 and 13 respectively. Thus total RNA was extracted from lymph node cells and a reverse transcription- multiplex PCR was used to amplify a putative GOLGB1-FLT3 transcript. Sequence analysis of PCR product revealed a fusion of GOLGB1 exon 14 with a part of FLT3 exon 14. This fusion transcript was in-frame that incorporated 36 pb of intron 14 of GOLGB1. The GOLGB1-FLT3 transcript sequence is predicted to encode a chimeric protein containing the N-terminal portion of Giantin, a large coiled-coil protein encode by GOLGB1, and the C-terminal portion of FLT3 including the two tyrosine kinase domains.
Summary / Conclusion: We report here a novel partner gene for FLT3 identified in a patient with a myeloid/lymphoid neoplasm with eosinophilia harbouring a t(3;13)(p13;p12) translocation. Functional analysis will have to be performed and FLT3 inhibitors tested to determine the consequences and significance of the fusion

P254

DEFINING THE ONCOGENIC SIGNALLING PATHWAY OF JAK2-V617F BY TRANSCRIPTOME SEQUENCING AND IDENTIFICATION OF SPECIFIC DOWNSTREAM TARGETS

C Cleary[1,*] M Mayerhofer[2], R Kralovics[1]
[1]CeMM, Research Center for Molecular Medicine of the Austrian Academy of Sciences, [2]Laboratory Medicine, Medical University of Vienna, Vienna, Austria

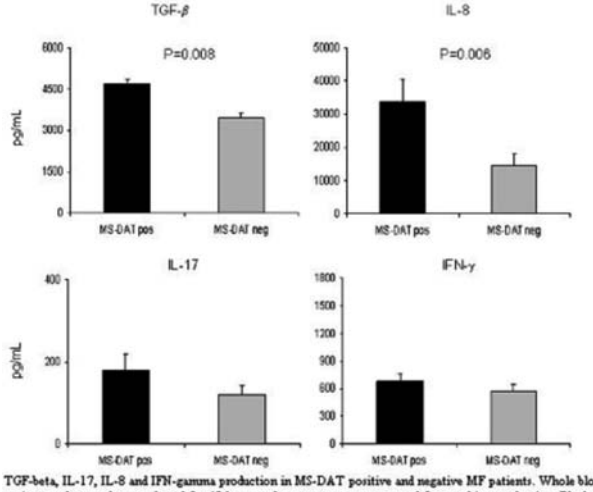
Background: Myeloproliferative neoplasms (MPN) constitute a heterogeneous group of diseases in which there is an excess of terminally differentiated myeloid cells. In recent years, the *JAK2*-V617F mutation has emerged as a key player in the development of the disease, present in up to 90% of cases of polycythemia vera (PV) and 50-60% of cases of essential thrombocythemia (ET) and primary myelofibrosis (PMF). Major research efforts have been made to delineate the exact mechanism by which *JAK2*-V617F influences the development of the disease and how it results in starkly different phenotypes, however, many questions remain. The murine IL3-dependent Ba/F3 cells have been successfully used in the past to characterize cytokine responses of hematopoietic oncogenes and may serve as a useful model for investigating the action of *JAK2*-V617F in humans.
Aims: In order to gain a deeper insight into the *JAK2*-V617F signalling pathway and identify novel downstream targets, we analysed the transcriptome of the Ba/F3 cell line expressing the human *JAK2*-V617F and *JAK2* wild type cDNA in a tetracycline inducible manner
Methods: Ba/F3 cells were incubated with IL-3 and doxycycline for 72 hours with a 12 hour IL-3 starvation step prior to cell lysis. RNA was extracted and fragment libraries were synthesised. Sequencing was performed on the HiSeq2000 Illumina platform. The reads were analysed with the help of the TopHat/Cufflinks software suite and custom R scripts. Patient samples from *JAK2*-V617F negative PMF (n=9) and *JAK2*-V617F positive PMF (n=9) were also sequenced alongside healthy controls (n=6).
Results: Overall, 216 genes were found to be specifically expressed in *JAK2*-V617F cells upon doxycycline induction. Surprisingly a small number of genes (n=48) were induced upon expression of the wild type *JAK2*, 20 of which were specific to the wild type *JAK2*. We detected known *JAK2*-V617F targets such as *Myc*, *Osm*, *Stat1* and *Socs3*. Analysis of the gene set using the DAVID tool showed a strong enrichment for a variety of pathways including JAK-STAT and interferon response (P=0.0039). We also detected a set of novel dysregulated kinases, microRNAs and secreted proteins which included *Mir715*, *Pim1*, *Aurkb* and *Lif*. These hits represent novel pathways and kinases that may play a key role in the oncogenic signalling of the *JAK2*-V617F mutation.
Summary / Conclusion: Validations of the identified pathways and dysregulated genes are currently in progress, using data from sequenced patient samples. Moreover, functional assays will enable the identification of the genes that play a pivotal role in *JAK2*-V617F oncogenic signalling.

P255

INCREASED PREVALENCE OF AUTOIMMUNE PHENOMENA IN MYELOFIBROSIS: RELATIONSHIP WITH CLINICAL AND MORPHOLOGICAL CHARACTERISTICS, AND WITH IMMUNOREGULATORY CYTOKINE PATTERNS

F Guidotti[1,*] T Radice[1], F Imperiali[2], A Zaninoni[2], F Bruno[1], P Bianchi[2], A Cortelezzi[1], A Iurlo[2], W Barcellini[2]
[1]U.O. Ematologia e Centro Trapianti di Midollo, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano e Università degli Studi di Milano, [2]U.O. Ematologia e Centro Trapianti di Midollo, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Milano, Italy

Background: Autoimmune phenomena are frequent in myelofibrosis (MF), both in terms of serologic markers of autoimmunity and of clinical defined diseases; however their prevalence and relationship to the grade of bone marrow fibrosis and clinical risk are not known. The role of the immune system in the pathogenesis of MF is supported by the existence of a non-clonal, non-neoplastic disease which resembles MF, named primary autoimmune myelofibrosis. In addition, MF patients showed an abnormal cytokine expression, which could contribute to bone marrow fibrosis, angiogenesis and constitutional symptoms; on the other hand, it is well established that immunoregulatory cytokines play a critical role in the pathophysiology of autoimmune diseases.
Aims: The aim of this study was to investigate the prevalence of autoimmune phenomena in MF, focusing on anti-erythrocyte antibodies, anti-platelets antibodies and organ- and non organ-specific autoantibodies. Further aim was to relate the presence of autoimmune phenomena with cytokine profiles (IL-17, TGF-β, IFN-γ, and IL-8) and with the grade of bone marrow fibrosis and clinical risk.
Methods: 100 consecutive MF patients were enrolled from May 2010 to April 2011 and followed prospectively for a median of 18 months until September 2012 (range 1-23). Patients were classified according to grade of bone marrow fibrosis and DIPSS-plus scoring system. Anti-erythrocyte antibodies were detected by standard direct antiglobulin test and mitogen-stimulated (MS)-DAT, anti-platelets antibodies and organ- and non organ-specific autoantibodies were detected by standard techniques. Cytokine production was evaluated in cultures supernatants.



TGF-beta, IL-17, IL-8 and IFN-gamma production in MS-DAT positive and negative MF patients. Whole blood from patients and controls was cultured for 48 hours and supernatants were assayed for cytokine production. Black columns represent MS-DAT positive patients and grey columns MS-DAT negative patients Values are the mean+SE.

Figure 1.

Results: Patients (51 males and 49 females; median age 72 years, range 34-86) were classified as follows: 58 primary, 32 post-thrombocythemia or 10 post-polycythemia; 18 MF-0, 65 MF-1, 15 MF-2, and 2 MF-3; 13 LR, 54 IR-1, 22 IR-2, and 11 HR. MS-DAT was positive in 45%, anti-platelets antibodies in 15% and serologic autoantibodies in 57% of cases; considering altogether autoimmune phenomena, positivity for at least one of the tests performed was found in 82 patients. None of the positive cases displayed an overt autoimmune disease. Autoimmunity was more frequent in MF-0/MF-1, and in LR and IR-1 DIPSS-plus groups. MS-DAT positive cases displayed increased TGF-β (P=0.008), and IL-8 production (P=0.006); IL-17 and IFN-γ were higher as well, although not significantly (Figure 1). Likewise, IFN-γ production was increased in patients with positive serological markers of autoimmunity (P=0.03). Finally, TGF-β and IL-17 were found elevated in early clinical and morphological stages, while IL-8 was increased in advanced MF stages.
Summary / Conclusion: Our results suggest that autoimmune phenomena and cytokine disregulation are particularly relevant in early MF stages according to clinical and morphological criteria, although they are not associated with clinically-overt autoimmune diseases. Overexpression of autoimmune phenomena could contribute to establish an unfavorable microenvironment, that may provide an advantage for the emergence of neoplastic and non-neoplastic clones, as already hypothesized in myelodysplastic syndromes and in paroxysmal nocturnal hemoglobinuria. The presence of autoimmune phenomena and cytokine disregulation may offer additional hints for therapeutic strategies (such as thalidomide, lenalidomide, and pomalidomide) aimed also at modulating the immune system.

P256

TYROSINE KINASE (TK) GENE FUSIONS IN CHRONIC MYELOPROLIFERATIVE DISORDERS (CMPD): A FISH STUDY

P Bernasconi[1],* I Dambruoso[1], B Marina[1], P Cavigliano[1], I Giardini[1], B Rocca[1], R Zappatore[1], C Calvello[1], M Caresana[1], A Orlando[1], A Pasi[1], E Rumi[1], M Cazzola[1]
[1]Division Of Hematology, Foundation IRCCS Policlinico San Matteo, Pavia, Italy

Background: CMPDs are a heterogeneous spectrum of hematopoietic stem cell disorders due to the constitutive activation of specific TK genes because of mutations or exceptionally chromosomal translocations often escaping cytogenetic (CC) identification as most TK genes map within poorly stained regions. Their demonstration is clinically relevant as in 2008 the WHO classification introduced a new entity.
Aims: FISH with probes specific for TK genes was applied in order to assess the incidence of these chromosomal translocations, to identify uncommon TK translocation partners, to establish whether eosinophils are part of the clonal cell population and any correlation with clinical parameters and outcome.
Methods: The 31 consecutive patients (pts) analysed came to our observation in the period January 1998-December 2006 and were 9 females and 22 males with a median age of 45 years (range 22-72). According to WHO classification, 17 pts were classified as atypical chronic myeloid leukemia (aCML), 14 as chronic eosinophilic leukemia (CEL) and one as AML/T lymphoblastic lymphoma (T-LL). Median follow-up was 29 months (range 1-124). At the time of the study one pt died and none experienced disease progression. FISH probes were obtained from Kreatech (Amsterdam, NL), Abbot Molecular Inc. (Chicago, Il, USA) and from BACPAC Resources Center at C.H.O.R.I. (Oakland, USA) after determining their Mb position using UCSC genome browser on Human Feb. 2009 assembly. The commercial probes, applied according to manufacturer's guidelines were: ON FIP1L1-CHIC2-PDGFRA (4q12) Del, Break; ON PDGFRB (5q33) Break; ON FGFR1 (8p12) Break; ON JAK2 (9p24) Break; LSI BCRABL. The BAC probes labelled and applied as previously described were RP11-484L21 and RP11-880I16 covering the PCM1 gene. For i-FISH, cut-off values, obtained from the analysis of 300 nuclei from ten normal samples, were fixed at 10%.
Results: An abnormal FISH pattern was revealed in 9 pts (29%): 3/16 (18.7%) with aCML, 5/14 (35.7%) with CEL and one with AML/T-LL. Two aCML pts presented a trisomy 8 and the last one a t(9;13)(q34;q14) which involved the ABL gene and a partner gene not yet identified. Two CEL pts showed a JAK2 rearrangement: one with a t(8;9)(p22;p24) rearrangement on CC presented the classical PCM1-JAK2 gene fusion, the other with a t(3;8)(?;p24) not revealed by CC presented a fusion between JAK2 and a partner not yet identified. Two additional CEL pts showed a PDGFRB rearrangement which escaped CC detection too. In these pts, one with a t(1;5)(?;q33) and loss of the reciprocal translocation product and the other one with a t(5;8)(q33;?), the PDGFRB translocation partner has been not yet identified. The last chromosomally normal CEL pt showed a PDGFRA deletion. The sole AML/T-LL pt carried a t(8;13)(p11;q12) which produced the classical FGFR1-ZNF198 gene fusion. Thus, in 3 pts FISH with BAC probes is still on-going in order to search the unknown translocation partners of JAK2 and PDGFRB. Noteworthy, despite these TK positive pts presented a relevant eosinophilia (≈65%), FISH performed on peripheral blood smears always provided negative results. From a clinical point of view no aCML/CEL pt showed a lymphoid neoplasms. Four pts were treated with TK inhibitors and presented a haematological improvement.
Summary / Conclusion: Our data suggest that FISH i) effectively reveals cryptic TK translocations in about 36% of chromosomally normal CMPDs; ii) these TK rearrangements are more common in CELs than in aCML; iii) peripheral blood eosinophils may show a normal FISH pattern.

P257

ALL-TRANS RETINOIC ACID POTENTIATES THE INHIBITORY EFFECTS OF INTERFERON ALPHA (IFN) ON CHRONIC MYELOPROLIFERATIVE NEOPLASMS (MPN) PROGENITORS IN VITRO.

N Pugliese[1],* C Quintarelli[1], B De Angelis[1], S Errichiello[1], L Marano[1], M Raia[1], C Cerchione[1], L Del Vecchio [1], M Picardi[1], V Martinelli[1], F Pane[1]
[1]Hematology, University of Naples Federico II, naples, Italy

Background: Although IFN has proven efficacy in Polycythemia Vera (PV) and Essential Thrombocythemia (ET), many patients experience unacceptable side effects. ATRA synergizes with the inhibitory effect of IFN on the growth of malignant and normal hematopoietic cells. Their pathways converge on the promoter of STAT1 that induces IRF-1 transcription. This tumor suppressor exerts pro-apoptotic effect trough TRAIL and caspase activation. ATRA activates TRAIL expression also by IRF1 independent mechanisms. These drugs cooperate in blocking cell cycle by inducing $p21^{WAF1/CIP1}$. This study aimed to *in vitro* investigate the synergistic activity of ATRA and IFN in MPN, in order to reduce IFN doses and its related side effects.
Aims: This study aimed to *in vitro* investigate the synergistic activity of ATRA and IFN in MPN, in order to reduce IFN doses and its related side effects.
Methods: HEL and SET2 cell lines characterized by JAK2V617F mutation were treated with a scalar dose of IFN (1-10000U/mL), ATRA (0,1nM-1x10^6nM) and a combination of the two drugs. Proliferation rate, apoptosis and cell cycle were evaluated after 24-48-72-96-120-168 hrs.
$CD34^+$ cells purified from BM of four MPN patients (PV=1, ET=3) at the time of diagnosis were plated (2x10^3 cells/mL) in semi-solid methylcellulose medium and were incubated with IFN (10000U/mL), ATRA (0,01mM) or their association. Colony forming cell assay (CFC) was performed at day 14. RARα,β,γ and RXRα,β,γ gene expression was evaluated both for cell lines and CD34+ cells from MPN patients.
Results: We observed in SET2 cell line an antiproliferative effect of IFN (10000U/mL) and ATRA (0,01mM) after 120-168 hrs of treatment.
Apoptosis assay showed that, at this concentration, HEL cell line is less sensitive to IFN (P=0,0002), ATRA (P=0,0026) and their combination (P=0,00001) than SET2. RT-qPCR showed a significant down-regulation of RARβ and up-regulation of RARγ in HEL respect to SET2. This differential expression of RAR subunit may explain the different responsiveness to ATRA. IFN and ATRA treatments were effective in inducing SET2 growth inhibition (P=0,0006; P=0,0008) and apoptosis (P=0,001; P=0,04) compared to untreated cell line. Moreover, their combination synergistically increased both growth suppression (IFN vs ATRA+IFN P=0,0001 and ATRA vs ATRA+IFN P=0,0006) and apoptosis (IFN vs ATRA+IFN P=0,036 and ATRA vs ATRA+IFN P=0,00001). Cell cycle analysis revealed a reduction of SET2 cells in S phase after IFN (6,2%) and IFN+ATRA treatment (3,9%), compared to untreated cell line (13,2%). CFC showed that IFN reduced CFU-GM (54±34; P=0,04) without affecting BFU-E and CFU-GEMM formation, while ATRA alone inhibited BFU-E (34±10 P=0,01) growth. Although the addition of ATRA seems to neutralize the IFN inhibitory effect on CFU-GM (127±24 P=0,25), their combination suppresses BFU-E (3±2 P=0,003) and CFU-GEMM (23±7 P=0,004).
Summary / Conclusion: These results indicate that, the *in vitro* combination of IFN and ATRA acts synergistically in inhibiting SET2 cell line and in suppressing BFU-E and CFU-GEMM growth and suggests that it has a potential interest for the treatment of PV and ET.

P258

SETBP1 OVEREXPRESSION IN CLASSICAL BCR/ABL1-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

F Albano[1],* L Anelli[1], A Zagaria[1], N Coccaro[1], G Tota[1], A Ricco[1], P Casieri[1], A Minervini[1], L Impera[1], C Francesco Minervini[1], G Specchia[1]
[1]DETO, Hematology - University of Bari, Bari, Italy

Background: SET binding protein 1 (*SETBP1*) gene encodes a protein containing a ski homology domain, a SET-binding region, and three nuclear localization signals. The encoded protein has been shown to bind the SET nuclear oncogene and to inhibit the activity of protein phosphatase 2A tumor suppressor protein. *SETBP1* represents the first gene identified to be recurrently mutated in atypical Chronic Myeloid Leukemia (aCML), accounting for about 25% of all cases. aCML belongs to the group of myelodisplastic/myeloproliferative (MDS/MPN) syndromes without specific recurrent genomic or chromosomal alterations and characterized by poor prognosis. *SETBP1* mutations were also detected in 10% of "unclassified MDS/MPN" and in 4% of chronic myelomonocytic leukemia (CMML) cases. The occurrence of *SETBP1* point mutations has also been investigated in classical *BCR/ABL1*-negative myeloproliferative neoplasms (MPN) but no mutation was identified.

Aims: To date the possible activation of *SETBP1* gene expression in MPN has never been explored. The aim of this study was to investigate the occurrence of *SETBP1* gene deregulation in classical *BCR/ABL1*-negative MPN.
Methods: A cohort of cases affected by polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) was examined. In detail, 47*BCR/ABL1*-negative MPN patients at diagnosis (including 24 PV, 12 ET, and 11 PMF cases) were analyzed by quantitative real-time PCR (qRT-PCR) experiments using the LightCycler 480II System (Roche) and specific primers for *SETBP1* gene. Statistical analysis of the relative expression results was performed by the Relative expression software (REST) tool.
Results: qRT-PCR analysis revealed a high *SETBP1* expression level in PV and PMF bone marrow samples when compared with healthy matched controls. In fact, *SETBP1* gene expression in PV and MPF was more than 5 (P<0.0001) and 9 (P<0.0001) fold when compared to controls, respectively. Regarding ET cases, *SETBP1* gene resulted to be overexpressed by a mean factor of 1.839, but the data was not statistically significant. Considering a cut-off of ≥ 5 fold-change, expression values ≥ 5 were revealed in 58% (14 out of 24), 33% (4 out of 12), and in 90% (10 out of 11) of PV, ET, and PMF cases, respectively. No association between *SETBP1* overexpression and *JAK2* mutational status (homozigosity/heterozygosity) was detected in PV whereas all analyzed *JAK2V617F*-negative PMF cases (3 out 11) showed high gene expression level.
Summary / Conclusion: Recently, several acquired mutations in genes such as *TET2, ASXL1* and *IDH1/2* were identified suggesting that, in cooperation with *JAK2V617F*, additional molecular alterations are involved in the MPN pathogenesis and in the initiation of a leukemic transformation. Our data revealed that *SETBP1* gene dysregulation is a recurrent event in MPN. It is noteworthy to note that in our study *SETBP1* overexpression was revealed in more than half of the analyzed cases; moreover, *SETBP1* was upregulated in almost all PMF cases included in our study. Further analysis are needed to verify the association between *SETBP1* gene expression and clinical factors in MPN cases.

P259

CUSTOM AMPLICON CAPTURE AND BENCH-TOP HIGH THROUGHPUT SEQUENCING TO SCREEN FOR MUTATIONS ASSOCIATED WITH MYELOPROLIFERATIVE NEOPLASMS

A Patel[1], MValgañón[1], H En Foong[1], S Ale[1], M Alikian[1], T Aitman[2], K Naresh[3], D Milojkovic[4], J Apperley[4], L Foroni[1], G Gerrard[1,*]
[1]Imperial Molecular Pathology, [2]Imperial NIHR Biomedical Research Centre, [3]Centre for Haematology, Imperial College London, [4]Dept of Haematology, Imperial College Healthcare NHS Trust and Academic Health Sciences Centre, London, United Kingdom

Background: Myeloproliferative neoplasms (MPN) are clonal disorders of terminally differentiated hematopoietic stem cells. Polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) are the classical form of Philadelphia chromosome-negative MPN. The *JAK2* V617F missense mutation is found in 95% of patients with PV and 40-50% of patients with ET and PMF. Screening for the V617F mutation in query MPN patients has become a routine diagnostic method. Further identification of other activating mutations such as *MPL* (codons 505 and 515) and complex indels affecting *JAK2* exon 12 have been found in mostly V617F negative patients. In addition, a range of mutations in genes involved in intracellular signalling, epigenetic regulation and leukaemic progression have been identified. Molecular genetic screening for these targets at the required depth of sensitivity using conventional techniques is laborious and expensive, but with the advent of benchtop-class high-throughput sequencers, the ability to test for all relevant mutations in one assay becomes a possibility.
Aims: Optimize a custom amplicon high throughput sequencing assay to screen for the most relevant MPN associated mutations and validate candidate hits using pyrosequencing or high resolution melt curve analysis (HRM).
Methods: 24 patient DNA samples (4 PV, 12 ET, 5 PMF, 4 unclassified; 10 *JAK2* V617F positive by pyrosequencing and 14 negative; 2 of which had known *MPL* mutations) were screened (with appropriate ethical consent) for mutations using the Ion Torrent PGM sequencing platform. AmpliSeq was used for the target capture and the panel was designed via the online portal targeting 23 regions of 13 genes associated with MPN. The workflow involved library preparation and multiplex sample pooling following qPCR quantification (8 samples per run), emulsion PCR template preparation, Ion 316 chip loading and sequencing. Alignment and variant calling was via the Torrent Server 3.4.2 plugins, using a custom BED file to define the regions of interest. Variant calls were annotated using IGV and UCSC and candidate hits matching the Catalogue of Somatic Mutations in Cancer (COSMIC) were taken forward for validation using HRM or pyrosequencing.
Results: All 10 *JAK2* V617F and the 2 MPL mutations were correctly called by the Ion Torrent platform, with very similar variant frequencies and no false positives. Additionally, a V617F positive (70.1%) PV sample also showed a heterozygous *TP53* missense mutation (c.832C>A; p.P278T; COSM43697) at a frequency of 10.6%. This was validated using pyrosequencing (11.9%). Also, a 33.8% *MPL* W515L mutation (c.1544G>T; COSM18918) from a V617F negative ET patient was identified, along with a 47.8% *MPL* W515K in a V617F negative PMF sample (c.1543_1544TG>AA; COSM19193). Both *MPL* mutations were validated using HRM.
Summary / Conclusion: Myeloproliferative neoplasms are a heterogeneous group of disorders with specific mutations that can inform the correct diagnosis, prognosis and subsequent treatment choices. The approach used in this study showed that it is possible to combine a high-throughput qualitative and quantitative analysis of multiple genes that individually are laborious and time consuming, with no loss of sensitivity (1-5%) or specificity. Additionally, the ability to multiplex many samples per run increases the labour and cost effectiveness and makes this technique a feasible diagnostic tool for mutation screening in MPN and other somatic variant disorders.

P260

QUANTITATIVE RT-PCR FOR PDGFR IS USEFUL FOR DIAGNOSIS AND MOLECULAR MONITORING OF PATIENTS WITH PDGFR REARRANGEMENTS TREATED WITH TYROSINE-KINASE INHIBITORS

A Bidet[1], W Auriol[1], M Migeon[1], C Claudine[1], J Pasquet[2], P Erben[3], O Blanchet[4], P Cornillet-Lefebvre[5], S Dulucq[1], F Mahon[1], E Lippert[1,*]
[1]Laboratoire d'Hematologie, CHU de Bordeaux, Pessac, [2]LHLCT - INSERM U1035, Universite Bordeaux Segalen, Bordeaux, France, [3]III. Medizinische Klinik, Universitätsmedizin Mannheim, Mannheim, Germany, [4]laboratoire d'hematologie, CHU d'Angers, Angers, [5]Laboratoire d'hematologie, CHU de Reims, Reims, France

Background: Hypereosinophilia (HE) may be the consequence of a *PDGFR* rearrangement. This possibility must be explored because a specific treatment by tyrosine-kinase inhibitors (TKI) will prevent life threatening complications of hypereosinophilias. However, the diversity of *PDGFR* rearrangements, which are often missed by cytogenetics, makes their detection sometimes difficult. All *PDGFR* fusion genes have an increased kinase activity, but also are subject to overexpression of the kinase domain encoded by the 3' end of the fusion. Thus overexpression of *PDGFRA* or *PDGFRB* may indicate the presence of a rearrangement.
Aims: We tested whether a quantitative PCR, modified form Erben *et al*, (Haematologica, 2010;95:738-744) assessing the level of expression of the *PDGFRA* and *PDGFRB* kinases could help detect *PDGFR* rearrangements, but also evaluate their response to TKI.
Methods: The *PDGFRA/PDGFRB* RT-qPCR was performed on the peripheral blood cells of 51 patients with unexplained hypereosiniphilia. Complete diagnosis work-up eventually allowed to classify these patients in 5 groups: 1- *PDGFRA* rearrangement (n=4), 2- *PDGFRB* rearrangement (n=4), 3- reactive hypereosinophilia (including lymphoid HE) (n=27) 4- myeloid HE (n=3), 5- idiopathic HE (n=13). In four patients diagnosed with a t(5;12) (ETV6-PDGFRB) a fusion specific RT-qPCR was performed on blood cells at diagnosis and during follow-up. Generic PDGFRA and PDGFRB RT-qPCR were also performed on follow-up peripheral blood samples for group 1 and group 2 patients.
Results: The RT-qPCRs for *PDGFRA* and *PDGFRB* had efficiencies ranging from 94 to 97% and coefficients of variation from 7 to 12%. Thresholds of 0.5 copies of PDGFRA for 100 copies of ABL1 and 50 copies of PDGFRB/100 copies ABL1 discriminated patients with PDGFR rearrangements (groups 1 and 2) from all other categories in 100% of cases (100% sensitivity and specificity). In patients without PDGFR rearrangement, there was no difference in PDGFRA or PDGFRB expression between groups 3 (reactive HE), 4 (myeloid HE) or 5 (idiopathic HE). The RT-qPCR for ETV6-PDGFRB (efficiency 96-98%) objectivates a decrease of the transcripts in treated patients ranging from 3 to 5 logs. The "generic" PCRs for the PDGFR kinase domain show similar decreases in treated patients, but with only a 3 log range of variations. The same range of decrease is observed in the 4 patients with FIP1L1-PDGFRA and the patient with CCDC6-PDGFRB.
Summary / Conclusion: The quantification of the kinase moiety of *PDGFRA* and *PDGFRB* is a simple, non invasive and unexpensive tool for the screening of *PDGFR* rearrangements. It also allows for a molecular follow-up of treated patients with such rearrangements whenever a fusion specific PCR is not available.

P261

CHARACTERIZATION OF PLATELET HYPERCOAGULABILITY IN HIGH-HEMATOCRIT POLYCYTHEMIA VERA PATIENTS

M Panova-Noeva[1,*] M Marchetti[2], L Russo[2], G Finazzi[3], A Rambaldi[3], T Barbui[3], H ten Cate[4], A Falanga[2]
[1]Internal Medicine, University Medical Center, Skopje, Macedonia, The Former Yugoslav Republic Of, [2]Immunohematology Division , [3]Hematology Division , Hospital Papa Giovanni XXIII, Bergamo, Italy, [4]Internal Medicine and Cardiovascular Research Institute Maastricht, Maastricht University, Maastricht, Netherlands

Background: Polycythemia Vera (PV) is a myeloproliferative neoplasm characterized by a hypercoagulable state and an increased rate of thrombotic complications that significantly impact patients' prognosis and quality of life. The current management of these patients is highly dependent on their thrombotic risk. Maintaining a hematocrit below 45% and platelet count below 400,000/μL are

used as guidance in the treatment intensity. The results of a recent randomized controlled trial show that in PV patients with a hematocrit <45% the rate of cardiovascular death and major thrombosis is significantly lower compared to patients with a higher hematocrit. However all blood cell quantitative and qualitative abnormalities have been repeatedly implicated**.** Platelets have an important role in this process.
Aims: To characterize platelet-associated hypercoagulability in PV patients in relation to hematocrit values.
Methods: Seventy consecutive PV patients have been enrolled in this study after giving an informed consent. 94% of patients were positive for JAK2V617F mutation. At enrolment, 57% of patients were treated with cytoreductive therapy and 20% had a history of thrombosis. The whole blood analysis of hematocrit, white blood cells, platelets and immature platelet parameters were determined by Sysmex XE-2100 hematology analyser. Flowcytometric analysis was used to characterize platelet surface P-selectin and TF expression. The platelet-associated thrombin generation potential was evaluated by the calibrated automated thrombogram in fresh platelet rich plasma spiked with 1pM TF.
Results: Our results show that 38 patients had hematocrit <45% (mean±SD: 41.9± 2.7%) and 32 patients had hematocrit >45% (47.1±1.3%). White blood cell count was higher in high- (>45%) compared to low-hematocrit group (9.9±6.4 vs 7.7±3.6x10^9/L, P=0.07; respectively). Platelet surface TF was significantly increased in high- compared to low-hematocrit PV patients (38.6 ±19 vs 25.4±20%; P<0.05). No significant differences were observed for platelet surface P-selectin or platelet count between the two groups. The TG peak and slope were significantly (P<0.05) increased in high-hematocrit compared to low-hematocrit group (peak: 172.4±44.5 vs 142.9±47.9 nM thrombin; slope: 38.9±20.7 vs 28.6±16.4, respectively).
Summary / Conclusion: This study showed that platelets from patients with high hematocrit (>45%) are characterized by an increased procoagulant profile, as assessed by the higher platelet surface TF expression and PRP-associated TG potential, compared to low hematocrit group of patients. New prospective studies are warranted to evaluate the usefulness of these biomarkers in identifying PV patients at the highest risk for thrombosis.

P262

CHARACTERIZATION OF MUTATIONS IN ASXL1, SRSF2, CBL AND JAK2 GENES IN CHRONIC MYELOMONOCYTIC LEUKEMIA

L Palomo[1,*] B Xicoy[2], S Marcé[2], O Garcia[2], M Cabezón[2], M Jiménez[2], M Arnan[3], H Pomares[3], E Alonso[3], I Granada[2], J Ribera[2], FSolé[1], J Ribera[2], E Feliu[2], F Millá[2], L Zamora[2]
[1]Myelodysplastic Syndromes Group, Josep Carreras Leukaemia Research Institute, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, [2]Hematology, Josep Carreras Leukaemia Research Institute-ICO, Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, [3]Hematology, ICO, Hospital Duran i Reynals, Barcelona, Spain

Background: Chronic myelomonocytic leukemia (CMML) is a myelodysplastic/ myeloproliferative neoplasm with a median overall survival (OS) of 20 months and 15-30% of progression to acute myeloid leukemia (AML). Molecular biology of CMML is poorly understood. Clonal cytogenetic abnormalities are found in 20-30% of cases. Recently, some recurrent gene mutations have been reported. The most frequent mutated genes are *TET2* (30-50%), *ASXL1* (35-56%), *SRSF2* (28-47%), *RUNX1* (8-37%), *CBL* (10-22%) and *K/NRAS* (2-22%), though less frequent mutations have also been described in other genes.
Aims: We sought to characterize type, frequency and prognostic implication of genetic mutations (*ASXL1*, *CBL*, *JAK2* and *SRSF2*) in a cohort of 55 patients with CMML.
Methods: According to the WHO classification, there were 43 CMML-1 and 12 CMML-2, while based on the FAB classification, 40 cases belonged to the myelodysplastic variant (MD) and 15 to the myeloproliferative one (MP). Median age at diagnosis was 69 years (range: 48-85 years), with a male predominance of 1.5:1 and a 31% frequency of progression to AML. Conventional cytogenetic G-banding was performed at diagnosis.To perform mutational analysis, DNA was extracted from bone marrow samples at diagnosis (n= 55). Sanger sequencing was performed to study mutations in exon 1 of *SRSF2* (n=52), exon 12 of *ASXL1* (n=34) and exons 8 and 9 of *CBL* (n=20), while *JAK2* V617F mutation was analyzed by endpoint genotyping (n=25). The rest of the cases are currently being assessed. Survival analysis was performed using Kaplan-Meier estimate and log-rank tests were used for comparisons. The χ^2 and Fisher's exact tests were used to analyze differences in the distribution of variables among patient subsets.
Results: Aberrant karyotypes were seen in 10/55 (18%) cases at diagnosis. Somatic *SRSF2* mutations were detected in 17/52 (33%) cases. All except from one corresponded to heterozygous, missense mutations located at hotspot P95 (6 P95H, 6 P95R and 4 P95L), while 1 case harboured a 3 nt duplication located at the same hotspot P95. Heterozygous somatic *ASXL1* mutations were detected in 12/34 (35%) cases. A total of 6 different mutations were seen in these cases, being the recurrent mutation G646WfsX12 the only one seen in more than one patient (7/31). *JAK2* V617F mutation was detected in 3/25 (12%) cases and no mutations were seen in *CBL* gene. *ASXL1* and *SRSF2* mutations did not correlate with either CMML-1/CMML-2 subtypes or MD/MP variants. All 3 cases with *JAK2* V617F mutation belonged to the MP variant. Mutations in these three genes were not mutually exclusive. Survival analysis revealed that the only adverse prognostic factors were CMML-2 subtype and MP variant. Patients with CMML-2 has worse OS and progression-free survival (PFS) compared to CMML-1 (P=0.001 and P=0.000), while MP cases also showed inferior OS and PFS compared to MD (P=0.012 and P=0.013). Mutations in *ASXL1* had no prognostic impact, while a higher PFS was seen in cases with *SRSF2* mutations, although it was not statistically significant.
Summary / Conclusion: Mutational study showed that *ASXL1* and *SRSF2* are frequently mutated in CMML. There are multiple *ASXL1* mutations located throughout the exon 12, while *SRSF2* mutations are located at the hotspot P95. Although patients with *SRSF2* mutations have have a trend towards higher PFS, CMML-2 and MP-CMML are still the only prognostic factors associated to worse OS and PFS. Mutational analysis in the whole cohort may show new prognostic factors.

P263

ADDITIONAL MUTATIONS TARGETING GENES UNRELATED TO RAS PATHWAY ARE FOUND IN SPORADIC JMML BUT NOT IN SYNDROMIC JMML

A Caye[1,2,*] M Strullu[1,2], B Cassinat[2], J Lachenaud[1,2], O Fenneteau[3], S Pereira[1], F Méchinaud[4], Y Bertrand[5], J Dalle[6], A Baruchel[6], C Chomienne[2], H Cavé[1]
[1]Molecular Genetics, Robert Debré hospital, [2]INSERM U940 , Institut universitaire d'Hématologie, [3]biological hematology, Robert Debré hospital, Paris, [4]Pediatric hematology, Nantes Hospital, Nantes, [5]Pediatric Hematology, IHOP, Lyon, [6]Pediatric Hematology, Robert Debré hospital, Paris, France

Background: Juvenile myelomonocytic leukemia (JMML) is a rare and severe myelodysplastic/myeloproliferative syndrome of early childhood. Up to 90% of patients present with non overlapping mutations of RAS or RAS regulatory intermediates, leading to RAS overactivation. With mutations found in up to 45% of JMML, *PTPN11* is the gene most frequently involved. *PTPN11* mutations can be either somatically acquired (sporadic JMML) or germline in the context of Noonan syndrome (syndromic JMML). Mutations in *NRAS*, *KRAS*, *NF1* or *CBL* can also be found. Intriguingly, the initiating mutation only partially explains clinical and biological heterogeneity among JMML.
Aims: To get further insight into JMML leukemogenesis, we searched for cooperative lesions in either sporadic or syndromic cases due to *PTPN11* mutations.
Methods: In 16 patients with a known *PTPN11* mutation (8 syndromic JMML, 8 sporadic JMML), whole exome sequencing (WES) was performed on paired tumoral and germline samples. Mutations were then searched by Sanger sequencing in the entire French JMML cohort (n =110, with 77 sporadic cases including 30 with *PTPN11* mutation, and 33 syndromic JMML including 18 with *PTPN11* mutations).
Results: WES revealed the presence of 0 to 5 somatic mutations per JMML. No gene was found mutated in addition to *PTPN11* in the 8 syndromic JMML. In contrast, several additional mutations were identified in the 8 sporadic JMML, including somatic *SETBP1* mutations in 2 patients, in line with Muramatsu *et al*. (ASH 2012). Eight other non-silent somatic variants were uncovered in 4 sporadic JMML. None of these variants affected genes known to be related to RAS pathway. Their analysis is still in progress. Targeted resequencing in the whole JMML cohort confirmed the absence of mutations in the 33 syndromic JMML regardless the underlying condition (Noonan syndrome, CBL syndrome). This finding is consistent with the absence of structural abnormalities previously revealed by SNP array analysis in these patients. With 14 additional mutations present in 11/77 (14%) cases, sporadic JMML showed a higher mutation frequency. *ASXL1* was mutated in 7/77 (9%) sporadic JMML, apparently unrelated with the original mutation. *SETBP1* screening showed 7/77 (9%) mutations in sporadic JMML, in addition to a somatic mutation in *PTPN11* (n=4) or *NRAS* (n=3). Six of the SETBP1 mutations affected codons 868 to 870 and are compatible with defective ubiquitinylation leading to *SETBP1* activation. Additional mutations found in sporadic JMML tended to concentrate on the same patients. Indeed, 5/7 *SETBP1* mutations were associated with a mutation of *ASXL1* and/or a clonal cytogenetic abnormalities. The presence of additional mutations at diagnosis may sign an aggressive clinical course since 9 of the 11 patients with at least one additional mutation presented with blast excess (>10%) in bone marrow at diagnosis, experimented subsequent transformation into acute leukemia, and/or early death.
Summary / Conclusion: Although infrequent, additional abnormalities targeting genes unrelated to RAS pathway are found in a subset of sporadic JMML. This clearly distinguishes them from syndromic forms for which no such abnormalities could be identified. This raises the question of a possible role of secondary alterations affecting chromatin conformation in a difference of prognosis between sporadic and syndromic JMML.

P264

DETECTION OF LEUKEMIA-ASSOCIATED MUTATIONS IN HEMATOLOGICALLY NORMAL ELDERLY INDIVIDUALS

N Cross[1,*] R Gale[2], K Waghorn[1], A Jones[1], A Chase[1], L Forsberg[3], C Rasi[3], J Dumanski[3], J Score[1]
[1]University of Southampton, Wessex Regional Genetics Laboratory, Salisbury, [2]Department of Haematology, UCL Cancer Institute, London, United Kingdom, [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: New sequencing technologies are facilitating the development of large gene panels that can be screened in patients with suspected hematological malignancies. Emerging evidence, however, has indicated that some malignancy-associated mutations might be detectable in the population at large, raising questions about the utility of broad mutation screening as a diagnostic tool.
Aims: To investigate this further we studied i) the Uppsala Longitudinal Study of Adult Men (ULSAM) cohort, an ongoing epidemiologic study of all available men born between 1920-24 in Uppsala County, Sweden and ii) 56 normal elderly women with known X-chromosome inactivation patterns (XCIP) in both T-cells and neutrophils.
Results: In a pilot study that included Illumina 1M-Duo beadchip analysis of 108 ULSAM cases, we previously identified one individual with normal peripheral blood counts and no other indication of a hematological disorder who had acquired a large (103Mb) region of terminal acquired uniparental disomy (aUPD) at chr 4q (Forsberg *et al*., AJHG. 2012;90:217-28). Since 4q aUPD in myeloid malignancies is associated with inactivating mutations of *TET2*, we sequenced this gene and identified a 21bp deletion that removed part of exon 4 and is therefore likely to be deleterious. The mutation was absent from B-cell, T-cell and fibroblast DNA but present in leukocyte and granulocyte DNA extracted at the age of 90, leukocyte DNA at ages 82 and 88 (aUPD detected at all three timepoints) and at the age of 71 when aUPD was not detected. Interestingly, the mutational load and level of aUPD noticeably declined between the ages of 88 and 90 for no apparent reason. To determine if aUPD is more widespread in elderly men, we analysed array data from a further ~1100 ULSAM cases and identified 14 individuals (1.3%) with aUPD (median size = 27Mb; range 13-87) at 1p (n=1), 6p (n=1), 9p (n=1), 9q (n=1), 11p (n=2), 11q (n=1), 14q (n=1), 15q (n=1), 17p (n=1), 19q (n=2), 22q (n=2). Of the 14 individuals, two had been diagnosed with a hematological malignancy: one with *JAK2* V617F positive PV (9p aUPD) and another with CLL (17p aUPD; p53 not tested). We did not detect *MPL* or *CBL* mutations in the cases with 1p or 11q aUPD; candidate somatically mutated genes have not been identified for the other aUPD regions. We then went on to analyze a cohort of 56 hematologically normal elderly women, of whom 10 had skewed XCIP in neutrophils but not T-cells, 21 had skewed neutrophils and skewed T-cells and 25 were either balanced in both fractions (n=21) or skewed in T-cells but not neutrophils (n=4). The skewing may simply be a consequence of age-related stochastic processes but might in some cases be caused by subclinical clonal expansion. We screened neutrophil DNA for *JAK2* V617F and mutations in *DNMT3A* (exons 15-23) and *TET2* (all coding exons). *JAK2* V617F was not seen but 2 variants in *DNMT3A* (G699D and R882C) and 4 in *TET2* (R1261H, G1365R, 91477insA_91478_delAGGT, 176230delA) were identified in 3 cases that were either absent or markedly reduced in T-cells from the same patient. Of note, *DNMT3A* R882C is seen recurrently in patients with leukemia, and two of the *TET2* mutations are frameshifts. A further 3 *TET2* missense variants (M1028I, M1701I and Y867H) were identified that were also seen in T-cells.
Summary / Conclusion: These findings reveal a complex pattern of mutations in elderly individuals and support the notion that somatically acquired driver variants are detectable in some individuals with otherwise apparently normal hemopoiesis.

Myeloproliferative neoplasms - Clinical 1

THE IDENTIFICATION OF A PSTAT5 GENE SIGNATURE AND ITS MODULATION IN RUXOLITINIB PHARMACODYNAMIC RESPONSE IN HEMATOLOGIC MALIGNANCY

Background: The JAK/STAT pathway is an important signaling pathway downstream of multiple cytokine and growth factor receptors. Receptor-associated JAKs are activated following receptor-ligand binding. Activated JAKs phosphorylate STAT proteins, which then dimerize and translocate to the nucleus where they modulate the expression of target genes. Dysregulated JAK/STAT signaling has been implicated in the pathogenesis of multiple human malignancies. Activating *JAK2* mutations and associated STAT5 activation in myeloproliferative neoplasia is an example of the involvement of this pathway in human cancer. Additionally, overactive JAK/STAT signaling has been suggested to be a survival mechanism in several human cancers. Given the importance of JAK/STAT dysregulation in human diseases, it is important to identify patients with an overactive JAK/STAT pathway for possible treatment with JAK inhibitors. Thus, we developed a gene signature assay to detect overactive JAK/STAT5 signaling.
Results: The cancer cell line encyclopedia (CCLE) and associated gene-expression data were used to correlate the activation status of STAT5 with the induction of a set of *STAT5* target genes. First, we used 27 tumor cell lines of hematologic lineage, with predetermined phosphorylated STAT5 (pSTAT5) status, to derive STAT5 activation gene signatures. Next, the putative gene signatures were validated against a different set of 13 hematologic tumor cell lines. With this approach, a collection of 7 target genes were identified (*PIM1*, *CISH*, *SOCS2*, *ID1*, *LCN2*, *EPOR*, and *EGR1*) whose expression significantly correlated with pSTAT5 status in the 40 hematologic tumor cell lines (P<.0001), either together or in specific subsets of 4 and 6 genes (Table 1). The STAT5 gene signature was then used to examine pharmacodynamic response to ruxolitinib in a preclinical setting. Seven hematologic tumor cell lines (5 positive for pSTAT5 and 2 negative for pSTAT5) were treated with ruxolitinib 0.2 μM or 1 μM, and samples were collected at 4 hours and 24 hours after treatment. Phospho-STAT5 was examined by Western blot analysis, and the expression of the 4 signature genes was determined by qPCR. In the pSTAT5-positive cell lines, ruxolitinib downmodulated pSTAT5, and there was a corresponding reduction of the expression of the signature genes (Figure, A). In the pSTAT5-negative cell lines, there was no clear effect on pSTAT5 modulation or change in signature gene expression (Figure, B).
Summary / Conclusion: These 4-, 6-, and 7-gene signatures provide a transcriptional surrogate for pSTAT5 and, therefore, ruxolitinib pharmacodynamic activity in hematologic cell lines. Additional studies are required to characterize the relevance of these signatures to JAK/STAT pathway activation and inhibition in human malignancies.

Background: The MPNs are comprised not only of three heterogeneous disease types histologically (polycythemia vera (PV), essential thrombocythemia (ET) and myelofibrosis (PMF, post-ET MF, post-PV MF), but of a multitude of variable disease phenotypes within each MPN subtype.

Aims: We sought to assess the relationship between MPN prognosis and symptom burden.

Methods: : Data was prospectively gathered from the MPN-QOL International Study Group. Patients completed the MPN-SAF and EORTC QLQ-C30. Data on diagnosis, clinical features, and clinical course was collected. Prognostic scoring was performed for MF (DIPSS criteria: age (>65), peripheral blasts (≥1%), hemoglobin (<10 g/dL), leukocyte count (>25x10^9/L), constitutional symptoms; Passamonti, 2012), PV (age >70 or 60-69 and leukocyte count (>15x10^9/L); Tefferi, 2012) and ET (IPSET criteria: age (≥60 years) leukocyte count (≥11x10^9/L), hx of thrombosis; Passamonti, 2012). Clusters were based on the nonhierarchical k-means method. Associations between patient/clinical variables and cluster were investigated using ANOVA, Kruskal-Wallis, and chi-squared tests.

Results: Data from 1470 prospectively enrolled MPN patients was collected including MF (n=329; PMF=223, post-ET MF=67, post-PV MF=39; age mean 59 yrs, male 53%), PV (n=519, age mean 61 yrs, male 57%) and ET (n=622, age mean 57 yrs, male 37%). *MF:* Four clusters were identified. Increasing symptom burden was associated with DIPSS risk (P<0.001), leukopenia (P=0.009), thrombocytopenia (P<0.001) and palpable spleen size (P=0.009). Although a correlation exists between clusters and DIPSS risk groups (P<0.001) significant symptom burden occurred in low and intermediate 1 risk disease (Table 1). Within DIPSS groups, MPN-SAF TSS >20 occurred at rates of 37% (low), 56% (int-1), 62% (int-2) and 67% (high). Longer MF duration trended towards higher cluster values (P=0.06). Weight loss, night sweats, fevers and MPN-SAF TSS increased with clusters progression (P<0.001). *PV:* Five clusters were identified. Clusters correlated with leukopenia (P=0.01), splenic size (P=0.002), and anemia (P=0.04). MPN-SAF TSS increased with cluster progression (P<0.001). No correlations were observed between PV risk group (including variables of age [P=0.13] and leukocytosis [P=0.69]) and clusters (P=0.87; Figure 2). There was a trend towards an inverse relationship between PV duration (mean durations of 6.2, 5.8, 6.4, 4.2, 4.4 years) and increasing symptomatic burden (P=0.73). *ET:* Five clusters were identified. Clusters differed by gender (P=0.04), anemia (P=0.01), prior hemorrhage (P=0.047) and median hemoglobin concentration (P=0.002). MPN-SAF TSS increased with cluster progression (P<0.001) while age was inversely associated with cluster progression (P=0.01). No correlations were observed between IPSET risk scores (including variables of leukocyte count [P=0.94] and history of thrombosis [P=0.24]) and clusters (P=0.43; Figure 3).

Summary / Conclusion: Significant heterogeneity exists both between and within each MPN subtypes. This heterogeneity in disease phenotype is not solely a surrogate for disease prognosis as assessed by MPN prognostic scores. Stages (as assessed by symptomatic burden and prognosis) within each of the MPN subtypes may exist but lack a linear chronological progression suggesting biological subsets within MPN subtypes may exist. Further efforts are ongoing on how to incorporate molecular data, prognostic data, and symptomatic phenotype into a useful staging model with MPN subtypes.

Background: Analysis for the 1849G>T mutation in *JAK2* (encoding JAK2-V617F) is routine in the diagnosis of myeloproliferative neoplasms (MPNs). The quantification of the allelic burden in JAK2-V617F positive patients is increasingly used to monitor treatment response of new targeted therapies as well as in transplanted patients.
Aims: Across Europe the quantitative JAK2-V617F analysis is performed using a number of different assays and analysis platforms and calibration is therefore needed in order to standardise the results.
Methods: Blood samples from 10 JAK2-V617F positive patients were aliquoted (1 ml) and sent out with overnight courier together with 4 reference DNA samples, a JAK2- V617F real time quantitative PCR (qPCR) reference assay and 4 DNA samples (blood samples were collected after informed consent according to the guidelines of the Danish Regional Science Ethics Committee). The reference DNAs were made from a 80 mL pool of normal donor DNA from blood samples by spiking four 10 fold dilutions of a 650 bp PCR product containing the JAK2-V617F mutation into 20 mL aliquots. The copy number of JAK2-V617F and JAK2 wild type in the 4 DNA pools were determined by qPCR and by digital PCR and the allelic ratios of JAK2-V617F were calculated to 75%, 23%, 2.9% and 0.2%, respectively. The qPCR reference assay (Larsen *et al* BJH 2007) that is recommended by the ELN for quantitative PCR (Jovanovic *et al* submitted) was prepared as 10 fold concentrated wild type and V617F mutant primer/probe mixtures. The 4 DNA samples contained either wild type DNA (normal donor DNA), V617F positive DNA (HEL cell line DNA), water (negative control) or normal donor DNA spiked with 1% JAK2-V617F. Two local JAK2-V617F positive DNA samples were also included and these were analysed as both non-diluted and ten fold diluted in order to identify a potential inhibition.
Results: Twenty four laboratories from 13 European countries participated in the study. DNA from the 10 patient blood samples was purified according to local protocols. All samples were run in triplicates (or in duplicates in a few labs) with both the local JAK2-V617F assay and the supplied reference assay (384 qPCR wells per lab). Protocol information, Ct (PCR cycle) values and calculated copy numbers from the local assay were sent to Vejle for analysis (approximately 14,000 data points). Although the reported copy numbers in the 10 patient samples varied between labs the percentage of JAK2-V617F alleles was rather consistent for both the local assay and the reference assay. All labs were able to indentify the 1% JAK2 V617F sample as positive when using the reference assay. However, in several labs the allelic burden of the 1% sample was not significantly different from the normal wild type DNA sample when using the local JAK2 assay indicating limited specificity due to nonspecific amplification
Summary / Conclusion: In 24 labs across Europe the detection and quantification of the JAK2-V617F mutation was relatively consistent in patient samples with an allelic burden above 1%. For values below 1% the specificity and thereby the sensitivity of the analysis varied between labs and this was related to the JAK2-V617F assay used.

P268

MUTATIONS IN THE RNA SPLICING MACHINERY GENES IN MYELOFIBROTIC TRANSFORMATION OF ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA

B Bellosillo[1],* L Martínez-Avilés[1], A Álvarez-Larrán[2], L Camacho[3], S Pairet[1], C Fernández-Rodriguez[3], A Angona[3], S Serrano[1], Carlos Besses[2]
[1]Pathology, [2]Hematology, Hospital del Mar, [3]Grup de Recerca Clínica Aplicada en Neoplàsies Hematològiques, Hospital del Mar-IMIM, Barcelona, Spain

Background: Mutations in genes that codify for several spliceosome subunits, including *SF3B1*, *SRSF2* and *U2AF1* have been recently described in myeloid malignancies including myelodysplastic syndromes, chronic myelomonocytic leukemia, essential thrombocythemia (ET) and primary myelofibrosis (PMF). However, there is limited information about the incidence of alterations in this group of genes in patients with ET or with polycythemia vera (PV) who develop myelofibrotic transformation during the evolution of the disease.
Aims: To analyze the incidence of *SF3B1*, *SRSF2*, and *U2AF1* mutations in a cohort of ET and PV patients who transformed to myelofibrosis.
Methods: A total of 62 patients were included in the study: 22 PV and 14 ET patients who transformed to myelofibrosis, and 26 PMF patients .Screening for mutations of *SF3B1* (exons 14 and 15), *SRSF2* (exon 1) and *U2AF1* (exons2,6 and 7) was performed by pyrosequencing with a next generation sequencing (NGS) 454GSJunior platform (Roche), using DNA extracted from purified granulocytes. Mutations were confirmed by Sanger sequencing.
Results: We identified one out of 22 (4.5%) post-PV MF patient who simultaneously harboured a *SRSF2* mutation (p.P95H) and a *SF3B1* mutation (p.I671T), and two out of 14 (14%) post-ET MF patients with the p.K666N *SF3B1* mutation. A diagnostic sample from one of the *SF3B1* positive ET patients 8 years before transformation, showed the presence of the p.K666N mutation by NGS in 2.4% of sequences in contrast to the 45% observed in the sample at the time of transformation, suggesting an expansion of the clone during the evolution of the disease. On the other hand, a diagnostic sample from the PV patient, 2 years before transformation, showed the presence of both *SF3B1* and *SRSF2* mutations in a similar percentage at both time points. Concerning *U2AF1*, no mutations were detected in any of the patients analyzed. Regarding the group of 26 PMF patients, we detected mutations in the *SRSF2* gene in 6/26 (23%) cases. All mutations affected the P95 hotspot (3 p.P95H, 2 p.P95R and 1 p.P95_R103delinsR). *SF3B1* mutations were detected in 2/26 (8%) patients analyzed (2 p.K666N) and *U2AF1* mutations were observed in 4/26 (15%) PMF patients (2 p.Q157P and 2 p.Q157R).
Summary / Conclusion: Pathogenic mutations in *SRSF2* and *SF3B1* genes are present in a low percentage of post-PV and post-ET MF patients, in contrast to a higher incidence of *SRSF2* mutations in PMF patients. *U2AF1* mutations are found only in PMF patients. These findings suggest a different profile of spliceosome gene mutations in primary and secondary myelofibrosis.

MULTIVARIATE ANALYSIS OF THE ASSOCIATION OF CYTOKINE LEVELS AND REDUCTIONS IN SPLEEN SIZE IN COMFORT-II, A PHASE 3 STUDY COMPARING RUXOLITINIB TO BEST AVAILABLE THERAPY (BAT)

C Harrison[1,*] J Kiladjian[2], H Gisslinger[3], F Passamonti[4], A Sirulnik[5], M Marker[5], M Squires[6], L Knoops[7], G Barosi[8,8], T Barbui[9], F Cervantes[10]
[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [3]Medical University of Vienna, Vienna, Austria, [4]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [5]Novartis Pharmaceuticals Corporation, East Hanover, United States, [6]Novartis Pharma AG, Basel, Switzerland, [7]Cliniques Universitaires Saint-Luc and de Duve Institute Université catholique de Louvain, Brussels, Belgium, [8]IRCCS Policlinico San Matteo Foundation, Pavia, [9]A.O. Ospedali Riuniti di Bergamo, Bergamo, Italy, [10]Hospital Clínic, IDIBAPS, Barcelona, Spain

Background: Ruxolitinib is a potent JAK1/JAK2 inhibitor that has demonstrated rapid and durable improvements in splenomegaly, disease-related symptoms, and quality of life in the two phase 3 COMFORT studies in patients with myelofibrosis (MF). Prolonged survival was observed in patients receiving ruxolitinib compared with both placebo (COMFORT-I) and BAT (COMFORT-II). Recent findings have suggested that cytokine biomarkers may be prognostic in patients with primary MF, and monitoring cytokine levels may prove valuable in predicting and analyzing responses to therapy.
Aims: To evaluate associations between cytokine levels and spleen size reductions in COMFORT-II to determine whether any cytokines are prognostic for changes in spleen size or predictive of decreases in spleen volume with ruxolitinib treatment.
Methods: COMFORT-II is a randomized (2:1), open-label, phase 3 study comparing ruxolitinib with BAT. Spleen volume was measured by MRI every 12 wk and spleen length by palpation at each study visit. Plasma samples were analyzed using Rules-Based Medicine's HumanMAP v1.6; 89 cytokines were measured at baseline and wk4, 24, and 48.
Cytokines with a high proportion (≥ 30%) of values below the lower level of quantification were excluded. The association between the remaining 59 cytokines at baseline and percent reduction in spleen volume from baseline at wk 48 was estimated via a multivariate linear model. The penalized regression Elastic Net method (Zho and Hastie), which combines the penalty terms of the Ridge and Lasso regression, was used to estimate the linear model. Explanatory variables included in the model were baseline cytokines (standardized after a $\log_2$ transformation), treatment arm, and interaction between the treatment and baseline cytokine levels. The tuning parameters for the Elastic Net were selected via 5-fold cross-validation. 10,000 runs of the Elastic Net were performed with different random splits for cross-validation; the most frequent model was selected as the most likely estimated model.
Results: The model identified 10 markers for which the baseline level had a prognostic effect on spleen volume change: alpha-fetoprotein (AFP), beta-2 microglobulin (B2MICG), CD40 ligand, carcinogenicembryonic antigen (CEA), lymphotactin (LTN), myoglobin (MGB), prostatic acid phosphatase (PAP), RANTES, thyroxine-binding globulin (TBG) and vascular cell adhesion molecule-1 (VCAM1). Lower levels of AFP, CEA, LTN, MGB and TBG and higher levels of B2MICG, CD40 ligand, PAP, RANTES and VCAM1 were associated with enhanced spleen volume changes. Lower baseline levels of AFP, eotaxin, insulin and interleukin-18 were identified as potentially predictive of an enhanced effect on spleen volume reduction with ruxolitinib treatment. The association between spleen volume and change in cytokine levels from baseline to wk 4 was also analyzed using similar methodology and will be presented. Additional validation of the above multivariate model on an independent dataset to determine the utility of these cytokines in predicting response as well as investigation into the potential mechanism of these effects are needed.
Summary / Conclusion: This analysis has demonstrated a set of cytokines that are prognostic for spleen volume changes irrespective of treatment and a different set that are potentially predictive of spleen volume change upon ruxolitinib therapy. The impact of baseline cytokine level, although significant, was small in comparison to the effect of ruxolitinib treatment in reducing spleen volume compared with BAT.

P270

SPLICEOSOME COMPONENT MUTATIONS AND CYTOGENETIC CORRELATES IN WORLD HEALTH ORGANIZATION (WHO)-DEFINED CHRONIC MYELOMONOCYTIC LEUKEMIA

S Parikh[1,*] M Patnaik[1], T Lasho[2], C Finke[2], C Hanson[2], J Hodnefield[2], R Knudson[2], R Ketterling[2], A Pardanani[2], A Tefferi[1]
[1]Hematology, [2]Mayo Clinic, Rochester, United States

Background: Chronic myelomonocytic leukemia (CMML) is a clonal, heterogeneous stem cell disorder characterized by overlapping features between myelodysplastic syndrome (MDS) and myeloproliferative neoplasm (MPN). CMML is characterized by persistent monocytosis, myelodysplasia, and an inherent risk for progression to acute myeloid leukemia. Approximately 20-40% of CMML patients have cytogenetic abnormalities on routine karyotype analysis and approximately 90% have molecular aberrations. The prognostic correlation between cytogenetic and molecular abnormalities is not well established.
Aims: We examined the association of karyotype abnormalities using routine cytogenetics with molecular aberrations involving the spliceosome machinery in World Health Organization (WHO)-defined CMML patients seen at our institution from 1997-2007.

Table 1.

Karyotype	N	*SF3B1* N (%)	*SRSF2* N (%)	*U2AF35* N (%)
Diploid ± -Y	160	6 (4)	69 (46)	15 (10)
Complex/Monosomal	15	1 (7)	2 (13)	1 (7)
Trisomy 8	15	1 (7)	9 (60)	0
Monosomy 7	6	0	4 (67)	0
Other	26	4 (16)	6 (17)	4 (11)
Total	**222***	**12 (5)**	**90 (40)**	**20 (8)**

*: karyotype results were not available in 4 patients

Results: Out of 226 patients with CMML seen during this time interval, 153 (67%) were males, the median age was 71 years (range, 17-90 years), and 192 (85%) had CMML-1. Sixty-two patients (28%) had an abnormal karyotype. According to the Spanish cytogenetic risk stratification model, 163 (72%) patients were low-risk, 31 (14%) were intermediate risk and 32 (14%) were high-risk. The various karyotype abnormalities include the following: diploid with or without loss of Y chromosome (± -Y) in 160 (72%) patients, trisomy 8 in 15 (7%), monosomal karyotype in 10 (4%), monosomy 7 in 6 (3%), complex (≥ 3 abnormalities) in 5 (2%), 20q- in 4 (2%), +21 in 4 (2%), translocations involving chromosome 11 in 4 (2%), idic(X)(q13) in 3 (1%),13q- in 2 (1%), i(17)(q10) in 1 patient and other abnormalities in 8 (4%) patients. Karyotype results were not available in 4 patients. The Spanish cytogenetic risk stratification model was prognostic for overall survival (OS) on univariable analysis (P=0.04), however, on multivariable analysis it lost significance (Patnaik, ASH 2012). Ninety patients (40%) had *SRSF2* mutations, 20 (9%) had *U2AF35* mutations, and 12 (6%) had *SF3B1* mutations, all of which were mutually exclusive. The Table shows the association between various cytogenetic abnormalities and mutations involving the spliceosome machinery. A significantly higher proportion of patients harboring *SF3B1* mutations had >15% ringed sideroblasts in their marrow. None of the molecular aberrations in the spliceosome machinery impacted OS or leukemia-free survival (LFS).
Summary / Conclusion: Approximately 30% newly diagnosed CMML patients have an abnormal karyotype. Fifty-five percent patients have molecular abnormalities in the spliceosome machinery, all of which are mutually exclusive. *SRSF2*, *SF3B1* and *U2AF35* mutations do not predict OS or LFS.

P271

ACQUIRED COPY-NEUTRAL LOSS OF HETEROZIGOSITY OF CHROMOSOME 1P AS A MOLECULAR EVENT ASSOCIATED WITH MARROW FIBROSIS IN MPL MUTATED MYELOPROLIFERATIVE NEOPLASMS

E Rumi[1,*] D Pietra[1], P Guglielmelli[2], R Bordoni[3], I Casetti[1], C Milanesi[1], E Sant'Antonio[1], V Ferretti[1], A Pancrazzi[2], G Rotunno[2], M Severgnini[3], A Pietrelli[3], C Astori[1], E Fugazza[1], C Pascutto[1], E Boveri[4], F Passamonti[5], G De Bellis[3], A Vannucchi[2], M Cazzola[1]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo Pavia, Pavia, [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, [3]Institute for Biomedical Technologies, National Research Council of Italy, Segrate, [4]Anatomic Pathology Section, Fondazione IRCCS Policlinico San Matteo, Pavia, [5]Division of Hematology, Department of Internal Medicine, Ospedale di Circolo e Fondazione Macchi, Varese, Italy

Background: The unique *JAK2* (V617F) mutation is found in about 60-70% of patients with essential thrombocythemia (ET) and primary myelofibrosis (PMF). Several studies have been conducted to elucidate the molecular mechanisms underlying the remaining 30-40% of patients with *JAK2* (V617F)-negative ET and PMF. A subset of these patients carry activating somatic mutations in exon 10 of the *MPL* gene, located at chromosome 1p and encoding thrombopoietin receptor. Only minor correlations have been found between *MPL* mutations and clinical phenotype. Acquired copy neutral-loss of heterozigosity (CN-LOH) represents a common molecular mechanism of disease in myeloid malignancies. A paradigmatic example is acquired CN-LOH of chromosome 9p, responsible for the transition from heterozygosity to homozygosity for the *JAK2* (V617F) mutation. The clinical effect of acquired CN-LOH of chromosome 1p and *MPL* mutant allele burden has not been investigated systematically in patients with myeloproliferative neoplasms (MPN).
Aims: To evaluate the clinical phenotype of *MPL*-mutated MPN in comparison with *JAK2*-mutated or *JAK2/MPL*-unmutated MPN and to define whether the

MPL allele burden, rather than the mere presence or absence of *MPL* mutations, might have a clinical effect in *MPL* mutated MPN.
Methods: The study design included 2 parts. First we evaluated a cohort of 892 consecutive patients with Ph-negative MPN other than PV (661 ET, 197 PMF, 44 post-ET MF) diagnosed and followed at the Department of Hematology Oncology, Fondazione IRCCS Policlinico S. Matteo Pavia, between 2002 and 2012. We analyzed *JAK2* (V617F) using a qPCR-based allelic discrimination assay and *MPL* exon 10 mutations using a high resolution melt (HRM) assay. Patients who were found to be *MPL*-mutated at HRM were further characterized using direct sequencing. The 3 genotypic subgroups of MPN patients (*JAK2*-mutated, *MPL*-mutated, *JAK2/MPL* unmutated) were compared in terms of phenotype at diagnosis and outcome. Next, in order to define the effect of *MPL* mutant allele burden on clinical phenotype, we analyzed the Pavia cohort of 43 *MPL*-mutated patients together with a second cohort of 19 *MPL*-mutated patients followed at the University of Florence. *MPL* mutant allele burden was assessed using multiplexed 454 GS-FLX ultramassive sequencing. Analysis of 1pLOH was performed in representative patients with mutant allele burden >75% by SNP genotyping and *MPL* copy number analysis.
Results: Somatic mutations of *MPL*, all but one involving codon W515, were detected in 26/661 (4%) patients with ET, 10/187 (5%) with PMF, and 7/44 (16%) patients with post-ET myelofibrosis. Comparison of *JAK2*-mutated and *MPL*-mutated subjects showed only minor phenotypic differences. In the merged group of 62 *MPL*-mutated patients from Pavia and Florence, the granulocyte mutant allele burden ranged from 1 to 95%, and was significantly higher in patients with PMF or post-ET myelofibrosis compared with those with ET. Patients with higher mutation loads had evidence of acquired CN-LOH of chromosome 1p in granulocytes, consistent with a transition from heterozygosity to homozygosity for the *MPL* mutation in clonal cells. A significant association was found between *MPL* mutant allele burden greater than 50% and marrow fibrosis.
Summary / Conclusion: Acquired CN-LOH of chromosome 1 p, involving the *MPL* location, may represent a molecular mechanism of fibrotic transformation in *MPL*-mutated MPN.

P272

MODULATION OF PLASMA CYTOKINES AND ITS ASSOCIATION WITH CLINICAL RESPONSE TO TREATMENT WITH THE JAK2-SELECTIVE INHIBITOR SAR302503 IN A PHASE 2 STUDY OF PATIENTS WITH MYELOFIBROSIS (MF)
M Talpaz[1,*] C Jamieson[2], N Gabrail[3], C Lebedinsky[4], F Liu[4], H Cao[4], A Tefferi[5], A Pardanani[5]
[1]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [2]Department of Medicine, Moores UCSD Cancer Center, La Jolla, [3]Gabrail Cancer Center, Canton, [4]Sanofi Oncology, Cambridge, [5]Division of Hematology, Department of Internal Medicine, Mayo Clinic, Rochester, United States

Background: Abnormal cytokine expression may represent an inflammatory response that contributes to the clinical phenotype of MF. Some of the constitutional symptoms of MF (e.g. fever, fatigue, pruritus, cachexia) are thought to be caused by elevated cytokine levels. We previously reported that patients in a phase 2 study treated with 3 cycles of the JAK2-selective inhibitor SAR302503 at doses of 300, 400, or 500 mg had clinically meaningful reductions in splenomegaly and disease-related symptoms with acceptable toxicity (*Blood* 2012;120:21 Abs 2837; NCT01420770).
Aims: We analyzed the expression of 97 cytokines in patients enrolled in this study to assess their modulation and the relationship between changes in circulating cytokines and clinical response (change in spleen volume), pharmacokinetic (PK) exposure, and body weight changes in patients with MF.
Methods: Thirty-one patients were randomized to receive 300, 400, or 500 mg of SAR302503 orally, once daily, continuously in 4-week cycles. Plasma cytokines were measured at baseline and at the end of4, 8, and 12 weeks of treatment using a microsphere-based immuno-multiplex assay (Rules-Based Medicine Inc). Spleen volume was measured by MRI/CT at baseline and at the end of 12 weeks of treatment (3 cycles). All patients provided written informed consent.
Results: Complete sample sets were available for 29/31 randomized patients. A total of 28 cytokines predominantly involved in immune/inflammation pathways were regulated ≥1.5-fold (ANOVA P<0.05), of which 19 were regulated at all time points, indicating rapid and sustained modulation by JAK2 inhibition. At 4 weeks, 16 cytokines were down-regulated, including TNFα, IL-1RA, and IL-18, and six were up-regulated, including leptin, EPO, and adiponectin. Hierarchical clustering of the 22 regulated cytokines enriched patients into spleen responder (≥35% reduction in spleen volume) and non-responder groups, suggesting a link between cytokine modulation and clinical response. Moderate correlations (P<0.05) with spleen volume reduction at the end of week 12 were seen for a subset of regulated cytokines, including adiponectin and TNFα. Levels of the majority of the regulated cytokines tended to correlate with steady-state PK exposure at week 4. A positive association with weight gain at week 24 was observed for changes in leptin and adiponectin levels at week 4 (P<0.05).
Summary / Conclusion: This analysis shows that SAR302503 treatment modulated the expression of circulating cytokines in MF patients in association with changes in spleen volume, PK exposure, and weight gain.

P273

MYELOPROLIFERATIVE NEOPLASM QUALITY OF LIFE (MPN-QOL) STUDY GROUP: DUAL SERIAL ASSESSMENT STUDIES FOR IMPACT OF STANDARD THERAPEUTIC APPROACHES IN MPN POPULATIONS (MEASURE AND SYMPTOMS TRIALS)
H Geyer[1,*] R Emanuel[1], V Fauble[2], A Dueck[3], E Knight[2], A Vannucchi[4], A Fuentes[5], C Andersen[6], E Ejerblad[7], G Birgegard[7], P Johansson[8], B Andreasson[8], D Ross[9], F Sackmann[10], J Demory[11], C Tam[12], J Michiels[13], R Mesa[14]
[1]Internal Medicine, [2]Hematology, [3]Biostatistics, Mayo Clinic, Scottsdale AZ, United States, [4]Department of Medical and Surgical Care, University of Florence, Florence, Italy, [5]Department of Haematology, University Hospital La Paz, Madrid, Spain, [6]Department of Hematology, Roskilde Hospital, Roskilde, Denmark, [7]Internal Medicine, NU Hospital Organization, [8]Uddevalla Hospital, Uddevalla, Sweden, [9]Haematology, University of Adelaide, Adelaide, Australia, [10]Fundaleu Hospital, Buenos Aires, Argentina, [11]Centre Hospitalier, Lens, France, [12]Hematology, St. Vincent's Hospital, Fitzroy, Australia, [13]Department of Clinical Hematology, Goodheart Insitute, Rotterdam, Netherlands, [14]Department of Hematology, Mayo Clinic, Scottsdale AZ, United States

Background: Myeloproliferative neoplasms (MPNs), including polycythemia vera (PV), essential thrombocythemia (ET) and myelofibrosis (MF) are characterized by burdensome symptom profiles and impaired quality of life. Although patient reported outcomes (PROs) have been assessed in clinical trials with new therapies (JAK-2 inhibitors), little is known about the symptomatic impact of non-experimental therapies including pharmacological therapy, phlebotomy and bone marrow transplant.
Aims: The Myeloproliferative Neoplasm Quality of Life (MPN-QOL) International Study Group seeks to serially assess, in a prospective fashion, the impact of non-clinical trial therapies upon MPN-related symptoms and quality of life.
Methods: Utilizing the validated Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF), we began two prospective trials serially assessing the impact of non-clinical trial therapeutic intervention on MPN patients from baseline and post-baseline time point(s) using paired t-test(s). Additional analyses will include correlation between MPN-SAF total symptom score (TSS) and other PROs at each time point, and correlation between changes in MPN-SAF TSS as well as other PROs at each post-baseline time point. Global Impression of Change items will be used to assess responsiveness of the MPN-SAF TSS in each study. Associations between changes in MPN-SAF TSS and clinical endpoints will also be investigated.
Results: These ongoing, multi-national trials began open enrollment in the summer of 2012 and remain in recruitment phase. Updated data will be presented at the EHA conference.
MEASURE (MPN Experimental Assessment of Symptoms by Utilizing Repetitive Evaluation) trial is a prospective study evaluating the responsiveness of the MPN-SAF in detecting symptomatic changes in target symptoms for ET, PV and MF (including primary MF, post-ET and post PV MF) patients receiving non-experimental medical therapy (aspirin, hydroxyurea, anagrelide, interferon, busulfan, melphalan, cladribine, thalidomide, lenalidomide, prednisone, danazol, commercial ruxolitinib and/or phlebotomy). Patients complete the MPN-SAF (24-hour recall) for seven consecutive days at the time of enrollment and repeat the survey between 90 days and six months. Patients also complete the MDASI and EORTC QLQ-C30 on the first day of the both assessments and Global Impression of Change items on the first day of the second assessment only. Physicians acquire demographic, laboratory, physical examination and radiographic data, along with serial response assessments. SYMPTOMS (Symptoms Yielded in Myelofibrosis Patients after Transplant as Objectified by MPN-SAF) trial is a prospective, randomized study evaluating symptomatic responses in MF patients (including primary MF, post-ET and post PV MF) who are potential candidates for allogeneic stem cell transplant. All participants complete the MPN-SAF (7-day recall) and FACT-BMT at pre-transplant, day 30, 100, and year 1. Global Impression of Change items are completed at follow-up time points only. Physicians will acquire demographic information, along with laboratory, physical examination and radiographic data at each follow-up visit.
Summary / Conclusion: Myeloproliferative neoplasms have been associated with burdensome symptom profiles. To date, no studies have quantified symptomatic improvements to standard-of-care treatments. This abstract introduces two MPN-QOL Study Group prospective studies evaluating improvements in MPN symptoms and quality of life via the use of an MPN-specific, validated PRO instrument.

P274

LONG-TERM EFFICACY AND SAFETY OF CLADRIBINE (2-CDA) IN ADULT PATIENTS WITH MAST CELL DISEASE: A FRENCH MULTICENTER STUDY OF 68 PATIENTS
S Barete[1,*] O Lortholary[2], I Hirsch[3], M Hamidou[4], I Durieu[5], O Hermine[3]
[1]Dermatologie, CEREMAST, Hôpital Tenon, [2]Maladies infectieuses, [3]Hématologie, CEREMAST, Hôpital Necker, Paris, [4]Médecine Interne, CHU de Nantes, Nantes, [5]Médecine Interne, Hôpital Pierre benite, Lyon, France

Background: Mast cell disease (MCD) is a myeloproliferative disabling disorder without consensual curative therapy available. 2-CdA, is a synthetic purine analogue that has been used for MCD treatment as a cytoreductive drug for aggressive variants (ASM). Few patients (pts) with indolent (ISM), smouldering systemic (SSM) variants or cutaneous mastocytosis (CM) with mediator related symptoms refractory to symptomatic treatments have been treated so far. In addition, long term follow-up evaluation with this treatment is lacking.
Aims: We conducted a retrospective multicenter study to evaluate the efficacy and safety of 2-CdA in 68 patients with different subtypes of MCD.
Methods: From 2001 to 2010, 68 patients with MCD diagnosis according to WHO criteria were treated by 2-CdA. Patients had ISM (n=28, 41%), SSM (n=2, 3%), ASM (n=14, 21%), mast cell leukemia (MCL=1, 1%), CM (n=6, 9%) SM-AHNMD (n=17, 25%). Mediators release and mast cells infiltration symptoms and biological data (serum tryptase level, complete blood cell count, liver enzymes, serum alkaline phosphatise) were recorded at baseline, after each cycle and two months after the last cycle. A cycle consisted of 2-CdA delivering (0.14 mg/kg/d infusion (Leustatine®) or subcutaneously (Lytak®) from 1 to 5 days. Each cycle was repeated at 4 to 12 weeks intervals from 1 to 15 consecutive cycles which defined a block of treatment (55 pts). 2-CdA cycles with a time interval >9 months were considered as a second block (13 pts). Efficacy was evaluated with the consensus statement for response criteria and notified as complete (CR), major (MR), partial (PR) and no (NR) responses and overall response rate (ORR). Safety of 2-CDA was recorded with acute serious adverse event (SAE) during 2-CdA and late SAE > 3 months after last dose. The severity of neutropenia and lymphopenia was scored (CTCAE V3). Analysis was done by Mc Nemar's chi-squared testing between baseline and end of 2-CdA.
Results: 35 F/33 M with respectively mean age at MCD diagnosis and at 2-CdA treatment of 46 and 54 yrs were included. Clinical mediator release symptoms were improved significantly including fatigue, flush, pruritus, diarrhea, abdominal pain, neuropsychiatric symptoms, headache/pain, and nausea/vomiting (P<0.0001). Mast cell infiltration symptoms improved including urticaria pigmentosa, hepatomegaly, splenomegaly, weight loss/fever/chills/ night sweats and ascitis (P<0.0001). Biological parameters did not improve except for tryptase level (P=0.01). Mean 2-CdA number of cycles was 4.2 and the total dose received averaged 2.34 mg/kg. The ORR was 72% (49 out of 68 pts). The best response rate was observed in indolent subtypes (P<0.0001) (Figure 1). Median time of follow-up was 5.8 years (21d-9 yrs). Disease free survival was 4.5 years. Time to progression averaged 30.5 months (9 to 108). Twenty one patients (31%) died but any case was related to 2-CdA treatment. Causes included MCD progression for 9 pts (43%), other causes for 12 pts (57%). Most SAE were infectious (22%) with 8 recovering opportunistic infections and linked to myelosuppression. Any ISM died of SAE related to 2-CdA. Patients developed neutropenia grade 3-4 (47%) and chronicle lymphopenia (82%). 3 F gave birth after treatment.
Summary / Conclusion: 2-CdA is an effective and safe treatment in symptomatic MCD, which may improve mast cell burden. Its long-term safety and efficacy argue for a possible use in symptomatic CM or ISM with disabilities. Further work is warranted to define optimal regimen and usefulness of maintenance 2-CdA therapy.

Background: Transformations from ET to PV, and from both of these entities, to myelofibrosis are not uncommon. These observations have challenged the conception of the conditions as distinct disease entities. Evidence of a biological continuum has been presented by demonstration of increasing *JAK2*V617F allele burden in blood leukocytes from ET over PV to PMF (Vanucchi *et al*, Leukemia 2006, Larsen *et al*, Eur J Haematol 2007) and evidence has also been presented by the use of gene expression patterns. (Skov *et al*, Exp Hematol 2012). YKL-40 (Chitinase-3-like protein 1) has been implicated in haematological malignancies. Elevated serum levels of YKL-40 have been shown to correlate with disease activity and impaired overall survival in acute myelogenous leukemia (Bergmann *et al*, Clin Can Res 2005) and multiple myeloma (Mylin *et al*, Int J Cancer 2009) The role of YKL-40 in MPNs has never been established.
A multicenter study on the efficacy and safety of vorinostat in ET and PV has most recently been presented, confirming that vorinostat reduces elevated cell counts in a substantial proportion of ET and PV patients in concert with a decrease in spleen size. (Andersen *et al*, ASH 2012)
Aims: Firstly, to investigate YKL-40 in ET and PV as a potential marker of disease burden. Secondly, to investigate circulating YKL-40 in patients during treatment with vorinostat from the recently presented multicenter study.
Methods: From the non-randomized, open-label phase II multicenter study, YKL-40 serum samples were analyzed from 31 PV and 16 ET patients at baseline and again after 3 months of therapy along with quantitative *JAK2* analyses and other routine laboratory parameters. The reference interval for plasma YKL-40 was determined in 3130 healthy subjects (1293 men, 1837 women) aged 21-84 years from the Danish general population.
Results: When adjusting for age YKL-40 baseline values were 1.8 times higher in ET patients than expected from healthy controls (P<0.0001) and PV YKL-40 values were 1.8 times higher than in ET (P=0.02). We observed a significant correlation between YKL-40 at baseline and the level of CRP (rho=0.43, P=0.03), LDH (rho=0.49, P=0.009) and *JAK2* mutant allele burden (rho=0.43, P=0.02) in PV patients. PV patients who experienced a clinicohematological response after 3 months of therapy exhibited a significantly greater reduction of YKL-40 levels compared to non-responders. We did not observe this correlation among ET patients (P=0.5); however, we could only compare 16 patients. Changes in YKL-40 during treatment did not correlate with changes in any of the measured laboratory markers in PV patients, but correlated with platelets (rho=0.76, P=0.003) and leukocytes (rho=0.74, P=0.009) in ET patients.
Summary / Conclusion: We show for the first time that circulating YKL-40 levels are increased in ET and PV patients depicting a continuum between the entities and furthermore correlate significantly with important markers of tumor burden – the leukocyte count, the LDH-value and the *JAK2*V617F-allele burden. The YKL-40 levels also showed a significant correlation with the CRP-concentration, which might reflect YKL-40 to be a novel marker of ongoing inflammation in MPNs. Furthermore; during HDACi-treatment we have shown that YKL-40 to correlate significantly with the clinicohematological response in PV patients. Our observations call for experimental and clinical studies to unravel the cells of origin of YKL-40 in MPN-patients, the importance in disease pathogenesis and progression from early disease stage (ET, PV) to the advanced (MF).

P276

IMPACT OF HEMATOCRIT ON SYMPTOM BURDEN AMONG POLYCYTHEMIA VERA PATIENTS

R Emanuel[1,*] R Marchioli[2], A Dueck[3], H Geyer[1], G Finazzi[4], R Cavazzina[5], A Masciulli[6], M Scarano[6], A Vannucchi[7], T Barbui[4], R Mesa[8]
[1]Internal Medicine, Mayo Clinic, Scottsdale, United States, [2]Consorzio Mario Negri Sud, Santa Maria Imbaro, Italy, [3]Mayo Clinic, Scottsdale, United States, [4]Ospedale Papa Giovanni XXIII, Bergamo, [5]Consorzio Mario Negri Sud, Santa Maria Imbaro (CH), [6]Istituto Mario Negri Sud, S. Maria Imbaro, [7]University of Florence, Florence, Italy, [8]Dept of Oncology/Hematology, Mayo Clinic, Scottsdale, United States

Background: Current guidelines suggest that polycythemia vera patients maintain a strict hematocrit (hct) less than 45%. The recent CYTO-PV trial (N Engl J Med 2013;368:22-33) found that patients undergoing strict hct control had significantly decreased mortality from cardiovascular death and thrombosis, but suffered from overall increased symptom burden. To date, little is known about the relationship between hemocrit control and PV patient symptom burden.
Aims: The purpose of this comparison study is to evaluate the impact hct level on PV associated symptoms and quality of life.
Methods: PV patient data was analyzed from two large prospective investigations including the CYTO PV trial and the MPN-SAF study (JCO 2012; 30(33):4098-4103). The CYTO PV trial was a randomized, clinical trial assessing the impact of traditional (hct maintained at less than 45%) versus experimental (hct maintained at 45% to 50%) hct control. The MPN-SAF study was an international assessment of MPN symptom burden at the time of an office visit. Surrogate hct was calculated from MPN-SAF data as three times hemoglobin. Quality of life assessments included the MPN-SAF and BFI (Cancer 1999;85(5)1186-1196).
Results: Patients and Baseline Symptom Burden: Symptomatic burden was compared between 224 CYTO PV trial patients and 561 MPN-SAF PV patients. Mean age (CYTO-PV 64.7 years, MPN-SAF 63.0), gender (CYTO PV 42% female, MPN-SAF 48% female) and distribution of prognostic scoring were similar between the two studies. Among the MPN-SAF cohort, 299 PV patients had hct up to 45%, 89 had hct greater than 45 to 50%, and 23 with hct greater than 50% (150 no data). Hct Control and Symptom Burden: For both cohorts, end-organ complaints including headache (MPN-SAF 2.1(65%) vs 1.7(54%), CYTO PV 6mo change +0.4 vs +0.0) and cough (MPN-SAF 1.6(48%) vs 1.3(46%), CYTO PV 6mo change +0.3 vs +0.1) were more severe in those with hct greater than 45%. Conversely, strict hct control was associated with increased concentration problems (MPN-SAF 2.4(63%) vs 2.1(59%), CYTO PV 6mo change +0.6 vs +0.4) and insomnia (MPN-SAF 3.0(68%) vs 2.8(66%), CYTO PV 6mo change +0.5 vs +0.2). Strict hct control was also associated with increased weight loss (MPN-SAF 1.1(34%) vs 1.0(32%), CYTO PV +0.2 vs -0.3) and night sweats (MPN-SAF 2.1(53%) vs 1.8(49%), CYTO PV 6mo change +0.4 vs 0.0). Pruritus was most severe and frequent among individuals with stricter hct control for MPN-SAF (2.7(61%) vs 2.3(56%)). HCT Control and Fatigue: When comparing MPN-SAF patients, patients with lower hct had significantly higher rate of fatigue (89% vs 81%, P=0.04). Similarly, analysis of CYTO PV patients undergoing six months of strict hct control had increased worst fatigue (+0.4 vs -0.2, P=0.08) and mean BFI (+0.2 vs -0.3, P=0.04) at 6 months.
Summary / Conclusion: This study assesses the impact of hemodynamic management among two of the largest prospective evaluations of PV symptom burden to date. Iron deficiency likely contributes to cognitive and fatigue complaints seen among patients with strict hct control. Conversely, vascular complications may contribute to the end organ complaints seen in those with lenient hct control. Future studies are needed to further delineate differences in the means of hct control (medicinal vs. phlebotomy) on PV associated symptom burden.

P277

WHITE BLOOD CELLS COUNT INFLUENCE THE PROGNOSIS OF POLYCYTHEMIA VERA PATIENTS: A SUB-ANALYSIS OF THE CYTO-PV STUDY.
R Marchioli[1,*] R Cavazzina[1], A Masciulli[1], M Scarano[1], T Barbui[2]
[1]Consorzio Mario Negri Sud, Santa Maria Imbaro (CH), [2]Ospedale Papa Giovanni XXIII, Bergamo (BG), Italy

Background: In Cyto-PV randomized clinical trial (Marchioli *et al*, NEJM 2013), polycythemia vera (PV) patients with a hematocrit (HCT) target of less than 45% had a significantly 4 times lower rate of cardiovascular death and major thrombosis than did those with a hematocrit target of 45 to 50%. Moreover, patients in the high-hematocrit group had significantly higher leukocyte (WBC) counts than did those in the low-hematocrit group, likely due to lower dose of Hydroxyurea prescription.
Aims: To assess whether the persistence of leukocytosis in this trial could have contributed to an excess of fatal and nonfatal cardio vascular events we carried out the present analysis.
Methods: Multivariable time-dependent analysis, adjusted for age, gender, previous thrombosis and hematocrit levels was performed to assess whether the level of exposition to WBC count, recorded in the last clinical visit before the CV event, was associated with the probability of having CV events during follow-up, with censoring at first event, death, or last follow-up visit. WBC count was categorized into four groups and tests for trend were calculated by assigning the median value of each of the 4 WBC categories.
Results: During the study period (median 31 months) of 365 PV patients randomized to different intensity of cytoreductive treatments, the median hematocrit level in the low-hematocrit group was 44.4%, as compared with 47.5% in the high hematocrit group. The WBC count remained significantly higher in the high hematocrit group than in the low-hematocrit group (P<0.001) while no significant difference between groups was noted in the platelet count. Interestingly the risk of thrombosis was clearly increased in patients with a white blood cell count above 6 10^9/L, becoming statistically significant when the white blood cell count was above 12x10^9/L (hazard ratio [HR], 4.89; 95% confidence interval [CI], 1.1-22.7; *P* =0.04).
Summary / Conclusion: Keeping HCT levels >45% and leukocyte count > 12x10^9/L, the risk of fatal and nonfatal cardiovascular events is significantly increased suggesting a role for leukocyte count as well as hematocrit in the pathogenesis of these events. Future clinical studies are needed to evaluate the benefit-risk profile of more aggressive therapy to target the WBC counts.

Table 1. Time-dependent multivariable analysis on the risk of major thrombosis in CYTO-PV study (N=365).

WBC class (x10^9/l)	Events/Pts (%)	Hazard ratio (95% CI), P-value
< 6.0	2/54 (3.7)	1 (Reference)
6.0-10	13/187 (7.0)	2.39 (0.5-10.8), 0.26
10-12	2/50 (4.0)	1.40 (0.2-10.1), 0.74
> 12	11/74 (14.9)	4.89 (1.1-22.7), 0.04

*Model adjusted for: age, gender, previous thrombosis, leukocyte count class, and HCT.

P278

SAFETY OVERVIEW OF PHASE I-II STUDIES OF PACRITINIB, A NON-MYELOSUPPRESSIVE JAK2/FLT3 INHIBITOR, IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES
S Verstovsek[1,*] S Liang[2], R Komrokji[3], R Mesa[4], J Seymour[5], J Dean[2], L Wang[2], J Singer[2], H Myint[2], A Younes[6]
[1]MD Anderson Cancer Center, Houston, [2]Cell Therapeutics, Inc, Seattle, [3]H. Lee Moffitt Cancer Center, Tampa, [4]Mayo Clinic, Scottsdale, United States, [5]Peter MacCallum Cancer Centre, East Melbourne, Australia, [6]Memorial Sloan Kettering Cancer Center, New York City, United States

Background: In phase I and II clinical trials, a total of 191 patients (pts) with hematologic malignancies have been treated with pacritinib (SB1518), an oral, once-daily JAK-2/FLT-3 inhibitor. JAK2 inhibition has been associated with anemia and thrombocytopenia, possibly due to inhibition of Epo and TPO signaling, but this was not observed in pacritinib preclinical studies.
Aims: This integrated analysis was performed to quantitate clinical toxicities, including hematologic effects, of pacritinib.
Methods: We reviewed the safety database which included 4 clinical studies: a phase I/II study in advanced myeloid malignancies, a phase I and a phase II study in advanced lymphoid malignancies, and a phase I/II study in myelofibrosis.

Table 1.

Safety population (n=189) (> 1 post-baseline value)	Hb shift from baseline to last value	Platelet shift from baseline to last- value
No shift	101 (53.4%)	108 (57.1%)
Cytopenia Improvement		
1 grade improvement	28 (14.8%)	17 (9%)
2-4 grade improvement	6 (3.2%)	2 (1.1%)
Cytopenia Decline		
1 -2 grade decline	51 (27%)	52 (27.5%)
3-4 grade decline	1 (0.5%)	8 (4.2%)

Results: 191 pts were treated with pacritinib: 129 with advanced myeloid malignancies including 122 myelofibrosis pts [primary 72/122 (59%)] and 7 AML pts; and 62 with advanced lymphoid malignancies including 38 NHL pts and 24 Hodgkin lymphoma pts. The median age was 65 years and the median time from initial diagnosis was 3.8 years. 44% of pts with myeloid disorders had baseline platelet counts <100,000/μL. Pacritinib was dosed from 100 to 600 mg daily during phase I and 400 mg during phase II. The median treatment duration was 306 (range 2- 1210) days for those with myeloid disorders and 910.5 (range 1 – 631) days for lymphoid disorders. 59 pts (31%) stayed on treatment for ≥12 months (including 2 pts for 40 and 36 months, respectively) and another 33 pts (17%) for ≥6 months. The median dose delivered was 98% of intended. The most common adverse events (AEs) were gastrointestinal (GI) (all grades/grade 3-4): diarrhea (73%/8%), nausea (48%/1%), vomiting (30%/1%), constipation (24%/0%) and abdominal pain (21%/4%). Time to onset of diarrhea was ≤30 days in 89% of those affected and was the major cause of dose reduction, interruption, or discontinuation. Anti-motility prophylaxis was not used rou-

tinely in these early studies. Hematological AEs are summarized in the Table 1. Most pts had no decline in hemoglobin or platelet count. Of the 30 myeloid disorder patients with baseline platelet counts <50,000/μL from phase I and II studies, the median decline in platelet count observed at the end of study was3,000/μL. In the 11 patients with myelofibrosis with baseline platelet counts <50,000/μL enrolled in phase II studies, no dose reductions were required for thrombocytopenia. There were no late toxicities noted in the 2 pts treated beyond 3 years. 22 deaths (12%) occurred within 30 days from the last dose of study drug. All but one pt died from a variety of causes not associated with drug related toxicities.

Summary / Conclusion: Pacritinib does not cause suppression of red cell or platelet production in pts with myeloid or lymphoid disorders. Even pts with initial platelet counts <50,000/μL tolerated therapy, maintained stable blood and platelet counts and did not require dose reductions. Grade 1 or 2 GI events, particularly diarrhea, were the most common AEs and were usually controlled with early administration of standard anti-motility agents. Due to the absence of myelosuppression in these studies, ongoing phase III development of pacritinib in myelofibrosis does not restrict study entry due to thrombocytopenia. The lack of bone marrow suppression also suggests that pacritinib could be used in combination with marrow suppressive therapies in pts with JAK2 or FLT3 dependent disorders.

P279

A PHASE II STUDY OF VORINOSTAT (MK-0683) IN PATIENTS WITH PRIMARY MYELOFIBROSIS (PMF) AND POST-POLYCYTHAEMIA VERA MYELOFIBROSIS (PPV-MF)

C Andersen[1],* N Mortensen[1], H Vestergaard[2], O Bjerrum[3], T Klausen[4], H Hasselbalch[1]

[1]Department of Haematology, Roskilde University Hospital, Roskilde, [2]Department of Haematology, Odense University Hospital, Odense, [3]Department of Haematology, Copenhagen University Hospital, Copenhagen, [4]Department of Haematology, Herlev Hospital, Herlev, Denmark

Background: Elevated histone deacetylase (HDAC) levels have been reported in patients (pts.) with PMF and have been shown to correlate to the degree of splenomegaly, suggesting that HDAC may be recruited as ET or PV progress into myelofibrosis or PMF progresses into a more advanced stage. A recent report has documented clinical efficacy of HDAC inhibition (HDACi) in MF pts.

Aims: Primarily to investigate if the HDACi vorinostat as monotherapy in pts. with PMF or PPV-MF could induce a clinical response per the International Working Group response criteria at the end of an intervention (6 months) and observation period (3 months), respectively. Secondly, to investigate whether treatment influenced the *JAK2* mutant allele burden and quality of life as assessed by the Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF) and the EORTC QLQ-C30.

Methods: Fourteen pts. (11 PMF, 3 PPV-MF) from whom informed consent was obtained from Denmark were included and given 400mg of Vorinostat daily.

Results: We report data for 14 pts. (m:f=79%/21%) with a median age of 65 years (52-80). Seventy-one percent were *JAK2*V617F-postive with a median allele burden of 68 % (0-99). Median time from diagnosis to inclusion was 6.4 years (0-22.5). Treatment prior to vorinostat included hydroxyurea (57%), interferon –alpha (21%) and anagrelide (7%). No patient had received experimental therapies or JAK-inhibitors.

Of 9 pts. (64%) evaluable for response assessment after 6 months of therapy, 1 achieved complete remission and 1 achieved clinical improvement. An intention-to-treat response rate of 14% was identified. We were able to compare spleen sizes to baseline values for four pts. In 4/4 we observed a decrease (median =4,5 cm (1-14)). 7/10 *JAK2*V617F-pts. (70%) experienced an increase in *JAK2* tumor allele burden between baseline and 3 months of therapy; (P=0.04). The numerical median increase was 3.2%. We did not observe any significant differences in MPN-SAF total symptom scores, EORTC QLQC30 functional – or symptom scales combined, but could only compare 7 pts. Six pts. (43%) were evaluable after the observation period. Of pts. only having been treated with vorinostat in the intervention period we did not observe any lasting responses after the 3 months without vorinostat. One pt. recommenced vorinostat in the observational period with an ensuing "stable disease"-response.

Seventy-one percent of pts. reported fatigue at least once during the intervention period (grade 2 max) and 50% reported diarrhoea (grade 2 max). Only one pt. was not dose-reduced during the study. Causes of discontinuation included "progressive disease" (3 pts.), missing compliance (1 pt.), transformation to AML (1 pt.) and death caused by pneumonia (1 pt.). One patient discontinued due to a combination of hair loss, fatigue, renal insufficiency and hyperglycemia. One pt. discontinued due to fatigue, dry mouth and progressive splenomegaly.

Summary / Conclusion: Despite that large spleens partially regressed in a proportion of the patients, vorinostat monotherapy 400 mg. daily was associated with significant side effects, which limited long-term treatment. Future studies on the role of HDAC-inhibitor treatment in myelofibrosis should use a lower dosage design, which might allow for longer treatment. Gene expression profiling and epigenome studies are ongoing in an attempt to elucidate particular patterns of deregulation which might contribute to a better understanding of the pathogenetic mechanisms accounting for the observed clinical and biochemical effects of vorinostat in our patient cohort.

Sant'Andrea, [9]Hematology, University Campus Biomedico, [10]Hematology, Hospital S. Pertini, Rome, [11]Hematology, ASL Viterbo, Viterbo, [12]Hematology, Hospital Sant'Andrea, [13]Hemathology, University La Sapienza, Rome, [14]Hematology, University Polo Pontino, Latina, [15]Hematology, Hospital S. Camillo-Forlanini, Rome, [16]Hematology, ASL VT, Viterbo, Italy

Background: At diagnosis, about 15-20% of patients with Essential Thrombocythemia (ET) have spleen enlargement. The role and the clinical characteristics of these patients are still unknown

Aims: In the present retrospective analysis, we report data from 1,097 patients with ET diagnosed from January 1979 to December 2010 in 11 haematological Centers (5 universitary Institutes and 6 community-based Hospitals) that were collected in the database of our lazial cooperative group.

Methods: The diagnosis was made according to PVSG criteria or WHO 2001 and 2008 criteria, based on the date in which the patients were observed. Spleen enlargement was defined as the presence at diagnosis of a palpable spleen under costal margin or a longitudinal splenic diameter > 12,5 cm at the ultrasound examination. On the whole, 213/1097 patients (19.4%) had a spleen enlargement (sET), while 884/1097 (80.6%) had a normal spleen size (oET). Clinical characteristics of the two groups are reported in the table.

Results: From these data, 2 different types of patients seem to be defined as to gender, WBC, PLTs, rate of positivity and median allelic burden of JAK-2 V617F mutation. Patients without spleen enlargement had features similar to "true-ET" (female prevalence, lower WBC and PLTs count, lower rate of positivity of JAK-2 V617F mutation with lower allelic burden); patients with spleen enlargement were more similar to "early MF" (M/F ratio 1/1, higher WBC and PLTs count, higher rate of positivity of JAK-2 V617F mutation with higher allelic burden). Patients with spleen enlargement had a significantly shorter Thrombosis-Free Survival (P= 0.007) while the Overall Survival was similar in both groups (P= 0.11). At multivariate analysis, spleen enlargement retained its value as independent additional risk factor for thrombosis. In conclusion, the evidence of spleen enlargement at diagnosis in ET patients seems to be associated with a different pattern of disease and should be considered in the evaluation of thrombotic risk.

Summary / Conclusion: The role of spleen enlargement as discriminative feature between "true ET" and "early MF" and its comparison/association with bone marrow biopsy warrant further prospective studies.

Table 1.

Feature	No spleen enlargement (oET)	Spleen enlargement (sET)	P value (95%CI)
N° patients	884	213	--
Median age (yrs) (IQR)	59.7 (47,7 – 72,3)	58.2 (44,4 – 72,4)	0.23
M/F (%)	294/590 (33.3/66.7)	105/108 (49.3/50.7)	0.04
Median Hb (g/dl) (IQR)	13.9 (13,0 – 15,0)	14.0 (12,9 – 15,2)	0.45
Median WBC (x10⁹/l) (Interquartile range)	9.3 (7,1 – 10,8)	9.8 (7,6 – 11,3)	0.0385 (30.3-110.83)
Median PLTs (x10⁹/l) (IQR)	879 (659 – 1000)	933 (699 – 1096)	0.04 (2.28-107.52)
JAK-2 V617F (+/evaluated)	235/566	79/129	0.02
Median allele burden (%) (IQR)	24.3 (8,0 – 37,4)	33.5 (13,8 – 44,2)	0.016 (1.73-16.67)

Non-Hodgkin Lymphoma - Biology

P281

BMI1, THE POLYCOMB-GROUP GENE, IS RECURRENTLY REARRANGED IN PROGRESSIVE/TRANSFORMED CLL AND MCL

Wlodarska[1,*] L Rouhi[1], J Ferreiro[1], N Put[1], T Tousseyn[2], C Lefebvre[3], A Gardiner[4], W De Kelver[1], H Demuynck[5], J Verschuere[6], I Theate[7], C Vicente[1,8], L Michaux[1], J Cools[1,8], P Vandenberghe[1]
[1]Center for Human Genetics, [2]Department of Pathology, KU Leuven, Leuven, Belgium, [3]Department of Oncogenetics, CHU Albert Michallon, Grenoble, France, [4]Department of Hematology, Royal Bournemouth Hospital , Bournemouch, United Kingdom, [5]Department of Hematology, Hospital of Roeselare, Roeselare, [6]Department of Hematology, Hospital of Ronse, Ronse, [7]Department of Pathology, Cliniques Universitaires Saint-Luc, Brussels, [8]Department of Molecular and Developmental Genetics, VIB, Leuven, Belgium

Background: Chronic lymphocytic leukemia (CLL) has a variable clinical course, ranging from a very indolent to a rapidly progressing disease. In up to 10% of CLL patients, transformation to highly aggressive and usually fatal lymphoma (Richter syndrome) has been reported. Although several factors predisposing CLL to a high grade transformation and/or chemoresistance have been recently identified (e.g. mutations of *NOTCH1, SF3B1* and *BIRC3*), molecular events associated with Richter transformation remain largely unknown. However, accumulating evidence indicate that this process may be conducted by several oncogenes, including *MYC, BCL3* and *NOTCH1*, activated by *IG*-related translocations acquired during clinical course of disease.
Aims: Our study aimed at molecular characterization of the novel t(10;14)(p12;q32)/t(10;22)(p12;q11) identified in six cases of progressive/ transformed CLL, and various 10p11p13 rearrangements recurrently observed in mantle cell lymphoma (MCL).
Methods: The work was performed using FISH, qRT-PCR, IHC, high-resolution array CGH (aCGH), Sanger sequencing and RNA-sequencing.
Results: (i) Six cases of progressive/transformed CLL with the *IGH*- or *IGK*-involving translocations targeting 10p12 were collected. Molecular profiles of these leukemias were heterogeneous (mutated or unmutated VH, presence of either del(11q) or del(13q14), or trisomy 12) and the leukemia cells were negative for common mutations of *NOTCH1* and *TP53*. All patients died within 1-37 months after detection of t(10;14)/t(10;22). The extensive BAC-walking FISH analysis eventually mapped the 10p12 breakpoint in the region harbouring *BMI1* gene. Upregulation of *BMI1* mRNA was demonstrated by QRT-PCR analysis in one case documented by paired diagnostic/follow-up samples. (ii) 16 MCL cases with various 10p11-13 aberrations were initially subjected to FISH and aCGH analysis. All the rearrangements affected *BMI1* which was either duplicated/amplified (4 cases), or involved in non-reciprocal translocations (9 cases), or affected by balanced translocations/insertions (3 cases). RNA-sequencing performed in three available cases did not identify *BMI1*-related fusions/mutations, but demonstrated a significant upregulation of *BMI1*, in addition to overexpressed cyclin D1 and *SOX11*.
Summary / Conclusion: We show for the first time that *BMI1*, the Polycomb group gene and postulated lymphoma-related oncogene, is recurrently targeted by chromosomal aberrations in two human B-cell malignancies, CLL and MCL. In the former neoplasm, *BMI1* was constantly affected by *IG*-mediated translocations exclusively detected at time of CLL progression or Richter transformation. MCL displayed a much broader spectrum of *BMI1* rearrangements of which the most frequent were unbalanced (non-*IG*) translocations. These aberrations were associated with upregulation of *BMI1* by mechanisms which remain elusive. Of note, the previously identified amplification of *BMI1* occurred in only 40% of MCL cases with the 10p12/*BMI1* rearrangements.
Collectively, our work identified *BMI1* as a new player implicated in progression and high grade transformation of CLL and confirmed its involvement in the pathogenesis of MCL. Although many solid tumors and haematological malignancies display an aberrant expression of BMI1, the underlying 10p12 chromosomal rearrangements (except of gain/amplification) have never been reported in human cancers.

P282

MASSIVE IMMUNOGLOBULIN REPERTOIRE BIAS IN PRIMARY INTRAOCULAR LYMPHOMAS SUGGESTS ANTIGENIC SELECTION OF THE NEOPLASTIC CELLS DURING LYMPHOMAGENESIS.

N Belhouchi[1], E Stalika[2], B Bodaghi[3], M Boudjoghra[4], N Cassoux[5], C Fardeau[5], P Le Hoang[3], H Merle-Beral[1], K Stamatopoulos[2], F Davi[1,*]
[1]Hematology, Hopital Pitie-Salpetriere & UPMC Paris6, Paris, France, [2]Hematology and HCT unit, G. Papanicolaou Hospital, Thessaloniki, Greece, [3]Ophtalmology, Hopital Pitie-Salpetriere & UPMC Paris6, [4]Hematology, [5]Ophtalmology, Hopital Pitie-Salpetriere, Paris, France

Background: Primary intraocular lymphoma (PIOL) is a high grade lymphoma, which affects the retina,vitreous and/or the optic nerve. The vast majority of cases are classified as diffuse large B cell lymphoma and considered as a subtype of primary central nervous system lymphoma.
Aims: To gain insight of the unusual localisation of these lymphoma, we analysed the immunoglobulin (IG) repertoire of 55 cases of PIOL, the largest series to date.
Methods: Monoclonal IG heavy chain rearrangements, and for a fraction of cases also light chain rearrangements, were sequenced from PCR products obtained by amplification using either framework 1 or peptide leader primers. In a few cases sequencing was performed after subcloning of PCR products generated with high fidelity Taq polymerase. Comparison with germline sequences was done using IMGT data and tools.
Results: We observed a highly restricted IGHV usage, with a single gene, namely IGHV4-34, present in 69.1% (38/55) of cases. The second most frequent gene was IGHV3-7, utilized in 7.3% (4/55) of cases. Thus, only two IGHV genes accounted for more than three quarters of the PIOL IGHV repertoire. Bias in IGHD and IGHJ genes were also observed, although to a lesser extent, with an underrepresentation of IGHD6 subgroup genes and a high IGHJ5 / IGHJ6 ratio as compared to other B-cell malignancies. Heavy complementarity-determining region 3 (VH CDR3) were short (median length 14 amino acids) and in half of cases (28/55) carried electropositive residues with predicted isoelectric values of 7.0 or greater (up to 13.0). Remarkably, 3 of the 4 cases expressing the IGHV3-7 gene had 11 aminoacid-long, electropositive VH CDR3s with shared motifs, which could be considered as "stereotyped" antigen-binding sites. Except for two unmutated cases, all sequences had a high number of somatic hypermutations (SHM) as the mean % of identity from their germline counterpart was 86.7%. Analysis of the distribution of SHM in the subgroup of PIOL cases utilizing the IGHV4-34 gene revealed high replacement (R) to silent (S) mutation ratios in CDRs (R/S>3.0) along with low R/S ratios in FRs. Identical replacement mutations ("stereotyped" amino acid changes) at certain codon positions were identified amongst rearrangements utilizing the IGHV4-34 gene, some of which were distinct from those previously reported for IGHV4-34 rearrangements in other B cell malignancies. In addition, the IGVH4-34 specific motif responsible for binding in superantigenic fashion the N-acetyllactosamine antigenic determinant was altered in a minority of sequences (6/38,15.8%); however, the most critical residue of this motif (TRP at position 7 in FR1) was intact in all 38 cases. Sequencing of multiple (at least 20) clones in 9 cases of PIOL (including 6 IGHV4-34 cases) showed intraclonal diversity in all of them. Finally the repertoire of IG light chains was also biased for IGHV4-34 PIOL as 7/23 cases (30.4%) had a IGKV3-20 / IGKJ1 rearrangement. Identical amino-acid replacements resulting from SHM were also observed among these sequences.
Summary / Conclusion: PIOL display a highly biased IG gene repertoire with very precise targeting and distinctive features of SHM, suggestive of selection by specific (super)antigen(s) in lymphomagenesis.

P283

JUNCTIONAL ADHESION MOLECULE C CONTROLS PROLIFERATION, HOMING AND ENGRAFTMENT OF NORMAL AND MALIGNANT HUMAN B CELLS

C Doñate[1,*] C Ody[2], B Imhof[2], T Matthes[1]
[1]Hematology department, University Hospital Geneva, [2]Pathology and Immunology department, University Medical Center, Geneva, Switzerland

Background: The junctional adhesion molecules (JAMs) are a subgroup of the Immunoglobulin superfamily. JAM members localize at endothelial tight junctions and have been involved in the formation and maintenance of inter-endothelial junctions and in leukocyte transmigration. Earlier studies have also demonstrated that tight junction molecules can regulate cell polarity and vascular permeability, as well as cell proliferation and differentiation. JAM-C is also expressed in human B cells and its expression is tightly controlled during differentiation. Expression on malignant B cells was found to be disease-specific, allowing the classification into JAM-Cpos and JAM-Cneg B-cell lymphomas.
Aims: In the current study, we investigated the role of JAM-C in the proliferation, homing and engraftment of normal and malignant B cells.
Methods: Human B cells were isolated from peripheral blood of healthy donors and lymphoma patients. To analyze the role of JAM-C in proliferation, cells were activated and cultured in the presence of anti-JAM-C antibodies, and proliferation was measured by flow cytometry. The signaling pathways induced by binding of JAM-C antibodies were monitored at a single cell level. Using phospho-specific antibodies for p38, Erk 1/2, JNK (Mitogen-activated protein kinases, MAPK), Stat3 (Signal transducer and activator of transcription), and for Akt (PI3K/AKT/mTOR cell survival pathway), phosphorylation profiles for each protein were analyzed by phospho-specific flow cytometry. To investigate the role of JAM-C in B cell migration, B cells were incubated with six different anti-JAM-C antibodies and injected i.v. into NOD/SCID mice. Homing of cells to lymphoid organs (bone marrow, spleen, lymph nodes) was analyzed one hour later by flow cytometry. To investigate the role of JAM-C in lymphoma dissemination, the JAM-C positive mantle cell lymphoma B-cell line Jeko-1 was used for long-term engraftment assays. Jeko-1 cells were injected into NOD/SCID mice and animals were treated for three weeks with anti-JAM-C antibodies. Tumor burden was evaluated in lymphoid organs on day 26.
Results: Incubation of normal and malignant JAM-Cpos B cells with anti-JAM-

C antibodies significantly reduced proliferation by 30-35%. Moreover, the binding of anti-JAM-C antibodies inhibited the phosphorylation of ERK1/2 by 35%, without affecting other signaling pathways. Treatment with 2 out of 6 monoclonal anti-JAM-C antibodies reduced the homing of normal and JAM-Cpos lymphoma B cells to lymph nodes (50%), bone marrow (30%) and spleen (65%). These two antibodies recognize different epitopes on the JAM-C molecule, as demonstrated by competitive binding and Plasmon resonance assays. Long-term administration of the most efficient anti-JAM-C antibody reduced drastically the engraftment of JAM-Cpos Jeko-1 cells in the bone marrow (94%), spleen (100%) and lymph nodes (99%) of NOD/SCID mice.
Summary / Conclusion: Despite considerable progress in the treatment of mature B-cell lymphomas, aggressive forms still remain incurable and new treatment strategies are needed. Our results demonstrate a functional role of JAM-C in B cell homing, proliferation and engraftment into lymphoid organs. We also identified for the first time the intracellular MAPK cascade as the JAM-C driven signaling pathway in JAM-Cpos B cells. Anti-JAM-C antibodies could thus represent an efficient therapeutic approach reducing cell proliferation and preventing lymphoma B cells from reaching supportive lymphoid microenvironments in bone marrow, lymph nodes and spleen.

P284

DETECTION OF PERIPHERAL BLOOD MONOCLONAL T LYMPHOCYTOSIS AND RISK OF T LYMPHOPROLIFERATIVE DISEASE DEVELOPMENT
R Di Gaetano[1],* V Gasparetto[1], C Laura[1], B Callegari[1], G Tagariello[1]
[1]Haematology, Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Background: Occasional evidence of monoclonal gammopathy of undetermined significance (MGUS) or monoclonal B lymphocytosis (MBL) are considered predisposing to the development of multiple myeloma and chronic lymphocytic leukemia (CLL) respectively and it is recommended to monitor them for possible early diagnosis. In cutaneous T lymphoma (CTL), such as mycosis fungoides and Sezary syndrome, has been demonstrated the presence of clonal T lymphocytes even in the peripheral blood.
Aims: It seems possible that the detection of asymptomatic clonal proliferations lymphocytosis attributable to CTL may represent a predisposing condition to the development of cutaneous lymphomas.
Methods: Every year we analyze by flow cytometry about 1700 samples. Patients with peripheral lymphocytosis undergo a standard panel for T, B and NK cells. If clonal B is excluded, we proceed to phenotypic T CD4 subsets (CD7, CD26), analysis of Vβ chains and TCR when necessary.
Results: From January 2010 to September 2012 we observed 28 cases of CD3 T> 80% of total lymphocytes (CD3 ≥ 3.000/mm^3). Lymphocytosis was variable between3,000 and 10.000/mm^3, with an average of5,350. 14 subjects with CD4+CD8- > 75% of T cells showed CD7 low/neg, CD26 low/neg- and TCR Vβ suggestive of monoclonality, then confirmed by molecular biology. These subjects were followed up with blood count and clinical / dermatological evaluation twice a year in the event of increased peripheral lymphocytosis or appearance of symptoms suggestive of lymphoma. Two patients developed erythematous skin lesions and skin biopsy diagnosed the presence of Sezary syndrome, also confirmed on lymph node and bone marrow biopsies. Both these patients belonged to the subgroup with CD3 + CD4 + CD7-/ + CD8-CD26- phenotype, typical of Sezary syndrome.
Summary / Conclusion: 7.1% (2/28) of patients with monoclonal T lymphocytosis have developed a Sezary syndrome in a median follow-up of 20 months. Based on these preliminary data the occasional finding of T lymphocytosis with "atypical" phenotype CD3 + CD4 + CD7-/ + CD26-, may be a useful tool in order to allow early diagnosis of CTL in analogy with the strategy currently used for patients with MBL. If the hypothesis will be confirmed in larger cohort this approach could represent an advantage in terms of early diagnosis and timely treatment in this subset of patients.

P285

WHOLE EXOME ANALYSIS REVEALS MUTATIONS OF TET2 IN ADULT T-CELL LEUKEMIA/LYMPHOMA
Y Nagata[1],* A Sato-Otsubo[1], Y Okuno[1], Y Shiraishi[2], K Chiba[2], H Tanaka[2], A Kon[1], K Yoshida[1], M Sanada[1], K Ishiyama[3], S Miyawaki[3], A Kitanaka[4], K Shimoda[4], S Miyano[2], T Watanabe[5], S Ogawa[1]
[1]Cancer Genomics Project, The University of Tokyo, [2]Laboratory of DNA Information Analysis, Human Genome Center, The University of Tokyo, [3]Division of Hematology, Tokyo Metropolitan Ohtsuka Hospital, Tokyo, [4]Department of Gastroenterology and Hematology, Faculty of Medicine, University of Miyazaki, Miyazaki, [5]Department of Medical Genome Science, The University of Tokyo, Tokyo, Japan

Background: Adult T-cell leukemia/lymphoma (ATL) is an aggressive form of peripheral T-cell lymphoma (PTCL), which is etiologically associated with human T-lymphotropic virus type I (HTLV-1) infection during early infancy. Although HTLV-1 can effectively immortalize T-cells, there is a long latency period of ~50 years prior to the onset of ATL, suggesting that HTLV-1 infection alone may not be sufficient for the development of ATL, but additional acquired genetic hits that occur in immortalized T-cells during the later life are essential for its pathogenesis. However, little has been known about those genetic hits that are involved in the pathogenesis of ATL.
Aims: The purpose of this study is to understand the genetic basis of ATL, we performed whole exome sequencing and follow-up mutation analysis in a large series to confirm the findings in the exome analysis.
Methods: We performed whole exome sequencing of paired-tumor/normal DNA from a single case with ATL lymphoma type. In addition, mutations of *TET2*, *IDH1/2,* and *DNMT3A* were screened in an extended cohort of 145 ATL cases using targeted deep sequencing.
Results: A total of 77 non-silent somatic mutations were detected by whole exome sequencing. Among them, we identified a *TET2* mutation (R1261C). *TET2* mutations have been found in a wide variety of myeloid malignancies at high frequencies. The TET family of proteins is thought to be involved in the epigenetic regulation of gene expression through catalyzing conversion of 5'-methyl cytosine to 5'-hydroxymethyl cytosine, which are supposed to be further converted to unmethylated cytosine. One of the recent interests is frequent mutation of *TET2*, *IDH2* and *DNMT3A* in other PTCLs, such as angioimmunoblastic T-cell lymphomas (AITL) and PTCL not otherwise specified (PTCL-NOS). So we investigated mutations of these genes in a cohort of 145 ATL.
In total, 17 *TET2* mutations were found in 14 (9.6%) out of the 145 ATL samples. Less frequent mutations of *IDH2* and *DNMT3A* were also identified. Different subtypes of ATL were affected with 6 out of 47 acute, 3 out of 36 chronic and 5 out of 46 lymphoma types having *TET2* mutations. Biallelic involvement was suggested in 4 out of the 14 cases. *TET2* mutations seemed to have no significant impacts on overall survival. Less common mutations were found in *IDH2* (p.R172K and p.R172T) and *DNMT3A* (p.G543fs and p.R882H), of which 2 *IDH2* mutations coexisted with *TET2* mutations. In deep sequencing, it revealed that the *TET2* mutations harbored a major tumor population in most evaluable cases, while the *TET2* mutations in two cases only involved a minor population. In some cases, *TET2* mutations seemed to be among early genetic event in ATL, but nevertheless, it should not before HTLV-1 infection, and in other cases, *TET2* mutations could be relatively late events, found in a subpopulation. So our finding of *TET2* mutations in ATL suggested that mutated *TET2* have unique roles in T-cells, contributing to the development of peripheral T-cell neoplasms, most likely through epigenetic deregulation (Figure).
Summary / Conclusion: *TET2* was mutated in ~10% of ATL patients, indicating common pathogenesis between AITL and other PTCLs. Our finding suggested a common role of deregulated epigenetic machinery in the development of mature T-cell neoplasms including ATL.

VITAMIN D3 AND LENALIDOMIDE SYNERGIZE TO INDUCE APOPTOSIS IN MANTLE CELL LYMPHOMA VIA THE INDUCTION OF THE BH3-ONLY BIK PROTEIN
C Brosseau[1,2,3,4],* C Dousset[1,2,3,4,5], T Cyrille[1,2,3,4], S Maiga[1,2,3], P Moreau[4,5], M Amiot[1,2,3], C Pellat-Deceunynck[1,2,3,4], S Le Gouill[1,2,3,4,5]
[1]INSERM UMR892, [2]CNRS UMR6299, [3]Université de Nantes, [4]Service d'Hématologie, CHU, [5]CIC INSERM, Nantes, France

Background: Targeted therapies are being tested in the MCL. Among all new treatment options, lenalidomide appears as one of the most efficient molecule. Lenalidomide has multiple modes of action targeting the tumor cell and its environment including immune system. It is widely reported that cancer patients are deficient in vitamin D3 (1,25-dihydroxyvitamin D3, VD3) and recent studies in lymphomas have shown that VD3 rate is significantly associated with survival. While relations between VD3 and incidence of cancer remain unresolved, it was

shown that VD3 contributes as an anticancer agent through its anti-proliferative, pro-differentiation, anti-inflammatory and anti-angiogenic properties.
Aims: We assessed the efficacy of VD3 to potentiate cell death induced by lenalidomide in MCL cell lines and patients' samples and unraveled the mechanism of cell death.
Methods: Experiments were conducted in a panel of 6 MCL cell lines (JEKO-1, MINO, GRANTA-519, UPN-1, REC-1 and Z138) and 8 primary samples.
Results: After 6 days of treatment, MCL cells were weakly sensitive to low doses of lenalidomide (1 μM and 10μM for cell lines and samples, respectively). Addition of physiological doses of VD3 (100nM) significantly and synergistically increased cell death in 67% of cell lines and in 63% of primary samples. Apoptosis, characterized by Annexin V staining, appearance of a subG1 peak and caspase 9 activation, was accompanied by cell cycle arrest in G1 phase. VD3 plus lenalidomide combination dramatically increased expression of the BH3-only Bik without affecting expression of other Bcl2 molecules. By immunoprecipitation assays, we showed that induced-Bik was not bind to anti-apoptotic molecules Bcl2, BclxL or Mcl1 in treated cells but free to activate effectors molecules such as Bax. Moreover, silencing of *BIK* by siRNA prevented apoptosis induced by VD3/lenalidomide, confirming the direct involvement of Bik in cell death. Bik accumulation induced by lenalidomide and VD3 was not related to an increase in transcription factor TEF expression but to an increase of the ratio unmethylated over methylated of *BIK* CpG island. Similar epigenetic regulation of *BIK* expression was obtained with the inhibitor of methylation, 5-azacytidine.
Summary / Conclusion: We show that lenalidomide and VD3, similarly to 5-azacytidine, induce the expression of Bik via the unmethylation of *BIK* GpG island, which is responsible for cell death. Indeed, our results show for the first time an original and non-toxic approach to significantly potentiate apoptosis induced by lenalidomide in MCL cells by simply adding physiological doses of VD3. These data underline the interest 1) to measure the level of VD3 in MCL patients especially those receiving lenalidomide, 2) to define if this level is correlated with the response, 3) to define whether supplementation with VD3 could increase response rate of patients receiving lenalidomide.

CXCR4 IS CRITICAL FOR NON HODGKIN LYMPHOMA CELL SURVIVAL, INTERACTION WITH BONE MARROW MICROENVIRONMENT AND DRUG RESISTANCE *IN VITRO* AND *IN VIVO* IN ANIMAL MODEL
K Beider[1,*] E Rosenberg[1], M Abraham[2], I Weiss[2], H Wald[2], E Ribakovsky[1], M Koren-Michowitz[1], A Avigdor[1], A Shimoni[1], A Peled[2], A Nagler[1]
[1]Bone Marrow Transplantation, Sheba Medical Center, Tel-Hashomer, [2]Institute of Gene Therapy , Hadassah and Hebrew University, Jerusalem, Israel

Background: CXCR4/CXCL12 chemokine axis has been implicated in the progression of hematological malignancies. CXCR4 is highly expressed in a variety of B cell neoplasms, including NHL. CXCR4 inhibition in combination with rituximab has been shown to be an effective strategy in targeting lymphoma cells in BM environment in disseminated NHL xenograft model.
Aims: To provide a mechanistic insight into CXCR4-regulated lymphomagenesis *in vitro* and *in vivo*.
Results: High mRNA and surface CXCR4 levels were detected in most of NHL cell lines (n=7) and primary samples from NHL patients with BM involvement (n=7). Cell lines expressing high CXCR4 (BL-2 and Raji) demonstrated higher migration rate in response to CXCL12 and firmer adhesion to fibronectin and BMSC monolayer than low CXCR4-expressing BJAB cells. Interaction with BMSC protected the cells with high CXCR4 from rituximab-induced apoptosis. In contrast, BJAB cells with low CXCR4 were not protected by stroma. To further investigate the role of CXCR4 in NHL progression, *in vivo* xenograft model was established. Immuno-compromised mice inoculated subcutaneously with BL-2 cells produced highly invasive local tumors with BM dissemination and succumbed to lymphoma. In contrast, injection of low CXCR4 expressing BJAB cells resulted in local slow-growing tumor development without BM involvement and long-term animal survival. Notably, BL-2 cells that arrived to the BM demonstrated higher levels of mRNA and surface CXCR4, compared to the bulk tumor, therefore suggesting the role of CXCR4 in clonal selection and homing of lymphoma cells to the BM. To further establish the role of CXCR4 in lymphoma progression, we blocked endogenous CXCR4 expression in BL-2 and Raji cells, using anti-CXCR4 shRNA construct. CXCR4 silencing resulted in significant decrease in cell viability *in vitro*, from 92% to 2% in BL-2 cells, and from 85% to 23% in Raji cells (P<0.002). Importantly, we found that anti-apoptotic proto-oncogene BCL-6 was down-regulated in the lymphoma cells following CXCR4 silencing. In accordance, CXCR4 silencing in BL-2 cells significantly (P<0.001) inhibited local tumor growth and prevented NHL spread to BM. As complementary research strategy, we ectopically expressed CXCR4 in low-CXCR4 expressing BJAB cells. Exogenous expression of CXCR4 significantly increased the *in vitro* growth rate and promoted cell survival in the presence of BMSCs (P<0.01). Furthermore, interaction with BMSCs resulted in strong and prolonged pErk1/2 activation in exogenously expressing BJAB-CXCR4 cells, comparing to the native line expressing low CXCR4. Finally, CXCR4 overexpression significantly promoted the growth of xenograft subcutaneous tumors and their spread to the BM.
Summary / Conclusion: Taken together, our findings clearly demonstrate an important pathophysiological role of CXCR4 in NHL. Our model may further serve to elucidate CXCR4-regulated molecular events potentially involved in the pathogenesis of NHL, and strongly support targeting CXCR4 as therapeutic strategy.

Emanuele", Catania, [2]Division of Hematology, Amedeo Avogadro University of Eastern Piedmont, Novara, [3]Dipartimento di Medicina Interna, Sezione di Ematologia, University of Pisa, Pisa, [4]Department of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, [5]Department of Haematology, Santo Spirito Hospital, Pescara, [6]Divisions of Hematology and Pathology, IRCCS Policlinico San Matteo, Pavia, [7]Division of Oncology and Clinical Hematology, Hospital of Mirano, Venice, [8]Division of Hematology, S. Maria Nuova Hospital, Reggio Emilia, [9]Department of Cellular Biotechnology and Hematology, La Sapienza University, Rome, [10]SOD Ematologia, Azienda Ospedaliero Universitaria Careggi, Florence, [11]Division of Hematology, Spedali Civili of Brescia, Brescia, [12]Division of Hematology, Niguarda Hospital, Milan, [13]Division of Medical Oncology A, National Cancer Institute, Aviano, [14]Division of Haematology, Ospedale "Bianchi-Melacrino-Morelli", Reggio Calabria, [15]Division of Medicine and Hematology, G. da Saliceto Hospital, Piacenza, Italy

Background: Follicular lymphoma (FL) is the most frequent indolent lymphoma subtype. Though most FL biomarkers rely on features of the tumor, the genetic background of the host may also be relevant for outcome.
Aims: Here we aimed at verifying the contribution of single nucleotide polymorphisms (SNPs) to the prognostic stratification of FL patients treated with immunochemotherapy.
Methods: The study was based on 428/504 (85%) FL patients enrolled in the FOLL05 phase-III prospective trial comparing R-CVP vs R-CHOP vs R-FM as initial treatment. Seventy-six patients were not assessable due to lack of biological material. Candidate SNPs were selected because known to be relevant for: i) immunochemotherapy outcome or toxicity (MLH1 rs1799977, GSTA1 rs3957357, CYBA rs4673, NCF4 rs1883112, FCGR2A rs18011274, FCGR3A rs396991); ii) FL course (6p21.33 rs6457327). SNPs were genotyped by Sanger sequencing or real time PCR on peripheral blood DNA samples. The primary endpoint was time to treatment failure (TTF). Median follow up of alive patients was 34 months.
Results: Patients (n=428) were representative of the entire FOLL05 study cohort and SNP genotypes distributed in Hardy-Weinberg equilibrium. Though FCGR2A and FCGR3A SNPs have been suggested to influence rituximab single agent activity in FL, our data document that they do not affect treatment results when rituximab is combined with chemotherapy. Indeed, by pooled analysis of the treatment arms, the 3-year TTF did not differ according to FCGR2A (AA: 59% vs AG: 57% vs GG: 62%; P=.742) or FCGR3A (TT: 61% vs GT: 55% vs GG: 61%: P=.252) genotypes. These results were consistent also after compensating for treatment received and FLIPI by multivariate analysis (FCGR2A: P=.793; FCGR3A: P=.490). MLH1 is a component of the DNA mismatch repair that regulates the genotoxic effects of doxorubicin and impairs R-CHOP performance in diffuse large B-cell lymphoma. Consistently, the MLH1 genotype affected the 3-year TTF in the R-CHOP arm (AA: 66% vs AG: 68% vs GG: 30%; P=.011), but not in arms lacking doxorubicin (p for R-CVP=.298; p for R-FM=.601). The impact of MLH1 on TTF was independent (P=.004) after adjusting for FLIPI in the multivariate analysis. The remaining SNPs (GSTA1, CYBA, NCF4, 6p21.33) had no significant effect on TTF. Concerning toxicity, the FCGR2A genotype, which modulates rituximab binding to effector cells, correlated with G3-4 neutropenia (AA: 56% vs AG: 43% vs GG: 40%; P=.026). Also the genotype of GSTA1, which is involved in cyclophosphamide detoxification, affected G3-4 neutropenia risk (CC: 58% vs CT: 43% vs TT: 42%; P=.018).
Summary / Conclusion: Taken together, these data indicate that: i) MLH1 genotype is consistently associated with outcome in FL treated with R-CHOP, thus providing a more general and prospective validation of the usefulness of this host-related biomarker in R-CHOP treated lymphomas; ii) FCGR2A and FCGR3A genotypes have no impact when FL is treated with rituximab combined to chemotherapy; iii) GSTA1 and FCGR2A SNPs may represent biomarkers for the identification of FL patients at risk of severe neutropenia.

P289

GENERATION AND CHARACTERIZATION OF A CD30 POSITIVE T-CELL LYMPHOMA MOUSE MODEL RESEMBLING HUMAN ANAPLASTIC LARGE CELL LYMPHOMA (ALCL)

C Klingeberg[1,*] A Illert[1], N Schneider[2], C Peschel[2], C Miething[3], J Duyster[1]
[1]First medical department, Universitätsklinikum Freiburg, Freiburg, [2]Third medical department, TU München, München, Germany, [3]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Anaplastic large cell lymphomas (ALCL) are a subgroup of aggressive Non-Hodgkin-Lymphomas mainly affecting children and young adults. In 60% of systemic ALCLs, a translocation t(2;5) (p23;q35) resulting in NPM-ALK fusion gene expression is found. The constitutively activation of ALK tyrosine kinase expressed from the NPM-promoter causes increased proliferation and inhibition of apoptosis thereby promoting cell survival and tumorigenesis.
Aims: Immunphenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or Null-Cell-origin and resulted in promising clinical trials with CD30-coupled antibodies. However, the impact of CD30 on diseases development as well as NPM-ALK signal transduction in course of disease remain unclear and appropriate mouse models to answer these questions are missing.
Results: In this regard, we established a retroviral murine bone marrow transplantation model resembling a human ALCL-like T-cell neoplasia. Therefore we use an inducible Cre/loxP system where NPM-ALK expression is controlled and expressed in a special type of early T-cells. For generation of this vector, we inserted a floxed translational 'stop-cassette' between the retroviral promoter MSCV-LTR and the NPM-ALK cDNA, which guaranties specific expression of NPM-ALK only in cells, where the enzyme Cre-recombinase is expressed. Recognition of loxP-sites by Cre-recombinase leads in our system to deletion of the stop-cassette and consequently NPM-ALK expression. Using different Cre-expressing cell types allowed us to study pathogenesis of ALCL in more detail. In our recent study, we infected bone marrow of transgenic mice expressing Cre-recombinase under the control of the Lck-promotor with our MSCV-Stop-NPM-ALK-IRES-EGFP (MSNAIE) vector and transplanted it into lethally irradiated C57/Bl6 recipient mice. With a latency of 4-5 months, these mice developed Thy1.2-positive lymphomas and died from neoplastic infiltration of bone marrow and lymphatic organs with T-cells. Immunphenotypic analyses confirmed T-Cell origin of the lymphomas and showed importantly highly CD30-expression. Staining of the different T-cell-subpopulations demonstrated highest NMP-ALK expression in immature CD4/CD8 double negative T-cells and not fully differentiated CD4/CD8 double positive T-cells. Interestingly, FACS-staining of the proliferation marker Ki-67 revealed highest expression in CD4/CD8 double negative T-Cell, in contrast to the other subpopulations where Ki-67 is less detected. Therefore we hypothesized, that the lymphoma initiating cell (LIC) must be within this early T-cell population. Most interestingly we found highest CD30-expression just in the same CD4/CD8 negative T-cell population, pointing to a crucial role of CD30 in lymphoma initiation. To further substantiate our hypothesis we performed secondary and tertiary transplantations with different sorted T-Cell subpopulation and indeed, the immature CD4/CD8 double negative population was able to initiate lymphoma growth in recipient mice. Future analyses of these mice will help to identify the leukemia initiating cell in ALCL.
Summary / Conclusion: Taken together, our murine LckCre-NPM-ALK bone marrow transplantation model represents a precise and versatile tool to study disease initiation and development resembling human ALCL. Moreover, the impact of specific proteins (e.g. CD30) in the course of disease can be addressed by combining Knockout (e.g. CD30)/LckCre transgenic mice with our model.

P290

LYMPHOMAS AS ESTROGEN RELATED DISEASES - POSSIBLE TARGET FOR ESTROGEN RECEPTOR BETA AGONIST TREATMENT.

K Yakimchuk[1,*] MS Hasni[1], J Guan[1], S Nilsson[2], S., M Jondal[3], B Sander[4], S Okret[1*]
[1]Dept. of Biosciences and Nutrition and [4]Dept. of Laboratory Medicine, Karolinska Institutet, Novum, SE-141 83 Huddinge, Sweden, [2]Karo Bio AB, Novum, SE-141 57 Huddinge, Sweden and [3]Dept. of Microbiology, Tumor and Cell Biology (MTC), Karolinska Institutet, SE-171 77 Stockholm, Sweden

Background: Lymphomas are generally not considered as endocrine related cancers. However, most lymphoid malignancies show a gender differences in incidence and prognosis with males being more affected. Furthermore, epidemiological data in females show an association between reproductive hormonal factors and oral contraceptives with a significantly reduced risk for Non-Hodgkin lymphomas, indicating a protective role of estrogens. More recent studies have demonstrated estrogen receptor beta (ERb) to be the major ER expressed in normal and malignant cells of lymphoid origin.
Aims: The aim of the study was to investigate whether estradiol and selective ERa and ERβ agonists may affect lymphoma growth in culture and *in vivo.*
Methods: We have analyzed the effects of estradiol and selective ERa and ERβ agonists on lymphoma growth by grafting mice with lymphoma cells. RT-qPCR, microarray analysis and immunohistochemistry/immunofluorescence were used in our study.
Results: Treating lymphoma cells with estradiol or ERa selective agonist had minor or no effect on cell growth, while selective ERβ agonist treatment showed an anti-proliferative effect. When grafting mice with murine T lymphoma cells, male mice developed larger tumors compared to female mice, a difference that was abolished following ovariectomy, demonstrating estrogen dependent growth *in vivo*. To investigate whether lymphoma growth may be inhibited *in vivo* by ERβ agonist treatment, mice were grafted with murine T and human B lymphoma cells and treated with ERb selective agonists. Results showed that treatment with ERb selective agonists strongly inhibited lymphoma growth of several lymphoma types due to reduced proliferation and in some cases increased apoptosis. In addition, ERb selective agonists reduced lymphoma dissemination. Gene expression studies have identified target genes and mechanism that could explain the above effects of ERb agonists. Preliminary results from immunohistochemical staining of primary mantle cell lymphoma material showed that ERb is expressed in the tumor cells.
Summary / Conclusion: In summary, our results demonstrate an ERβ ligand-dependent antiproliferative effect on lymphoma cells expressing endogenous ERβ and that lymphoma cell growth and dissemination *in vivo* can efficiently be reduced by ERβ agonists. The results suggest that ERβ agonists may be useful in the treatment of lymphomas. The results may also explain the gender difference in incidence and prognosis of lymphomas.

P291

A COMPARATIVE ANALYSIS OF NEXT-GENERATION SEQUENCING AND REAL-TIME QUANTITATIVE PCR FOR MINIMAL RESIDUAL DISEASE DETECTION IN FOLLICULAR LYMPHOMA

C Pott[1,*] L Monitillo[2], E Genuardi[2], B Mantoan[2], H Trautmann[1], M Kneba[1], M Brüggemann[1], M Faham[3], M Ladetto[2]
[1]Second Medical Department, UNIVERSITY HOSPITAL SCHLESWIG-HOLSTEIN, CAMPUS KIEL, Kiel, Germany, [2]Department of Molecular Biotechnology and Health Science, University of Torino, Torino, Italy, [3]Sequenta Inc, 400 East Jamie Court, Suite 301 , San Francisco, United States

Background: The detection of minimal residual disease (MRD) by t(14;18) Real-Time Quantitative (RQ) PCR has become an important tool for treatment monitoring in follicular lymphoma (FL). However, only 50% to 65% of patients can be assessed by t(14;18) RQ-PCR and alternative targets as the immunoglobulin heavy chain variable region (IGH) can be used only with limitations. IGH-based next-generation sequencing (NGS) might provide an alternative approach with further increase in sensitivity, specificity and accuracy. Therefore we comparably analysed both approaches on diagnostic and post-treatment follow-up samples in 29 FL patients.
Aims: To verify the suitability of NGS for MRD detection we comparably analysed diagnostic and post-treatment follow-up samples in 29 FL patients.
Methods: Overall, 206 samples (85 bone marrow, 114 peripheral blood, 6 stem cell aliquots and one lymph node sample) were investigated from 29 FLenrolled in clinical trials. Overall, 33 diagnostic and 173 follow-up (FU) samples were analysed. 23/29 patients had a PCR detectable t(14;18) rearrangement, 5 patients had a clonal IGH rearrangement only and one patient had no marker by consensus PCR. RQ-PCR was carried out as previously published by our group and results were analysed according to ESHLO criteria. NGS was performed independently at the Sequenta facilities in San Francisco and data remained blinded until comparison. Using universal primer sets IGH variable, diversity, and joining gene segments were amplified and sequenced with a coverage of 14 reads per each IGH molecule and analyzed using standardized algorithms for clonotype determination. Tumor-specific clonotypes were identified based on their high-frequency in diagnostic sample and then quantitated in FU samples. A quantitative and standardized measure of clone level among all leukocytes was determined using internal reference DNA. Discordances of MRD results by both methods were classified as follows: a positive/negative discordance between two results was defined as major when the positive result was >1 E-05 and minor when ≤1 E-05; a quantitative discordance was defined as two positive results with a quantitative discrepancy >1 log.
Results: 29 patients were evaluable with at least one method. 15 patients were evaluable for MRD by RQ-PCR and NGS. Here, in 97 FU samples a significant concordance between both MRD methods could be demonstrated (r^2=0.80) (P<0.0001). Of these samples, 44 were MRD positive and 45 were MRD negative with both tools .Quantitative discordances occurred in 12/44 MRD+ samples where in 7 samples MRD was higher and in 5 was lower by NGS. A major discordance occurred in 4 samples where RQ-PCR was positive and NGS was negative. A minor discordance was detectable in 4 samples where in 2 samples RQ-PCR was positive and NGS was negative, and in the other 2 samples the opposite was correct. Seven patients were only quantifiable by RQ-PCR while NGS did not identify an index clone for sequencing. In all but one diagnostic samples demonstrated low level lymphoma infiltration with MRD below 10^{-3}. In one of these cases, IG kappa could be successfully sequenced for MRD indicating that not only low level MRD but also somatic mutation of IGH is a potential pitfall for MRD detection by NGS. In 5 t(14;18)

negative cases with a clonal IGH rearrangement IGH-RQ-PCR resulted in non quantifiable assays. Here, NGS detected MRD successfully, as well as in one further case where an unusual large t(14;18) rearrangement did not allow MRD quantification by RQ-PCR.
Summary / Conclusion: NGS represents a feasible tool for MRD monitoring that allows analysis of a larger group of FL patients. Our results show that lymphoma infiltration of diagnostic samples is critical for identification of the tumor-specific clonotypes by NGS and that different MRD methods may complement each other to allow MRD assessment for the majority of FL patients.

P292

MYD88 L265P MUTATION IN WALDENSTROM MACROGLOBULINEMIA: INCIDENCE AND FUNCTIONAL STUDY

S Poulain[1,*] C Roumier[2], A Decambron[1], C Herbaux[3], E Bertrand[4], A Renneville[5], A Daudignon[1], S Tricot[6], O Nibourel[5], C Roche-Lestienne[7], B Quesnel[3], P Duthilleul[8], C Preudhomme[5], X Leleu[9]

Background: Mutation of *MYD88* gene has recently been identified in activated B-cell like diffuse B-cell lymphoma, and enhanced JAK STAT and NF-kB signalling pathways. Whole exome sequencing study in Waldenstrom macroglobulinemia (WM) suggested a high frequency of MYD88 L265P mutation in WM. Although the genetic background is not fully deciphered in WM, the role of NF-kB and JAK STAT pathways has been demonstrated in WM.
Aims: We aimed to analyze MYD88 mutation in exon5, to characterize the clinical significance of this genetic alteration in 67 WM and to study the effects of MYD88 inhibition in WM cell lines
Methods: 67 patients (42 males, 25 females) diagnosed with WM were included in this study. Patients were untreated at time of BM collection. Clinical features, immunophenotypic markers using flow cytometry (Matutes score panel, CD38, CD138, CD27, CD80), conventional cytogenetic, FISH and SNP array data (n=46) were analysed. B cells from bone marrow and T cells from blood were isolated respectively using B cell isolation kit and Pan T isolation kit (Myltenyi Biotech). For DNA sequencing of exon 5 of MYD88, the exon 5 of MYD88 gene was amplified from genomic DNA by PCR.The purified PCR products were directly sequenced in both directions using BigDye® Terminator Cycle Sequencing Kit (Applied Biosystems, CA, USA) and analyzed on the Applied Biosystems 3130xl Genetic Analyzer. BCWM1, MWCL1 (WM cell lines with MYD88 L265P mutation), MEC-1, RL, and MM.1S cell lines were used in this study. Cells were treated with a MYD88 inhibitor (MYD inh) ant its control peptide (Peptide crtl). Viability and cell growth of treated cells were determined using the MTS assay. Apoptosis was quantitated using annexin V - propidium iodide staining, mitochondrial membrane potential and caspase activity analysis using flow cytometry.
Results: MYD88 L265P mutation (MYD^{mut}) was observed in 79% of patients, including homozygous mutation in two patients (3%). MYD88 mutation was not identified in T lymphocytes isolated from 4 WM patients. We haven't observed any other mutation on exon 5. We then sought for other mechanisms of MYD88 gene alteration, such as copy number alteration (CNA) and copy neutral –loss of heterozygosity (CN-LOH) at MYD88 locus. We found an CN-LOH at MYD88 locus in solely one patient (2%), and haven't identified any deletion at 3p22. On the contrary, we observed a gain on chromosome 3 at 3p22 locus (including MYD88 gene) in 7/57 (12%) patients. Taking together, we identified alteration of the MYD88 locus in 85% of patients with WM, by either gain-of-function mutation (79%) or CNA (12%). Interestingly, we found gain on chromosome 3 more frequently in the MYD^{wild} group than in the MYD^{mut} group (P=0.02). Twenty one percent of the patients with WM had no mutation of MYD (MYD^{wild}), and were characterized with a female predominance, a splenomegaly, gain of chromosome 3 and CD27 expression. We did not observed difference in terms of survival according to the MYD88 mutation status. MYD88 mutation was not related to deletion 6q, gain of4, deletion 11q, deletion 17p, deletion 13q14 in our study. Overall, 63% of WM had at least one additional genetic alteration in the NF-kB pathway in our cohort, but no significant difference was observed according to the MYD88 mutation status. Inhibition of MYD88 signalling induced cytotoxicity and inhibited cell growth in cells expressing MYD88 L265P mutation. Inhibition of MYD88 homodimerization also significantly inhibited MYD88 signalling in the MYD^{mut} as compared to the MYD^{wild} cell lines, as exemplified by the marked downregulation of IRAK4 and STAT3 phosphorylation, downstream targets of MYD88.
Summary / Conclusion: Our results confirm a high frequency of MYD88 L265P mutation in WM that may become a useful biomarker for diagnostic in WM and may help better understand the physiopathogeny of WM. From a therapeutic standpoint, this data also suggested that direct targeting of MYD88 signalling may provide a novel approach for the treatment of MW in the future.

P293

MINIMAL RESIDUAL DISEASE (MRD) DETECTION BY NEXT-GENERATION SEQUENCING AND REAL-TIME QUANTITATIVE PCR: A METHODICAL COMPARISON IN ALL, MCL AND MM

M Ladetto[1,*] M Brüggemann [2], L Monitillo[1], S Ferrero[1], F Pepin[3], D Drandi[1], A Palumbo[1], R Passera[4], M Boccadoro[1], V Carlton[3], H Trautmann[2], M Faham[3], C Pott[2]
[1]Department of Molecular Biotechnology and Health Science, University of Torino, Torino, Italy, [2]Second Medical Department, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, [3]Sequenta Inc (www.sequentainc.com) 400 East Jamie Court, Suite 301 , South San Francisco, United States, [4]Statistical Consultant, University of Torino, Torino, Italy

Background: Real-Time Quantitative (RQ)-PCR-based MRD detection using primers derived from the immunoglobulin heavy chain variable region (IGH) is an established disease monitoring tool in ALL, MCL and MM. It is highly sensitive and has been standardized in the context of international cooperative groups such as the European Scientific Foundation for Laboratory Hematooncology (ESHLO). However it has some limitations, including marker identification failure, and false negatives due to clonal evolution.
Aims: To verify if IGH-based next-generation sequencing (NGS) might overcome some of these limitations of RQ-PCR and further increase sensitivity, specificity, accuracy and reproducibility, we have performed comparison of the two methods on diagnostic (DG) and post-treatment follow-up (FU) samples on a panel of 55 pts.
Methods: 378 samples (62 DG, 316 FU) were collected from 55 pts enrolled in clinical trials (15 ALL, 30 MCL, 10 MM). IGH-based RQ-PCR was carried out as previously described [Ladetto *et al*, BBMT 2000; Brüggemann *et al*, Blood 2006], according to the ESHLO criteria [van der Velden *et al*, Leukemia 2007], at two experienced MRD laboratories. NGS was performed at the Sequenta facilities. Using universal primer sets, we amplified IGH variable, diversity, and joining gene segments from gDNA. Amplified products were sequenced to obtain a high degree of coverage (14 reads per each IGH molecule) and analyzed using standardized algorithms for clonotype determination. Tumor-specific clonotypes were identified for each patient based on their high-frequency in DG sample and then quantitated in FU samples. A quantitative and standardized measure of clone level among all leukocytes was determined using internal reference DNA. NGS analysis was performed independently under blinded conditions. Comparability of results by RQ-PCR and NGS was assessed by bivariate correlations between methods (software R 2.15.1 package irr). Discordances were classified as follows: a positive/negative discordance was defined as major when the positive result was >1 E-05 and minor when ≤1 E-05; a quantitative discordance was defined as the presence of two positive results with a quantitative discrepancy >1 log.
Results: 51 pts (93%) were evaluable with at least one tool (RQ-PCR 45, NGS 49), 43 (78%) with both and 4 (7%) with none. Disease-specific success rates are shown in Table 1. Sequences identified with both tools were identical or nearly identical in 41 cases and unrelated in two. Overall, 330 samples (87,3%) were evaluated with at least one tool (RQ-PCR 279, NGS 316) and 265 (70%) with both. In terms of MRD output, concordance was significant (P<0.001) and 214/265 (80,8%) samples had an optimal concordance (96 MRD neg and 118 MRD pos). Of these major discordances were 16 (6%); minor discordances were 24 (9,1%); quantitative discordances were 11 (4,1%). In 2 ALL clonal evolution hampered straightforward MRD assessment. In one case IGH RQ-PCR underestimated MRD while a second RQ-PCR marker (TCRD) overlapped NGS. In a second case NGS did not detect the tumor diagnostic clone due to loss of the complete IGHV at relapse whereas the preceding IGHDJ was preserved and detected by RQ-PCR.
Summary / Conclusion: NGS is an effective tool for MRD monitoring in ALL, MCL and MM. Good concordance was seen in the vast majority of cases. However, disease-specific pitfalls (clonal evolution, somatic hypermutations, frequency of complete IGH rearrangements) have to be considered for both methods. Prospective comparative analysis of unselected cases is required to verify the clinical impact of NGS-based MRD assessment.

Table 1. Rates of success of RQ-PCR abd NGS among ALL, MCL, an MM by patient.

Disease	Patients	Patients evaluable PCR	Patients evaluable NGS	Patients evaluable with both tools	Patients evaluable with at least one tool	Patients not evaluable
ALL	15	15	15	15	15	0
MCL	30	22	26	22	26	4
MM	10	8	8	6	10	0
TOT	55	45	49	43	51	4

B-CELL REPERTOIRE ANALYSIS OF INDOLENT MCL WITH SPLENIC PRESENTATION : A DISTINCT ONTOGENY FROM CLASSICAL MCL?

C Sarkozy[1,*] M Cheminant[2], M Boudgrha[2], J Lazarovic[1], S Le Gouill[3], F Berger[4], A Traverse-Glehen[4], L Baseggio[5], P Felman[5], P Talmant[6], A Le Bourgeois[3], A Moreau[7], S Lissandre[8], V Eclache[9], F Baran-Marsazk[9], F Jardin[10], J Brière[11], R Houlgatte[12], F Davi[2], C Thieblemont[1]
[1]Hematology, Hôpital Saint Louis, [2]hemato-biology, Hôpital de la Pitié Salpetrière, Paris, [3]hematology, CHU de Nantes, Nantes, [4]hemato-pathology, [5]hemato-biology, Centre Hospitalier Lyon Sud, Pierre Benite, [6]cytogenetic, [7]hemato-pathology, CHU de Nantes, Nantes, [8]hematology, CHU de tours, Tours, [9]hemato-biology, Hopital Avicennes, Bobigny, [10]hematology, Centre Henri Becquerel, Rouen, [11]hemato-pathology, Hôpital Saint Louis, Paris, [12]Unité Inserm U954, inserm, Nancy, France

Background: Mantle-cell lymphoma (MCL) is a heterogeneous but well-defined lymphoid malignancy characterised by the presence of a translocation, the t(11;14)(q13;q32), inducing a dysregulation of the cyclin D1 expression, a key protein for the cell cycle at the G1-S phase transition. MCL is characterized by a rapid and pejorative clinical evolution. Recently, it has been recognized that some patients experience a particularly indolent course with a prolonged survival without therapy. These patients generally present with splenomegaly, blood involvement and minimal lymphadenopathy. However, indolent cases with a splenic presentation (splenic iMCL) remain incompletely characterized, especially regarding the B-cell reprtoire.
Aims: The aim of our study was to characterize the clinical and biological features of splenic iMCL, including their IGHV-IGHD-IGHJ repertoire and mutational status.
Methods: Genomic DNA of 20 patients with splenic iMCL extracted from tissue specimen (blood, bone marrow biopsy, spleen) was used to characterise the IGHV-IGHD-IGHJ gene repertoire, to analyse somatic hypermutation (SHM) features, and to look for common CDR3 motifs.
Results: Patients characteristics include a median age of 65 years (range : 48-84), 5 females and 15 males, ECOG-PS ≤ 1 for all patients, MIPI score low in2, intermediate in 8 and high in 8. Median leucocyte count was 14.4G/L. Anemia was present in 6 patients, thrombocytopenia in 12, LDH > UNL in 4. The median follow up was 83 months (6-213). At time of analysis, 11 patients were alive without receiving polychimiotherapy. Immunophenotype was available in 19 patients: Matutes score was ≤ 3 (0-1 n=12, 5 n=2, 3 n=2), CD5 was negative in 4 patients, IgM (+/-IgD) expression was reported in 13 patients/13 (IgG in 0), κ and λ in 12 and 7 cases respectively. A monoclonal productive IGH rearrangement was obtained for 16 patients. There was a preferential usage of IGHV4-34 (4/16 cases) and IGHV3-7 (3/16 cases) genes. Interestingly, IGHV1-2 and IGHV3-21, the most frequent genes used in splenic marginal zone lymphoma (MZL) and classical MCL respectively, were not (IGHV1-2) or seldom (IGHV3-21, 1/16) represented. While the IGHD repertoire had no particularity, there was an over-representation of the IGHJ4 gene (9/16) and an absence of IGHJ5. The vast majority of cases (14/16) had undergone SHM; the mean value for percentage of identity to germline IGHV sequences was 96%, and 10/16 sequences could be considered as truly mutated (<97% identity). The median CDR3 length was 13 (6-20) and no stereotypic CDR3 motif could be identified.
Summary / Conclusion: Although this constitutes a small series, our results suggest that iMCL with splenic presentation might have a different IGH repertoire than those of and classical MCL as well as splenic MZL. Further insight into the potential of splenic iMCL to form a distinct entity is currently being investigated by comparative genomic analyses.

P295

NIPA DEFICIENCY LEADS TO ACCELERATION OF THE LYMPHOMA DEVELOPMENT IN EUMYC MICE

A Illert[1,*] C Klingeberg[1], C Albers[2], S Morris[3], U Keller[4], J Duyster[1]
[1]Department of Internal Medicine I, University of Freiburg, Freiburg, [2]Department of Internal Medicine III, Technical University of Munich , Munich, Germany, [3]Department of Pathology, St. Jude Children's Research Hospital, Memphis, TN, United States, [4]Technical University of Munich, Munich, Germany

Background: Timely degradation of proteins that control cell proliferation and apoptosis is an essential mechanism in keeping normal growth from turning into runaway malignancy. We previously reported the cloning of NIPA (Nuclear-Interaction-Partner-of-ALK) and characterized it as a F-Box-protein that defines an oscillating E3-ubiquitin-ligase.
Aims: To study *in vivo* function of the G_2/M checkpoint NIPA in greater detail, we inactivated the gene encoding *Nipa* using a conditional-knockout strategy.
Results: Nipa$^{-/-}$ animals are viable, but sterile due to a block of spermatogenesis. Our studies demonstrate that loss of Nipa has no substantive effect on physiological cell cycle progression of primary MEFs indicating that this cell cycle checkpoint is inactive under optimal proliferation conditions. Interestingly, Nipa checkpoint control can be unmasked by oncogenic c-Myc-transformation. Here we show significant differences in c-Myc-induced transformation: Focus formation ability of c-Myc-infected Nipa$^{-/-}$ MEFs was greatly reduced. Moreover, Nipa-deficiency leads to premature senescence in cultured primary MEFs. Ectopic reexpression of Nipa resulted vice versa in delayed senescence of knockout MEFs. Next, we sought to know, whether increased apoptosis in Nipa$^{-/-}$ c-Myc-transduced MEFs is dependent on a functional p53-Axis. Interestingly, the effect of Nipa deficiency on c-Myc-mediated transformation was totally abolished by p53-knockdown. We observed no differences in focus formation ability or growth behaviour in Nipa$^{-/-}$ MEFs with inactivated p53, suggesting the importance of p53 in Nipa-induced cell death. Looking in more detail on the c-myc-p53 axis we detected a substantial increase in Arf-p19 levels in Nipa$^{-/-}$ cells. Moreover, Nipa-knockdown in Zn-inducible-Arf-NIH/3T3 cells lead to stabilization of Arf p19. To test the impact of these findings in a relevant *in vivo* model we intercrossed Nipa$^{-/-}$ animals with a transgene EμMyc-Strain. Nipa$^{-/-}$EμMyc$^{TG/wt}$ animals developed lymphomas within a significantly shorter latency than Nipa$^{+/+}$EμMyc$^{TG/wt}$ animals. Furthermore, lymphomas of knockout animals were more aggressive. FACS- and biochemical-analyses showed no gross differences between Nipa$^{-/-}$ and wt lymphomas except highly elevated Arf-p19 levels in Nipa$^{-/-}$ lymphomas, pointing to an important role of Nipa in Myc-p19-signalling.
Summary / Conclusion: Taken together our results highlight the functional importance of the Nipa-p53-axis in cell cycle regulation and suggest that deregulation of the protein provides a substantial contribution during the process of tumorigenesis.

P296

INFLUENCE OF THE B-CELL RECEPTOR (BCR) SIGNALING PATHWAYS ON CD20 LEVELS IN TUMOR CELLS AND ANTITUMOR ACTIVITY OF ANTI-CD20 MONOCLONAL ANTIBODIES

M Winiarska[1,*] K Bojarczuk[1], M Wanczyk[1], M Dwojak[1], P Zapala[1], N Miazek[1], M Siernicka[1], J Golab[1]
[1]Department of Immunology, The Medical University of Warsaw, Warsaw, Poland

Background: Anti-CD20 monoclonal antibodies (mAbs) are widely used in the treatment of non-Hodgkin's lymphomas (NHL) and chronic lymphocytic leukemia (CLL). Combining new agents with already used anti-CD20 mAbs seems to be a reasonable approach to further improve current therapeutic options. It seems that signaling via the aberrantly activated B-cell receptor (BCR) plays a key role in the pathogenesis of B-cell tumors. Blocking BCR signaling complex network holds a great therapeutic potential in both NHL and CLL. Several trials are currently being conducted to investigate the effects of combination of BCR- targeting agents with anti-CD20 mAbs. To improve these therapeutic approaches it is utterly important to decipher actual mechanisms of interactions between BCR-targeted therapies and anti-CD20 mAbs in established *in vitro* models.

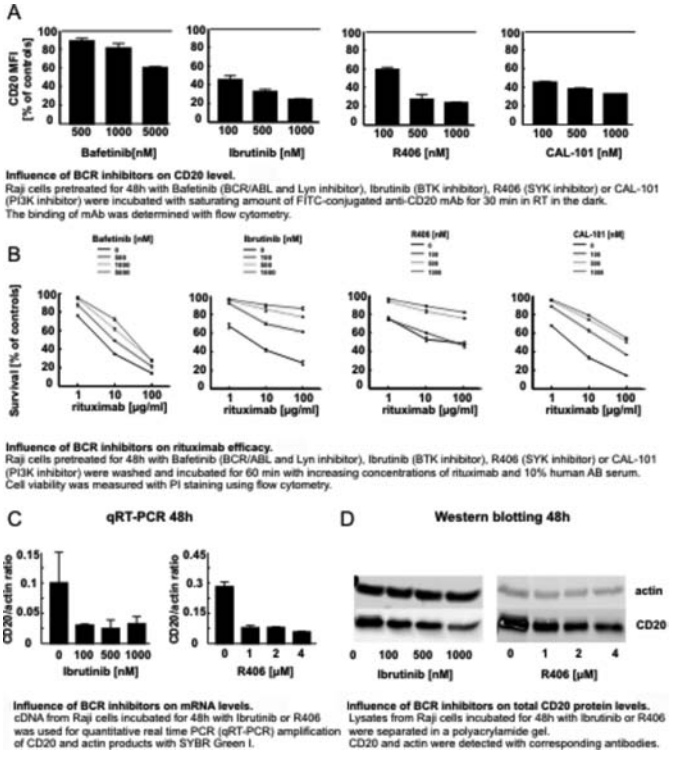

Figure 1.

Aims: The aim of this study is to elucidate the role of BCR signaling pathways in the regulation of CD20 levels in tumor cells and antitumor activity of anti-CD20 mAbs.
Methods: The project is realized fully in *in vitro* settings in the models of human lymphoma cells as well as primary cells from patients with B-cell tumors. Cells are pre-incubated for 48h with inhibitors of BCR signaling (SYK, BTK, PLC, PKC, PI3K, AKT) and subsequently tested using flow cytometry for their contribution to antitumor effect of anti-CD20 mAbs (Figure 1B). Membrane level of CD20 antigen is assessed with FITC-conjugated anti-CD20 antibody staining (Figure1A), total level of CD20 protein is assessed in Western blotting (Figure 1D). Transcription processes are monitored with quantitative real time PCR (qRT-PCR) (Figure 1C), ChIP and EMSA. Moreover, stably transduced lymphoma cells with silenced or overexpressed proteins of interest are employed.
Results: The results of our preliminary experiments show that blocking BCR network at many stages of the signaling cascade with specific chemical inhibitors or selective shRNA-mediated silencing of SYK or BTK results in considerable down-regulation of CD20 level as determined with flow cytometry. Moreover, a 48-hour incubation with BCR inhibitors leads to a substantial impairment of antitumor activity of anti-CD20 mAbs. Selected inhibitors of BCR signaling considerably decrease CD20 protein level in total cellular lysates as analyzed using Western blotting. In Raji cells incubated with selected BCR inhibitors qRT-PCR shows a significant decrease in CD20 mRNA level. The preliminary results from EMSA and ChIP indicate that mRNA decrease is not dependent on CD20 promoter and activity of transcription factors known to regulate CD20 expression. Further studies elucidating the exact mechanisms of the observed phenomena will be performed.
Summary / Conclusion: Blocking BCR complex network on nearly every step of signal initiation and propagation considerably down-regulates CD20 levels what might have extremely important consequences for the anti-cancer therapy that is based on the use of anti-CD20 mAbs. These studies should provide us with extensive knowledge on the biology of CD20 protein and pathways involved in CD20 regulation. In light of our recent experiments therapeutic combinations of BCR inhibitors and anti-CD20 mAbs-based modalities should be rationally and consciously introduced into clinic in optimized therapeutic schemes. We hypothesize that results of our experiments may lead to identification of the most beneficial therapeutic modalities that would improve the quality of life of patients suffering from B-cells originating tumors.

P297

GENETIC VARIATION IN INTERFERON REGULATORY FACTOR 4 AND INTERLEUKIN 10 GENES, AND THE RISK FOR DIFFUSE LARGE B-CELL LYMPHOMA

I Kim[1,*] M Kim[2], E Lee[1], S Kong[3]
[1]Department of laboratory medicine, Pusan National University Hospital, Pusan , [2]Department of internal medicine, Yeungnam University College of Medicine, Daegu, [3]Department of laboratory medicine, National Cancer Center of Korea, Goyang, Korea, Republic Of

Background: Immune alteration is a major risk factor for non-Hodgkin lymphoma (NHL), but the specific immune mechanisms responsible remain unresolved. In a large consortial study, it has been recently reported that an increased risk for NHL, especially the major lymphoma
Aims: We provide a comprehensive analysis of IRF4 and IL10 polymorphisms in a case-control study and risk association with DLBCL in Koreans.
Methods: The case-control series consisted of 192 *de novo* DLBCL treated at five hospitals throughout Korea from August 2001 through August 2009 and 192 individuals from the population with age and gender matched healthy volunteers. The DNA samples were genotyped using matrix-assisted laser desorption/ionization-time of flight mass spectrometry (Sequenom, Inc., San Diego, CA). We genotyped 15 haplotype-tagging SNPs (htSNPs) of IF4 (rs1877175, rs1877179, rs2001508, rs2666957, rs2671422, etc.) and 7 htSNPs of IL10 (rs1518111, rs1800871, rs1800872, rs1800890, rs3021094, rs3024490, rs3790622) genes, respectively. We determined if the allelic distribution of the nine SNPs was consistent with Hardy-Weinberg equilibrium using the □2 test. All the genotype frequencies were in accordance with Hardy-Weinberg equilibrium. The allele and genotype frequencies of these SNPs were compared between the cases and controls using the 2 test or Fisher's exact test. Unconditional logistic regression was done to estimate the odds ratios (OR) and 95% confidence intervals (95% CI) of the individual SNPs. The haplotypes were reconstructed according to the genotyping data and the linkage disequilibrium status of these nine SNPs.
Results: We did not find significant associations between IRF4 htSNPs and the risk of DLBCL. However, the minor allele heterozygotes of the rs3021094 htSNP of IL10 showed an increased risk of DLBCL (adjusted odds ratio = 1.453, P=0.034). On 10-million permutation testing, this haplotype including rs3021094 variant allele was significantly associated with an increased risk of DLBCL (P=0.001).
Summary / Conclusion: This study presents several novel aspects of the genetic susceptibility to develop DLBCL. Our data do not statistically support the association between IRF4 htSNPs and risk for DLBCL. However, we demonstrate that elevated DLBCL risk is associated with the rs3021094 htSNP of IL10. Larger studies that will focus on the role of the rs3021094 htSNP of IL10 for developing DLBCL are needed in the future.

P298

PROGNOSTIC IMPACT OF EZH2 EXPRESSION, H3K27 TRIMETHYLATION AND DNA METHYLATION IN DIFFUSE LARGE B CELL LYMPHOMA

S Lin[1,*] C Tsai[2], S Chuang[3], W Chou[4]
[1]Department of Internal Medicine, devision of oncology and hematology, [2]Department of Anatomical Pathology, Far Eastern Memorial Hospital, New Taipei City, [3]Department of Pathology, Chi Mei Medical Center, Tainan, [4]Department of Internal Medicine, devision of hematology, National Taiwan University Hospital, Taipei City, Taiwan

Background: International Prognostic Index (IPI) score is used to predict the prognosis in diffuse large B cell lymphoma (DLBCL) for around 20 years. However, few molecular prognostic factors were proposed. Overexpression of Enhancer of zeste homolog 2 (EZH2) and decreased histone 3-lysine 27 trimethylation (H3K27me3) are associated with poor prognosis in many cancers. Promoter CpG island hypermethylation of tumor-suppressor genes is a common hallmark of all human cancers. 5-methylcytosine (5-mC) levels in cancer cells can reflect the DNA hypermethylation status and measurement of 5-hydroxymethylcytosine (5-hmC) levels may estimate the DNA demethylation status in cancer cells. A unique EZH2 Tyr 641 somatic mutation was detected in DLBCL and follicular lymphoma. However, the clinical implications of DNA methylation status, DNA hydroxymethylation, EZH2 expression, the extent of H3K27me3 and EZH2 Tyr 641 somatic mutation in DLBCL patients have not been studied in a comprehensive or integrated way.
Aims: We aim to see significant impact of DNA methylation, DNA hydroxymethylation, EZH2 expression levels and mutation status, and H3K27 trimethylation on the clinical and biological presentation of DLBCL.
Methods: We enrolled the 110 DLBCL patients with complete remission (CR) after standard chemotherapy. These patients included 45 consecutive patients in Far Eastern Memorial Hospital and 65 consecutive patients in Chi Mei Medical Center (diagnosed between 2002 and 2009). The demographic data, treatment regimens, and response of disease were reviewed retrospectively. Immunohistochemistry (IHC) was used to examine 5-mC, 5-hmC, EZH2 expression and the extent of H3K27me3 in formalin-fixed, paraffin-embedded biopsy specimens of DLBCL. DNA extraction from the tissues was examined for EZH2 Tyr641 mutation. Statistical analysis was performed with the Stata statistical software (Small Stata, version 11.0, Stata Corp, College Station, TX).
Results: Statistical analysis was performed in 110 CR patients with Rituximab-CHOP (R-CHOP) and CHOP regimen. Totally we recruited 70 male (64%) and 40 female (36%) with a median age 57 years. Sixty-three percent of the patients had stage I/II disease. According to the IPI, 76% of the patients were classified as low/low-intermediate risk (IPI=0-2). Thirty patients received CHOP-like regimen and eighty patients received R-CHOP-like regimen as first-line chemotherapy. The median observation time for overall survival (OS) in the 110 patients was 49 mo. The clinical parameter of IPI score was correlated with OS. None of 48 patients harbored *EZH2* mutation at Tyr641. Low expression 5-mC tended to have lower H3K27me3 expression (P=0.019). And low expression 5-mC tended to have lower 5-hmC expression (P=0.002). There was no obvious relationship between the expression of EZH2 and degree of H3K27me3 in DLBCL tumor cells. There was no significant prognostic impact in single epigenetic marker. Then we subdivide the patients by combination H3K27me3 with 5-hmC. In this new-classification analysis, the high H3K27me3/ low 5-hmC patients were associated with longer OS in univariate (P=0.013) and multivariate analysis (P=0.017).
Summary / Conclusion: High H3K27me3/ low 5-hmC expression was a possible favorable prognostic factor in DLBCL patients with CR after standard chemotherapy. The incidence of *EZH2* mutation at Tyr641 in our cohort is much lower compared with western countries. Low expression 5-mC tended to have lower H3K27me3 expression and low expression 5-mC tended to have lower 5-hmC in DLBCL tumor cells. Our study suggests epigenetic markers may be an informative biomarker for prognosis prediction in DLBCL.

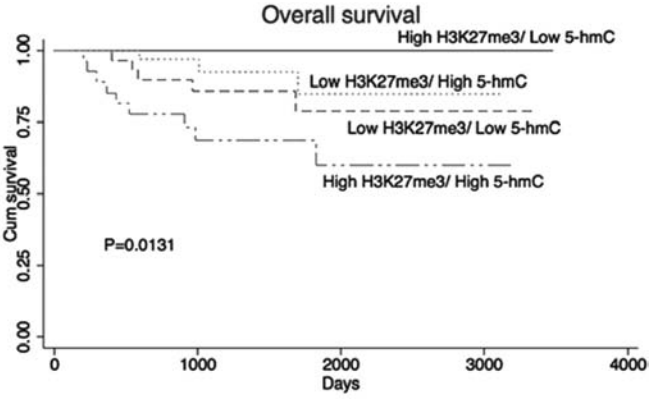

Figure 1.

P299

BMI1 EXERTS ITS ONCOGENIC EFFECTS VIA ENHANCEMENT OF ANTI-APOPTOTIC POTENTIAL IN MANTLE CELL LYMPHOMA

K Teshima[1],* M Nara[1], A Watanabe[1], M Ito[1], S Ikeda[1], N Takahashi[1], K Oshima[2], M Seto[3], K Sawada[1], H Tagawa[1]
[1]Department of Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, Akita, [2]Department of Pathology, Kurume University, Kurume, [3]Department of Molecular Medicine, Aichi Cancer Center Research Institute, Nagoya, Japan

Background: Mantle cell lymphoma (MCL) is categorized as an indolent $CD5^+$ B cell lymphoma and is associated with numerous genomic copy number alterations, including 9p21 deletion (*CDKN2A*) and 10p12 amplification (*BMI1*). The target gene of the 10p12 amplification is a proto-oncogene, *BMI1*. Its overexpression is recurrently observed in the blastoid variant of MCL, which suggests *BMI1* may play an important role in MCL tumorigenesis. Deletion of 9p21 is seen in 40-50% of MCL cases and results in dysregulation of the tumor suppressor gene *CDKN2A*, which encodes $p16^{INK4a}$ and $p14^{ARF}$. Earlier studies have shown that *BMI1*/Bmi1 exerts its oncogenic effects, at least in part, by silencing the *CDKN2A* tumor suppressor locus, thereby promoting cell cycle progression and suppressing apoptosis. Thus, Bmi1 has been thought to regulate *CDKN2A* in MCL. However, previous report showed that MCL recurrently exhibited both homozygous deletion of 9p21 (*CDKN2A*) and amplification of 10p12 (*BMI1*), suggesting that in that case, *BMI1* regulates other tumor suppressors.
Aims: The aim of this study is to determine the role of *BMI1* in MCL, especially in relapsed cases. And we identify a functional role of apoptotic regulation of *BMI1*.
Methods: We infected MCL cell lines with a robust inducible single-lentiviral vector knockdown reagent, pLKO-Tet-On, encoding either a non-targeting control siRNA or a Bmi1-targeting siRNA (siBMI1). Then using puromycin selection, stable polyclonal lines were generated. Chip assays were performed by use of SimpleCHIP™ Enzymatic Chromatin IP Kit (Cell Signaling Technology) according to manufacturer's protocol.
Results: We first examined *BMI1* expression in primary cases and found that its expression was significantly higher at recurrence than at initial diagnosis. Next, we found that transfection of siBMI1 induced apoptosis despite the absence of *CDKN2A*. Chip assay showed that Bmi1 interacted with pro-apoptotic genes (*BCL2L11*/Bim and *PMAIP1*/Noxa), which were recently shown to be Bmi1 targets. We also found that Bcl2 was up-regulated in MCL.Finally, we found that bortezomib, which is known to be a proteasome inhibitor, induced apoptosis with down-regulation of Bmi1 and up-regulation of Bim and Noxa in MCL.
Summary / Conclusion: We for the first time showed that *BMI1*/Bmi1 is associated with disease progression in MCL. We found that Bmi1 negatively regulates *BCL2L11*/Bim and *PMAIP1*/Noxa to exert an anti-apoptotic effects in MCL cells, which carry homozygous 9p21 (*CDKN2A*) deletions.

P300

THE ROLE OF CXC–CHEMOKINES IL-6, IL-8 AND CXCR2 RECEPTOR IN LYMPHOPLASMACYTIC LYMPHOMA: CORRELATIONS WITH MICROVASCULAR CHARACTERISTICS AND CLINICAL FEATURES

G Levidou[1],* T Tzenou[2], M Kyrtsonis[2], E Nikolaou[2], N Kavantzas[1], D Maltezas[2], K Xirokosta[2], E Koulieris[2], A Sepsa[1], K Bitsanis[2], I Pessach[2], V Bartzis[2], M Dimou[2], P Panayiotidis[2], G Pangalis[2], E Patsouris[1], P Korkolopoulou[1]
[1]Pathology, [2]Haematology Section of the First Department of Propaedeutic Internal Medicine, University of Athens, Medical School, Athens, Greece

Background: Increased neovascularisation is a vital process underlying the development and progression of malignant neoplasms. Limited information on the subject is available for Waldenstrom's macroglobulinaemia/Lymphoplasmacytic lymphoma (WM/LPL), a rare and usually indolent B-cell lymphoma.
Aims: To evaluate the microvessel characteristics and IL-6, IL-8, CXCR2 and VEGF expression in the bone marrow of WM/LPL patients and investigate any possible correlation with disease characteristics and outcome.
Methods: Sixty-three patients were studied (47 WM and 16 LPL) for whom paraffin-embedded tissue from bone marrow trephine biopsies performed at diagnosis, before treatment was available. The microvascular characteristics were evaluated using CD34 stained slides. Microvessel density (MVD), total vascular area (TVA) and several other size- and shape-related parameters were quantified in the region of most intense vascularization using a computerized image analysis software. Moreover, slides were immunostained with IL-8, IL-6, CXCR2 and VEGF and evaluation was performed blindly using light microscopy. A Histo-score (H-score) based on the percentage of stained neoplastic cells multiplied by staining intensity was calculated.
Results: Thirty-two, 25 and 6 patients were classified into low, intermediate and high risk respectively, according to the IPSSWM staging system. Seventy-six percent of the patients required treatment while 24% were asymptomatic and were regularly followed. Median patients' follow-up was 77 months. Microvascular characteristics, i.e microvessel density (MVD), total vascular area (TVA) and several other size- and shape-related parameters, were evaluated in CD34 stained bone marrow slides using computerized image analysis. A Histo-score (H-score) based on the percentage of immunopositive neoplastic cells multiplied by staining intensity was calculated for IL-6, IL-8, CXCR2 and VEGF immunohistochemical expression. MVD ranged from 7 to 393 μm^2 (median 36,5) and TVA from 2681 to 102480 μm^2 (median 32427). IL-6, IL-8, CXCR2 and VEGF expression was observed in 84%, 43%, 89% and 90% respectively. A positive correlation between IL-6 and CXCR2 H-scores was observed; IL-6 and VEGF H-scores correlated with hypoalbulinemia and increased serum β_2-microglobulin respectively and both with bone marrow lymphoplasmacytic infiltration and MVD. The degree of angiogenesis, microvessel shape, VEGF expression and CXCR2 expression correlated with a shorter time to first treatment in multivariate analysis.
Summary / Conclusion: In WM/LPL, increased expression of cytokines implicated in neovascularization and microvessel augmentation confer a more aggressive disease, reflected by an earlier need of treatment.

Non-Hodgkin Lymphoma - Clinical 1

P301

HIV STATUS DOES NOT INFLUENCE THE OUTCOME OF PATIENTS DIAGNOSED WITH DLBCL TREATED WITH R-CHOP IN THE HAART ERA

R Coutinho[1,*] M Flook[2], A Pria[2], S Gandhi[3], K Bailey[4], P Fields[5], K Cwynarski[4], A Wilson[1], F Burns[6], M Tenant-Flowers[7], R Marcus[3], C Orkin[8], J Gribben[1], S Montoto[1], M Bower[2]

[1]Centre for Haemato-Oncology, Barts Cancer Institute, QMUL, [2]Medical Oncology, Chelsea & Westminster Hospital, [3]Haematological Medicine, King's College Hospital, [4]Haematology, Royal Free Hospital, [5]Haematology, Guys and St Thomas Hospital, [6]HIV Medicine, Royal Free Hospital, [7]Sexual Health, King's College Hospital, [8]Infection and Immunity, Barts and The London NHS Trust, London, United Kingdom

Background: The prognosis of patients with HIV and Diffuse Large B-cell Lymphoma (DLBCL) has improved considerably since the advent of HAART, approaching that of patients with DLBCL in the general population when treated with the same chemotherapy regimens.
Aims: To analyze the outcome of patients diagnosed with DLBCL treated with R-CHOP in the HAART era according to HIV status.
Methods: From 2003 to June 2011, 294 patients were newly diagnosed with DLBCL at 5 university hospitals in London and treated with R-CHOP chemotherapy. The cohort comprised 208 HIV negative (HIV-) patients from St Bartholomew's Hospital and 86 HIV positive (HIV+) patients from that hospital and 4 other London Hospitals. In the same study period, a further 90 patients (48 with HIV infection) were diagnosed with DLBCL and offered different regimens (R-CODOX M-IVAC: 22 HIV+/20 HIV-). CNS prophylaxis was given according to each centre policy. Clinical features according to HIV status were compared using chi-square or Fisher's exact test. Survival analysis was performed using the Kaplan-Meier method and log-rank test. Multivariate analysis was done using the Cox regression proportional hazards model.
Results: Patients characteristics according to HIV status are shown in Table 1. HIV+ patients had significantly more B-symptoms and had more extranodal sites of disease at diagnosis, with more common involvement of the gastrointestinal tract, lung and spleen than HIV- controls. Central nervous system involvement was rare and similar between groups. The proportion of patients with high risk disease according to the International Prognostic Index was similar between groups. The HIV viral load (VL) was undetectable at the time of DLBCL diagnosis in 25 of 82 (30%) patients with available data. Forty-seven patients (57%) had a CD4 count <200/mL and 15% a CD4 count <50/mL. The majority (80/86; 93%) of patients with HIV infection received HAART concomitantly during chemotherapy. Response rate and median duration of response were similar for both cohorts. After a median follow-up of 45 months, 30 patients relapsed after achieving CR, including four HIV+ patients. Ninety-five patients have died (18 HIV+ patients), 72 of them due to DLBCL. Four patients (2 HIV+ and 2 HIV-) died due to treatment toxicity. Survival was similar with 2-year event-free survival (EFS) of 65% (95%CI: 56–72) for HIV+ and 59% (95%CI: 46–69) for HIV- cohort (P=NS). Five-year overall survival (OS) was 88% (95%CI: 80–92) and 79% (95%CI: 67–87) for HIV+ and HIV- patients respectively (P=0.05). HIV status did not predict OS or EFS on multivariate analysis including all variables comprising the IPI and HIV status.
Summary / Conclusion: In this retrospective study, patients diagnosed with DLBCL in the setting of HIV infection have more systemic symptoms and extranodal involvement. However this did not translate in a larger proportion of patients with high risk disease according to the IPI. HIV status does not influence the outcome of patients diagnosed with DLBCL treated with R-CHOP in the HAART era.

Table 1. Clinical characteristics of the patients included in the study.

	HIV+ (n= 86) No.(%)	HIV- (n= 208) No.(%)	p
Male	69 (80)	119 (57)	<0,001
Age, y (median, range)	48 (20 – 67)	64 (17 – 91)

P302

ALLOGENEIC-STEM CELL TRANSPLANTATION UPFRONT IN THE TREATMENT OF PATIENTS WITH ADVANCED T-CELL LYMPHOMA: AN INTENTION-TO-TREAT ANALYSIS FROM A SINGLE INSTITUTION.

M Loirat[1,*] P Chevallier[1], C Leux[1], A Moreau[2], T Guillaume[1], T Gastinne[1], J Delaunay[1], N Blin[1], B Mahé[1], V Dubruille[1], K Augel-Meunier[1], P Peterlin[1], H Maisonneuve[3], N Juge-Morineau[4], H Jardel[5], P Moreau[1], M Mohty[6], S Le Gouill[1]

[1]hematology, [2]anatomopathology, Nantes University Hospital, Nantes, [3]hematology, La Roche Sur Yon Hospital center, La Roche Sur Yon, [4]hematology, Clinical Center, Catherine de Sienne, Nantes, [5]hematology, Vannes hospital center, Vannes, [6]Hospital center Saint Antoine, Paris, France

Background: Non-cutaneous T-cell lymphomas (TCL) have a dismal outcome (except for ALK + anaplastic T-cell lymphoma) compared to B-cell lymphomas. Polychemotherapy regimens like CHOP remain standard of care but usually fail to cure most patients. Autologous stem cell transplantation (ASCT) upfront has been evaluated in several retrospective and few prospective studies. Results are heterogeneous and not comparable from one study to another. Experience regarding allogeneic-stem cell transplantation (allo-SCT) in TCL is still sparse. Allo-SCT is often, if not always, proposed as a salvage option for heavily pretreated relapsed or refractory patients. Thus, its role in the therapeutic arsenal of TCL remains to be established. However, a previous large study suggested that allo-SCT can cure relapsed/refractory patients (Le Gouill *et al*, JCO 2008).
Aims: We initiated a single centre homogenous and pre-defined treatment algorithm addressing the role of allo-SCT upfront for patients with advanced TCL. All patients aged <70 y. (except alk + ALTC) with stage >I disease at time of diagnosis that were referred to our institution were systematically planned to receive CHOP or CHOP-like induction chemotherapy followed by allo-SCT upfront from an HLA-matched related or unrelated donor or cord blood cells (CBU).
Methods: From November 2004 to December 2012, 49 patients met these criteria. Diagnosis were PTCL-NOS in 33 cases, AITL in 4 cases, Alk neg ALTCL in 7 cases; T/gd lymphoma in 2 cases or other entities in 3 cases. Median age at diagnosis was 50y (range, 29-67y). Thirty-one patients were males. IPI score was >or= to 2 in 35 cases, while 20 patients presented with at least two extranodal localizations. An HLA-matched donor (sibling in 15 cases, unrelated in 17 cases or suitable CBU units (n=7)) could be found for 39 patients. Overall, 15 patients (20%) reached CR and 25 patients (50%) reached PR. Eighteen patients had to receive salvage chemotherapy (high-dose aracytine in 8 cases; pentostatin in 4 cases and other in 6 cases). After salvage chemotherapy, two patients reached CR and 8 reached PR. Among these patients, 7 could proceed to allo-SCT. In all, 29 patients (60%) out of the total 49 patients proceeded to allo-SCT (mainly using a reduced-intensity conditioning regimen). 20 patients did not proceed to allo-SCT because of progressive disease (n=13), absence of matched donor (n=3), unfit patients with comorbidities (n=3) or patient refusal (n=1). Disease status prior to allo-SCT was CR1 in 12 cases and PR1 in 17 cases. Of note, three patients underwent ASCT prior allo-SCT because graft was not available on time.
Results: In the whole series of 49 patients, median follow-up (mFU) was 16.3 months. 1 and 2 years-PFS rates calculated from diagnosis were 56 % (CI95%; 43.6-71.5) and 51.3% (CI95%; 39-67.5), respectively. One and 2-years-OS were 60 % (CI95%; 47.7-75.2) and 50.3 % (CI95%; 40.6-69.2), respectively. For allo-SCT patients (n=29), 1- and 2y-PFS calculated from time of allo-SCT (mFU= 32.2 months) were 64.7% (CI 95%; 49.2-85.0) and 60.4 % (CI95%; 44.5-81.9); 1- and 2y-OS were 71.6 (CI95%; 56.7-90.4) % and 71.6 (CI95%; 56.7-90.4), respectively. Nine transplanted patients (including 2 patients in CR at time of allo-SCT) patients died. Causes of death were: disease progression (n=6) or toxicity (n=3). TRM at 1 year was 8.2% (CI95%; 0-18.5). In the non-transplanted group (n=20), only 6 patients are still alive.
Summary / Conclusion: In conclusion, the current series suggests that allo-SCT is feasible with low toxicity rate when performed upfront in responder patients and it can provide long term disease control. However, the intention-to-treat analysis suggests that only 60% of patients that were planned to undergo allo-SCT at diagnosis could be actually transplanted. Absence of response after induction chemotherapy was the major reason for patients not undergoing allo-SCT, underlining the urgent need for new therapeutic options to increase response rates in this yet incurable disease.

P303

INTRATHECAL METHOTREXATE IS NOT EFFECTIVE IN PREVENTING CENTRAL NERVOUS SYSTEM RELAPSE IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH R-CHOP

N Tomita[1,*] H Takasaki[2], Y Ishiyama[1], K Kishimoto[3], D Ishibashi[4], S Koyama[5], Y Ishii[1], H Takahashi[2], A Numata[3], R Watanabe[2], T Tachibana[3], R Ohshima[6], M Hagihara[1], C Hashimoto[7], S Takemura[6], J Taguchi[5], K Fujimaki[6], R Sakai[2], S Motomura[2], Y Ishigatsubo[1]

[1]Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Medical Oncology, Kanagawa Cancer Center, [3]Hematology, Yokohama City University Medical Center, Yokohama, [4]Hematology, Yokosuka City Hospital, Yokosuka, [5]Hematology, Shizuoka Red Cross Hospital, Shizuoka, [6]Hamatology/Immunology, Fujisawa City Hospital, Fujisawa, [7]Hematology, Yamato City Hospital, Yamato, Japan

Background: Central nervous system (CNS) relapse is a serious complication of diffuse large B-cell lymphoma (DLBCL), occurring in approximately 5% of patients. Rituximab (R) does not strongly penetrate the blood-brain barrier, and therefore, CNS relapse continues to be of great concern even in an era when R is routinely administered.
Aims: To evaluate the extent to which CNS prophylaxis is achievable using intrathecal methotrexate (IT-MTX) in DLBCL patients.
Methods: A total of 362 patients with newly diagnosed DLBCL received 6 cycles (maximum 8 cycles) of full-dose R-CHOP therapy between 2003 and 2009. Of these patients, 322 who achieved complete remission (CR) were enrolled in this study. Patients more than 70 years old with an Eastern Cooperative Oncology Group performance status (PS) greater than 1 were excluded if they were treated with a reduced dose but were included if they were treated with full-dose R-CHOP, at the discretion of the attending physician. Reduction of the initial therapy dose by more than 20% because of a major comorbidity was also an exclusion criterion. CNS prophylaxis was consisted of 4 doses of 15mg/body IT-MTX with 25 mg hydrocortisone administered once CR was achieved. In general, CNS prophylaxis was administered to patients with at least one of the following factors at presentation: 1) a lactate dehydrogenase (LDH) level equal to or more than twice the upper normal limit; 2) the presence of a bulky mass of at least 10cm in diameter; 3) a PS of more than 1; or involvement of the 4) bone marrow, 5) skin, 6) testicles, 7) nasal/paranasal tissue, 8) bone, 9) or breast. Although CNS prophylaxis was generally performed only for patients aged less than 70 years received prophylaxis at the discretion of the attending physician. CNS relapse was defined as the detection of malignant cells in cytocentrifuged preparations of cerebrospinal fluid or intracranial mass on computed tomography or magnetic resonance imaging.
Results: The median age of the 322 patients (male, 188: female, 134) was 64 years (range, 18-80 years). The median follow-up time was 61 months. Forty patients (12%) received CNS prophylaxis (group A) and the remaining 282 patients (88%) did not (group B). CNS relapse during the first complete remission (1CR) was noted in 3 patients in group A (8%) and in 8 patients in group B (4%) although this difference was not statistically significant. The median time between the initiation of R-CHOP and the CNS relapse was 8.2 months (range, 3.5-34.0 months). The cumulative incidence of CNS relapse was 3.6% at 3 years. The 3-year survival rate of the 11 patients with CNS relapse during 1CR was 62%. CNS relapse was of the parenchymal type in 2 patients and of the combined (leptomeningeal and parenchymal) type in 1 patient in group A and of the leptomeningeal type in 1 patient, of the parenchymal type in 5 patients, and of the combined type in 2 patients in group B. In subgroup analyses of patients with each risk factor for CNS relapse described above the incidence of CNS relapse was not statistically different between groups A and B. Furthermore, in subgroup analyses of patients with advanced stage disease, high/high-intermediate risk as defined by the International Prognostic Index, an elevated LDH level, and involvement of at least 2 extranodal sites, the incidence of CNS relapse was not statistically different between groups A and B.
Summary / Conclusion: In DLBCL patients treated with R-CHOP, IT-MTX administration was not an effective prophylaxis for CNS relapse. Alternative strategies such as intravenous MTX should be evaluated because most CNS relapses were of the parenchymal type.

P304

R-CHOP21 VS R-CHOP14 IN 1024 DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: RESULTS FROM A MULTICENTRE RETROSPECTIVE STUDY OF FONDAZIONE ITALIANA LINFOMI (FIL)

Background: Diffuse large B cell lymphoma (DLBCL) is the most common histotype of non-Hodgkin's lymphoma. R-CHOP21 (C21) is considered the standard therapy but a large number of studies tested the dose dense regimen R-CHOP14 (C14).
Aims: The aim of our multicenter retrospective study was to evaluate the efficacy in terms of Overall Survival (OS) and Progression free survival (PFS) of the two regimens C21 and C14 in a large cohort of patients (pts) with a diagnosis of DLBCL or follicular grade IIIb lymphoma, treated with curative intent.
Methods: Patients diagnosed between January 2002 to December 2011 were considered for the study: 1024 pts were collected in thirteen Italian Haematoloy Departments, all pts included in the analysis were treated consecutively over a period of time decided by each centre.
Results: 702 were treated with C21 and 322 were treated with C14. The two cohorts of pts were balanced for all clinical characteristics excepted for age higher than 60 years (66% in C21 vs 37% in C14 (P 0.000)), high-intermediate and high risk IPI (33% C21 vs 28% C14; P 0.01). All pts in C14 used primary prophylaxis with G-CSF, and patients treated with C21 used G-CSF as secondary prophylaxis. After induction therapy 817 pts (80%) obtained a complete remission: 553/702 (79%) after C21 and 264/322 (82%) after C14. After a median period of observation of 36 months 101 pts out of 817 CR pts relapsed, 69/553 (12,4%) in the C21 arm and 32/264 (12.1%) in the C14 arm. OS at 3 years was 81% in C21 and 85% in C14 (P:0.1); PFS was 70% in C21 and 72% in C14 (P:0.4). Univariate statistical analysis showed that OS was significantly superior in younger pts (<60 year), Ann Arbor stage I-II, absence of B-symptoms, no bulky disease, negative bone marrow biopsy, low and low-intermediate risk IPI; PFS was significantly superior for the same characteristics. Multivariate analysis showed that OS was affected by age (P .002) and IPI (P .0000) and PFS by stage (P .002) and IPI (P .0000). The results of univariate analysis performed stratifying for therapy shown that C14 is able to overcome some negative prognostic factors as symptoms and bulky disease at diagnosis. No differences in haematological or extra-haematological toxicities were observed in the two arms; four deaths for sepsis were observed (1 in C14 and 3 in C21).
Summary / Conclusion: Our results confirm that C14 does not improve either OS or PFS in comparison with standard C21 in the whole lymphoma population analysed. However, we observed in univariate analysis that the intensified therapy reduced the prognostic impact on OS of some important factors such as symptoms and bulky disease in comparison with standard C21, suggesting that C14 could be useful in a subset of pts. Due to the retrospective nature of this study these results should be confirmed in prospective multicentre studies.

P305

SINGLE-AGENT LENALIDOMIDE IN RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA: A COMBINED ANALYSIS FROM THE MCL-001, NHL-002, AND NHL-003 STUDIES

T Witzig[1,*] J Vose[2], P Zinzani[3], T Habermann[1], J Tuscano[4], R Sinha[5], M Williams[6], J Drach[7], R Ramchandren[8], S Besisik[9], L Zhang[10], S Cicero[10], T Fu[10], A Goy[11]

[1]Mayo Clinic, Rochester, [2]Nebraska Medical Center, Omaha, United States, [3]Institute of Hematology "Seràgnoli", University of Bologna, Bologna, Italy, [4]UC Davis Cancer Center, Sacramento, [5]Emory University Winship Cancer Institute, Atlanta, [6]University of Virginia Health System, Charlottesville, United States, [7]Medical University of Vienna, Oncology, Vienna, Austria, [8]Karmanos Cancer Institute, Detroit, United States, [9]Istanbul University Faculty of Medicine, Istanbul, Turkey, [10]Celgene Corporation, Summit, [11]John Theurer Cancer Center at HUMC, Hackensack, United States

Background: Mantle cell lymphoma (MCL) patients (pts) with relapsed/refractory disease have a poor overall prognosis and limited treatment options following bortezomib. Lenalidomide is an immunomodulatory agent with consistent clinical activity and a predictable safety profile, as shown in multiple phase II studies of relapsed/refractory pts with aggressive non-Hodgkin lymphoma, including MCL following bortezomib treatment.

Aims: Evaluate the combined efficacy and safety of single-agent lenalidomide in pts with relapsed/refractory MCL from 3 phase II studies: MCL-001 (n=134), NHL-002 (n=15), and NHL-003 (n=57).
Methods: Lenalidomide was given at 25 mg/day PO on days 1-21 of each 28-day cycle in pts with relapsed/refractory MCL as tolerated for 52 weeks (NHL-002) or until disease progression (NHL-003 and MCL-001). Efficacy data were examined by investigators for NHL-002 and independent central review for MCL-001 and NHL-003 studies.
Results: Relapsed/refractory MCL pts (N=206) had a median age of 67 years (range 33-84); 63% were ≥65 years, and 91% had stage III/IV disease. Pts received a median of 4 prior therapies (range, 1-13); 51% received ≥4 prior regimens and 76% had prior bortezomib. The efficacy data across studies are shown on Table 1: ORR was 32% (10% CR/CRu), median TTR of 2.1 months, and median DOR 16.6 months (not reached for CR/CRu pts at 38.9+ months). Kaplan-Meier estimates showed a median PFS of 5.4 months and OS of 23.9 months. The mean daily dose of lenalidomide was 21 mg. The most common grade 3/4 adverse events (AEs) were 44% neutropenia, 29% thrombocytopenia, 11% anemia, 7% fatigue. Other any-grade AEs included 7% tumor flare reaction, 7% venous thromboembolic events, and 3% invasive second primary malignancies. Lenalidomide treatment provided a consistent ORR across all subgroups except in patients with high LDH.
Summary / Conclusion: Relapsed/refractory MCL pts showed a consistent and predictable safety profile among 3 phase II studies of single-agent lenalidomide. The response to lenalidomide was rapid and durable in heavily pretreated pts, including pts who received prior bortezomib.

Table 1. Efficacy of lenalidomide in relapsed/refractory MCL.

Efficacy outcomes	(N=206)
ORR, % (95% CI)	32 (25-38)
CR/CRu, % (95% CI)	10 (6-15)
Median TTR, mo (95% CI)	2.1 (1.6-24.2)
Median DOR, mo (95% CI)	16.6 (9.2-32.4)
Median PFS, mo (95% CI)	5.4 (3.7-6.7)
Median OS, mo (95% CI)	23.9 (19.0-34.9)

CR/CRu, complete response/CR unconfirmed; DOR, duration of response; ORR, overall response rate; OS, overall survival; PFS, progression-free survival; TTR, time to response.

P306

PHARMACOKINETIC/PHARMACODYNAMIC MODELING OF THE BISPECIFIC T-CELL ENGAGER ANTIBODY BLINATUMOMAB IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

Y Hijazi[1,*] M Klinger[1], A Schub[1], B Wu[2], M Zhu[2], P Kufer[1], A Wolf[1], D Nagorsen[3]
[1]Amgen Research (Munich) GmbH, Munich, Germany, [2]Pharmacokinetics & Drug Metabolism, [3]Clinical Development, Amgen Inc., Thousand Oaks, United States

Background: Blinatumomab (AMG 103) is a novel, anti-CD19/anti-CD3 bispecific, T-cell engager (BiTE®) antibody that redirects T-cells to $CD19^+$ B-cells, resulting in target-specific B-cell lysis.
Aims: Using a pharmacokinetic/pharmacodynamic (PK/PD) modeling approach, we evaluated the exposure-response relationship in patients with non-Hodgkin's lymphoma (NHL) who received blinatumomab in a phase 1 study.
Methods: Patients (N=76) with NHL received blinatumomab by continuous intravenous (cIV) infusion at doses ranging from 0.5−90 $\mu g/m^2$/d in 4- or 8-week cycles. All patients provided written informed consent. PK parameters of blinatumomab were determined. Pharmacodynamic responses during blinatumomab treatment included peripheral B- and T-lymphocyte counts, serum cytokine levels, and sum of the products of the greatest diameters of tumor size in lymph nodes (SPD) at the end of treatment. Blinatumomab concentration in the serum at steady state (C_{ss}) and the cumulative area under the concentration–time curve (AUC_{cum}) over the period before the evaluation of SPD were used to determine the exposure-SPD relationship.
Results: Blinatumomab exhibited linear pharmacokinetics at the doses tested. The early pharmacodynamic response to blinatumomab was characterized by B-cell depletion, T-cell redistribution, and transient cytokine release. Following cIV infusion at doses from 0.5−90 $\mu g/m^2$/d, B-cells declined at a first-order rate with a dose-dependent rate constant ranging from 0.16−1.0 h^{-1}, resulting in complete B-cell depletion within 48 hours at doses ≥5 $\mu g/m^2$/d. T-cell counts decreased in a dose-independent manner within 24 hours of initiation of infusion, completely returning to baseline within 2 weeks. Cytokine elevation of greater frequency and magnitude was observed only in some patients who received higher blinatumomab doses. Cytokine elevation was transient and levels were highly variable across patients but diminished within 48 hours after start of infusion. The blinatumomab exposure-SPD relationship was best described by an inhibitory E_{max} model ($E = E_0-(I_{max}*C)/(IC_{50}+C)$). According to the model estimation, a C_{ss} of 2141 pg/mL and AUC_{cum} of 1381 μg· h/L would result in a 50% reduction in SPD. These exposure levels could be achieved with a blinatumomab dose of 54 $\mu g/m^2$/d administered over 4 weeks.
Summary / Conclusion: Blinatumomab doses ≥5 $\mu g/m^2$/d completely depleted B lymphocytes from the circulation, with a depletion rate proportional to the dose. Blinatumomab C_{ss} and AUC_{cum} were correlated with tumor reduction. Tissue accessibility and tumor microenvironment may explain why higher doses and a longer time were required for tumor reduction, compared with peripheral B-cell depletion. This PK/PD model can be used to inform dose selection for future studies of blinatumomab in NHL.

P307

INFERIOR OUTCOME OF ELDERLY DLBCL PTS WITH 25-OH VITAMIN D DEFICIENCY TREATED WITH CHOP PLUS RITUXIMAB: RESULTS OF THE RICOVER-60 TRIAL OF THE GERMAN HIGH-GRADE NON-HODGKIN LYMPHOMA STUDY GROUP DSHNHL

J Bittenbring[1,*] M Achenbach[1], B Altmann[2], M Ziepert[2], J Reichrath[3], J Geisel[4], E Regitz[1], N Murawski[1], C Zwick[1], G Held[1], M Pfreundschuh[1]
[1]Internal Medicine I, Saarland University Medical School, Homburg, [2]IMISE, University of Leipzig, Leipzig, [3]Dermatology, [4]Central Laboratory, Saarland University Medical School, Homburg, Germany

Background: Vitamin D deficiency was shown to be is associated with a worse outcome in patients with non-Hodgkin's lymphoma (Drake *et al*., 2010).
Aims: To study whether this observation could be confirmed in patients with aggressive B-cell lymphomas treated uniformly within a prospective trial, we analyzed 25-OH vitamin D serum levels in patients treated within the RICOVER-60 trial of the DSHNHL.
Methods: 25-OH Vitamin D serum levels were determined with a commercial chemoluminescence immunoassay in the serum from elderly patients of the RICOVER-60 trial which compared 6 or 8 cycles of CHOP, both with and without rituximab.
Results: 193 of 359 pts (53.8%) had vitamin D deficiency (<10 ng/mL) and 165/359 patients (46.0%) had vitamin D insufficiency (10-30 ng/ml) according to current definitions. When treated with R-CHOP, patients with vitamin D levels ≤8 ng/ml had a 3-year EFS of 59% compared to 79% of patients with vitamin D serum levels >8 ng/ml; the respective figures for 3-year overall survival were 70% and 82%, respectively. In R-CHOP pts these differences were significant in a multivariable analysis adjusting for IPI risk factors with a hazard ratio (HR) of 2.1 (P=0.008) for EFS and a HR of 1.9 (P=0.040) for OS. In pts treated without R effects of vitamin D deficiency were significant only for OS (HR 1.8; P=0.025), but not with respect to EFS (HR 1.2; P=0.388). These results were confirmed in an independent validation set of 63 patients treated within the prospective RICOVER-noRx study.
Summary / Conclusion: Vitamin D deficiency is with a significantly worse outcome of patients with DLBCL treated with R-CHOP. The stronger adverse effect of vitamin D deficiency in patients receiving rituximab suggests that vitamin D deficiency interferes with the mechanisms of action of this antibody. A prospective study evaluating the effects of vitamin D substitution on outcome of patients receiving R-CHOP is warranted.

SUBCUTANEOUS RITUXIMAB AND CHEMOTHERAPY ACHIEVES SIMILAR TROUGH LEVELS, SAFETY, AND RESPONSE AS INTRAVENOUS RITUXIMAB IN FIRST-LINE FOLLICULAR LYMPHOMA: STAGE 1 RESULTS OF THE PHASE 3 SABRINA STUDY

A Davies[1,*] F Merli[2], B Mihaljević[3], N Siritanaratkul[4], P Solal-Céligny[5], A Boehnke[6], C Berge[6], C McIntyre[7], M Barrett[7], D MacDonald[8]
[1]Cancer Research UK Centre , University of Southampton, Southampton, United Kingdom, [2]Hematology Unit, Azienda Ospedaliera Santa Maria Nuova, Reggio Emilia, Italy, [3]Clinic of Hematology, Clinical Center Serbia School of Medicine, Belgrade, Serbia, [4]Division of Hematology, Department of Medicine, Siriraj Hospital, Bangkok, Thailand, [5]Centre Jean Bernard, Le Mans, France, [6]Clinical Development, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [7]Clinical Pharmacology, Roche Products Ltd, Welwyn Garden City, United Kingdom, [8]QEII Health Sciences Centre, Halifax, Canada

Background: Rituximab (R) plus chemotherapy induction followed by maintenance R is the backbone therapy for follicular lymphoma (FL). Intravenous R (R^{IV}) administration time and patient convenience could be improved by the development of a subcutaneous formulation (R^{SC}).
Aims: R^{SC} is expected to have similar efficacy if it achieves non-inferior serum

C_{trough} levels compared with R^{IV}.
Methods: SABRINA (BO22334; NCT01200758) is a 2-stage phase 3 study of R^{SC} or R^{IV} plus chemotherapy (≤8 cycles CHOP [cyclophosphamide, doxorubicin, vincristine, prednisone] or 8 cycles CVP [cyclophosphamide, vincristine, prednisone]) followed by R^{SC} or R^{IV} maintenance in patients with FL. All patients gave informed consent. The stage 1 primary objective was to estimate the mean serum $C_{trough,SC}$:$C_{trough,IV}$ ratio at day 21 of induction cycle 7 for R^{SC} 1400 mg and R^{IV} 375 mg/m^2 given every 3 weeks. The non-inferiority limit was Θ_L=0.8. Here we report stage 1 end-of-induction outcomes.
Results: Patients with previously untreated confirmed CD20-positive grade1,2, or 3a FL (n=127) were randomized to R^{SC} (n=63) or R^{IV} (n=64). Patients were stratified by Follicular Lymphoma International Prognostic Index score, chemotherapy, and region. In each arm, approximately 63% received CHOP and 37% received CVP chemotherapy. R^{IV} was given in the first induction cycle regardless of randomization. At day 21 of induction cycle7, geometric mean serum C_{trough} levels were 134.6 µg/mL for R^{SC} (n=48) and 83.1 µg/mL for R^{IV} (n=54). $C_{trough,SC}$:$C_{trough,IV}$ was 1.62 (90% confidence interval [CI]: 1.36–1.94); SC non-inferiority was demonstrated by the lower limit of the CI exceeding the non-inferiority limit of 0.8. The geometric mean area under the curve (AUC) ratio (AUC_{SC}:AUC_{IV}) was 1.378 [90% CI: 1.241–1.530]. After a median follow-up of approximately 9 months, each arm had similar rates of all-grade adverse events (n=57 [92%] SC; n=57 [88%] IV) and grade 3/4 adverse events (n=29 [47%] SC; n=30 [46%] IV). Neutropenia was the only grade 3/4 adverse event in >10% of patients (26% SC, 22% IV) and was not associated with increased infection rates. Administration-related reactions (ARRs) occurred in 31 (50%) R^{SC} patients and 21 (32%) R^{IV} patients. 1 and 3 patients in the R^{IV} and R^{SC} arms, respectively, had a grade 3 ARR; none had a grade 4 ARR. ARRs (all grades) in ≥5% of R^{SC} and R^{IV} arms were: erythema (8% vs 3%), pruritus (6% vs 3%), chills (3% vs 6%), injection site erythema (10% vs 0%), and vomiting (3% vs 6%). Investigator-assessed overall response rates were 90.5% (95% CI: 80.4–96.4) in R^{SC} patients and 84.4% (95% CI: 73.1–92.2) in R^{IV} patients. Complete response (confirmed/unconfirmed) rates were 46.0% (29/63 patients, 95% CI: 33.4–59.1) for R^{SC} patients and 29.7% (19/64 patients, 95% CI: 18.9–42.4) for R^{IV} patients. Stable and progressive disease rates were similar in each arm. Consistent with the investigator assessment, results of an independent response review indicate that the switch to SC administration does not impair the anti-lymphoma activity of R.
Summary / Conclusion: The observed serum R^{SC} C_{trough} level was non-inferior to the R^{IV} C_{trough} level at day 21 of induction cycle 7. R^{SC} demonstrated comparable investigator-assessed ORR and CR rates, which were in line with those obtained upon independent review. The safety profile was similar. Stage 1 patients are continuing maintenance treatment; stage 2 has begun recruitment. In conclusion, subcutaneous R administration (1400 mg) is feasible, with a safety profile and efficacy similar to those obtained from intravenous administration.

Background: The clinical impact of maintenance treatment after intensive induction immunochemotherapy in diffuse large B-cell lymphoma (DLBCL) is still unclear. Rituximab (R) maintenance was not superior to observation in the ECOG 4494 study (Habermann TM *et al*. J Clin Oncol. 2006;24:3121-7), which was unfortunately not fully powered for this analysis.
Aims: The Austrian Study Group (AGMT) initiated a clinical trial (NHL13, Eudract Nr. 2005-005187-90, http://www.clinicaltrials.gov/ ct2/show/NCT00400478?term=ML+18223&rank=1) to investigate the value of R maintenance in patients with DLBCL and follicular lymphoma grade 3B (FL G3B) in complete or unconfirmed complete remission (CR, CRu) after induction with R-CHOP-like chemotherapy (Figure 1).
Methods: In the NHL13 multicenter, prospective trial 683 previously untreated adult patients with DLBCL (N=662) or FL G3B (N=21) recruited in 27 countries (163 sites) between June 2004 and September 2008 were randomized. Inclusion criteria were DLBCL at all stages in CR or CRu after treatment with 4 to 8 cycles of R-CHOP like therapy. Patients were randomized between R maintenance (375 mg/m^2 every 2 months for 2 years) (N=338) and observation only (N=345). The last patient received R in September 2010. The study was closed after 148 events had been reached in March 2012.
The primary endpoint of this study was event-free survival. Secondary endpoints included progression-free survival and overall survival. Data will be analysed using a Cox regression model.
Results: Both arms were well balanced regarding clinical presentation, sex or prognostic indices at study entry. No major safety signals were seen in 2 planned interim analyses. In the interim analysis in 2010 a significantly higher rate of infections (mainly NCI CTC V 2.0 grade 1 or 2) was noted in female patients in the R arm (P=0.004). Final analysis will be performed in March 2013 and the data will be presented at the meeting.
Summary / Conclusion: The AGMT NHL13 trial should provide a definitive answer to the question whether Rituximab maintenance therapy is beneficial for patients with DLBCL and FL G3B in general or in particular subgroups.

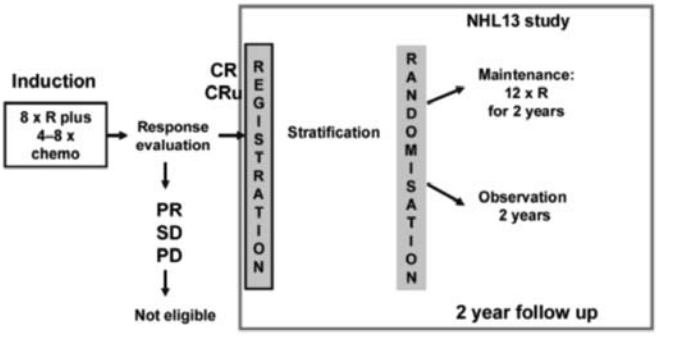

Figure 1. NHL13 Srudy design.

P310

PIXANTRONE MONOTHERAPY IN HISTOLOGICALLY CONFIRMED, RELAPSED OR REFRACTORY AGGRESSIVE B-CELL NON-HODGKIN LYMPHOMA: POST HOC ANALYSIS FROM A PHASE III TRIAL

R Pettengell[1,*] P Theocharous[2], P Cernohous[3], L Wang[3], J Singer[3], H Myint[3]
[1]Department of Haematology, St George's Hospital, [2]CTI Life Sciences, London, United Kingdom, [3]CTI Inc, Seattle, United States

Background: Pixantrone (PIX) is conditionally approved by the European Medicines Agency for the treatment of multiply relapsed or refractory aggressive B-cell NHL, and is the only therapy to be granted approval for these patients. The Phase III EXTEND trial was conducted in patients with aggressive *de novo* or transformed NHL who had previously received ≥2 regimens. Analyzed by ITT, PIX was associated with a higher rate of CR or unconfirmed CR (CRu) compared with physicians' choice of monotherapy (20.0% vs 5.7%, P=0.021) and longer PFS (5.3 vs 2.6 months [Pettengell R *et al*. Lancet Oncol 2012]).
Aims: To evaluate the efficacy of PIX in the subset of EXTEND patients who had aggressive B-cell lymphoma, as confirmed by central independent pathological review (histologically confirmed ITT [HITT] B-cell population). Within this group, we also investigated efficacy in clinically relevant subgroups: those with 2–3 previous regimens (i.e. excluding patients with ≥ 4 previous regimens) and those with and without previous rituximab.
Methods: EXTEND was a Phase III multicenter, open-label randomized trial of PIX (85 mg/m² PIX dimaleate intravenously on days1, 8, and 15 of a 28-day cycle, for up to 6 cycles) vs physicians' choice of monotherapy (vinorelbine, oxaliplatin, ifosfamide, etoposide, mitoxantrone, gemcitabine or rituximab). The primary endpoint was CR or CRu. For this *post-hoc* subgroup analysis, patients with DLBCL, follicular grade III lymphoma or transformed indolent lymphoma were retrospectively identified through consensus of two (three in case of disagreement) independent pathologists.
Results: A total of 140 patients (PIX/comparator; n=70/70), based on the site diagnoses, were randomized into the EXTEND study. In the HITT B-cell population after central independent histological review, (PIX/comparator; n=50/47), mean age was 59.6/55.3 years; 62.0%/51.1% were male; median previous regimens was 3.0/3.0; previous rituximab was recorded in 60.0%/55.3%. Diagnosis was DLBCL in 82.0%/87.2%, transformed indolent lymphoma in 14.0%/10.6%, follicular lymphoma grade III in 4.0%/2.1%. Compared with com-

parator, PIX was associated with significantly higher rates of CR at end of treatment (P=0.027) and at end of study (up to 18 months follow-up, P=0.013) and longer median PFS (Table). In the HITT B-cell population with 2–3 previous regimens, at the end of the study, PIX was associated with significantly higher rates of CR/CRu (P=0.047), CR (P=0.012), ORR (P=0.005) and improvement in PFS (Table 1). In patients with 2–3 prior regimens without prior rituximab (PIX/comparator; n=19/21), PIX was associated with a CR/CRu rate of 15.8% vs 4.8% (not significant, NS) and median PFS was 6.1 vs 3.5 months (HR 0.36, 95% CI 0.18–0.73). In those with prior rituximab, PIX (n=20) and comparator (n=18) led to CR/CRu rate of 30.0% vs 5.6% (NS) and a median PFS of 5.4 vs 2.8 months (HR 0.52, 95% CI 0.26–1.04). In all three subgroup analyses, OS was longer with PIX vs comparator, but did not reach statistical significance.
Summary / Conclusion: Compared with comparator monotherapy, PIX provided significantly improved efficacy (as measured by CR/CRu, ORR, and PFS) in patients with histologically confirmed aggressive B-cell lymphoma treated with 2–3 previous regimens. The results in this subgroup were similar to those in the ITT population.

Table 1.

End of Study	HITT aggressive B-cell (2–9 previous regimens)		HITT aggressive B-cell (2–3 previous regimens)	
	PIX	Comp	PIX	Comp
n	50	47	39	39
CR/CRu, n (%)	9 (18.0)	4 (8.5)	9. (23.1)*	2 (5.1)

P311

SOX11 CAN BE USED AS A MINIMAL RESIDUAL DISEASE MARKER FOR MANTLE CELL LYMPHOMA IN LONGITUDINAL STUDIES

A Simonsen[1],* H Bentzen[1], P Hokland[1], C Nyvold[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus C, Denmark

Background: Mantle cell lymphoma (MCL) is an aggressive subtype of Non-Hodgkin Lymphoma (NHL). It is characterized by the translocation t(11;14)q(13:32) which leads to the over-expression of Cyclin D1 (*CCND1*), although a subgroup of less than 5% does not express *CCND1*. Recent studies have also found the transcription factor *SOX11* to be a possible diagnostic marker for MCL, independent of *CCND1* expression. The advantage of *SOX11* is that it is not expressed in healthy donors, as opposed to *CCND1*, and can therefore be used as a sensitive minimal residual disease (MRD) marker as well as for diagnostic purpose.
Aims: To quantify the *SOX11* expression in a longitudinal study to verify its potential as an MRD marker for MCL using a highly sensitive and specific *SOX11* RT-qPCR assay.
Methods: A *SOX11* specific RT-qPCR assay with a sensitivity of $2x10^{-4}$ has been established without risk of genomic DNA contamination (1) which enables us to use *SOX11* as a molecular marker for detection of MRD in MCL. The *SOX11* expression is reported per 1000 reference genes (RG) copies (RG: *β2M* and *GUS*). The detection limit for *SOX11* was defined to Cq = 40. For *CCND1* the normal limit was defined as 5.5 copies per 1000 RG copies (Hamborg *et al*., Eur J Haem, 2012). In this longitudinal study we followed 16 patients, diagnosed with MCL, during their clinical disease course. The expression of *SOX11* and *CCND1* was quantified in peripheral blood (PB) and bone marrow (BM) and subsequently compared to the clinical status of the patients.
Results: The 16 patients were followed by simultaneous PB and BM sampling together with routine clinical evaluation and CT scan. In our study 15 out of 16 patients were *SOX11* positive in PB at either diagnosis or at relapse contrary to *CCND1* where only 11 out of 16 patients were above the defined normal limit of 5.5 *CCND1* copies per 1000 RG copies as shown in Figure 1A. Data from our study are merged with data from (Hamborg *et al*., Eur J Haem, 2012) and show *SOX11* mRNA level in diagnostic PB (n =44) and BM (n=19) samples, complete remission PB (n=30) and BM (n=22) samples; and relapse PB (n=11) and BM (n=6). We calculated the MRD level based on *SOX11* expression per 1000 RG copies and found a close relationship of *SOX11* expression and clinical status based on routine pathological examination of 16 patients diagnosed with MCL as exemplified in Figure 1B. In general, we saw a tendency for higher expression of *SOX11* in PB compared to BM at diagnosis. This could suggest that PB sampling for MRD monitoring could be used preferably to BM aspiration, which is more extensive and often a painful procedure.
Summary / Conclusion: By using an RT-qPCR assay, specifically targeting *SOX11* mRNA, we found that the over-expression of *SOX11* could be a useful marker for MRD quantification in MCL resembling the clinical status of the patients. This was demonstrated in patients with longitudinal sampling of blood and bone marrow. Furthermore, we postulate that the application of *SOX11* as an MRD marker in MCL could be precious in those cases where *CCND1* is not over-expressed at the time of diagnosis.

CONTRIBUTION OF CEREBROSPINAL FLUID SCD19 LEVELS TO THE DETECTION OF CNS LYMPHOMA: IMPACT ON DISEASE OUTCOME

C Muniz[1], L Martin[1], A Lopez[1], B Sanchez[2], A Salar[2], J Almeida[1], J Sancho[3], J Ribera[3], C Heras[4], F Penalver[5], M Gomez[6], E Gonzalez-Barca[7], N Alonso[8], T Olave[9], F Sala[10], E Conde[11], J Marquez[12], E Cabezudo[13], A Cladera[14], M Garcia-Malo[15], M Dolors Caballero[1], A Orfao[1],*
[1]Department of Medicine, Centro de Investigacion del Cancer (IBMCC CSIC/USAL) and Department of Hematology, University Hospital, IBSAL and University of Salamanca, Salamanca, [2]Hematology, Hospital del Mar, [3]Hematology, ICO-Hospital Germans Trias i Pujol, Barcelona, [4]Hematology, Hospital Infantal Leonor, [5]Hematology, Hospital Fundacion Alcorcon, Madrid, [6]Hematology, University Institute Parc Taulí, [7]Hematology, Hospital Duran i Reynals, Barcelona, [8]Hematology, Hospital of Santiago, Santiago de Compostela, [9]Hematology, Clinic University Hospital, Zaragoza, [10]Hematology, Hospital of Navarra, Pamplona, [11]Hematology, Marques de Valdecilla University Hospital, Santander, [12]Hematology, Hospital Basurto, Bilbao, [13]Hematology, Hospital Fundacion Althaia, Manresa, [14]Hematology, Hospital Son Llatzer, Mallorca, [15]Hematology, Hospital Vega Baja, Alicante, Spain

Background: Flow cytometry (FCM) is more sensitive than conventional cytology (CC) for detection of occult leptomeningeal lymphoma. However, still FCM-negative patients exist which show central nervous system (CNS) recurrence and/or CNS parenchymal disease.
Aims: Here we evaluated the cerebrospinal fluid (CSF) levels of a large panel of B-cell associated markers and its contribution to the diagnosis of CNS lymphoma.
Methods: We investigated the CSF levels of CD19, CD21, CD22, CD24, CD38, CD44, CD72, free light chain (FLC)-kappa, FLC-lambda, IgA, IgG, IgM and b_2-microglobulin in 114 B non-Hodgkin lymphoma (NHL) -92 diffuse large B-cell (DLBCL) and 22 Burkitt lymphomas (BL)- patients at risk of CNS disease who gave their informed consent to participate in the study, and determined their utility as surrogate markers for CNS lymphoma and patient outcome.
Results: From all markers investigated, only CD19 and to a less extent b_2-microglobulin were associated with CNS disease. Higher soluble CD19 (sCD19) CSF levels were associated with a greater frequency of neurological symptoms, parenchymal CNS lymphoma, lymphocytosis, poorer performance status and extra-nodal disease; conversely, sCD19 CSF levels showed no significant association with the degree of involvement of lymph nodes, blood, bone

marrow, liver and the spleen. When combined with occult CNS disease by FCM, sCD19 CSF levels emerged as an independent predictor for event-free and/or overall survival.
Summary / Conclusion: Presence of lymphoma cells by FCM and/or increased sCD19 CSF levels, are highly suggestive of leptomeningeal and/or parenchymal CNS lymphoma and are associated with a poorer event-free and/or overall survival of DLBCL and BL patients at risk of CNS disease.

P313

RITUXIMAB-PECC FOLLOWED BY 90Y-IBRITUMOMAB TIUXETAN CONSOLIDATION IN RELAPSED OR REFRACTORY DLBCL PATIENTS WHO ARE NOT ELIGIBLE FOR OR AFTER ASCT: PRELIMINARY RESULTS FROM A PHASE II HOVON STUDY
P Lugtenburg[1,*] J Zijlstra[2], J Doorduijn[1], L Bohmer[3], M van Marwijk Kooy[4], M Hoogendoorn[5], H Berenschot[6], A Beeker[7], F Valster[8], H Schouten[9], M Luten[10], H Hofwegen[10], D Chitu[10], R Brouwer[11], G van Imhoff[12]
[1]Hematology, Erasmus MC, Rotterdam, [2]Hematology, VU University Medical Centre, Amsterdam, [3]Hematology, Haga Hospital , The Hague, [4]Internal Medicine, Isala Clinic, Zwolle, [5]Hematology, Medical Center Leeuwarden, Leeuwarden, [6]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [7]Internal Medicine, Spaarne Hospital, Hoofddorp, [8]Internal Medicine, Lievensberg Hospital, Bergen op Zoom, [9]Hematology, University Medical Center Maastricht, Maastricht, [10]HOVON Data Center, Erasmus MC, Rotterdam, [11]Internal Medicine, Reinier de Graaf Group Delft, Delft, [12]Hematology, University Medical Center Groningen, Groningen, Netherlands

Background: Patients with relapsed or refractory diffuse large B-cell lymphoma (DLBCL) after- or not eligible for autologous stem cell transplantation (ASCT) have a poor prognosis. The optimum salvage therapy for these patients is not known. Treatment results with second-line chemotherapy have generally been disappointing. In some centers in the Netherlands PECC (Prednisone, Etoposide, Chlorambucil and Lomustine) combination chemotherapy is used as salvage treatment for such patients. PECC is a completely oral schedule. The efficacy and toxicity of PECC in this patient category has not been evaluated systematically before. ^{90}Y-ibritumomab tiuxetan (Zevalin®) showed clinical activity as a single agent in relapsed DLBCL.
Aims: We conducted a prospective multi-center phase II study evaluating induction therapy with Rituximab (R)-PECC followed in responsive patients by ^{90}Y-ibritumomab tiuxetan consolidation.
Methods: Patients aged ≥ 18 years with refractory CD20 positive DLBCL or first or second relapse, more than one year after or not eligible for ASCT, were enrolled. Treatment consisted of R-PECC (Prednisone 40 mg/m^2 po D1-5; Etoposide 100 mg/m^2 po D1-5; Chlorambucil 8 mg/m^2 po D1-5; Lomustine 80 mg/m^2 po D1 and Rituximab 375 mg/m^2 iv D1), every 28 days for 4 cycles. Patients with progressive disease after 2 cycles went off protocol. Patients in complete or partial remission after 4 cycles received consolidation treatment with ^{90}Y-ibritumomab tiuxetan at the standard single dose of 15 MBq/kg (0.4 mCi/kg) 6 to 12 weeks after start of the last R-PECC cycle. Response to treatment was evaluated according to the revised 2007 Cheson criteria.
Results: Between November 2008 and February 2012 62 patients were enrolled. We report data for response and toxicity after the R-PECC induction for all patients. Median age was 70 years (range, 45-82). All patients received CHOP at first-line, 12 without rituximab. Prior therapies consisted of (R)-CHOP (65%), R-CHOP and R-DHAP/VIM (24%) or R-CHOP and R-DHAP/VIM plus ASCT (11%). Fourteen patients (23%) were refractory to the last prior therapy. Progressive disease occurred in 20 patients (32%). Overall response rate (ORR) after R-PECC was 52% (34% CR,18% PR). ORR of relapsed patients vs refractory patients was 64% vs 9%, P=0.099. Median response duration was 7.4 months. One patient died because of therapy related toxicity due to sepsis and pneumonia after the first R-PECC cycle. The most common grade 3 or 4 adverse event was haematological toxicity (47%), followed by infection (18%), malaise (13%) and gastro-intestinal toxicity (8%). Forty-one serious adverse events (SAEs) occurred in 24 patients, Most SAEs were possibly or probably related to therapy (mainly hospitalisations due to infections). Approximately half of the patients (45%) have entered the ^{90}Y-ibritumomab tiuxetan consolidation phase of the study.
Summary / Conclusion: The R-PECC regimen shows good clinical activity in relapsed DLBCL patients. Its activity in refractory patients is low. This largely oral regimen provides patients not eligible for high-dose salvage treatment with a convenient treatment schedule with an acceptable safety profile.

P314

OUTCOME OF CHILDREN WITH MATURE B-CELL LYMPHOMA TREATED ON LMB-96 PROTOCOL; A CCHE REPORT
H Rahman[1,*] E Moussa[2], M Sedky[2], O Hassanein[3]
[1]Pediatric Oncology , National Cancer Institute, [2]Pediatric Oncology , [3]Clinical research, children cancer hospital, Cairo, Egypt

Background: The outcome of childhood non-Hodgkin lymphoma (NHL) has improved steadily, yet the therapy offered in oncology units in low-income countries is usually less aggressive.
Aims: To investigate treatment outcome of newly diagnosed mature B cell NHL patients treated on LMB-96 treatment protocol at the Children's Cancer Hospital Egypt (CCHE).
Methods: Retrospective review of patient charts was performed. Study period was between July 2007 till December 2011, and patients were followed till end of December 2012. All patients were treated with FAB LMB 96 protocol with no dose reduction.
Results: A total of 315 children were included in this retrospective study. They were 74females (23.5%) and 241 males (76.5%). Median age was 5.4 years (ranged 36 days-*18*.0 years). Diagnosis was Burkitt's lymphoma in 249 patients (77.7%), B-Cell ALL (L3) in 44 patients (13.96%), diffuse large B-cell lymphoma in 17 patients (5.39%), mediastinal B cell lymphoma in 3 patients (0.95%), and mature B NHL (NOS) in 2 patients (0.63%). According to the St. Jude stagingsystem, 11 patients (3.5%) had stage I, 92 patients (29.2%) had stage II, 141 patients (44.8%) had stage III, and 71 patients (22.5%) had stage IV. According to the LMB-96 protocol, risk stratification: 24 patients(7.6 %) were group A, 220 patients (69.8 %) group B, 36 patients (11.4 %) group C, while 35 patients were group C CNS positive (11.1%). Out of the 220 group Bpatients evaluated after the COP pre-phase; CR/PR was obtained in 186 patients (84.5 %), while 22 patients (10%) had Stable/Progressive disease. Of the 315 patients included in our study, 57 patients (18.1%) died (52 in active disease, while 5 died in CR). At the end of follow up period, 238 patients were alive in CR (76.3 %), 8 patients (2.5%) were alive but had a resistant disease, and 10 patients (3%) abandoned treatment. With a median FU period of 23.27m (range: 0.984 m- 59 m), overall survival was 81.1%. It was 100% for group A patients, 85.2% for Group B, and 61.8% for Group C patients. Event free survival was 77.5%. It was 100% for Group A, 81.3% for Group B, and 57.9% for Group C.
Summary / Conclusion: LMB-96 treatment protocol has proven to be effective for treatment of Egyptian mature B-cell NHL. Overall survival as well as EFS are comparable to international figures, and toxicity seen is within acceptable standards.

P315

INTERIM POSITRON EMISSION TOMOGRAPHY SCAN PREDICTS EARLY OUTCOMES OF DIFFUSE LARGE B-CELL LYMPHOMA IN THE POST-RITUXIMAB ERA
H Yhim[1,*] N Lee[1], E Song[1], S Jeon[1], C Yim[1], Y Han[2], M Sohn[2], B Lee[3], J Kim[3], Y Ha Park[4], W Choi[4], H Kim[5], J Kwak[1]
[1]Department of Internal Medicine, [2]Department of Nuclear Medicine, Chonbuk National University Hospital, Jeonju, [3]Department of Internal Medicine, [4]Department of Radiology, Catholic University of Korea, Seoul, [5]Department of Nursing, Woosuk University, Wanju, Korea, Republic Of

Background: The role of interim positron emission tomography (PET) scan to predict outcomes remains equivocal. Recently, in an attempt to standardize reporting criteria for interim PET, Deauville five-point scale (5-PS) and the rate of reduction in maximal standardized uptake value (SUVmax) were proposed. However, Deauville 5-PS might still be related to false positive results in some patients and the rate of SUVmax reduction not be suitable for patients with low baseline or high interim SUVmax.
Aims: The aim of this study was to investigate the prognostic value of interim PET assessment combining 5-PS and the rate of SUVmax reduction in patients with diffuse large B-cell lymphoma (DLBCL) treated with R-CHOP.
Methods: Interim PET responses of 132 patients with newly diagnosed DLBCL and treated with R-CHOP were investigated between 2006 and 2011 in two Korean institutions. Interim PET scan was performed after 3 or 4 cycles of R-CHOP, before 1 week of the next cycle. All PET scans were read by 2 nuclear medicine physicians at each institution who were unaware of any subject information. Interim PET response was assessed by 5-PS based on the Deauville criteria and quantitative analysis of FDG uptake changes based on the percentage of SUVmax reduction between initial and interim PET scans. After using the receiver operating characteristics analysis, SUVmax reduction <78.6% was selected as optimal cut-off for positive PET.
Results: The median age was 62 years (range, 15-88) and 85 (64%) were male. 64 patients (49%) were presented as advanced stage disease and 30 (23%) had B symptoms. ECOG performance status was 0 or 1 in 100 (76%) and serum LDH level was elevated in 76 (58%). Thus, 44 (33%) were classified as high-intermediate to high risk of International Prognostic Index (IPI). 123 patients (93%) completed planned R-CHOP±involved-field radiotherapy. Using 5-PS and SUVmax reduction rate, 28 (21%) and 26 patients (20%) were positive on interim PET scan, respectively. 18 patients (14%) showed positive PET in agreement between 5-PS and SUVmax reduction rate. However, 10 (8%) of the 28 PET positive patients on 5-PS showed negative PET based on SUVmax reduction rate. Similarly, 8 (6%) among 26 positive patients on SUVmax reduction rate were negative on 5-PS. Thus, 18 patients showed discordant interim PET results between 5-PS and SUVmax-based assessment. With a median follow-up of 25.3 (range, 5.6-75.5) months, 2-year progression-free survival (PFS) was significantly worse in patients with positive interim PET according to 5-PS (27.4% vs. 88.2%, P<0.001) and SUVmax reduction rate (25.4% vs. 86.6%,

P<0.001) than those with negative results, respectively. Combining both visual and quantitative assessments, 2-year PFS was significantly different according to the point of positive results in each assessment (0 point, 90.4% vs. 1 point, 57.3% vs. 2 point, 9.3%, respectively, P<0.001). In multivariate analysis for PFS, high-intermediate to high risk of IPI (HR, 4.67; 95% CI, 1.96-11.14) and 2 points in the combined assessment of 5-PS and SUVmax reduction rate of interim PET (HR, 7.20; 95% CI, 2.81-18.46) were independent prognostic factors for worse PFS

Summary / Conclusion: Visual and quantitative SUV-based assessments in the interim PET appears to predict early outcomes of patients with DLBCL in the post-rituximab era. Moreover, combined assessments with 5-PS and rate of SUVmax reduction make it possible to more clearly differentiate the clinical outcomes in patients with DLBCL. Further studies are needed to validate our results.

P316

EFFICACY OF NON-PEGYLATED LIPOSOMAL DOXORUBICIN IN ELDERLY PATIENTS WITH AGGRESSIVE B-CELL NON HODGKIN LYMPHOMA: A MULTICENTRIC STUDY

F Loscocco[1,*] A Isidori[1], F Ferrara[2], F Merli[3], F Ilariucci[3], S Falorio[4], F Angrilli[4], G Fioritoni[4], F Alesiani[5], F Pollio[2], M Celentano[2], D Cangini[6], G Musuraca[6], M Catarini[7], G Giglio[8], D Vallisa[9], A Arcari[9], R Paolini[10], B Guiducci[1], T Ricciardi[1], M Rocchi[11], P Picardi[1], G Visani[1]

[1]AORMN, Hematology and Stem Cell transplant Center, Pesaro, [2]Hematology, Napoli, [3]Hematology, Arcispedale Sant'Anna, Reggio Emilia, [4]Hematology, Pescara, [5]Oncohematology, San Severino Marche, [6]IRST, Meldola, [7]Internal Medicine, Macerata, [8]Hematology, Campobasso, [9]Hematology, Piacenza, [10]Oncology, San Donà di Piave, [11]Urbino University, Institute of Biomathematics, Urbino, Italy

Background: Diffuse Large B-cell Lymphoma is predominantly diagnosed in the elderly. However, elderly patients often have a variety of comorbidities and age-related decrease in organ function resulting in worse clinical outcomes related to high rate of adverse events and reduced dose intensity chemotherapy. Nonpegylated liposomal doxorubicin, when substituted for standard formulation in the combination therapy R-CHOP, was found to be with similar efficacy but well tolerated, decreasing anthracycline-related toxicities and early withdraw of chemotherapy.

Aims: We conducted a multicenter, phase II, double-arm trial comparing the efficacy and the safety of 2-weekly and 3-weekly R-COMP regimen.

Methods: Patients with confirmed histological diagnosis of B-cell non-Hodgkin lymphoma, aged≥ 65 years and IPI≥ 1were eligible. The dose-intensity for all patients was established according to a functional assessment of frailty, Activities of Daily Living (ADL). Thirty-nine patients with an ADL=6 were assigned to receive 6 cycles of dose-dense R-COMP14 regimen, whereas 90 patients with an ADL<6 were assigned to receive six cycles of R-COMP21 regimen. The clinical features were comparable in both study arms, without statistical differences.

Results: The median age was 74 years (65-89) at diagnosis and the study included 21 (16%) very elderly patients (≥80 years). The international prognostic index (IPI) score was 4-5 in 12 (31%) patients and in 18 (21%), whereas the Ann Arbor stage was stage III-IV in 27 (69%) and in 67 patients (74%) in the R-COMP14 and R-COMP21 arm, respectively. The Performance status was WHO<2 in 70% of all patients, the median number of comorbidities was 2 (1-7) and the median LVEF was 60% with 16% of patients having LVEF ≤ 50%. The number of cycles administered was 234 in R-COMP14 and 481 in R-COMP21, with the relative dose-intensity for the regimens of 93% and 90%, respectively. Toxicity was mainly hematological in both groups, grade 3/4 neutropenia occurred in 11% and 22% of cycles in the R-COMP 14 and 21 groups and febrile neutropenia of 3% and 8% respectively. Only 8/129 patients (6%) presented a grade II-IV cardiotoxicity. All patients were evaluable for response. With a median follow-up of 24 months the overall response rate (ORR) in R-COMP14 arm was 85%, with complete response (CR) rate of 72%, whereas the ORR in R-COMP21 was 90%, with CR rate of 73%; the event-free survival was 67% and 69 %, respectively. Univariate analysis revealed that event-free survival was negatively impacted by high risk IPI (1-3 vs 4-5; P=0.02). The prognostic factors for shorter overall survival (OS) were: age>70 years (P=0.009), high IPI score (IPI=1-3 vs 4-5; P=0.04), advanced-disease stage III-IV (P=0.01) and impaired WHO performance status 2-3 (P=0.003). Multivariate analysis showed that WHO performance status 2-3 (P=0.02) and age> 70 years (P=0.03) negatively impact the overall survival in both arms.

Summary / Conclusion: The functional assessment of frailty, with Activity of Daily Living (ADL), has allowed to identify really elderly, frail patients. The overlapping ORR and EFS between the dose-dense R-COMP 14 regimen and the standard R-COMP 21 regimen suggest that the use of NPLD may overcome the impact of a dose-dense immunochemotherapy, representing a therapeutic opportunity for frail elderly patients, not suitable for a dose-dense treatment.

Acknowledgements: The study was supported in part by AIL Pesaro Onlus.

Background: R-CHOP is superior to CHOP in PMLBCL. PET-Scan is an accurate method to detect the presence of active disease in diffuse LBCL after R-CHOP, as well as in Hodgkin lymphoma. PET-scan has not been evaluated separately in PMLBCL, where consolidation RT is also debatable. Thus, PET-Scan is used in PMLBCL based on the projection of data derived from Hodgkin and aggressive B-cell lymphomas.

Aims: The evaluation of PET findings in patients with PMLBCL who have responded to R-CHOP, the assessment of their prognostic significance and their impact on the decision for subsequent RT.

Methods: Among 94 consecutive patients with PMLBCL, who were treated in 11 Greek Centers, 71 underwent PET-scan after having responded to R-CHOP (CR, CRu, PR). The remaining 23 patients were not included in the study for the following reasons: documented progressive disease (n=10), PET done after RT (n=5), no PET availability (n=8). The endpoint was Progression Free Survival (PFS), measured from the time of PET examination.

Results: The median post-PET follow-up was 26 months for patients who have not progressed (up to 92). Among 71 evaluable patients, 42 were PET-neg (59%) and 29 (41%) PET-pos. Among 42 PET-neg patients, 24 (57%) did not receive RT and 18 (43%) were irradiated at a median dose of 3480 cGy. Three (3/24) non irradiated patients relapsed (mediastinum and 2 isolated CNS relapses respectively) vs. 0/28 irradiated patients. The 2-year PFS for PET-neg patients who were irradiated or not was 100% vs. 87% (P=0.11). If isolated CNS relapses, which could not be prevented by mediastinal RT, were censored, the corresponding figures were 100% vs. 95% (P=0.34). Among 29 PET-pos patients, 27 (93%) were irradiated at a median dose of 4000 cGy, one was not irradiated and one was forwarded to high dose therapy and autologous transplant: 6/29 patients relapsed (all irradiated). The 2-year PFS was only marginally better in PET-neg vs. PET-pos patients (93% vs. 73%, P=0.06). However, among PET-pos patients, SUVmax appeared to discriminate a subgroup with adverse outcome: The 2-year PFS was 92% vs. 53% (P=0.05) for patients with SUVmax<5 (1/16 relapsed) and SUVmax≥5 (5/13 relapsed) respectively.

Summary / Conclusion: PET-scan remains positive in a substantial proportion of PMLBCL patients who achieve a radiographic response with R-CHOP. In the majority of them, however, 18-FDG uptake is relatively low. Persistence of a positive PET only marginally associated with inferior outcome, when additional RT was administered, although higher SUVmax values might predict a substantially higher risk of relapse. Among 24 non-irradiated, PET-neg patients, only 1 relapse would be preventable by RT. According to these data: (1) R-CHOP responders with PMLBCL should not be forwarded to ASCT simply based on a positive PET/CT; (2) RT can be spared in the majority of PET-neg pts, but selection criteria still need to be defined.

P318

PRIMARY B-CELL CENTRAL NERVOUS SYSTEM LYMPHOMA: CLINICOPATHOLOGIC CHARACTERISTICS AND TREATMENT OUTCOMES OF 88 PATIENTS AT A TERTIARY REFERRAL CENTER

S Dalia[1,*] M Jaglal[1], C Bello[1], S Price[2], P Forsyth[3], P Chervenick[1], L Sokol[1], E Sotomayor[1], B Shah[1]

[1]Hematologic Malignancies, [2]Department of Pharmacy, [3]Neuro-Oncology, H. Lee Moffitt Cancer and Research Institute and The University of South Florida, Tampa, United States

Background: Primary central nervous system B-cell lymphoma (PCNSL) is a

rare aggressive variant of diffuse large B cell lymphoma (DLBCL) with a poor prognosis. Optimal therapeutic strategies have not been defined. Currently, high dose Methotrexate (HD MTX) and Rituximab (R) have been shown to be effective chemotherapeutic agents in the treatment of PCNSL. The role of intrathecal (IT) therapy in patients with PCNSL remains unclear.

Aims: To review clinicopathologic characteristics, therapy and outcomes of 88 patients (pts) with primary CNS DLBCL.

Methods: This was a retrospective review of patients at Moffitt Cancer Center (MCC). Data were obtained from the MCC electronic records. Patients at the MCC with PCNSL were identified using our institutional database from January1, 2000 to September 30, 2011. Baseline demographics, clinical, pathological and treatment data were collected and analyzed. Treatment information was recorded including if initial regimens contained: HD MTX (>3.5 g/m^2), R therapy, IT therapy, and radiation therapy (XRT). Descriptive statistical analyses were utilized. Kaplan-Meier (KM) method was used to estimate median Overall Survival (MOS) and log rank test was used to compare the groups in HIV negative patients. All data was analyzed using SPSS version 21.0 statistical software.

Results: 88 patients who underwent therapy for PCNSL from January1, 2000 to September 30, 2011 were used in this analysis. Mean age at diagnosis was 58.7±15.5. 49 (55%) were male, 79 (89%) were Caucasian, 54 (61%) had a performance status of ECOG 0 or1, 48 (54%) were over the age of 60, and 8 (9.1%) were HIV positive. 43 (49%) presented with motor deficits, and 60 (70%) presented with cerebral lesions. The MOS was 36 months (95% CI 30-42) in the entire cohort of patients. In the HIV negative cohort of patients, initial treatment regimens containing HD MTX versus (vs) no HD MTX the MOS was 42 vs. 4 months, (P=0.003), initial R vs no R the MOS was 50 vs 34 months (P=0.034) and initial treatments containing HD MTX and R vs no HD MTX and R the MOS was 50 vs 34 months, P=0.032. There was no difference in MOS between patients who received initial treatments containing HD MTX vs HD MTX + R, 36 vs 50 months (P=0.15). There was no difference in MOS between patients who recieved initial IT therapy vs those without inital IT therapy, 41 vs 36 months (P=0.60). Treatments containing initial XRT vs no inital XRT did not improve MOS, 37 vs 36 months (P=0.34).

Summary / Conclusion: Initial treatment with a regimen including HD MTX, R, or the combination improved MOS patients. Initial regimens containing IT or XRT therapy with or without chemotherapy did not improve MOS in our cohort of patients. Multicenter collaborative trials are needed to further assess the best initial therapy in this rare disease.

Cervello, Palermo, [7]Hematology, Ospedale San Camillo Forlanini, Roma, [8]Hematology, San Maurizio Regional Hospital, Bolzano, [9]Hematology, Ospedale S.Croce e Carle, Cuneo, [10]Hematology, Ferrarotto Hospital, Catania, [11]Hematology, Istituto Scientifico San Raffaele, Milano, [12]Hematology, Università di Verona, Verona, [13]Hematology, Azienda Ospedaliera Universitaria ospedali Riuniti, Ancona, [14]Hematology, Università di Padova, Padova, [15]Hematology, Ospedale San Bortolo, Vicenza, [16]Hematology, Ospedale Santa Maria della Misericordia, Perugia, [17]Hematology, Molecular Biotechnology Center, Ospedale Mauriziano Umberto I / University, , Torino, Italy

Background: At diagnosis, a peripheral blood lymphocytes to monocytes ratio (LMR) lower than 2.6, identifies a group of DLBCL patients with a poor prognosis when treated with R-CHOP (Rambaldi *et al*, ASH 2012). No data are available for patients treated upfront with Rituximab containing high dose sequential chemotherapy programs (R-HDS) and autologous stem cell transplantation (AST)

Aims: To investigate whether LMR ratio may identify a high-risk patient subgroup that benefits from a primary high-dose program with ASCT

Methods: We analysed LMR ratio at diagnosis in a series of DLBCL patients enrolled into a trial comparing R-CHOP 14 with R-HDS associated with AST (R-HDS 0305, Clinical Trials.gov.number NCT00355199 by GITIL). Patients characteristics: DLBCL without CNS involvement, with an age between 18–60 years and an High IPI (stage > II B-bulk with ECOG-PS=0-3 and age adjusted IPI (aaIPI) 2–3 or age 61–65 years with ECOG-PS = 0–2 and IPI > 3). R-CHOP 14 (8 cycles) or R-HDS regimen and AST were carried out as previously reported(Tarella C *et al*, Leukemia 2007)

Results: LMR data were collected in 216 evaluable DLBCL patients enrolled into this trial. We identified two groups of patients according to baseline LMR: 144 patients (67%) had a low LMR (≤2.6), while 72 patients (33%) had a high (>2.6) LMR. The two groups were comparable for age, gender, stage, ECOG, extranodal sites, bone marrow infiltration while high LDH level was associated with a low LMR (P= 0.009). In multivariate analysis OS and EFS corrected by age, gender, stage, ECOG, LDH, extranodal sites, BM involvement and treatment arm, resulted significantly improved by R-HDS and AST only in the low LMR group with an hazard ratio (HR) of 0.41 (95% IC 0.2-0.81), P=0.011. In the same patient population with a low LMR, a high ECOG was associated with a two times higher risk of events (HR 2.55, 95% IC 1.26-5.16, P=0.009). After a median observation of 35.4 months (0.3–89.2), the OS and EFS of patients treated by R-CHOP 14 or R-HDS and AST were 71% versus 86% (P=0.022) and 63% versus 83% (P=0.008) respectively.

Summary / Conclusion: The analysis performed among high-risk DLBCLpatients enrolled in a prospective, randomized study, confirms the negative impact of a low LMR at diagnosis in patients treated with R-CHOP. R-HDS and AST improved OS and EFS and overcome the prognostic value of LMR.

P320

DELAYS IN DIAGNOSIS AND TREATMENT OF DIFFUSE LARGE B-CELL LYMPHOMA DO NOT AFFECT SURVIVAL

A Nikonova[1],* R Buckstein[1], H Guirguis[1], M Cheung[1]
[1]Department of Medicine, University of Toronto, Toronto, Canada

Background: Although diagnostic and treatment delays in solid tumors are known to negatively impact on outcomes, little is known with respect to hematological malignancies. Diffuse Large B-Cell Lymphoma may present with a wide array of symptoms, thus rendering initial diagnosis challenging and time consuming.
Aims: We evaluated disease-specific, patient-related and socioeconomic factors leading to delays in DLBCL diagnosis and treatment and the respective impact on overall and progression-free survival.
Methods: We studied a comprehensive clinical database of 278 patients with a new diagnosis or new presentation of transformed DLBCL treated at our center between 2002 and 2010. All patients received at least one cycle of R-CHOP chemotherapy (median 6). We defined various time intervals based on Cancer Care Ontario guidelines as follows: **patient associated delay** – time from symptoms onset to first known contact with a primary care physician (PCP); **diagnostic delay** – >6 weeks from first PCP contact to initial hematology consultation; and **treatment delay** – >4 weeks between hematology consultation and first R-CHOP cycle.
Results: In the population studied (n=278), the median age was 63 and 46% were female. Patients waited a median of 4 weeks (IQR 2-13) before seeking medical attention. A further median of 8 weeks (IQR 4-17) was required for the PCP to diagnose DLBCL or at least to achieve enough clinical suspicion for referral to hematology. From initial hematology consult, a median of 3 weeks (IQR 1-4) passed until chemotherapy was initiated. In univariate analyses, patients who lacked bone marrow involvement (P=.005), had lower IPI scores (P=.031), higher Charlson comorbidity index (P=.048) and who had initiation of treatment in the outpatient setting (vs. inpatient; P=.021), were more likely to experience diagnostic delays >6 weeks. In multivariable logistic regression analysis, only bone marrow involvement (OR=0.41, P=.018), Charlson comorbidity index (OR=1.42, P=.017) and requirement for urgent inpatient chemotherapy administration (OR=0.40, P=.012) remained associated with diagnostic delays. With respect to treatment delays, in univariate analyses patients who did not have pathology diagnosis upon initial hematology consultation (P<.0001) and had B symptoms (P=.039) were more likely to experience treatment delays >4 weeks. On multivariable analysis, lack of pathological diagnosis at the time of hematology referral was the only factor that remained associated with treatment delays (OR=8.25, P<0.001). No socioeconomic factors (low income, level of education, and cohabiting alone) predicted for either diagnostic or treatment delays. On Cox multivariable regression analyses, we found that only IPI score and number of R-CHOP cycles significantly impacted overall survival (HR=1.82, P<.001; HR=0.70 P<.001) and progression free survival (HR=1.56, P<.001; HR=0.82, P=.004).
Summary / Conclusion: Selected disease and patient-related factors may be associated with delays in management of DLBCL. However, unlike in solid tumor presentations, we can reassure patients that waiting a reasonable time frame to complete diagnostic and staging milestones should not affect their disease course, as long as appropriate chemotherapy dosing is administered.

P321

NON-INTERVENTIONAL STUDY BE-1ST: FIRST LINE THERAPY WITH BENDAMUSTINE IN ADVANCED INDOLENT NON-HODGKIN LYMPHOMA (NHL) IN TREATMENT ROUTINE

M Becker[1],* B Tschechne[2], M Reeb[3], U Schwinger[4], H Bruch[5], L Straßl[6]
[1]Onkologische Praxis Minden-Porta, Porta Westfalica, [2]Praxis für Hämatologie und internistische Onkologie, Neustadt, [3]Onkologische Schwerpunktpraxis, Kaiserslautern, [4]Schwerpunktpraxis und Tagesklinik, Stuttgart, [5]Schwerpunktpraxis Bonn, Bonn, [6]iOMEDICO AG, Freiburg, Germany

Background: Bendamustine has become a standard for treatment of indolent non-Hodgkin lymphoma (NHL) in the past years. Current treatment recommendations and results derive from interventional clinical trial experience. The non-interventional study Be-1st reveals treatment and outcome in daily practice in Germany between 2010 and 2011.
Aims: To gain further insight into therapy, efficacy and safety of Bendamustine in clinical routine.
Methods: From 04/2010 until 10/2011 324 patients (pts) were enrolled at 57 study centres in Germany. Tumor entities to be observed were follicular lymphoma and other indolent NHL (except CLL) as well as mantle-cell lymphoma. Treatment modalities were electronically recorded for 6 months until 12/2011. Data sets include demographic information, treatment regime, efficacy and side effects. Major inclusion criteria are advanced indolent NHL according to WHO-classification, patients requiring 1st-line treatment with Bendamustine, no previous chemotherapy, no pre-treatment with Interferone or Rituximab. Exclusion criteria are contraindications according to the applicable SmPC.
Results: Data of 307 pts were analyzed for treatment modalities and efficacy. Concerning safety, data of 323 pts with at least one documented treatment cycle were evaluated.
Gender was balanced, with a mean age of 69 years. Follicular lymphoma (FL) were most frequent (50%), followed by marginal-zone lymphoma (MZL, 17% incl. MALT-lymphoma), immunocytoma (IC, 15%) and mantle-cell lymphoma (MCL, 12%). The combination of Bendamustine/Rituximab (BR) was most common (94%), complemented by Dexamethasone or Prednisone in 11% of these pts. Most pts received Bendamustine during the first 2 days of the cycle (87%). In the majority of cases, treatment was administered at 4-week intervals. The median dose of Bendamustine was 88,4 mg/m^2 d1+2 as recommended in current consensus guidelines. The median treatment duration was 6 cycles (n=277, evaluable pts). The overall response rate (ORR) was 85%, for pts with completed documentation (n=281). Complete response (CR) was 42,7%, partial response (PR) 43,1% and stable disease (SD) 6%. Progressive disease occurred in 10 pts (3,6%). In 161 of 323 pts (50%) a total of 429 side effects of Bendamustine of all CTCAE grades were documented. Most frequently reported CTCAE categories were blood/bone marrow (35% of pts), gastrointestinal (13% of pts), constitutional symptoms (8% of pts), dermatology/skin (5% of pts), neurology (3% of pts) and infections (2% of pts). A total of 74 grade 3/4 adverse events or 17% of all cases occurred in 54 out of 323 pts (17%) - with 65 of grade 3 (15%) and 9 of grade 4 (2%). The majority of cases were leucopenia/neutropenia (12%). Two grade 5 toxicities were documented. One death was associated with thrombocytopenia. The reason of death in another case was unknown.
Summary / Conclusion: Be-1st reflects the treatment routine of Bendamustine for indolent NHL in Germany in 2010/2011 and provides valuable information on administration, outcome and safety. Bendamustine is mostly applied in combination with Rituximab. CR and ORR are comparable to reported data values. The observed adverse reactions were in accordance to the SmPC. In addition to experiences from interventional trials, the favorable efficacy and toxicity profile of Bendamustine could be demonstrated in clinical routine as well.

Non-Hodgkin Lymphoma - Clinical 2

P322

THE PROGNOSTIC ROLE OF EBV IN PERIPHERAL BLOOD OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

M Tisi[1],* E Cupelli[1], M Giachelia[1], V Bozzoli[1], E Maiolo[1], F Bartolomei[1], R Santangelo[2], M Martini[3], F D'Alò[1], M Voso[1], L Larocca[3], G Leone[1], S Hohaus[1]
[1]hematology, [2]microbiology, [3]Pathological Anatomy, Catholic University , Rome, Italy

Background: The Epstein-Barr virus (EBV) belongs to the herpes virus family and infects more than 90% of the human population establishing persistent latent infection in the host. Although EBV infection is benign in most individuals, it has been linked to the etiology of a number of lymphoproliferative diseases. 'EBV-positive diffuse large B-cell lymphoma of the elderly' was included as a provisional entity of DLBCL in the revised 2008 WHO classification. We recently showed that the plasma EBV-DNA load at HL diagnosis is an indicator of disease activity and biological characteristics associated with negative prognosis (*Hohaus et al,Clin Cancer Res,2011;17(9); 2885–92*).
Aims: We studied the role of EBV-DNA copy number in different blood compartments (whole blood, mononuclear cell fraction, and plasma) in patients with DLBCL at diagnosis, as a potential predictive indicator for the presence of EBV in lymphoma cells and as a prognostic marker in patients treated with immunochemotherapy (R-CHOP).
Methods: We analysed 136 patients with DLBCL (median age 62 years, range 15-92 years; 60 females and 76 males). EBV was detected using a commercial real-time PCR kit, amplifying a 191 bp region of the EBNA-1 gene (*Bio-Quant EBV, Biodiversity, Brescia, Italy*) in peripheral blood compartments (whole blood n=133, plasma n=55, and mononuclear cells n=52). Lymph node samples from 61 DLBCL patients were analyzed for EBV infection through in situ hybridization for EBV-encoded small RNAs (EBER).
Results: EBV was frequently detected in peripheral blood: 35 of 133 whole blood samples (26%) resulted positive. The copy number varied between 200 and 196000 copies. The presence and copy number of EBV in whole blood and mononuclear cells were correlated (P<0.05, P<0.01, respectively), while there was no correlation to the detection of EBV in plasma. We did not find any association between the presence or viral load of EBV-DNA in any blood compartment and the presence of EBV in the lymphoma cells of 61 patients studied with EBER–ISH (11 patients EBER pos). The presence and viral load of EBV in PB was not related to age or gender, and other disease characteristics as LDH level, stage, and IPI. In univariate analysis on 133 patients treated with R-CHOP, the presence of EBV-DNA in peripheral blood was associated with a significantly shorter event-free survival (EFS): 60% versus 79% at 2 years, P<0.04). As well, the EBV copy number was correlated with a worse outcome (hazard ratio of 1.86 for each logarithmic increase; 95% C.I, 1.17-2.97; P<0.009). Correcting for IPI in a multivariate Cox analysis, the presence of EBV-DNA in peripheral blood retained its prognostic significance (hazard ratio 2.02; 95% C.I., 1.03-3.95; P<0.04).
Summary / Conclusion: Our findings suggest that EBV can be frequently detected in peripheral blood at DLBCL diagnosis, which does not reflect the EBV status of the lymphoma cells, but associates with a worse outcome following standard immunochemotherapy. Further studies are needed to explore the mechanisms that permit the expansion of EBV-positive cells in peripheral blood of patients with DLBCL.

P323

RITUXIMAB AND CHLORAMBUCIL AS FIRST LINE THERAPY OF LOW-GRADE OCULAR ADNEXAL LYMPHOMAS: LONG TERM FOLLOW-UP RESULTS

B Puccini[1],* L Rigacci[1], M Puccioni[2], E Fabbri[1], S Kovalchuk[1], V Carrai[1], R Alterini[1], G Benelli[1], A Bosi[1]
[1]Hematology, AOUCAreggi, [2]Ophthalmology, AOUCAREGGI, Florence, Italy

Background: Ocular adnexal lymphomas (OALs) represents 8% of primary extranodal lymphomas, 80% of OALs constitutes extranodal marginal zone lymphomas (EMZL). Radiotherapy is associated to high rates of local disease control, but also to the risk of relapse and immediate or delayed complications, such as xerophtalmy, corneal ulcerations, cataract and retinal damage. Single-agent chemotherapy with alkylating agents and rituximab are used for the treatment of low-grade lymphomas, including OALs.
Aims: We investigated the efficacy and the safety of a combination of chlorambucil and rituximab as first line treatment in patients (pts) with OALs.
Methods: Pts with histologically proven low-grade OALs were enrolled in this study. Staging included CT-scan (orbit, neck, chest and abdomen) MR of the orbit, Chlamydia psittaci (Cp) detected by PCR and bone marrow biopsy. Treatment consisted of chlorambucil (0,1 mg/Kg/die for 45 days, then on days 1 to 15 monthly for 4 months) and rituximab (375 mg/sqm weekly for 4 doses, then monthly for 4 infusions). At the end of therapy pts were restaged clinically and with a MR of the orbit.
Results: Since November 2003 to November 2012 22 consecutive OALs (20 EMZL, 2 follicular lymphoma, FL) have been treated according to protocol. The median interval between onset of symptoms and diagnosis was 13 months (range 4-36). Eight pts were male (36%) and 14 pts were female (64%). Median age at diagnosis was 68 yrs (range, 35-86 yrs). Disease was localized in the conjunctiva in 16 pts (72%), in the lacrimal glands in 3 pts (14%) and in other orbital sites in 3 pts (14%). Twenty-one pts presented a stage I disease, 1 stage IV, and no pts showed B-symptoms. LDH was within normal range in 19 of 22 pts (86%), ECOG-PS was 0 and IPI was low or low-intermediate in all pts. We evaluated PCR for Cp in the first 10 consecutive pts and it was negative. All pts completed the treatment without delay; there was no grade III-IV toxicities neither hospitalizations. Five pts had grade 1-2 rituximab infusion-related reactions usually during the first infusion and haematological toxicity was mild. At the end of treatment 21 pts (95%) resulted in CR, and 1 obtained a PR (5%). After a median follow-up of 62 months (range, 10-106) all pts are alive, 17 maintained CR and 4 relapsed after3,4,5 and 7 yrs. Three pts were retreated with the same protocol: one of them attained a new CR and 2 pts are currently under treatment; the other relapsed systemically as FL. The patient in PR after 1st line obtained CR with 2nd line therapy (rituximab fludarabine and cyclophosphamide). The median PFS was 50 months (range, 1-98). All pts performed ophthalmologic follow-up: we didn't report ocular toxicities, and all pts conserved a normal visual function, including acuity. No secondary myelodisplastic syndrome or neoplasms are reported.
Summary / Conclusion: After a long follow-up the combination of rituximab and chlorambucil proved to be low toxic, feasible and effective therapy for primary OALs. No delayed ocular or haematological complications are reported. For these reasons this regimen should be considered for first line of this indolent lymphoma.

P324

LYMPHOMAS WITH MYC-TRANSLOCATION OTHER THAN BURKITT'S: BAD PROGNOSIS DESPITE SPECIFIC IMMUNOCHEMOTHERAPY FOR BURKITT'S LYMPHOMA

J Navarro[1],* M Baptista[1], G Tapia[2], O García[1], A Muñoz-Mármol[2], J Sancho[1], L Rodríguez-Fernández[3], I Granada[1], F Milla[1], E Feliu[1], J Ribera[1]
[1]Department of Hematology, ICO-Germans Trias i Pujol. Josep Carreras Leukemia Research Institute. Universitat Autònoma de Barcelona, [2]Department of Pathotlogy, Germans Trias i Pujol Hospital, Badalona, [3]Hematology, Hospital General de Vic, Vic, Spain

Background: *MYC* translocations involving chromosome 8q24 have been strongly associated with Burkitt's lymphoma (BL). However these translocations can occur in a wide variety of B-cell lymphomas, especially diffuse large B-cell lymphoma (DLBCL) and B-cell lymphoma unclassifiable with intermediate features between DLBCL and BL. Unlike BL, these lymphomas have bad prognosis and the standard treatment has to be established.
Aims: The objective was to study the clinical-biological characteristics and prognosis in a series of lymphomas with *MYC*-translocation other than BL focusing in the given treatment.
Methods: Retrospective study of patients with *MYC*-translocation other than BL treated in a single institution from 2006 to 2012. Cases with diagnosis of BL, Burkitt's-like lymphoma and any other lymphoma with *MYC*-translocation were reviewed by 2 pathologists and classified according to the WHO 2008 criteria. The status of *MYC*, *BCL2* and *BCL6* genes was evaluated by fluorescent *in situ* hybridization (FISH) using dual-colour break-apart commercial probes (LSI MYC DC BA, LSI BCL6 DC BA and LSI BCL2 DC BA; Abbot Molecular, Abbot Park, IL, USA) on whole tissue sections of formalin-fixed paraffin-embedded tissue. Main clinical and biological data were collected from the records.
Results: From 2006 to 2012, 27 patients with a median follow-up of one year (range 0.3-5.3) were included. Median age was 59 years (range 36-33) and 16 (53%) were male. ECOG score at diagnosis was ≥2 in 12 patients (46%), 11 (42%) had ≥2 extranodal sites involved, serum LDH was increased in 17 out of 25 (68%), Ann Arbor stage III/IV in 17 (65%) and B symptoms were present in 12 of 25 (48%). IPI was high or intermediate/high in 13 out of 25 (52%). Seventeen cases were diagnosed with DLBCL and 10 with B-cell lymphoma unclassifiable with intermediate features between DLBCL and BL. Isolated *MYC* rearrangement without *BCL2* or *BCL6* rearrangements was observed in 11 (41%) cases, 13 were double hit, and 3 triple hit lymphomas. Neither differences regarding the main clinic and biologic features between patients with *MYC* translocation alone and patients with double and triple hit were observed, nor between patients with DLBCL and those with intermediate features between DLBCL and BL. Sixteen cases were treated with R-CHOP (14 DLBCL and 2 intermediate), and 11 with a specific immunochemotherapy for BL (8 intermediate and 3 DLBCL) (P=0.003). Complete response (CR) was achieved in 7 out of 24 (29%) cases (5/15 treated with R-CHOP and 2/9 with Burkitt-type immunochemotherapy) (1 patient is still pending of reevaluation and 2 were not evaluable for response). Four of the 5 patients in CR after R-CHOP relapsed, versus none patients in CR after Burkitt-type immunochemotherapy. The 2-

year (95% CI) overall survival (OS) and progression-free survival (PFS) probabilities for the whole series were 34% (11%>57%) and 18% (1%>35%) respectively. Patients with isolated *MYC* translocation had worse OS probability at 2 years than those with double and triple hit: 17% (95% CI: 0%>45%) versus 44% (95% CI: 13%>75%) (P= 0.036); but PFS at 2 years were similar: 14% (95% CI: 0%>38%) for *MYC* translocation and 20% (95% CI: 0%>4%) for double and triple hit (P= 0.26). Two-year OS and PFS probabilities were not different between patients treated with Burkitt-type immunochemotherapy and those treated with R-CHOP: 52% (95% CI: 21%>83%) versus 36% (95% CI: 10%>62%) for OS; and 31% (95% CI: 2%, 60%) versus 16% (95% CI: 0%, 36%) for PFS (Figure 1).

Summary / Conclusion: Lymphomas with *MYC* translocations other than BL present aggressive characteristics at diagnosis and have poor prognosis despite treatment with a specific immunochemotherapy for BL.

Supported in part by grants EC11-041 from Ministerio de Sanidad and RD12/0036/0029 RTICC from Instituto Carlos III, Spain .

P325

UBLITUXIMAB (TG-1101), A NOVEL ANTI-CD20 MONOCLONAL FOR RITUXIMAB RELAPSED/REFRACTORY B-CELL MALIGNANCIES

C Deng[1,*] J Amengual[1], M Schreeder[2], E Pauli[2], K Cutter[2], P Sportelli[3], H Miskin[3], O O'Connor[1]
[1]Columbia University Medical Center, New York, [2]Clearview Cancer Institute, Huntsville, [3]TG Therapeutics, Inc., New York, United States

Background: Anti-CD20 therapy (rituximab or RTX) in treating patients (pts) with B-cell lymphomas has resulted in significant improvement in treatment response and clinical outcomes. Despite advances, pts continue to relapse from, or are refractory to, RTX-based regimens. Ublituximab (UTX) is a novel, chimeric mAb targeting a unique epitope on the CD20 antigen. UTX has been glycoengineered to enhance affinity for all variants of FcγRIIIa receptors, and therefore demonstrates greater ADCC activity than RTX (Le Garff-Tavernier, 2011). UTX displayed greater antitumor activity than RTX in NHL *in vivo* models and in low CD20 expressing tumors (ASH 2011). A Phase I trial with UTX used as a single agent in pts with Rel/Ref CLL reported an ORR of 45%.

Aims: Herein we report on two ongoing Phase I dose-escalation studies of UTX in pts with RTX Rel/Ref B-cell malignancies: TG-1101-101, a single agent dose escalation study of UTX; and TG-1101-102 a dose escalation study of UTX in combination with lenalidomide (REV), an immunomodulator that has displayed single agent activity in pts with NHL and CLL, and through activating effects on NK cells has been shown to enhance the ADCC activity of anti-CD20 mAbs.

Methods: Eligible pts are Rel/Ref to a prior anti-CD20 regimen; have evaluable disease with confirmed CLL/SLL or NHL diagnosis with no active Hep B/C, and must provide informed consent to participate. For TG-1101-101 (single agent UTX), the Ph I dose-escalation uses a sequential 3+3 design in dose cohorts of 450, 600, 900, and 1200 mg. UTX is administered once weekly for 4 infusions followed by monthly maintenance therapy. In TG-1101-102 (UTX+REV), the dose escalation is a sequential 3+3 design with 4 cohorts of escalating UTX. REV is started at 10 mg and allowed to increase by 5mg per cycle (up to 20mg) if well tolerated. UTX is administered days1, 8, 15 of Cycles 1 & 2 (Cycle=28 days) with maintenance. REV is started Cycle 1/Day 9 and continued daily. In both studies, safety and efficacy are primary and secondary endpoints, respectively. PK and correlative PD data are also being collected in both studies.

Results: In TG-1101-101, 9 pts (5 FL, 3 MZL, 1 MCL) have been enrolled. Med age 63; Gender: 3M/6F. Med prior therapies = 4 (range 2-6). RTX refractory (44%). 8/9 pts are evaluable for safety and efficacy; no DLT's and no Gr 3/4 AE's to date. 8/9 pts have had at least one response assessment: 1 CR (RTX refractory MZL); 3 PR's (2 MZL, 1 FL); 2 SD (FL) and 2 PD (1 FL, 1 MCL). PK analysis ongoing. In TG-1101-102, 4 pts have been enrolled (3 CLL/SLL and 1 MCL). Med age 68; all male; Med prior therapies = 3. Two pts progressed: Cycle 2 (MCL) and Cycle 3 (CLL) – study was later amended to start monthly maintenance in Cycle 3. Two remain on study. No DLTs have been observed to date. Gr 3/4 AE's to date include: Gr 4 neutropenia and thrombocytopenia in 1 pt; Gr 3 anemia, leukopenia, dyspnea and UTI in 1 pt. Data evaluation is ongoing; lymphocyte depletion has been rapid and profound in all pts.

Summary / Conclusion: UTX has been well tolerated to date in both Ph I studies with demonstrated early clinical activity confirmed at all doses in TG-1101-101. 7/9 pts in TG-1101-101 continue to receive UTX treatment (range 3–28+ wks). 2/4 pts in TG-1101-102 continue to be treated and display remarkable B-cell depletion. Enrollment in a 900mg expansion cohort is now open in TG-1101-101 with an emphasis on RTX relapsed/refractory indolent or low CD20-expressing lymphomas, including MZL. Enrollment into the dose escalation phase of TG-1101-102 is ongoing.

P326

THE POTENTIAL OF CD127 AS A PROGNOSTIC AND RESIDUAL DISEASE MARKER IN CHRONIC ADULT T CELL LEUKEMIA/LYMPHOMA.

H Kagdi[1,*] S Hilburn[2], A Rowan[2], L Cook[2], A Melamet[2], A Hodson[2], N Gillet[3], M Demontis[2], C Bangham[2], G Taylor[2]
[1]Haematology, [2]Infectious Disease, Imperial College London, London, United Kingdom, [3]Molecular and Cellular epigenetics, Interdisciplinary Cluster for Applied Genoproteomics (GIGA) of University of Liège , Leige, Belgium

Background: Human T cell Lymphotropic Virus type 1 (HTLV-1) is a complex delta retrovirus infecting 15-20 million people worldwide. Most are chronic asymptomatic carriers (AC) but a minority [2-6%] develop a mature T-cell neoplasm Adult T cell Leukemia/Lymphoma (ATL). ATL has been classified into 4 subtypes: smouldering; chronic leukemic; lymphoma and acute; the latter two being aggressive subtypes with poor prognosis. The diagnosis depends on clinical features, immunophenotype, demonstration of HTLV-1 infection and ideally of monoclonal proviral integration. Treatment options include zidovudine with interferon, combination chemotherapy and novel agents. There are significant challenges in diagnosis, monitoring and treatment of ATL. The typical immunophenotype of ATL, CD3+/wkCD4+CD8-CD25+CD7-, is neither specific nor reliable. The methods used to detect monoclonal proviral integration are labour-intensive and/or expensive and not widely available. T Cell Receptor studies lack sensitivity and specificity. There is a need for a rapid, specific, reliable, widely available and cost effective method for diagnosis and monitoring.

Aims: To develop a new flow cytometry based assay for diagnosis and monitoring of leukaemic ATL.

Methods: Patients attending the National Centre for Human Retrovirology at Imperial College (St Mary's Hospital), London, UK donated peripheral venous blood samples after informed consent and ethical approval. Samples from 2 HTLV-1 immortalized cell lines (MT-2 and C8166) and peripheral blood mononuclear cells (PBMCs) from 3 uninfected individuals, 25 HTLV-1 non-ATL and 12 ATL [2 cutaneous lymphoma,1 cutaneous lymphoma/chronic, 1 acute and 8 chronic] patients were analysed. Cells were subjected to 11 colour immunophenotyping, real-time HTLV-1 proviral load [PVL] quantification and ligation mediated polymerase chain reaction followed by high through-put sequencing [HTPS] for HTLV proviral integration site analysis.

Results: The non-ATL patients had CD127+ & CCR7-lo expression in circulating CD25+CCR4+ cells and polyclonal integration site pattern. Four ATL patients had similar CD127+ & CCR7-lo expression in circulating CD25+CCR4+ cells (2 chronic, 2 cutaneous). These patients have remained well with PUVA only or no ATL treatment. Where examined the integration site analysis in PBMCs resembled the non-ATL patients (N=3). Eight ATL patients had CD127-lo expression on CD4+ CD25+ CCR4+ cells [1 acute, 1 cutaneous/chronic and 6 chronic] with a mono/oligoclonal integration site pattern. These patients have all required treatment for ATL. One of nine chronic ATL and the one acute ATL patient had high CCR7 expression [defined as >50% positivity]. Foxp3 expression was variable. IRF4 was not expressed in any of the patients with chronic ATL and all responded to first line zidovudine/interferon-a therapy. Longitudinal study of 5 patients during treatment for chronic ATL found the frequency of CD25+CCR4+ to correlate with PVL whilst CD127 expression correlated with integration site analysis and disease remission status.

Summary / Conclusion: In non-malignant HTLV-1 infection CD25+CCR4+ cells are CD127+ and the integration sites are polyclonal. In ATL CD25+CCR4+ cells were CD127+ or CD127-lo with CD127+ expression associated with a polyclonal and CD127-lo a mono/oligoclonal integration site pattern. Increased CD127 expression during therapy correlated with remission, a return to a poly-

clonal integration site pattern. CD127 expression appears to be useful to identify patients needing treatment and for monitoring the treatment of chronic ATL.

P327

EVALUATION OF THE PROGNOSTIC SIGNIFICANCE OF THE BODY MASS INDEX (BMI) IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) RECEIVING RITUXIMAB-CHOP (R-CHOP) OR SIMILAR IMMUNOCHEMOTHERAPY

T Vassilakopoulos[1,*] G Pangalis[2], S Papageorgiou[3], A Anastasopoulou[1], E Verrou[4], M Dimou[5], K Petevi[1], G Boutsikas[1], A Kanellopoulos[1], L Papageorgiou[1], M Kyrtsoni[5], M Siakantaris[5], M Kaparou[6], V Pappa[3], E Ioannidou[3], K Zervas[4], E Papadaki[6], P Tsaftaridis[1], P Panayiotidis[5], N Konstantinou[4], J Meletis[1], M Angelopoulou[1]
[1]Haematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, [2]Haematology Department, Athens Medical Center, [3]2nd Propedeutic Department of Internal Medicine, Attikon General Hospital, National and Kapodistrian University of Athens, Athens, [4]Haematology Department, Theagenion Hospital, Thessalonki, [5]1st Propedeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, [6]Haematology Department, University of Crete, Heraklion, Greece

Background: Recent data correlate high BMI with better outcomes in Caucasian male Americans with DLBCL. Despite the large number of patients, the study referred to a highly selected patient population, included patients who did not receive Rituximab and does not provide an explanation of the findings. Thus, the prognostic significance of BMI in DLBCL must be further studied in an unselected patient population treated with R-CHOP.
Aims: The evaluation of the prognostic significance of BMI in a large multicenter cohort of patients with DLBCL treated with R-CHOP or similar immunochemotherapy combinations.
Methods: We evaluated 457 patients with DLBCL with a median age of 64 years (18-91), who had received R-CHOP or similar chemotherapy combinations in 4 Greek Medical Centres. Freedom From Progression (FFP) was the selected endpoint, including toxic deaths as events, while unrelated deaths without prior treatment failure were censored.
Results: The median BMI was 26.5 (IQR 23.9-29.4). Overall, 97/457 (21%) of patients were obese (BMI≥30). Higher BMI was correlated with more advanced age, while lower BMI with PS≥2, ≥2 extranodal sites and stages III/IV. There was no correlation with gender, LDH and B-symptoms. In spite of these correlations, the incidence of obesity was not correlated with none of the above neither with IPI. The 7-year FFP for patients with BMI≥30 and <30 was 82% and 70% (P=0.03) respectively. Among 329 patients without B-symptoms, the 7-year FFP for the patients with BMI≥30 and <30 was 87% and 74% (P=0.03), while the corresponding results for 104 patients with B-symptoms were 79% and 55% (P=0.12). Among males, the corresponding percentages were 83% and 66% (P=0.04), while among females 81% vs 76% (P=0.52). For patients <60 years old, the 7-year FFP with BMI≥30 and <30 was 85% and 81% (P=0.37), while for older patients 80% and 61% (P=0.03) respectively. Multivariate analysis revealed that BMI<30 was marginally associated with inferior FFP (relative risk 1.79, 95% confidence interval 0.92-3.49, P=0.085).
Summary / Conclusion: The present study suggests that obese patients with DLBCL may have better prognosis under R-CHOP or similar immunochemotherapy. This was not due to the potentially adverse prognosis of patients with weight loss, since the observation was valid for patients without B-symptoms. The effect of BMI on prognosis is more pronounced for males and older patients. The study will be expanded to include a larger patient population and take into account the actually delivered dose-intensity of immunochemotherapy regimens in obese and non-obese patients.

P328

AIDS-RELATED LYMPHOMAS (ARL), OUTCOME AND PROGNOSTIC FACTORS

T Garrido[1,*] T Melo[1], J Andrade[1], J Guimarães[1]
[1]Centro Hospitalar São João, Porto, Portugal

Background: HIV infection correlates to an increased risk of lymphoma, mainly diffuse large B-cell lymphoma (DLBCL) and Burkitt's lymphoma (BL). Primary central nervous system lymphoma (PCNSL) is a particular group with very poor outcome. Hodgkin's lymphoma (HL), although not included in the definition of AIDS, has also been unquestionably linked to HIV infection.
Aims: Retrospective analysis of the prognostic factors in ARL, looking for variations amongst 3 main groups: HL, NHL and PCNSL.
Methods: We assessed the available data of 96 patients (pts), HIV-positive, diagnosed with lymphoma between 2000 and 2012.
Results: The median age at diagnosis was 41 years-old [23;79]; 81.3% of the pts were male. Nineteen (19.8%) pts had HL and 77 (80.2%) had NHL, of which 13 (16.9%) were PCNSL; histologically, NHL were mostly DLBCL (49.4%) and BL (18.2%). Most pts were diagnosed at an advanced (III/IV) stage (92.7%), had IPI ≥3 (65.1%) and ECOG performance status (PS) ≥2 (51.3%). Extra-node involvement was present in 79.2%: bone marrow (35.4%), liver (27.1%), gastrointestinal (27.2%), CNS (27.1%) and lung (12.5%). All PCNSL pts had prior AIDS-defined disease, and 69.2% of them had CD4+ lymphocytes <50/mm^3 (P=.034). Merely 36.5% of the pts were on anti-retroviral therapy (ART) at the time of diagnosis (68.4% HL, 32.8% NHL, 7.7% PCNSL; P=.001). HL group had a higher percentage of pts with undetectable HIV (by PCR) at diagnosis (47.4% HL, 7.8% NHL, 0% PCNSL; P<.0001). One fourth of the pts had no conditions to initiate curative treatment (26.3% HL, 10.9% NHL, 92.3% PCNSL). Chemotherapy schedules included: HL - ABVD (10), ChlVPP (2); NHL - CHOP (29), Da-EPOCH (8), HyperCVAD (3), M-BACOD (3) among others; PCNSL - HDMTX (1). Radiotherapy was part of the treatment (curative/palliative) in 11.5% of the pts. A complete (CR) or partial (PR) response was achieved in 30.2% of the pts (66.6% HL; 34.5% NHL; 100% PCNSL- 1patient). 67pts died: due to lymphoma (63) or other causes (4); 27pts are alive (22 free from lymphoma); 2 were lost to follow-up. Median overall survival (OS) for the complete series was 6 months. The 3 groups HL/ NHL/ PCNSL had very different outcomes (10-year OS: 40.6%/ 17.1%/ 7.7%; P=.039). Age and sex had no impact on survival. None of the patients with early stage disease (3) have died. There was worse survival for PS ≥2 (P=.002); extra-node involvement (P=.017); lung involvement (P=.007); low platelet count (P<.0001); and IPI ≥3 (P=.013) in NHL group. Low hemoglobin levels (P=.018) and leukopenia (P=.026) had an impact on survival only for the HL group. There was inferior outcome for those pts with prior AIDS-defined disease (1-year OS: 31.3% vs. 60.6%; P=.025) and lower CD4+ T-lymphocyte counts [1-year OS: 26.7%(<50/mm^3), 36.4% (50-200/mm^3), 67% (>200/mm^3); P=0.004], particularly in the NHL's group. ART previous to diagnosis showed impact on survival only for HL's group (1-year OS: 69.2% vs. 0%; P<.0001). Detectable HIV was not associated to worse survival. As expected, response to treatment (CR/PR) is a major prognostic factor, regardless of type of lymphoma (1-year OS: HL 87.5% vs. 20%, P=.019; NHL 94.4% vs. 23.3%, P<.0001; PCNSL 100% vs. 9.1%, P=.008). On multivariate analysis, CD4+ T-lymphocyte counts (P=.023) and response to treatment (P=.001) were independently associated to OS in the NHL group.
Summary / Conclusion: Prognostic factors in ARL differ from those of HIV-negative lymphomas and vary for each subtype. A considerable percentage of patients do not present with conditions to initiate curative treatment, hence the high short-term mortality; however, when response is achieved, they seem to behave similarly to those without HIV infection.

P329

HIGH RATE OF DURABLE REMISSIONS AFTER TOXICITY-ADAPTED INTENSIVE INDUCTION, AUTOLOGOUS STEM CELL TRANSPLANTATION AND RITUXIMAB MAINTENANCE IN MANTLE CELL LYMPHOMA PATIENTS.

V Vorobyev[1,*] S Kravchenko[1], E Gemdjian[1], Y Lorie[1], A Magomedova[1], J Mangasarova[1], E Dubrovin[1], A Melikyan[1], N Turina[2], V Savchenko[3]
[1]High Dose Chemotherapy and Intensive Care, National Research Center for Hematology, [2]High Dose Chemotherapy, P.A. Herzen Moscow Oncological Research Institute, [3]National Research Center for Hematology, Moscow, Russian Federation

Background: Mantle cell lymphoma (MCL) is aggressive B-cell neoplasm diagnosed predominantly among elderly men. Upfront use of high-dose AraC (12 g/m^2 per course), autoSCT and rituximab at all stages of therapy is the most effective treatment but possible only with patients younger 60-65 years. Prominent efficacy of gemcitabine-oxaliplatin combinations in relapsed and refractory MCL patients allowed including these drugs in first-line therapy.
Aims: Toxicity and efficacy assessment of schemes R-DA-EPOCH/R-GIDIOX and R-DA-EPOCH/ R-HD-Met-AraC, autoSCT and R-maintenance in primary MCL patients.
Methods: Since May 2008 41 untreated MCL pts (median 54 years (29-64), M/F 73%/27%, MIPI$_b$: 32% low, 34% intermediate, 34% high risk) were enrolled. After first R-EPOCH course pts were stratified according to toxicity they had received either R-DA-EPOCH/R-HD-Met-AraC or R-DA-EPOCH/R-GIDIOX. In the absence of hematological toxicity gr.4 for more than 3 days, severe infection complications and signs of renal failure pts underwent R-HD-Met-AraC (R 375 mg/m^2 day 0, methotrexate 1000 mg/m^2 24 hours CI day$_1$, AraC 3000 mg/m^2 q 12 hrs days 2-3). If there was one of these complications pts underwent R-GIDIOX (R 375 mg/m^2 day 0, gemcitabine 800 mg/m^2 days 1 and$_4$, oxaliplatin 120 mg/m^2 day$_2$, irinotecan 100 mg/m^2 day$_3$, dexamethasone 10 mg/m^2 IV days 1-5, ifosfamide 1000 mg/m^2 days 1-5). Further these courses are rotated: either R-DA-EPOCH/R-HD-Met-AraC or R-DA-EPOCH/R-GIDIOX. Depending on the terms of response, pts received 6-8 courses (3-4 cycles) and autoSCT (BEAM-R) with *in vivo* purging by rituximab. Pts with residual tumor after autoSCT were consolidated with local radiotherapy. R-maintenance was performed every 3 months for 3 years. Since Nov. 2011 all pts received intrathecal CNS prophylaxis (including patients who had undergone autoSCT for one year before Nov. 2011). The protocol was approved by the local ethics committee. Pts were analyzed in an intent-to-treat basis.
Results: A median follow-up is 21 months (range 2-58). Toward Feb. 2013 34 patients underwent autoSCT: 20 from R-HD-Met-AraC arm and 14 from R-

GIDIOX arm. 1 induction death after first HD-Met-AraC course (acute renal failure and septic shock). R-maintenance therapy was completed in 4 pts. All pts achieved CR in R-HD-Met-AraC arm. In R-GIDIOX arm OR was 93%: 13 CR, 1 PR (without progression for 26 months after autoSCT) and 1 PD after 4 courses. Main non-hematological toxicity of R-GIDIOX was hepatic, with elevated aminotransferases grades 1-2 and 3-4 in 59,5% and 7,1% of courses respectively, without clinical signs. The sources of stem cells were PB in 30 patients and BM in 4 cases of harvest failure after 3 R-GIDIOX and 1 HD-Met-AraC. Hematological toxicity of R-GIDIOX course: leukopenia gr.4 was in 71,4% (medium duration was5,4 days, range 1-13), thrombocytopenia gr.4 was in 42,9%. The estimated 4-years OS for the R-GIDIOX arm and the R-HD-Met-AraC arm were 100% and 78±12%. The estimated 4-years EFS for the R-GIDIOX group and the R-HD-Met-AraC group were 85±10 % and 71±13 %. There were 3 CNS relapses in 6-14 months after autoSCT. One patient was from R-GIDIOX arm and 2 patients were from R-HD-Met-AraC arm. 2 patients died in 6 months after CNS relapses, and in one case, CR was achieved again with radiotherapy and intrathecal treatment (CR more than 13 months). After these 3 early CNS relapses we included CNS prophylaxis in this treatment protocol.
Summary / Conclusion: HD-Met-AraC scheme is highly toxic and its use is possible only in 2/3 of patients younger 65 years. R-GIDIOX scheme is less toxic than HD-Met-AraC and equally effective in response induction and mobilizing, so it could be recommended for those in whom high-dose AraC and methotrexate can potentially cause severe adverse consequences.

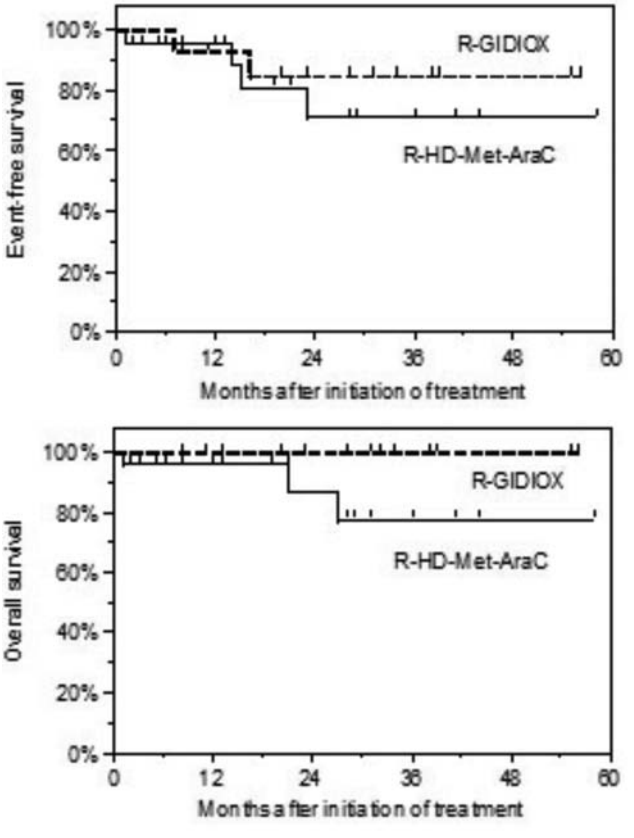

Figure 1.

P330

THE USE OF SYSTEMIC THERAPY DOES NOT IMPROVE THE RESULTS OF LOCOREGIONAL TREATMENT IN LIMITED STAGE (I-II) FOLLICULAR LYMPHOMA: STUDY OF 112 PATIENTS.

J Sancho[1,*] S Mercadal[2], H Pomares[3], M Moreno[1], O Garcia[1], E González-Barca[3], E Domingo-Domènech[3], J Navarro[1], A Fernández de Sevilla[3], E Feliu[1], J Ribera[1]
[1]Clinical Hematology, ICO-Hospital Universitari Germans Trias i Pujol, Institut Josep Carreras, Universitat Autonoma de Barcelona, Badalona, [2]ICO-Hospital Duran i Reynals, Hospitalet de Llobregat, Spain, [3]Clinical Hematology, ICO-Hospital Duran i Reynals, Hospitalet de Llobregat, Spain

Background: 20-25% of the patients with follicular lymphoma (FL) are in limited stage (I-II) at diagnosis. Involved field nodal or regional radiotherapy is the standard therapy but recurrence out of radiation field is the main cause of treatment failure.

Aims: The objective of this study was to investigate the value of the use of systemic therapy in a series of patients diagnosed with limited stage FL.
Methods: Retrospective study of patients with limited stage (I and II) FL diagnosed and treated in two Spanish hospitals. Clinical and biological characteristics, as well as therapy and response were collected.
Results: From 1989 to 2012, 112 patients were included. Median age was 57 years (range 17-93), 71 (63%) were females. ECOG score at diagnosis was <2 in 99 patients (91%) and B symptoms were present in only 7 (6%). Grade of FL histology was available in 105 cases: grade 1 in 39 (37%), grade 2 in 39 (37%) and grade 3a in 27 (26%). Ann Arbor stage: I in 61 (55%) (extranodal involvement in 15 of them) and II in 51 (45%) (extranodal involvement in 8). FLIPI score (available in 97 cases) was 0-1 in 73 (75%) and 2-3 in 24 (25%). Fifty-four patients (48%) were treated with a locoregional strategy (radiotherapy in 43, surgical resection in the remaining 11) and 58 (52%) received systemic chemotherapy (combined with radiotherapy in 21 [19%]); 31 cases received rituximab as part of their chemotherapy. The groups of locoregional (n=54) and systemic therapy±radiotherapy (n=58) were well balanced except for a higher number of patients with grade 3a histology and stage II in the group of systemic therapy±radiotherapy compared to locoregional treatment (46% vs 2%, P<0.001, and 64% vs 26%, P<0.001, respectively). Overall response was achieved in 95 (95%) of cases (CR in 90 patients [90%], 42 [96%] in locoregional therapy vs 48 [86%] in systemic therapy±radiotherapy), whereas 5 (5%) showed stable disease or progression. Thirty-one (35%) out of 90 patients achieving CR relapsed (18 in locoregional therapy vs 13 in systemic therapy±radiotherapy, P=0.181). DFS, PFS and OS probabilities at 8 years were, respectively, 58% (95% CI 45%>71%), 64% (95% CI 53%>75%) and 83% (95% CI 75%>91%) without differences according to treatment strategy (locoregional [n=54] vs systemic therapy±radiotherapy [n=58]), although patients treated with systemic therapy±radiotherapy showed a trend to longer CR duration (74% [95% CI 60%>88%] vs 48% [95% CI 27%>69%], P=0.07) (Figure 1).
Summary / Conclusion: Conclusions. Patients with FL in limited stage show good response to therapy. In this series no benefit from the use of systemic therapy was observed in terms of DFS, PFS and OS compared to locoregional treatment.

P331

OCCULT BONE MARROW INVOLVEMENT DETECTED BY FLOW CYTOMETRY MAY AFFECT OVERALL SURVIVAL AND PROGRESSION FREE SURVIVAL IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

O Wolach[1,*] M Luchansky[2], A Fraser[3], M Lishner[4], O Shpilberg[1], M Lahav[2]
[1]Institute of Hematology, Davidoff Cancer Center, Rabin Medical Center, [2]Department of Medicine, Rabin Medical Center, Petah Tikwa, Israel, [3]Medical Research Council Centre for Causal Analyses in Translational Epidemiology, University of Bristol, Bristol , United Kingdom, [4]Department of Medicine, Meir Medical Center, Kfar Saba, Israel

Background: Diffuse large B cell lymphoma (DLBCL) is a common aggressive and potentially curable lymphoma. Histologic involvement of the BM at diagnosis affects disease stage and the International Prognostic Index (IPI) score that are both associated with outcome. In some cases flow cytometry (FC) detects occult marrow involvement which was not detected in microscopy. The clinical

relevance of such occult BM involvement is still not clear. Current guidelines lack clear recommendations as to the role of flow cytometry of BM aspirates in the staging of DLBCL.
Aims: To study the prognostic significance of occult BM involvement based on flow cytometry findings in DLBCL.
Methods: The medical charts of all consecutive DLBCL patients over the age of 18 that were diagnosed with DLBCL at a single center between 1994-2003 were reviewed. We defined 3 groups within the cohort of patients: 1. patients with histologic involvement of the BM as diagnosed by BM biopsy (BM+ group). 2. patients negative for histologic involvement or that BM results were inconclusive but that demonstrated cytometric evidence for involvemnt in BM aspirate (BM-FC+). 3. patients with neither histologic or cytometric evidence for lymphoma involvement in the BM (BM-FC-). Flow cytometry was performed on BM aspirates using two color flow cytometry. Data was aquired using the EPICS-XL (BECKMAN COULTER) flow cytometer from 1999 onwards, and the PROFILE II (BECKMAN COULTER) flow cytometer before 1999. B cell monoclonality was defined as either a ratio of immunoglobulin light chain expression of kappa:lambda >3:1 or lambda:kappa >2:1 in at least 2% of the gated population. BM biopsies were treated with standard procedures, stained with haematoxylin and eosin (H&E) and subjected to standard immunohistochemistry studies. Statistical analysis: Study endpoints included overall survival (OS) and progression free survival (PFS). Survival was studied using Kaplan-Meyer plots and compared using log rank test [Stata 12 (Texas)]. Patients were followed-up from time of diagnosis until death or April 2005, whichever came first.
Results: One hundred and one patients were included in the analysis. Median age of the cohort was 67 (range 21-90). Male and female were represented equally. Disease stages I to III were documented in 19%, 16% and 21%, respectively. Stage IV disease was documented in 33% of patients and stage was not available in 11% of patients. Low risk, low intermediate, high intermediate and high risk IPI were demonstrated in 38%, 10%, 20% and 20%, respectively. IPI was not available in 12% of patients. BM+ group included 13 patients (13%). The BM-FC+ group comprised of 16 patients (16%) and the BM-FC- included 72 patients (71%). Within the BM-FC-, BM-FC+ and BM+ groups IPI was Low risk in 42%, 38% and 15%; low intermediate risk in 12%, 6% and 0%; high-intermediate in 12%, 31% and 46% and high risk in 16%, 25% and 38%, respectively (P=0.01). Most patients were treated with CHOP or CHOP-like regimens (78%) and 5 patients were treated with palliative intent. Importantly, the vast majority of patients in this study were treated before rituximab was available and consequently only 10% of patients were treated with rituximab containing regimens. Median OS for the BM-FC-, BM-FC+ and BM+ were 4.6 years, 2.2 years and 0.88 years, respectively (log rank P=0.01). Median PFS for the BM-FC-, BM-FC+ and BM+ were 3.2 years, 1.4 years and 0.58 years, respectively (log rank P=0.01).
Summary / Conclusion: Occult involvement of the BM at diagnosis as assessed by FC of BM aspirates in patients with DLBCL identifies patients with inferior outcome. These data must be reproduced in the era of immunochemotherapy.

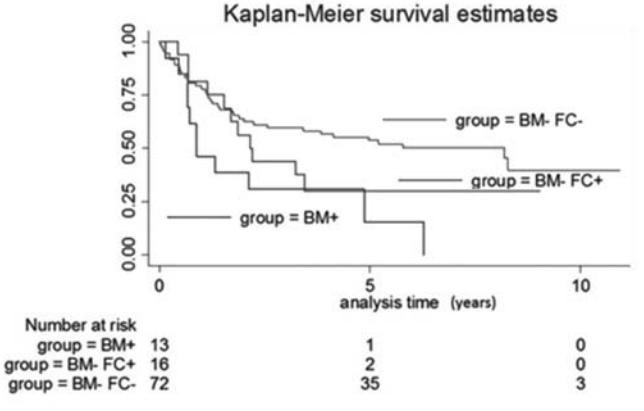

Figure 1.

P332

CLINICAL AND MOLECULAR SIGNIFICANCE OF TUMOR NECROSIS IN NEWLY DIAGNOSED PATIENTS WITH HODGKIN'S LYMHOMA AND DIFFUSE LARGE B CELL LYMPHOMA

I Elrahman[1,*] V Rapoport[1], T Neuman [2], L Appelbaum [3], R Perlman [1], D Ben-Yehuda [1]
[1]Hematology, [2]Pathology, [3]Imaging, Hadassah - Hebrew University Medical Center, Jerusalem , Israel

Background: Lymphoma of various types in newly diagnosed patients may exhibit necrotic areas in the tumor mass on imaging. To date, little is known about the clinical significance of this finding and even less is known about the mechanism of cell death in the necrotic tissue - apoptosis, molecular necrosis or autophagy
Aims: The objective of this study was to investigate the prognostic significance of tumor necrosis in newly diagnosed Hodgkin's lymphoma (HL) and diffuse large B cell lymphoma (DLBCL) patients and to define the molecular mechanism of cell death responsible for the necrosis.
Methods: Two hundred and four CT scan or CT-PET studies from newly diagnosed patients with DLBCL (131) and HL (73) were analyzed for the presence of tumor necrosis.Among 56 HL and DLBCL patients that underwent an open surgical biopsy of the tumor mass nineteen presented necrotic morphology in the biopsied tissues: 8 HL and 11 DLBCL. Biopsies without evidence of necrotic morphology (10 patients from the above 56) and reactive lymph nodes (4) were included as controls. All sections were stained for ki-67, a proliferation marker, activated caspase-3, apoptosis marker, and HMGB-1, a necrotic cell death marker.
Results: Radiographic appearance of necrosis was present in 47% of all patients, 34% of HL and 53% of DLBCL patients. A statistically significant correlation was found between necrosis and bulky disease (tumor mass size≥10 cm) ($P=0.0002x10^{-6}$) and also between necrosis and elevated LDH (P=0.00002). When DLBCL and HL patients were analyzed separately, we found significant correlation between necrosis and elevated LDH in DLBCL patients (P=0.0001) however in HL patients, there was no significant correlation between necrosis and LDH at the time of diagnosis. No statistically significant correlation was found between necrosis and age >60 or more advanced stage of disease. Surprisingly, we did not find correlations between patients' prognosis and tumor necrosis. There were no differences in interim response to treatment, disease-free survival and overall survival between patients with necrosis and without it. When DLBCL and HL patients were analyzed separately, we found better outcome in patients with tumor necrosis: Among DLBCL patients with elevated LDH there was a trend for better outcome, by disease-free survival and overall survival, in those with tumor necrosis (P=0.098 and 0.093, respectively). In HL patients, disease-free survival was greater in patients with necrosis compared to those without necrosis. More over, we found a significant correlation between tumor necrosis and disease stage- more HL patients without tumor necrosis had an advanced disease (stages III-IV) compared to those with necrosis (P=0.027). Our results show that in contrast to solid tumors, tissue necrosis in lymphoma is not a predictor of worse prognosis: though more patients with radiographic appearance of necrosis had also the known bad prognostic signs- elevated LDH and/or bulky disease, this group did not have worse outcome. We suggest that necrosis can lead to a better response to treatment in lymphoma.DLBCL cells showed high proliferation rate, with ki-67 index ranging from 40 to 90% and in HL cells the ki-67 index ranged from 5 to 50%. All HL patients were positive for HMGB-1 with no significant staining for caspase-3. Conversely, 10 DLBCL patient samples out of 11 were positive for activated caspase-3, none of them were positive HMGB-1. These results show a differential molecular mechanism of cell death in the tumor mass of newly diagnosed HL and DLBCL patients.
Summary / Conclusion: In summary, tumor necrosis in HL and DLBCL is correlated with bulky disease and high LDH, yet unlike solid tumors tumor necrosis is not correlated with worse prognosis. Rather, tumor necrosis seems to be associated with better outcome. The molecular mechanism of cell death differs between the two types of lymphoma.

P333

PREDICTIVE VALUE OF EARLY 18FDG POSITRON EMISSION TOMOGRAPHY (PET) IN HIGH-RISK AGGRESSIVE B-LYMPHOMAS TREATED WITH RITUXIMAB, INTENSIVE INDUCTION THERAPY AND AUTOLOGOUS TRANSPLANTATION

R Pytlik[1,*] D belada[2], D Salek[3], O Belohlavek[4], J Kubinyi[5], A Berkova[1,6], M Trneny[1]
[1]1st Department of Medicine, 1st Medical Faculty, Charles University, Prague, Prague, [2]Department of Medicine - Hematooncology, Medical Faculty Hradec Králové, Charles University, Prague, Hradec Králové, [3]2nd Department of Medicine - Hematooncology, Medical Faculty, Masaryk University, Brno, Brno, [4]Department of Nuclear Medicine, Hospital Na Homolce, [5]Institute of Nuclear Medicine, [6]Center of Tumor Cytogenetics, Institute of Medical Biochemistry and Laboratory Analysis, 1st Medical Faculty, Charles University, Prague, Prague, Czech Republic

Background: ^{18}FDG-PET results at the end of treatment have independent prognostic value in aggressive B-cell lymphomas. The value of early or interim PET is unclear. Also, it is unclear whether eventual negative prognostic impact of positive early PET can be reversed with intensified consolidation treatment.
Aims: We have studied the impact of early PET after 2 to 3 cycles of intensified induction therapy on prognosis of patients 18-62 years old with diffuse large B-cell lymphomas (DLBCL) and primary mediastinal B-cell lymphomas (PMBL) with age-adjusted prognostic index (aaIPI) 2-3.
Methods: Patients were treated in 2002-2011 with 3 cycles of high-dose R-CHOP (rituximab, 375 mg/m^2, cyclophosphamide, 3 g/m^2, doxorubicin, 75 mg/m^2, vincristin, 2 mg and Prednison, 300 mg m^2 + G-CSF), 3 cycles of R-ESHAP, and autologous transplantation (ASCT), with or without radiotherapy. PET was performed on 15th to 21st day of 2nd or 3rd cycle of high-dose R-CHOP. Overall survival (OS), progression-free survival (PFS) and lymphoma-free survival (LFS) was calculated according to Kaplan-Meier. Multivariable analysis for independent predictive factors was calculated according to Cox model.
Results: 91 patients with median age of 39 years (18-62) was treated. aaIPI was 2 in 56% of patients and 3 in 44% of patients. OS was 82±4 % at 3 years, PFS was 79±4 %, and LFS was 82±4 %. 36 patients (40 %) were early PET positive and 55 patients (60%) negative. Early PET negative patients had better 3-year LFS (90±4 % v. 70±8 %, P=0.03), and PFS (87±5 % v. 68±8 %, P=0.05) than early PET positive patients, but not better OS (88±5 % v. 73±8 %, P=0.21). Age less than 45 years and negative PET were the only independent variables for LFS and PFS on multivariate analysis.
Summary / Conclusion: Intensive treatment in early PET positive patients with high-risk aggressive lymphomas at least partially overcomes the results of positive early PET, however, early PET negative patients still have better PFS and LFS.

P334

CLINICOPATHOLOGICAL FEATURES AND BONE MARROW PATTERN ANALYSIS IN CASES OF HEPATOSPLENIC GAMMA DELTA T- CELL LYMPHOMA

A Khan[1,*] S Bhavsar[1],Y Badrinath[2], P Subramanian[2], N Patkar[2], PTembhare[2], T Shet[1], E Sridhar[1], P Amare[3], H Menon[4], M Senger[4], S Banavali[5], B Aurora[5], G Narula[5], S Gujral[1]
[1]Pathology, [2]Hematopathology Laboratory, [3]Cancer Cytogenetics, [4]Medical Oncology, [5]Paediatric Oncology, Tata Memorial Hospital, Mumbai, India

Background: Peripheral T- cell lymphomas account for approximately 10-15% of all Non Hodgkin lymphomas (NHL). Hepatosplenic gamma delta T-cell lymphoma (HSGDTCL) accounts for <1% of all NHLs. It is important to differentiate rarer HSGDTCL with a dismal prognosis from commoner T-cell acute lymphoblastic leukemia (T-ALL) with a good prognosis. Diagnosis may also be delayed due to lymphocytic morphology and subtle patterns of involvement in tissues.
Aims: Study clinicopathological features and morphological patterns in bone marrow (BM) biopsy of HSGDTCL.
Methods: Ours is a referral cancer hospital. Cases of HSGDTCL from Jan 2008 – Dec 12 were selected. Diagnosis was based on flow cytometric immunophenotyping (FCI) of peripheral blood (PB)/BM aspirate (BMA) in 14, hepatosplenic biopsy evaluation in5, FCI and hepatosplenic evaluation in1, and BM biopsy morphology with immunohistochemistry (IHC) in 1 case. Clinicopathological findings were recorded. BM aspirate was categorized on predominant tumor population as blastic, lymphocytic or mixed. BM biopsy was categorized on pattern of infiltration as intrasinusoidal, interstitial, both and diffuse. FCI was performed (4 to 8 color, FACS Canto II). Fluorescent in situ hybridization (FISH) was done for common mutation studies including isochromosome 7q. Response to treatment was noted, wherever available.
Results: We had 21 cases (0.22%) of HSGDTCL out of approximately 9478 cases of NHL. Age range was 5 – 51 years (median – 29 years) with 2: 1 M: F ratio. 16/19(84.2%) cases had hepatosplenomegaly, while 5(26.3%) had lymphadenopathy. Anemia and thrombocytopenia was seen in 13/16 (81.3%) and leukocytosis in 6(37.5%) cases. Diagnostic BM aspirate revealed mixed morphology in 12(57.2%), blastic in 4(19.1%) and lymphocytic in 5(23.8%) cases. BM infiltration pattern at presentation was both intrasinusoidal and interstitial in 10/21(47.6%), intrasinusoidal in 9(42.9%), interstitial and diffuse in 1 case each. Splenectomy specimens (3 cases) showed a diffuse red pulp involvement by CD3 positive tumor cells. Liver biopsy(4 cases) showed subtle intrasinusoidal CD3 positive T-cell infiltrate. FCI(18 cases) revealed mature aberrant T-cell immunophenotype. Tumor cells expressed CD3(18/18), CD7(18/18), TCR gamma-delta(15/15) and CD2(16/16). CD5 was expressed in 6/18(33.3%), CD8 in 6/18(33.3%) and CD56 in 7/18(38.9%) cases. Stains for CD4, CD34 and Tdt were negative in all.HLADR was positive in 1 case(5.6%). FISH studies revealed iso 7q in 8/11 cases(72.7%) with additional findings of trisomy 8(3 cases), t(7q;q22)(1 case), 7q;5q deletion(1 case), while 1 case showed no abnormalities. Median period of follow-up was 3 months with maximum survival of 11 months.
Summary / Conclusion: HSGDTCL is common in teenage and young adults (48% were <26 years). Hepatosplenomegaly was absent in 15.8% while lymphadenopathy was present in 26.3% cases. All cases were referred as ALL based on BMA morphology. Mature lymphoid cells were admixed with blast like cells. Expression of surface CD3 along with Tdt negativity raised a high suspicion for HSGDTCL. CD8 expression was noted in 33.3% cases as against common belief of double negative T-cells. CD5 was also expressed in 33.3% cases. Common patterns in BM biopsy were both intrasinusoidal and intersitial. IHC stain for CD3 was mandatory to highlight subtle infiltrates in trephine, liver and spleen biopsies. Iso 7 was seen in 72.7% cases. Chemotherapy protocols included CHOP, DHAP and SMILE; however, most patients were lost to follow up due to the cost involved and poor prognosis explained.

P335

CLINICAL RELEVANCE OF INTERNATIONAL PROGNOSTIC INDEX AS A PREDICTOR FOR VENOUS THROMBOEMBOLISM IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: RESULTS OF A SINGLE CENTER PROSPECTIVE COHORT STUDY

S Lim[1,*] S Kim[1], J Lee[1], W Kim[1]
[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, , SEOUL, Korea, Republic Of

Background: Venous thromboembolism (VTE) is a life threatening condition in lymphoma patients. Although high rates of VTE have been reported in patients with lymphoma, the majority of data were from retrospective studies with heterogeneous subtypes. Thus, it is still not clear about the risk factors for VTE in lymphoma patients. Although Khorana risk score has been proposed as a predictive model for cancer-associated thrombosis, there is few data prospectively validating the role of this risk model in lymphoma patients.
Aims: we explored risk factors influencing the occurrence of VTE in diffuse large B-cell lymphoma (DLBCL) patients who were uniformly treated with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone).
Methods: We analyzed the incidence of VTE from DLBCL patients enrolled in our prospective cohort study (NCT00822731). VTE was defined as pulmonary embolism (PE) and deep vein thrombosis (DVT). VTE was diagnosed with radiologic imaging studies including CT scan and ultrasound imaging. All patients were newly diagnosed with DLBCL and initially treated with R-CHOP via central venous catheter between July 2008 and December 2011.
Results: A total of 352 patients were analyzed, and prospectively monitored regarding the occurrence of VTE with the median follow-up duration of 22.6 months. There were 36 cases of VTE including DVT (19/36, 52.8%), PE (13/36, 36.1%) and both (4/36, 11.1%). The median time to VTE was 2.35 months, so the majority of VTE occurred within 6 months after diagnosis. The actuarial incidence of VTE at one year was 10.3%. A half of patients with VTE (18/36, 50.0%) were symptomatic and anticoagulation therapy was used for 22 patients with symptomatic DVT or PE. However, incidental cases of DVT or PE found during imaging follow-up for evaluation of tumor response did not require therapy. There were two deaths-related with VTE including refractory hypoxemia due to PE and bleeding due to anticoagulation. Age older 60 years and poor performance status (≥ ECOG grade 2) were significantly associated with VTE. However, other host factors including co-morbidity, body mass index, and gender were not related (P>0.05). Disease-related factors representing high tumor burden such as extranodal involvements, and Ann Arbor stage III/IV were significantly associated with VTE (P<0.05). However, the involvement of a particular extranodal site including stomach, pancreas, intestine, and mediastinum did not influence the occurrence of VTE. Khorana score-based risk model including cancer type, body mass index, prechemotherapy white blood cell, hemoglobin, and platelet count failed to predict VTE. The multivariate analysis showed that international prognostic index (IPI, high or high-intermediate risk) was the only factor that independently associated with the occurrence of VTE (OR 2.74, CI 1.27-5.88, P=0.01).
Summary / Conclusion: The IPI score is a predictive factor for the occurrence of VTE in DLBCL patients in the era of rituximab.

P336

PERIPHERAL T CELL LYMPHOMA AND ROLE OF AUTOLOGOUS TRANSPLANTATION

Y Jethava[1,*] V Noriega[1], P Fields[2], B Roomallah[1], C Wykes[1], S Devereux[1], T Pagliuca[1], R Marcus[1]
[1]Kings College Hospital, [2]Haematology, Guys and St Thomas' Hospital, London, United Kingdom

Background: Peripheral T cell is a rare type of lymphoid malignancy with incidence of approximately 15% in most US and European series The most common histopathologic subtypes are PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AILT), and anaplastic large-cell lymphoma (ALCL), with or without anaplastic lymphoma kinase (ALK) expression. The median age at diagnosis is 60 years, with increase male prevalence (2:1) and it carries a poor prognosis with DFS in first remission of no more than 35% in most series In chemosensitive disease, CHOP like chemotherapy followed by autologous hematopoietic transplant (auto-HCT) has shown to improve the response rates with increase in OS to 40-50% at 3 years, with a low non-relapse mortality. We have performed a retrospective analysis of 37 patients who underwent autologous hematopoietic stem cell (Auto-HCT) transplantation as a part of first line therapy our centre, to determine overall survival (OS), disease free survival (DFS), non-relapse mortality (NRM) and to analyse factors affecting the outcome.
Aims: To assess the role of disease status in patients with T- cell lymphoma patients undergoing autologous hematopoietic stem cell transplant
Methods: Thirty seven consecutive patients with diagnosis of PTCL who underwent Auto-HCT as part of their primary therapy between 1998 to 2011 were analysed. The clinicopathological characteristics of the patients are summarized in Table 1. Median age at transplantation was 51.5 yrs. 30 patients (81%) received CHOP as first line chemotherapy. Disease status on 33 patients prior to auto-HCT was confirmed but the pre-transplant disease status of remaining 4 patients was unavailable. Of these 33 patients, 26 were in first CR at the time of auto- HCT and 7 were in PR. 6 patients had received a 2nd line of chemotherapy to induce CR prior to transplant
Results: With a median follow up of 868 days (267-4725), the 3 year OS for the whole cohort was 58.3%, with a 3 year DFS of 41.3% (Figure 1) and a CIR of 50.4% 2 patients (5%) died due to transplant related complications within 1 year. Patients in CR at the time of auto-HCT (n=26) had an OS of 83.3% at 3 years (Figure 2) and DFS of 59.5% (Figure 3) compared to patients not in CR (n=7) (P=0.000 and P=0.001 respectively). The cumulative incidence of relapse was also higher in patients who were not in CR at the time of transplant (Figure 4). No differences in the outcome on univariate analysis was found taking into account age, CD34+ cells infused or number of chemo lines prior to transplant.
Summary / Conclusion: Patients in 1st CR at the time of auto- HCT have an excellent OS and DFS. This outcome was independent of age, CD34+ cells infused or number of chemotherapy lines prior to transplant and relates only to remission status at the time of transplant. On the basis of this analysis and other published data, auto-HCT is recommended for peripheral T cell lymphoma patients in 1st CR but not for those not achieving CR who should be considered for alternative treatment strategies

RETROSPECTIVE ANALYSIS OF DIFFERENT TREATMENT APPROACHES TO PATIENTS WITH EXTRA-GASTRIC MALT LYMPHOMA

S Woehrer[1],[*] B Kiesewetter[1], J Fischbach[1], L Muellauer[2], M Troch[3], M Raderer[1]
[1]Internal Medicine1, [2]Pathology, Medical University of Vienna, Vienna, [3]Internal Medicine3, Salzburger Universitaetsklinikum, Salzburg, Austria

Background: MALT Lymphoma is a relatively common Non-Hodgkin Lymphoma. In contrast to gastric MALT lymphoma, which can be effectively treated with Helicobacter pylori (HP) eradication therapy, treatment strategies for extra-gastic diseases are less well defined and several different treatment strategies, including surgery, systemic chemotherapy, radiation therapy, and antibiotic therapy have shown efficiency in previous studies.
Aims: To investigate if one treatment modality might be superior.
Methods: 185 patients treated at our institution were retrospectively analyzed. Since most MALT lymphoma patients do not die from lymphoma, we used time to progression and therapy free interval as surrugate endpoints for effectiveness.
Results: 72 male and 113 female patients with a median age of 63 (IQR: 50-74) years at diagnosis had a median follow up time of 49 (IQR: 18-103) months. 81 (44%) patients received systemic chemo/immunotherapy, 34 (18%) radiation therapy, 30 (16%) surgery, and 15 (8%) antibiotic therapy. 13 (7%) were followed closely without receiving therapy. Patients undergoing received surgery had significantly less (P=0.002) stage IV disease. Patients having either surgery (100%), chemo/immuno therapy (85.5%), or radiation (80%) had significantly (P=0.01) higher response rates than patients treated with antibiotics (33.3%). However, significantly (P=0.018) more patients had progressive disease after radiation (58%) compared to chemo/immuno therapy (33.3%), or surgery (27.6%). There was no significant difference in the median time to progression (P=0.141) but the estimated time to progression (P=0.023) as well as the estimated therapy free interval (P=0.021) were significantly different among the various cohorts. Stage had no influence on the estimated time to progression (P=0.442). Furthermore, stage (P=0.442), elevated LDH (P=0.141), decreased hemoglobin (P=0.069), elevated beta 2 microglobulin (P=0.570), plasmacellular differentiation (P=0.839), monoclonal gammopathy (P=0.836), or autoimmune disease (P=0.127) did not influence the occurrence of disease progression.
Summary / Conclusion: Surgery for patients with early stages and chemo/immuno therapy for early and advanced stages seem to be superior to radiation therapy. Antibiotic therapy seemed to be the least effective treatment for extra-gastic MALT lymphoma.

P338

LOWER INCIDENCE OF EBV-POSITIVITY IN ELDERLY DIFFUSE LARGE B-CELL LYMPHOMA: POSSIBLE NEW SUBGROUP OF ELDERLY B-CELL LYMPHOMA

T Tomikawa[1],[*] M Tokuhira[1], M Sagawa[1], T Nemoto[1], T Tabayashi[1], R Watanabe[1], S Mori[1], M Higashi[2], J Tamaru[2], M Kizaki[1]
[1]Department of Hematology, [2]Department of Pathology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Diffuse large B-cell lymphoma (DLBCL) has been considered as a heterogeneous aggressive lymphoma. Recently, Epstein-Barr Virus (EBV)-positive DLBCL of the elderly has introduced as a new category of DLBCL by Japanese investigators (Asano N, *et al*. Blood 2009; 113: 2629-36), and documented in the 4th edition of WHO classification. EBV-associated DLBCL has characterized as age over 50 years, and the background of this subgroup of DLBCL disease has strongly affected by the underlying immunodeficiency. It has reported that these patients have a worse prognosis than those with EBV-negative DLBCL.
Aims: Recently, the population of EBV-associated B-cell lymphoma has been increased among patients aged over 50 years according to aging process. However, little is still known about clinical and biological characters in these patients; therefore, the aim of this study was to clarify the clinicopathological features and EBV infection in 125 patients with DLBCL in aged over 50 years.
Methods: Clinical and pathological data on 125 DLBCL patients aged over 50 years, who were diagnosed in our institute from January 2008 to January 2013, were retrospectively analyzed. Diagnoses were confirmed by immunohistochemistry performed on paraffin-embedded tissue sections, using selected members of a panel of monoclonal antibodies including CD3,4,5, 8, 10, 20, and 30, and the all cases were examined for the positivity of EBV by the *in situ* hybridization detection technique, and for EBV early RNAs (EBER) by using a REMBRANT detection kit (Zymed, San Francisco, CA). The patients diagnosed as transformation from low grade lymphomas such as follicular lymphoma and mantle cell lymphoma to aggressive B-cell lymphoma were excluded. The comparison between EBV-positive ratio by the detection of EBER in tumor samples and each clinical data according to age in every 10 years in aged over 50 years were carried out.
Results: Of 125 DLBCL patients, mean age was 72 years (51-97) and sex ratio was 69:56 (M:F). The patient population was 23 (50-59 y/o), 28 (60-69 y/o), 43 (70-79 y/o), and 31 patients (more than 80 y/o), respectively. The average positivity of EBER by using immunohistologic studies for the EBV-latent gene products on paraffin sections was 6.8% in all patients, and the ratio of EBER in each aged group was 6.3 (50-59 y/o), 0 (60-69 y/o), 16 (70-79 y/o), and 3.6% (more than 80 y/o), respectively. We also performed CD5 immunostaing as well, and the positive ratio in each aged group was 13 (50-59 y/o), 7.1 (60-69 y/o), 4.7 (70-79 y/o), and 6.5 (more than 80 y/o), respectively. These data on CD5 positivity showed that this cohort of DLBCL was same as general population.
Summary / Conclusion: It has reported that the incidence of EBV-associated lymphoproliferative disorders (LPD) increases with advancing age, and EBER-positive DLBCL in aged over 50 years showed more than 20% of patients (Shimoyama Y, *et al*. Pathol Int. 2009; 59: 835-43). However, in our analysis, only 6.8 % of patients with DLBCL in aged over 50 years showed EBER-positivity. Although the peak of EBER-positive ratio was shown in the group of 70-79 years (16%) as described in the previous report, other 3 aged groups showed a lower incidence of EBV-positivity (6.3% in 50-59-years, 0% in 60-69-years, and 3.6% in 80-years, respectively). The incidence of CD5 positivity was almost similar among each aged group; therefore, the patient population used in this study was not deviated. In conclusion, the incidence of age-related EBV-positive DLBCL is low as reported and it might be existed in new subgroup of B-cell lymphoma. This study was performed in a single institute; thus, it will be necessary to accumulate the patients with precious EBV-associated DLBCL in aged over 50 years, and we are now analyzing the clinical outcome of EBV-negative elderly DLBCL compared to that of EBV-positive cases.

P339

POLYMORPHISMS OF GLUTATHIONE S-TRANSFERASE MU 1 (GSTM1), THETA 1 (GSTT1) AND PI 1 (GSTP1) GENES AND THEIR CORRELATIONS IN DIFFUSE LARGE B CELL LYMPHOMAS

M Delamain[1],* E Miranda[1], C de Oliveira[1], I Lorand-Metze[1], C De Souza[1], C Lima[1]
[1]Hematology, University of Campinas - São Paulo- Brazil, Campinas, Brazil

Background: The role of genetic polymorphisms in the pathogenesis of lymphomas is not clear. The polymorphisms in detoxification enzymes of the glutathione S-transferase T1 and M1 (GSTT1 and GSTM1) family have been associated with development and the outcome of several lymphomas.
Aims: To study the influence of the GST polymorphisms Mu1 *(GSTM1), Theta1 (GSTT1)* and *Pi1 (GSTP1* Ile(105)Val) in 94 patients with DLBCL, comparing to distribution of 94 control cases and correlate with clinical, prognostic factors and survival.
Methods: Our prospective analysis included 94 patients, diagnosed between July 2009 to July 2012. Median age 59 years old (19-89) and 47 males. DLBCL was diagnosed according to the WHO classification and staged by Ann Arbor criteria. At diagnosis 41 (43.6%) patients had stages I/II and 53 (56.4%) stages III/IV; 33 (35.1%) patients with International Prognostic Index (IPI) >2. All patients were treated with R-CHOP. Genomic DNA from peripheral blood of all individuals and control was analysed by the multiplex-PCR for identification of the GSTM1 and GSTT1 genotypes and PCR-RFLP for identification of genotypes of the GSTP1 Ile(105)Val.

Table 1. *GST* genotypes in DLBCL patients and controls.

Genotypes	Patients Number (%)	Controls Number (%)	*P* value	OR* (95% CI)
GSTM1				
Null	33 (35)	43 (45)	0.14	0.64 (0.35–1.15)
Present	61 (65)	51 (55)		reference
GSTT1				
Null	13 (14)	18 (19)	0.33	0.67(0.31-1.47)
Present	81 (86)	76 (81)		Reference
GSTP1				
Ile/Ile	30 (32)	43 (45)		1.8 (0.99–3.25)
Ile/Val	55 (59)	46 (49)	0.05	
Val/Val	09 (9)	05 (6)		reference

Results: The frequencies of the *GSTM1, GSTT1* and GSTP1 Ile(105)Val genotypes among DLBCL patients and controls is presented in Table 1. No statistical difference was found between DLBCL patients and controls concerning the frequency of GSTM1and GSTT1, while that of GSTP1 ile/ile, ile/val and val/val were subtly different among patients and control.
When DLBCL patients were compared to clinical and diagnostic factors, it was found a higher frequency of older patients in GSTM1 deleted (P=0.02); female gender and IPI index > 2 in GSTT1 undeleted (P=0.03 in both factors); and the presence of B symptoms in GSTP1 (P=0.004). Median follow-up:17 months (1-47) and 77% (95%CI 69-85%) of overall survival. GSTM1 and GSTT1 had no statistical different survival. Patients with GSTP1 ile/val had a better survival than those with val/val and ile/ile (P=0.02).The disease -free survival showed no statistical differences among these groups.
Summary / Conclusion: our analysis revealed that GSTP1 ile/ile genotype conferred a worse overall survival, but not a longer disease- free survival. The other polymorphisms had no influence in development and outcome of the patients. Hence, these genes in the pathogenesis of DLBCL seems to influence the survival and can be another key for understanding the interaction between the risk of acquisition of DLBCL and the genetic polymorphism.

P340

SERUM ALBUMIN RETAINS INDEPENDENT PROGNOSTIC SIGNIFICANCE FOR SURVIVAL IN DLBCL IN THE POST-RITUXIMAB ERA

S Dalia[1],* J Chavez[1], B Little[1], C Bello[1], K Fisher[2], J Lee[2], P Chervenick[1], L Sokol[1], E Sotomayor[1], B Shah[1]
[1]Hematologic Malignancies, [2]Biostatistics, H. Lee Moffitt Cancer and Research Institute and The University of South Florida, Tampa, United States

Background: Serum albumin (SA) levels may serve as a good indirect measure of general health, co-morbid conditions, and/or disease biology, facilitating its use as a prognostic marker when assessed prior to chemotherapy in patients with diffuse large b-cell lymphoma (DLBCL) treated in the post rituximab (R) era. SA has been shown to be a prognostic marker in patients with Hodgkin lymphoma, splenic marginal zone lymphoma, and was shown to be a prognostic marker in patients with DLBCL prior to the introduction of R. There has been conflicting evidence of SA as a prognostic marker in the post R era of DLBCL treatment.
Aims: To evaluate if SA at diagnosis can predict clinical outcomes in patients with DLBCL in the post R era of treatment.
Methods: Patients at the Moffitt Cancer Center (MCC) between 2007 and 2010 who presented for diagnosis or treatment for DLBCL were identified using an institutional database. Only patients who received primary treatment at MCC with rituximab, cyclophosphamide, vincristine, doxorubicin, and prednisone (R-CHOP) were included in the study. Patients who were referred for second opinions or for relapsed/refractory disease were excluded. Clinical and treatment data was recorded including SA levels at diagnosis. Survival time was estimated using the Kaplan Meier (KM) method, and a Cox Proportional Hazard model was used to identify potential risk factors for the time to event data. A p-value< 0.05 was considered significant.
Results: 295 patients were initially identified. 171 patients were excluded for not having primary treatment at MCC (n=161) or because they did not receive standard induction with R-CHOP (n=10). Mean age at diagnosis was 56 years, 56 (46%) were age older than 60 years, 77 (62%) were male, 113 (91%) were Caucasian, 10 (8%) were HIV positive, 45 (36%) were Ann Arbor Stage 1 or2, 47 (38%) were international prognostic index (IPI) score 0-1, and 33 were IPI intermediate high or high risk (27%) . Overall survival (OS) and progression free survival at 4 years were estimated to be 65% and 58%, respectively. Median follow up was estimated to be 36 months. In univariate analysis SA ≥ 3.7g/dL was found to be a statistically significant predictor for OS in our series with a HR of 0.3 (95% CI 0.16-0.59, P<0.001). Initial lymphocyte count (HR 0.45, 95% CI 0.25-0.81, P=0.008), initial serum lactate dehydrogenase (HR 3.58, 95% CI 1.57-8.20, P=0.003), IPI-Risk (HR 1.95, 95% CI 1.43-2.66, P<0.001) also were found to be statistically significant predictors for OS. Age >60 years (HR 1.72, 95% CI 0.93-3.17, P=0.08) trended towards being a statistically significant predictor for OS. The KM survival curve for SA ≥3.7g/dL is shown in the Figure 1. Further, the prognostic significance for SA on OS was maintained after adjusting for IPI-risk.
Summary / Conclusion: SA ≥ 3.7g/dL was associated with a significant reduction in the risk of death among those with DLBCL treated with R-CHOP at MCC. This effect was maintained after adjusting for the IPI-risk, suggesting that SA may account for unmeasured elements of disease biology, such as proliferative rate, and/or inflammatory profile, as well as possible co-morbid conditions incompletely assessed by age or performance status. These data highlight the need for further analysis of SA in the context of larger prospective studies.

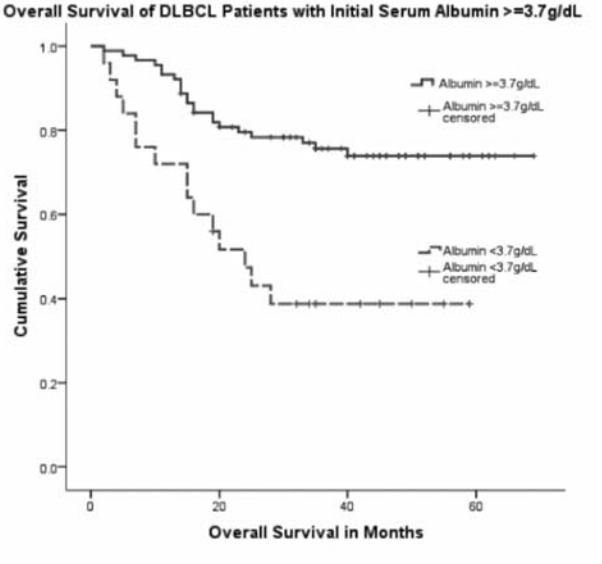

Figure 1.

P341

UTILITY OF F-18 FDG PET/CT FOR THE DIAGNOSIS AND THERAPEUTIC MANAGEMENT FOR EXTRANODAL NATURAL KILLER (NK)/T CELL LYMPHOMA, NASAL TYPE

B Xu[1,*] R Li[1], P Shi[1], H Dong[1], X Guo[1], Z Fan[1], F Huang[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Extranodal natural killer (NK)/T-cell lymphoma, nasal type (ENKTL) is quite rare in western populations, but relatively common in East Asia (especially China) and Latin America. ENKTL is an aggressive disease with poor prognosis, requiring risk stratification. Similar symptoms, such as nasal obstruction and purulent nasal discharge, are found in patients with nasal NKTL and in patients with chronic rhinosinusitis. The images from contrast-enhanced computed tomography (CT) frequently show no prominent mass. As a result, the diagnosis is often delayed because it is frequently misdiagnosed as sinusitis. F-18 FDG PET/CT is a powerful imaging tool for diagnosis, staging, and evaluation of therapeutic effect in oncology.
Aims: This study was designed to investigate the value of FDG PET/CT in the therapeutic management of extranodal natural killer (NK)/T-cell lymphoma, nasal type.
Methods: A total of 26 patients with NK/T-cell lymphoma, nasal type were diagnosed according to morphologic and immunophenotypic criteria as specified in the World Health Organization (WHO) classification. All patients underwent FDG PET/CT and clinical information was obtained by review of medical records.
Results: In 26 cases, all nasal/extranasal lesions were FDG-avid evidented to be neoplasm on CT scan and histopathological examinations. FDG-avid lesions in nasal/maxillary areas were uniformly more localized than demonstrated on CT scan, suggesting soft tissue masses on CT were partly due to inflammatory reaction. Among the 26 patients with definite diagnosis, 9 patients were restaged on the basis of F18 FDG PET/CT with 5 patients down-staged and 4 patients up-staged. Statistical difference of the standardized uptake values (SUV) after 6 courses of chemotherapy and/or radiotherapy between the complete remission (CR) group and the partial remission (PR) group can be found (4.1±2.3 versus 7.8±1.7, P=0.006). The SUV value between pre-reatment and post-treatment were also of statistical significance in 22 patients (11.4±6.2 versus 5.6±2.1, P=0.000).At a follow up of 18 months, patients got CR had a longer survival time than those got PR, stable disease (SD) or progress disease (PD) in 20 patients out of 26 patients. (median survival:310 days vs 284 days, 95% CI: 0.7156 to 1.365, P<0.05).
Summary / Conclusion: Our preliminary study suggests that FDG PET/CT can provide more accurate information on the diagnosis, staged and therapeutic response assessment in extranodal natural killer (NK)/T-cell lymphoma, nasal type. FDG PET/CT can be an invaluable imaging modality in this clinical setting. Further investigation with large patients enrollment is warranted.

P342

THE PROGNOSTIC IMPACT OF CONCORDANT AND DISCORDANT BONE MARROW INVOLVEMENT IN DIFFUSE LARGE B-CELL LYMPHOMA, INDEPENDENT OF THE REVISED INTERNATIONAL PROGNOSTIC INDEX AND CELL OF ORIGIN

M Park[1], P Park[1], Y Seo[1], K Kim[1], J Jeong[1], M Kim[1], J Ahn[1,*] J Lee[2], J Park[2], J Hong[2], H Kim[3]
[1]Laboratory Medicine, [2]Internal Medicine, Gachon University Gil Medical Center, Incheon, [3]Laboratory Medicine, Chung-Ang University College of Medicine, Seoul, Korea, Republic Of

Background: Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous disorder with various outcomes. Many studies have suggested prognostic factors, such as International Prognostic Index (IPI), gene-expression profiles, and cell of origin (COO) such as germinal center B-cell (GCB) and non-GCB subtypes. Prior studies suggested bone marrow (BM) involvement histology, such as concordant and discordant, could be prognostic factor. However, the impact of discordant BM involvement remains unclear, and there are few data about multivariate analysis of BM involvement type and COO type.
Aims: The aim of this study was to evaluate the prognostic impact of BM involvement type in patients with DLBCL treated with R-CHOP after controlling for the revised IPI (rIPI) score and COO.
Methods: Patients with DLBCL treated with R-CHOP at Gachon University Gil Medical Center, between November 2004 and December 2011 were enrolled. Sex, rIPI using five factors such as age > 60, LDH, ECOG performance status, Ann Arbor stage, and extranodal involvement were collected retrospectively. If there were ≥ 5 large, non-cleaved cells per HPF on BM biopsy sections, it was considered as concordant BM involvement (cBMi), otherwise it was considered as discordant BM involvement (dBMi). COO type was defined using immunohistochemical stain of CD10, BCL-6, and MUM-1 according to the algorithm proposed by Hans *et al*. Clinical characteristics were compared using the Chi-square test (data not shown). The overall survival (OS) and progression-free survival (PFS) were assessed using Kaplan-Meier method and the log-rank test was used for comparison between groups. Multivariate analysis was performed using Cox regression model to assess the independent effect of prognostic variables on outcome.
Results: In total of 152 patients with DLBCL, 126 (82.9%) had negative BM, and 26 (17.1%) had BM lymphomatous involvement. 15 (9.9%) had cBMi and 11 (7.2%) had dBMi. In 107 patients classified by COO, 40 patients (37.4%) had GCB type, 67 patients (62.6%) had non-GCB type. Compared to patients with negative in BM, the PFS was significantly shorter for patients with either concordant (log-rank P <0.001) or discordant (log-rank P =0.002) BM involvement. OS was significantly shorter for patients with cBMi compared to those with negative BM (log-rank P <0.001). However, there was no significant difference in OS between patients with negative BM and dBMi (log-rank P =0.065). In addition, there was no significantly difference in PFS and OS between patients with cBMi and dBMi (log-rank P=0.336, 0.159, respectively). In 107 patients, patients with non-GCB type showed significantly shorter PFS compared to those with GCB type (log-rank P =0.043). In multivariate analysis, both cBMi and dBMi remained as a significant negative prognostic factor for both PFS and OS independent of the rIPI score and COO. Non-GCB type did not have significant prognostic impact on the PFS and OS after controlling for the rIPI score and BM involvement (Table 1).**Summary / Conclusion:** Both concordant and discordant BM involvement had adverse prognostic impact for PFS and OS; it was independent of the rIPI score and COO (non-GCB). The outcomes of patients with cBMi were poorer than those with dBMi, but there was no statistically significance. However cBMi had higher relative risk for OS than dBMi in multivariate analysis (RR=5.9 for cBMi, 3.3 for dBMi).. Although patients with non-GCB showed shorter PFS than those with GCB in log-rank test, non-GCB type did not have significant prognostic impact on the PFS after controlling for the rIPI score and BM involvement.

Table 1. Cox regression model of concordant BM involvement rIPI factors for PFS an OS.

	PFS			OS		
Variable	P	RR	95% CI	P	RR	95% CI
Concordant vs negative BM						
BM involvement, COO, and rIPI score						
Concordant BM	.002	7.0	2.0 to 24.3	< .001	5.9	2.2 to 15.8
COO (non-GCB)	.638	1.4	0.4 to 5.6	.377	0.6	0.2 to 1.8
rIPI (1-3)	.458	1.4	0.6 to 3.1	.015	2.5	1.2 to 5.2
BM involvement, COO, and individual rIPI factors						
Concordant BM	.003	8.7	2.1 to 35.5	.002	5.1	1.8 to 14.4
Age > 60 years	.677	0.8	0.3 to 2.5	.285	1.7	0.7 to 4.2
LDH > 485 U/L	.375	0.5	0.1 to 2.4	.929	0.9	0.2 to 3.3

Haematology & Oncology, Univ. Hosp., Pilsen, Pilsen, Czech Republic, [16]Erasmus University Medical Center, Rotterdam, Netherlands, [17]Hospital Clínic de Barcelona, Barcelona, Spain, [18]Hopital Saint Antoine, Paris, France

Background: The introduction of Tyrosine kinase inhibitors (TKIs) has likely modified the natural history of Philadephia chromosome Acute Lymphoblastic Leukemia (Ph+ALL). Indeed, TKIs used pre and post- allogeneic hematopoietic stem cell transplantation (allo-HSCT) may allow for improved outcome. However, data are still scarce in this field.
Aims: The current study aimed to assess outcomes in a cohort of 473 Ph+ALL patients who received allo-HSCT in first complete remission (CR1) between 2000-2010 and focused on the role of TKIs in this setting.
Results: In this series, median age was 42 (range 18-70) and 55% were males. Median time from diagnosis to CR1 was 44 days and from diagnosis to allo-HSCT 158 days. 225 patients (47.4%) received allo-HSCT from an HLA-identical sibling, while 249 (52.6%) received an HLA-matched unrelated graft. 79% patients underwent a myeloablative conditioning (MAC) regimen and 21% underwent a reduced intensity conditioning (RIC) regimen. 329 patients received a TKI at time of induction therapy- mainly imatinib (90%)- and 157 patients received TKI in the post transplant period. The overall incidences of acute GVHD and chronic GVHD (cGVHD) were 40% and 53% respectively. At 3 years, overall survival (OS) and leukemia-free survival (LFS) were 53% and 42%. The relapse incidence (RI) was 35% and non-relapse mortality (NRM) 23%. In multivariate analysis, 2 predictive factors were associated with LFS: TKI use during induction therapy improved LFS (P=0.03 HR=0.76, 95%CI, 0.59-0.97) while age>42y was associated with lower LFS (P=0.02 HR=1.01, 95%CI, 1.01-1.02). In multivariate analysis for relapse, 2 factors were associated with decreased relapse: use of TKI in pre-allograft treatment (P=0.04 HR=0.71, 95%CI, 0.52-0.98) and use of an unrelated donor (UD) vs. identical sibling (P=0.001, HR=0.6, 95%CI, 0.44-0.81). Also, a RIC regimen was associated with an increased incidence of relapse (P=0.007 HR=1.64, 95%CI, 1.14-2.35). Concerning NRM, age>42 and UD were factors associated with higher NRM (P=0.02, HR=.02, 95%CI, 1.01-1.03;P=0.0 HR=1.46,95%CI,1.01-2.12), while a RIC regimen was the only factor associated with lower NRM (P=0.02 HR=0.51,95%CI=0.3-0.89). Concerning the incidence of cGVHD, peripheral blood stem cell vs bone marrow was the only risk factor of developing a cGVHD (P=0.005 HR=1.63,95%CI=1.16-2.28). Interestingly, post-transplant TKI was a protective factor of cGVHD development (P=0.006 HR=0.64 95%CI=0.47-0.88).
Summary / Conclusion: Overall, this large study demonstrated that the introduction of TKIs in Ph+ALL treatment paradigm (pre and post transplant) allowed for a significant outcome improvement after allo-HSCT including LFS, relapse, but also incidence of cGVHD, suggesting that further prospective studies are needed to refine the use of TKIs after allo-HSCT.

P344

LONG TERM SURVEY OF 180 PATIENTS TRANSPLANTED AFTER RIC REGIMEN USING THREE DOSES OF ATG: A BELGIAN HEMATOLOGY SOCIETY (BHS) NATIONAL PROSPECTIVE TRIAL

D Bron[1],* M Ngirabacu[1], P Zachee[2], X Poiré[3], K Theunissen [4], W Schroyens[5], P Lewalle [1], C Doyen [6], L Noens[7], N Straetmans[8], D Selleslag[9], H Demuynck[10], R Schots[11], M Paesmans[1], J Maertens[12]

Background: The use of RIC allows older patients (pts) and those with comorbidities to be treated by allogeneic SCT. However, the optimal conditioning remains debatable and particularly the role of Anti-thymocytes globulin (ATG).
Aims: We report the 10 yrs follow-up of a prospective multicenter dose-finding study where the aim was to determine the optimal dose of ATG in terms of engraftment, acute and chronic GVHD, and event-free survival (EFS).
Methods: From Jan 2000 to Dec 2007, 184 pts (not eligible for myeloablative transplant (MAC) due to older age or comorbidities) were transplanted with a HLA identical sibling after RIC containing fludara (30 mg/m²/d x 4 days) and cyclophosphamide (CPA) (1 g/m²/d x3 days). GVHD prevention consisted of cyclosporine A and rabbit ATG (Fresenius). The first cohort of patients (n=26) receiving rATG 10mg/kg/day x4, was stopped because of protocol stopping rules (50% relapse, 37% TRM). The second group receiving 10 mg/kg/day x2, (n=20) was prematurely closed because of 50% of acute GVHD. A third group of patients didn't receive any rATG but additional MMF (n=33). The fourth cohort received 2 days of 10 mg/kg ATG and mycophenolate mofetil (MMF)(n=101). The whole study included 184 pts: 26 AML, 18 MDS, 21 CLL, 12 CML, 46 MM, 45 NHL, 3 MPN, 8 HL and 1 AA.
Results: 180 pts were analyzed. Median age was 54 (13-74) yo. Median follow-up was 8 yrs (90 mos). 43 pts (24%) are in CR before alloSCT and 92 (51%) are in CR after SCT with 30% remaining in continuous CR. The overall survival (OS) is 42%/ 8 yrs. There was no difference in OS according to disease or doses of rATG. EFS is 29%/8 yrs. Pts with MM had worse EFS compared to other patients (15% vs 48% for CLL, 38% -for NHL, 27% for AML and MDS). Concerning the role of rATG, pts who received 4 days of rATG had a worse EFS compared to the other patients (11% vs 30 -35% for the other rATG groups, P=0.09). There were no significant differences in EFS according to age. AGVHD was related to the dose of rATG: 52% of grade 2-4 aGVHD in the rATG 2 vs 25% in the rATG 4. cGVHD was not statistically different according to the doses of rATG but the group treated with rATG 2 and MMF had 34% of cGVHD but only 8% of extended cGVHD. Pts who developed extensive chronic GVHD had a better outcome than patients without chronic GVHD (relapse rate: 16.7% vs 53%). TRM was lower in the rATG 2-MMF group (20%). TRM was higher above 60 yo (46% vs 18% P=0.02).
Summary / Conclusion: Fluda/CPA/ATG-based RIC-SCT enables transplants in older pts or pts unfit for MAC with excellent long term outcome (45% OS, 29% EFS/8 yrs). Two doses of rATG combined with CSA and MMF allow limited cGVHD and lower TRM and was thus chosen for subsequent trials. This approach resulted in 48 and 38% of cure in CLL and NHL but is not sufficiently effective in MM, AML and MDS.

P345

SPECTRUM OF EPSTEIN-BARR VIRUS-ASSOCIATED DISEASES IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Xuan[1], X Jiang[1], J Sun[1], Y Zhang[1], F Huang[1], Z Fan[1], X Guo[1], M Dai[1], C Liu[1], G Yu[1], X Zhang[1], M Wu[1], Q Liu[1],*
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou , China

Background: Epstein-Barr virus (EBV)infection may result in a spectrum of diseasesin recipients ofallogeneic hematopoietic stem cell transplantation (allo-HSCT), including fever, post-transplant lymphoproliferative diseases (PTLD) and endorgan diseases(pneumonia, encephalitis/ myelitis, hepatitis and so on).Now PTLD has been widely studied; however, there are only scattered reports about EBV-associated diseases other than PTLD.
Aims: To investigate the incidence, clinical characteristics and prognosis of the spectrum of EBV-associated diseases.
Methods: A total of 263 recipients undergoing allo-HSCT were enrolled. The blood EBV-DNA loads were regularly monitored by quantitativereal-time polymerase chain reaction.
Results: The 3-year cumulative incidence of total EBV-associated diseases, PTLD, EBVfever and EBV endorgan diseases were 15.6%±2.5%, 9.9%±2.0%, 3.3%±1.3% and 3.3%±1.2%, respectively. In the EBV endorgan diseases, the 3-year cumulative incidence of EBV pneumonia,encephalitis/ myelitisand hepatitis were 2.2%±1.0%, 1.6%±0.8% and 0.9%±0.6%, respectively. Of the 36 patients with EBV-associated diseases, 7 onlyhadfever without tissue involvement, and 29 had tissue involvement including 19 with extranodal involvement. The involved area included the lymph nodes (n=18),central nervous system (CNS, n=14), lung (n=9), tonsil (n=6), liver (n=4), spleen (n=3) and nasalcavity (n=1). Thirty patients presented with fever, 4 with lymphadenectasis and 2 with CNS symptoms as the initial manifestations. Fever wasthe most common symptom of EBV-associated diseases. The median time to onset of PTLD and EBV endorgan diseases was 61 (range, 22-337) days and 60 (range, 43-95) days post-transplantation, respectively (P=0.209). The EBV-DNA loads of secretions (cerebrospinal fluid, bronchoalveolar lavage fluid,hydrothorax and ascites) were significantly higher than that of blood (39620±8875 copies/mL versus 17619±5275 copies/ml, P=0.030).Thecell immunophenotype of secretions was consistent with histopathology of affected tissue. Patients with PTLDhad better response rate torituximab-based treatments, compared to those with

EBV endorgan diseases (including PTLD accompanied by EBV endorgan diseases)(P=0.014).The 3-yearoverall survival was 37.3%±13.7%, 100.0% and 0.0%±0.0% in patients with PTLD, EBV fever and EBV endorgan diseases, respectively(P=0.001).
Summary / Conclusion: EBV-associated diseases other than PTLD are not rare in recipients of allo-HSCT. The clinical manifestations and onset time of EBV endorgan diseases and PTLD are similar.EBV detection and cell immunophenotypic analysis in the secretions of affected tissues could be proposed as an alternativemethod of diagosis for patients unsuitable for biopsy. EBV endorgan diseases do not respond well to rituximab-based therapy, compared with PTLD.

P346

ENTERAL VERSUS PARENTERAL NUTRITIONAL SUPPORT POST ALLOGENEIC HAEMATOPOIETIC CELL TRANSPLANTATION – RESULTS OF A RANDOMIZED CONTROLLED TRIAL

S Andersen[1], G Kennedy[2],* M Banks[1]
[1]Nutrition and Dietetics, Royal Brisbane and Women's Hospital, [2]Clinical Haematology, Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: Nutritional support during allogeneic haematopoietic progenitor cell transplantation (HPCT) is imperative to prevent malnutrition and resultant inferior patient outcomes. However, there is currently no high quality studies or consensus in the literature as to the most efficacious approach to supplemental feeding post HPCT, leading to wide variation in practice in the use of enteral (EN) or parenteral (PN) feeding across HPCT units.
Aims: To determine the tolerability and efficacy of EN *versus* PN in patients undertaking HPCT.
Methods: Randomized controlled study in patients undertaking HPCT with either myeloablative or reduced intensity conditioning (RIC). Informed consent was obtained from patients before commencing conditioning and they were randomized to receive either EN or PN after commencing HPCT if they could not maintain adequate oral nutritional intake, defined as maintaining >60% of daily caloric requirements orally. Patients with severe gastro-intestinal toxicity, including severe mucositis, were excluded from randomisation. The primary endpoint of the study was tolerance of route of supplemental nutritional support, defined as <30% of patients needing to change to the alternative route of support for any reason.
Results: In total 38 patients were enrolled onto the study, including 9 patients undertaking myeloablative and 29 patients RIC HPCT. Only 19 patients (50%) required nutritional support post-HPCT. Of these 19 patients, only 9 (47%) were able to be randomized between EN (n=5) and PN (n=4), with 10 patients excluded from the study due to presence of severe gastrointestinal toxicity in7, markedly deranged liver function in1, and withdrawal of consent in 2. The 5 patients randomized to EN met on average 74% of their goal nutrition and 100% required changing to PN due to (gastro-intestinal) intolerance. The 4 patients receiving PN met on average 91% of requirements, with none requiring change to EN.
Summary / Conclusion: For patients undertaking myeloablative or RIC HPCT, supplemental feeding with EN commencing at failure to maintain adequate oral nutritional intake is not feasible, due to the presence of significant gastrointestinal toxicity in these patients at this time. Further research is needed to investigate whether prophylactic nasogastric tube placement would improve the feasibility and tolerance of EN in this patient population.

P347

COMBINED CMV REPLICATION AND CHRONIC GVHD GENERATE A SIGNIFICANT SYNERGY OF ANTI-LEUKEMIC EFFECT AFTER ALLOGENEIC HSCT IN ACUTE MYELOID LEUKEMIA

J Jang[1],* Y Kim[1], S Hyun[1], D Hwang[1], S Kim[1], J Kim[1], J Cheong[1], Y Min[1]
[1]Department Of Internal Medicine, SERANCE HOSPITAL, Seoul, Korea, Republic Of

Background: Cytomegalovirus (CMV) reactivation is regarded as an important cause of death after allogeneic hematopoietic stem cell transplantation (alloHSCT). Recently, the hypothesis that the early CMV replication is an independent factor for reducing the leukemic relapse risk has been suggested by Elmaagacli *et al*.
Aims: The purpose of this study was to elucidate the effect of CMV replication on leukemic relapse risk after alloHSCT in AML patients and to evaluate the association of CMV replication with another impact factors for relapse risk.
Methods: 78 AML patients who underwent alloHSCT between August 2006 and December 2012 were analyzed retrospectively. All patients were regularly monitored by CMV qualitative PCR. If qualitative PCR was positive, then viral load was determined by quantitative PCR.
Results: The median age was 35 years and the ratio of male to female was 41 to 37. Disease statuses just before alloHSCT were the first complete remission (CR1) of 61 patients (78%), over than CR1 of 5 patients (6%) and non-CR of 12 patients (15%). In 60 of 78 patients (77%), first CMV replication as detected by CMV-specific qualitative PCR developed at a median of 37 days (range, 11-653) after alloHSCT without relapse. 11 of 60 patients (18%) with CMV replication relapsed at median 124 days (range, 43-714) after alloHSCT. Univariate analysis identified several factors for reducing the 5-year cumulative incidence of relapse (CIR); CMV viremia (negative vs. positive; 56% vs. 24%, P=0.001), disease status at alloHSCT (the first Complete remission (CR1) vs. over than CR1 vs. non-CR; 26% vs. 60% vs. 56%, P=0.026) and chronic graft-versus-host disease (GVHD) (negative vs. positive; 43% vs. 13%, P=0.003). Chronic GVHD is a well known factor for preventing relapse. In our data, CMV replication also offers prolonged leukemia-free survival (LFS) and overall survival (OS) as well as chronic GVHD (LFS 5years after HSCT with vs. without CMV; 48% vs. 20%, P=0.002; OS 5years after HSCT with vs. without CMV; 50% vs. 19%, P=0.005). Of note, in patients with higher than 75,000 copies/mL of CMV-PCR titer, CMV replication had no influence on LFS. As the patients were divided into 4 subgroups according to the existence of CMV replication and chronic GVHD (cGVHD), the patients with both CMV replication and cGVHD showed the lowest 5-year CIR (CMV(-)/cGVHD(-) vs. CMV(-)/cGVHD(+) vs. CMV(+)/cGVHD(-) vs. CMV(+)/cGVHD(+); 61% vs. 33% vs. 62% vs. 11%, P<0.001). The patients with both CMV replication and chronic GVHD had the best outcome on leukemia free survival (P<0.001) and overall survival (P<0.001).
Summary / Conclusion: In this study, CMV replication was a prognostic factor for leukemia-free survival in AML. Furthermore, when CMV replication was combined with chronic GVHD, relapse rate after allogeneic HSCT was most significantly decreased in AML patients. Therefore, we suggest that the immunologic understanding of graft-versus-leukemia effect in this setting is critically required.

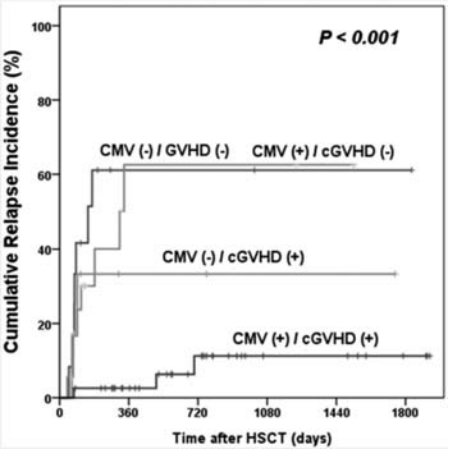

Figure 1.

P348

HUMAN HERPESVIRUS-6 REACTIVATION AND HHV-6 ENCEPHALITIS AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION: A MULTICENTER, PROSPECTIVE STUDY.

Masao Ogata[1],* Takako Satou[1], Jun-ichi Kadota[1], Noriyuki Saito[2], Hirokazu Okumura[3], Toshimitsu Ueki[4], Koji Nagafuji[5], Shinichi Kako[6], Nobuhiko Uoshima[7], Mitsuru Tsudo[8], Hidekazu Itamura[9], Takahiro Fukuda[10]
[1]Hematology, Oita University Hospital, Yufu, [2]Hematology, Hamanomachi Hospital, Fukuoka, [3]Internal Medicine, Toyama Prefectural Central Hospital, Toyama, [4]Hematology, Nagano Red Cross Hospital, Nagano, [5]Hematology and Oncology, Kurume University School of Medicine, Fukuoka, [6]Hematology, Saitama Medical Center, Saitama, [7]Hematology, Matsushita Memorial Hospital, [8]Hematology, Osaka Red Cross Hospital, Osaka, [9]Hematology, Respiratory Medicine and Oncology, Saga University, Saga, [10]Hematopoietic Stem Cell Transplantation Division, National Cancer Center Hospital, Tokyo, Japan

Background: The epidemiology of human herpesvirus (HHV)-6 encephalitis after allogeneic hematopoietic cell transplantation (HCT) and its relationship with HHV-6 reactivation have not been sufficiently characterized.
Aims: To clarify the 1) morbidity of HHV-6 encephalitis, and 2) the effect of HHV-6 reactivation on the development of HHV-6 encephalitis after allogeneic HCT.
Methods: This prospective, multicenter study including 230 allogeneic HCT recipients investigated the epidemiology of HHV-6 reactivation and HHV-6 encephalitis. Plasma HHV-6 DNA load was prospectively evaluated twice weekly until 70 days after HCT. the relationship between plasma HHV-6 load and development of HHV-6 encephalitis using data on prospectively monitored HHV-6 load.
Results: Cumulative incidence (CI) of positive HHV-6 DNA and high-level HHV-6 reactivation (plasma HHV-6 DNA $\geq 10^4$ copies/ml) at day 70 after HCT was 72.2% and 37.0%, respectively. Multivariate analysis identified myeloablative conditioning (hazard ratio [HR], 1.9; P=0.004), umbilical cord blood transplantation (UCBT) (HR, 2.0; P=0.003), and male sex (HR, 1.6; P=0.04) as risk fac-

tors for displaying high-level HHV-6 reactivation. HHV-6 encephalitis occurred in 7 patients, and CI at day 70 was 3.0%. None of the144 patients without high-level HHV-6 reactivation and 7 of 86 patients (8.1%) with high-level HHV-6 reactivation developed HHV-6 encephalitis (P=0.0009). The prevalence of HHV-6 encephalitis was significantly higher in patients receiving UCBT than in patients with other sources (CI at day 70, 7.9% vs. 1.2%, P=0.008). In each of 7 patients with HHV-6 encephalitis, CNS symptoms developed concomitant with peak plasma HHV-6 DNA (range, 21,656 – 433,639 copies/mL).
Summary / Conclusion: High levels of plasma HHV-6 DNA are associated with higher risk for HHV-6 encephalitis. UCBT is a significant risk factor for HHV-6 encephalitis. HHV-6 encephalitis should be considered if CNS dysfunction develops concomitant to high-level plasma HHV-6 DNA after allogeneic HCT.

P349

CENTRAL NERVOUS SYSTEM (CNS) RELAPSE IN AML PATIENTS WITH CNS DISEASE UNDERGOING ALLOGENIC STEM CELL TRANSPLANTATION- RISK FACTORS AND PROGNOSIS

K Gundabolu[1], S Hashmi[1], M Litzow[1], W Hogan[1], M Patnaik[1,*]
[1]Hematology, Mayo Clinic, Rochester, Rochester, United States

Background: Approximately 2-4% of patients with acute myeloid leukemia (AML) have involvement of the central nervous system involvement (CNS). High presenting white blood count (WBC), peripheral blast (PB)%, elevated LDH, FAB AML subgroups M4 & M5, younger age (<50 years), extra-medullary (EM) involvement, and cytogenetic abnormalities such as inv (16) and 11q23 abnormalities appear to be risk factors. Guidelines with regards to optimal diagnostic and therapeutic strategies for these patients are limited.
Aims: To describe clinical and pathological features of patients with AML diagnosed to have CNS involvement prior to proceeding with allo-SCT. To determine the efficacy of current treatment strategies in preventing post-transplant CNS relapse.
Methods: After due IRB approval, 351 patients of all age groups that underwent allo-SCT for AML at the Mayo Clinic from 1985 to 2012 were reviewed. Patients who were diagnosed to have CNS disease pre transplant were identified. All patients with AML at our institution have a lumbar puncture (LP) performed prior to allo-SCT. Clinical, pathological, prognostic and transplant related data were abstracted retrospectively. Transplant conditioning regimens and graft versus host disease (GVHD) prophylaxis were according to institutional standards.

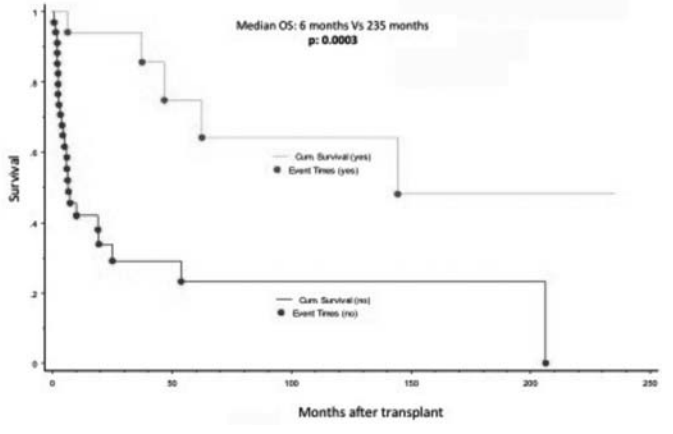

Figure 1. Survival based on chronic GVHD in patients with AML with CNS involvement.

Results: Forty-four (13%) of 351 AML patients had CNS disease detected prior to allo-SCT. Of these 17 (39%) were detected at AML diagnosis due to clinical signs/symptoms, 11 (25%) were detected to have CNS involvement at the time of AML relapse and 16 (36%) were asymptomatic; diagnosed on routine pre transplant L.P. Twenty six (59%) were males, with a median age of 40 years (range; 4-71 years). Eleven (25%) patients received IT-chemotherapy alone (Methotrexate or Ara-C), 3 (7%) received systemic chemotherapy alone and 26 (59%) received IT with systemic chemotherapy (high dose ARA-C). Twenty-two (50%) received cranio-spinal radiation. Twenty (45%) had concurrent EM disease. Eleven (25%) patients underwent allo-SCT in CR1, 14 (32%) in CR2, while 14 (32%) had residual disease. Donor sources were; 26 (59%) matched sibling donors, 17 (39%) matched unrelated donors, and 1 haploidentical transplant. Thirty seven (84%) were peripheral blood grafts, while the remainder were bone marrow grafts. 37 (84%) had total body irradiation (TBI) based conditioning (34- Cytoxan/TBI, and 3 with TBI/Thiotepa/Cytoxan/ATG), 1 patient received Cytoxan and Busulfan while 3 received fludarabine and melphalan. Sixteen (36%) had AML M4/M5, 7 (16%) patients had a core binding factor AML, while 3(7%) had MLL gene rearrangements. At diagnosis median WBC was 71.3x10^9/L, PB blasts % 55, Hemoglobin 9.8 gm/dL and platelet count 76.3x10^3/mL. Five (11%) patients had post-transplant CNS relapse (1 with monocytic leukemia) in spite of CNS directed therapy. Three patients had received IT alone, while 2 received IT and HIDAC. Four (80%) underwent a TBI based myeloablative allo-SCT. With the exception for a higher presenting WBC (median; 124x10^9/L), there were no other clinical, pathological or cytogenetic differences noted. Two (40%) patients had additional EM disease pre-SCT and 1 had EM relapse post SCT. Median OS for these 5 patients was 7 months, compared to 39 months for the patients without CNS relapse. Fifteen (38%) of 39 patients without CNS relapse had chronic GVHD compared to only one patient with CNS relapse. Patients with chronic GHVD had a median survival of 235 months compared to 6 months in those without chronic GVHD (P=0.0003) (Figure 1).
Summary / Conclusion: Routine pre transplant L.P helps identifying a significant number of patients with asymptomatic CNS involvement, resulting in better CNS directed therapies. In spite of this, approximately 10% of patients do have a post-transplant CNS relapse. Major prognostic factors for this phenomenon include higher WBC at presentation and the lack of chronic GVHD.

P350

COMPARISON OF MESENCHYMAL STEM CELLS AND MESENCHYMAL STEM CELLS COMBINED WITH CORD BLOOD FOR TREATMENT OF ENGRAFT FAILURE FOLLOWING AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION: A PROSPECTIVE PI

Q Liu[1,*], Y Xiong[1], M Dai[1], Z Fan[1], H Zhou[1], F Huang[1], Y Zhang[1], Y Peng[2], Q Fan[1], X Guo[1], J Sun[1], P Xiang[2], X Huang[3]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Center for Stem Cell Biology and Tissue Engineering, Sun Yat-sen University, Guangzhou , [3]Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Engraft failure after autologoushematopoieticstem cell transplantation (auto-HSCT) is a formidable complication which occurs in 2.0-9.5% of patients and is associated with considerable morbidity and mortality related to infections and hemorrhagic complications. To investigate the efficacy of mesenchymal stem cells (MSCs) alone or combined with cord blood (CB) to engraft failure in auto-HSCT, this multicenter randomized trial was conducted.
Aims: In this study, the efficacy of MSCs alone or combined with CB to engraft failure in auto-HSCTwas evaluated.
Methods: Sixteen patients were enrolled in this multicenter randomized trial.The median age was 40 years with a range of 14 to 60 years. Primary diseases included acute myelogenous leukemia AML(n=10), acute lymphoblastic leukemia (n=1), multiple myeloma (n=4) and Non-Hodgkin's lymphoma (n=1). These patients were randomized into alone MSCs(n=8) or MSCs combined with CB treatments. MSCs obtained from ex-vivo-expanded MSCs derived from HLA-mismatch bone marrow donor, and CB from unrelated CB. In MSCs group, MSCs were administered at a median dose of 1×10^6/kg once with an interval of two weeks, and 2 doses were a cycle of MSCs. If patient was not responsive to the treatment within 28 days after a cycle of MSCs, CB would be used. In MSCs combined with CB group(CB group), MSCs were administered as abovemention single-unitCB was administered withthe first application of MSCs. If patient was not responsive to the treatment within 28 days after treatment, MSCs would continue to administer for 2 doses.
Results: With 56 days after treatments, 5/8 and 8/8 obtained the hematopoietic reconstruction, respectively, in MSCs and CB groups(P=0.20). Of the 3 patients who did not obtain the hematopoietic reconstruction in MSCs group, 2 patients obtained the hematopoietic reconstruction, one was ineffective after CB treatment, who died of leukemia relapse at 103 days post-transplants. Chimerism analysis from peripheral blood samples showed that CB genetic markers were not detected at 15 and 30 days, respectively, after CB infusion.None of patients experienced GVHD. The median time obtaining the hematopoietic reconstruction was 30 (range 11-43) and 22 (range 17-48) days, respectively, in MSCs and CB groups(P=0.516). With a median follow up of 240 (range 103-350) days after transplantation, 13 were alive and 3 patients died of the relapse of primary diseases.
Summary / Conclusion: Our data indicate that MSCs alone are effective to engraft failure and CB can facilitate the effect of MSCs to engraft failure.

P351

ABCG2 OVEREXPRESSION NEGATIVELY AFFECT OUTCOME OF ALLOGENEIC STEM CELL TRANSPLANT IN ACUTE MYELOID LEUKEMIA PATIENTS

M Tiribelli[1,*], A Geromin[1], A Michelutti[1], E Simeone[1], M Cerno[1], A Candoni[1], M Medeot[1], A Sperotto[1], F Patriarca[1], R Fanin[1], D Damiani[1]
[1]Division of Hematology and BMT, Azienda Ospredaliero-Universitaria di Udine, Udine, Italy

Background: Long term survival of acute myeloid leukemia (AML) patients

remains dismal, with a cure rate of 20-40%. So, allogeneic stem cell transplantation (SCT) is considered the recommended therapy. Over-expression of MDR-related protein ABCG2 is associated with higher relapse risk in AML patients achieving remission with chemotherapy. However, little is known on the impact of ABCG2 in patients undergoing allogeneic SCT.
Aims: In the present work we retrospectively analyzed 135 patients with AML who underwent allogeneic HSCT at our Institution between 2002 and 2011, to evaluate the effect of ABCG2 expression on long term outcome of transplantation.
Methods: Median age at SCT was 48 (range: 17-70) years. Sixty eight patients (50%) received grafts from a sibling donor, 67 (50%) from a matched unrelated donors (MUD). In 88 patients (65%) stem cells source was peripheral blood (PB), while bone marrow (BM) stem cells were used in 47 cases. Status at SCT was complete remission (CR) in 91 patients, while 44 patients were transplanted with relapsed or refractory disease.
Results: Fifty-seven of 135 patients (42%) over-expressed ABCG2, while 78 cases (58%) did not. Two-years progression-free survival (PFS) from transplant was 55% for the entire population. PFS was not associated with patient's age, donor type, stem cell source or CD34+ quantity. The only factors positively affecting PFS were status at transplant (CR vs active disease, P<0.0001) and ABCG2 status (negative vs positive, P=0.02). Among the 57 ABCG2+ patients, 31 relapsed (53%), compared with 25 relapses in 78 ABCG2- cases (35%). As a consequence, both 1-year and 2-years PFS were higher in the ABCG2- patients (70% and 67%, respectively) than in the ABCG2+ patients (51% and 46%, respectively) (Figure 1). The difference in relapse rate between the two cohorts was significant in the 91 patients transplanted in CR (13 relapses in 36 ABCG2+ vs 8 relapses in 55 ABCG2-, P=0.03) while was similar in the 44 cases who underwent SCT with active leukemia (18/21 in ABCG2+ vs 17/23 in ABCG2-, P=0.55).
Summary / Conclusion: Our data suggest that overexpression of ABCG2 is associated with a worse outcome in patients undergoing SCT for AML, mainly for a higher risk of relapse, especially in those transplanted in CR. This finding could suggest for a stricter follow-up and prompt intervention (e.g. DLI) in ABCG2+ cases

"PLERIXAFOR ON DEMAND" IN ASSOCIATION WITH CHEMOTHERAPY AND G-CSF HALVES RATE OF MOBILIZATION FAILURE IN LYMPHOMA AND IN MULTIPLE MYELOMA: PRELIMINARY RESULTS OF A MULTICENTER PROSPECTIVE STUDY

G Milone[1],* P Scalzulli[2], M Martino[3], G Sortino[4], S Toscano[4], S Lingenti[1], A Spadaro[1], M Azzaro[4]
[1]Hematology, BMT UNIT, Catania, [2]Hematology, Ospedale Sollievo della Sofferenza, San Giovanni Rotondo, [3]Hematology, Ospedali Biachi Melacrino Morelli, Reggio Calabria, [4]Hematology, Azienda ospedaliera Policlinico Vittorio Emanuele, Catania, Italy

Background: Failure in PBSC harvest interests 7-10% of Multiple Myeloma (MM) cases and 20-30% of Lymphoma cases. "On demand" use of Plerixafor (PLX) in association with "G-CSF" has recently been reported. However, no prospective data are available on "PLX on demand" in association with "chemotherapy and G-CSF". We have previously published the development of an algorithm for the use of PLX "on demand" in association with High CTX and G-CSF (Milone G, Blood Transfusion 2012).
Aims: We present preliminary results of a phase II, prospective study in which PLX was employed "on demand", according to our algorithm, in patients mobilized using High Dose CTX (4 gr/sqm) or DHAP and G-CSF.
Methods: Seventy-three patients were registered, 68 were evaluated for treatment efficacy; 5 patients did not receive PLX in spite of having criteria for its use. Evaluated patients had a mean age of 54 y., 41 were male and 27 female, 52 were affected with MM and 16 with Lymphoma, 53 were mobilized using HD-CTX and 15 using DHAP. PLX was administered if, on day +13 after chemotherapy, CD34+ cell count in PB was below $10x10^6$/l, or if CD34+ count was between 10 and $20x10^6$/L and first apheresis yielded a CD34+ $<1x10^6$/kg.
Results: Overall success rate of CD34+ mobilization (defined as a CD34+ count in PB > $20x10^6$/L) was 95.5%. Mobilization failure was registered in only 3.9% of MM and in 6.3% of Lymphoma. Overall success rate in harvesting a CD 34+ $>2x10^6$/kg was 94% (MM: 96.1%; Lymphoma: 86.6%). Negative predictive value of the algorithm used was 100%, in fact, 61/61 patients were correctly predicted to reach a successful mobilization and harvest without requiring PLX. Five patients were predicted to not reach successful mobilization. However, due to drug shortage, these patients did not receive PLX. Only one of the five (20%) reached successful mobilization, thus confirming the high positive predictive value of the algorithm (80%). Seven patients were predicted as not reaching successful mobilization according to algorithm and were treated with PLX, 4/7 (57%) had a successful harvest. Overall the rate of PLX indication according to the algorithm was 16.4% (MM 6.5%, Lymphoma 30%).
Summary / Conclusion: Compared to chemotherapy + G-CSF, on demand use of PLX in association with chemotherapy and G-CSF is able to halve the mobilization and harvest failure rate: failure of harvest in MM patients is reduced from 7-10% to 3.5% and in Lymphoma patients from 20-25% to 13.4%.

P353

A LEBANESE-ITALIAN COLLABORATIVE INITIATIVE ON BONE MARROW TRANSPLANTATION IN PEDIATRIC PATIENTS WITH B-THALASSEMIA MAJOR

A Inati[1,2], J Gaziev[3], S Korjian[4], Y Daaboul[1], M Kahale[2], H Abbas[5,*] K Paciaroni[3], G De Angelis[3], A Taher[2], S Koussa[2], T A Nasr[2], G Lucarelli[3]
[1]School of Medicine, Lebanese American University, Byblos, [2]Hematology, Chronic Care Center, Baabda, Lebanon, [3]Mediterranean Institute of Hematology, Rome, Italy, [4]School of Medicine, Lebanese American University, [5]Faculty of Medicine, American University of Beirut, Beirut, Lebanon

Background: Bone marrow transplantation (BMT) is the only available curative modality for β-Thalassemia Major (β–TM) with best results obtained in younger regularly transfused and chelated patients. We hereby report treatment outcomes of 36 Lebanese children who received BMT in the Mediterranean Institute of Hematology (IME) centers in Italy as part of an Italian - Lebanese collaboration.
Aims: This study aims at assessing treatment outcomes and complications in 36 Lebanese children with β–TM who underwent BMT in Italy. It also addresses the favorable impact of an international collaborative work in facilitating cure for thalassemia.
Methods: 36 children with β–TM receiving transfusion and chelation at the Chronic Care Center, Lebanon underwent BMT from HLA compatible donors in IME centers, Italy supported by the Italian government. Percutaneous liver biopsies were performed on all patients before BMT and children were assigned a Pesaro risk category. Conditioning regimen consisted of busulfan, cyclophosphamide±Thiotepa and ATG. GVHD prophylaxis included cyclosporine A, methotrexate and prednisolone. Engraftment was evaluated by fluorescence in situ hybridization. Estimates of overall survival and event-free survival were calculated by the Kaplan–Meier method. Transplant related mortality (TRM) and other complications were calculated as cumulative incidence. Analyses were performed using SPSS software version 15.0.
Results: 36 HCV PCR negative children with β –TM (M/F 1: I), median age 8.5 years, median follow 6.20 years, underwent BMT from HLA identical donors. 25%, 52% and 23% had Pesaro risk class1, 2 and3, respectively. The donor was an immediate family relative in 95% and unrelated in 5%. Mean injected CD34+ cells, total nucleated cells and CD3+ cells/recipient were $10.7x10^6$ /Kg, $8.78x10^8$/Kg and $6.4x10^7$ /Kg. Absolute neutrophil count $>0.5x10^9$ and platelet count >20 x 10^9 were reached in all patients within a mean of +19.25±4.2 and +21.6 ±3.8 days. 35/36 children (97.3%) had complete engraftment in +20 to + 60 days while 1/36 (2.7%) had partial engraftment but continued to be transfusion independent with a mean Hb of 9g/dcl for +1155 days. 32/36 (89%) children are alive and transfusion independent. 4/36 (11%) died: 1 with multi organ failure, 2 with grade 4 acute GVHD and 1 with fulminant interstitial pneumonitis. 8/36 (22%) had grade 2 - 4 acute GVHD of which 75% resolved on treatment while 25% (all grade 4) were fatal. 9/32 (28%) surviving children had chronic GVHD completely resolved on treatment. Other transplant related complications included CMV reactivation, sepsis, EBV and candida infections, hemorrhagic cystitis, transient cyclosporine related renal and neurotoxicity, cerebral toxoplasmosis and tuberculosis all completely resolved on treatment. Iron overload data on 27 children at + 3.1 year median follow up showed that 9/27 (33.3%) had significant iron overload defined as SF >2500 ng/ml, or LIC >15 mg Fe/g dw, or T2* <20 msec.
Summary / Conclusion: This Italian–Lebanese collaborative study on BMT of children with β –TM reveals an excellent treatment outcome with low TRM and transient and manageable associated complications. It also underscores the importance of post BMT iron overload monitoring and treatment. This scientific work demonstrates the effectiveness of international collaboration in facilitat-

ing cure for thalassemia in developing countries as Lebanon and prompts initiating larger scale collaborations in the Mediterranean regions for achieving cure for other inherited hemoglobin disorders. Given the genetic similarity among Mediterranean populations, establishing a regional BM donor database is warranted

P354

VITAMIN D DEFICIENCY INCREASES THE RISK OF COMPLICATIONS IN ALLOGENEIC STEM CELL TRANSPLANTATIONS

L Von Bahr[1,2,*] J Alm[1], G Moll[1], R Jitschin[1], A Björklund[1], K Malmberg[1], K Le Blanc[1]
[1]dep of Laboratory medicine, Karolinska Institutet, [2]Hematology Center, Karolinska University Hospital, Stockholm, Sweden

Background: Patients undergoing allogeneic hematopoietic stem cell transplantation (HSCT) have an increased incidence of vitamin D deficiency which can be explained by prolonged illness, hospitalization and nutritional problems. Vitamin D has in later years been shown to have great impact on the immune system and to play a role in the development of autoimmune diseases. Vitamin D receptor is expressed on all immune cells, most pronounced on T lymphocytes, macrophages and dendritic cells, and activation of the receptor leads to a suppression of the immune response. Because of this, vitamin D deficiency has been suggested to increase the risk of development of graft-versus-host disease (GvHD) following HSCT.
Aims: To evaluate a possible association between vitamin D and development of chronic GvHD.
Methods: We have retrospectively investigated vitamin D levels in serum from the time of transplantation in 169 patients undergoing HSCT at Karolinska University Hospital between 2005 and 2010.
Frozen serum from a biobank was analyzed for 25-OH-cholecalciferol (in this paper referred to as vitamin D) at the Laboratory for Clinical Chemistry, Karolinska University Hospital. Normal levels for the method are 75-250 nmol/L. Levels below 50 nmol/L are considered insufficient, and below 25 nmol/l are deficient. The serum levels of vitamin D were then correlated to incidence of extensive chronic GvHD.
Results: A majority of the patients, 65%, had vitamin D insufficiency (<50 nmol/l) , and 12% had deficiency (<25 nmol/L). The median level was 42 nmol/l, range 10-118. Lower levels of vitamin D at transplantation correlated significantly with an increased incidence of extensive chronic GvHD, grade moderate to severe according to NIH criteria, P<0.05, with a relative risk of2,2 for a cut-off at 60 nmol/L. There was also a significant correlation between low levels of vitamin D and increased mortality, P<0.05.
Summary / Conclusion: To conclude, we found a high incidence of vitamin D insufficiency and deficiency in patients planned for HSCT, and these low levels are associated with an increased incidence of extensive chronic GvHD and increased mortality. It is possible that early monitoring of vitamin D levels and substitution could increase outcome in HSCT.

P355

NON TBI MYELOABLATIVE CONDITIONING REGIMEN FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC ALL.

E Gousetis [1], A Paisiou[1,*] V Kitra[1], I Peristeri[1], G Vessalas[1], M Theodosaki [1], E Petrakou [1], S Graphakos [1]
[1]Bone Marrow Transplantation Unit , Pediatric Hospital of Athens “Agia Sofia” , ATHENS , Greece

Background: Total body irradiation (TBI) – based preparative regimens have been considered the gold standard for allogeneic HSCT in children with ALL; however, there are emerging concerns about the long-term sequeal of TBI in childhood. Substituting i.v. for oral busulfan (Bu) reduces variability in drug exposure, potentially improving the safety and efficacy of the treatment.
Aims: We retrospectively evaluated 60 ALL patients (male 41 /female 19) transplanted in our institution, between January 2005 to November 2012, who received allogeneic HSCT, using a myeloablative i.v. Bu-based conditioning.
Methods: The median age of the patients was 8,4 years (0,6 – 19,9 years). Thirty-six (36) patients were in CR1, 17 in CR2, 5 in CR3 and 2 in advanced disease. Donors were: HLA-matched siblings (n=18), matched unrelated (n=38), 1-Ag mismatched related donors (n=2) and haploidentical (n=2). Thirty-nine (39) patients received bone marrow, 16 peripheral blood stem cells and 5 cord blood. Busulfan was administrated as a 2hs, infusion every 6hs over 4 days (16 doses) in combination with Cyclophosphamide and VP-16 in 44 patients. Graft versus host disease (GVHD) prophylaxis consisted of CSA+MTX in patients receiving blood or marrow stem cells and CSA only in those who received cord blood. Anti-thymocyte globulin was added to those who were transplanted from unrelated donor.
Results: All patients but two achieved sustained engraftment. Median time to ANC>500, and platelets>20.000 was 19 days (14-30 days) and 21 days (12-50 days) respectively. One patient died on day 10 and another patient relapsed on day 22; both were not evaluated for engraftment. There were 14 cases of mild veno-occlusive disease and 12 cases of hemorrhagic cystitis. Grade II-IV acute and chronic GVHD occurred in 28/60 and 9/60 patients, respectively. At median follow-up of 50,7 months (4,5-112,9 months) 40 patients are alive/disease free and one is alive with leukemia. Ten patients relapsed and died and 10 died of transplant-related causes. The overall survival (OS) rate, relapse rate and TRM were 69%, 23% and 10%, respectively.
Summary / Conclusion: Our results are comparable to those reported with TBI- based preparative regimens and suggest that i.v. Bu may be a reliable alternative to TBI in the setting of HSCT for ALL in children.

P356

CIDOFOVIR AS SECOND LINE THERAPY IN CMV REACTIVATION: CLINICAL AND BIOLOGICAL CORRELATES.

F Farina[1,2,*] D Lewis[1,2], S Nagra[2], S Chaganti[2], J Nunnick[2], P Moss[1], R Malladi[1,2], C Craddock[2]
[1]Institute for Cancer Sciences, University of Birmingham, [2]Centre for Clinical Haematology, University Hospital Birmingham, Birmingham, United Kingdom

Background: One of most important causes of morbidity and mortality following allogeneic haematopoietic stem cell transplantation (HSCT) is Cytomegalovirus (CMV), in particular in patients that don’t achieve a rapid CMV clearance. It has been shown that the risk of CMV reactivation following HSCT can be assessed by measuring the CMV-specific T cell response.
Aims: We report cidofovir (CDF) activity in ganciclovir (GCV) resistant patients. We also evaluated $CD8^+$ CMV-specific T cell responses in order to identify predictors of ganciclovir response.
Methods: Between 2004 and 2010, 156 patients following HSCT were treated for CMV reactivation. Of these, 55 were treated with CDF because of GCV resistant CMV infection (n=40), CMV disease (n=11), or pre-engraftment CMV infection (n=4). Patients received 5mg/kg CDF weekly with dose adjustment for renal impairment. Failure of treatment with GCV was defined as CMV PCR positivity after 2 weeks’ treatment. 62 (40%) patients received stem cells from HLA identical sibling transplants, 86 (55%) from matched unrelated donors and 8 (5%) from cord blood units. 63 patients (40%) received myeloablative conditioning, 93 (60%) received reduced intensity conditioning. 126 (81%) patients underwent T-cell depletion with alemtuzumab. Data was collected and analyzed retrospectively. The CMV specific $CD8^+$ T cell response was retrospectively studied in a group of GCV-responsive (n=11) and GCV-resistant patients who received CDF (n=7), using HLA:peptide tetramers specific to CMV peptide-MHC complexes of pp65 and IE-1.
Results: We looked at responses in patients who received at least 12 days’ prior GCV prior to CDF for persistent viremia (n=35), of whom 80% (n=28) responded to CDF. 11 patients were commenced on CDF for CMV disease, of whom 55% (n=6) responded to CDF. No patients died from a cause related to treatment, 18 patients had renal toxicity (only 1 required dialysis). These events led to treatment discontinuation but they had no impact on the CMV reactivation outcome. Renal function improved after CDF discontinuation. 70 patients experienced recurrent CMV reactivation. In this group, 36 patients were treated with CDF. 20/36 patients received CDF for all reactivations, also in this group of patients CDF was well tolereted and 17/20 required dose reduction for reduction in GFR. The median time to eradicate CMV viremia was 15 days (median of 3 administrations). Patients treated with GCV had significantly higher tetramer responses compared to CDF treated patients (P=0.0013 by Mann Whitney test). Looking at day +50 (P=0.012), +100 (P=0.0175) and + 150 (P=0.0426) post HSCT this difference remains significant. Total lymphocyte count, $CD3^+$ and $CD8^+$ T cell counts were not different between the 2 groups. Cidofovir-treated patients were able to clear CMV viremia despite a low absolute $CD8^+$ CMV-specific T-cell response. The CMV viremia was cleared in 4/7 patients whose tetramer responses were measured despite very low absolute tetramer responses measured.
Summary / Conclusion: CDF has a good safety profile and should be considered as second-line therapy in patients who have not responded to GCV. Furthermore it appears to be an important in management of CMV infection in patients who have failed to develop an antigen specific CD8+ T cell response.

P357

IS IMATINIB MAINTENANCE REQUIRED FOR PATIENTS WITH RELAPSE CHRONIC MYELOID LEUKEMIA POST-TRANSPLANTATION OBTAINING CMR? A PILOT RETROSPECTIVE INVESTIGATION

H Jin[1], Y Xiong[1], J Sun[1], Y Zhang[1], F Huang[1], H Zhou[1], Z Fan[1], D Xu[1], Y Wei[1], M Dai[1], R Feng[1], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou , China

Background: Imatinib is capable of inducing durable molecular responses in relapsechronic myelogenous leukemia (CML) after allogeneic hematopoietic stem cell transplantation (allo-HSCT), but it is indefinite whether imatinib therapy is required to maintain this response for patients obtaining complete molecular remission (CMR).We retrospectively reviewed 37 patients with relapse

CML post-transplants who were treated with imatinib (n=20) or donor lymphocyte infusion (DLI) (n=17).
Aims: To compare the efficacy between imatinib and DLI to the relapse CML post-transplants, andevaluate the results of ceasing imatinib in the patients who had achieved CMRand complete donor chimerism via imatinib treatment.
Methods: Once leukemia relapse was diagnosed, immunosuppressants were tapered or discontinued if the patient's condition was acceptable. Those who were in molecular or cytogenetic relapse tapered or discontinued immunosuppressants as a front-line therapy. If these patients were not responsive to this treatment after one month, DLI- or imatinib-based treatments were administrated. Those who were in molecular, cytogenetic or chronic phase (CP) relapse received DLI or imatinib monotherapy as a front-line therapy, and the patients in advanced phase received DLI or imatinib combined with chemotherapy as a front-line therapy. In the DLI-based treatments, patients received DLI once every four weeks until patients obtained complete cytogenetic remission (CCR) or developed graft versus host disease (GVHD). In the imatinib-based treatments,when the patients had recovered donor complete chimerism and had achieved CMR as defined by negative quantitative RQ-PCR at three consecutive time points within a period of 3 months, the patients continued or ceased imatinib therapy according to their willingness.
Results: The rate of CMR was 85% and 76.47%, respectively, in the imatinib and DLI group (P=0.509). The treatment-related mortality was0% and 29.4%, respectively, in the imatinib and DLI groups (P=0.019). Fifteen of the 17 patients obtaining CMR voluntarily ceased imatinib, and did not experience relapse. Eight-year overall survival (OS) was 85%±8% and 40.3±12.1% (P=0.017), 8-year disease-free survival (DFS) was 85%±8% and 40.3±12.1% (P=0.011), respectively, in the imatinib and DLI groups.
Summary / Conclusion: Imatinib therapy resulted in higher OS and DFS than that of DLI in relapse CML post-transplants. Imatinib maintenance might not be required for patients with relapse CML post-transplants after they achieved full donor chimerism and CMR.

P358

CHARACTERISTICS AND RISK FACTORS FOR HOSPITAL READMISSION IN PATIENTS RECEIVING HEMATOPOIETIC CELL TRANSPLANTATION
S Bobillo[1,*] P Barba[1], N Castillo[1], J Montoro[1], I Ruiz[2], F Bosch[1], D Valcarcel[1]
[1]Hematology, [2]Infectious disease, Hospital Universitari Vall d´Hebron, Barcelona, Spain

Background: Patients who received hematopoietic cell transplantation (HCT) (autologous [auto-HCT] or allogeneic [allo-HCT]) are often readmitted after hospital discharge. However, these hospitalization episodes have been little studied.
Aims: We conducted a retrospective study to identify the risk factors for readmission in recipients of HCT after 90 days of discharge, and its impact on the outcome of the procedure.
Methods: All consecutive patients receiving HCT in our center between March 2009 and December 2012 were reviewed. Only patients discharged from the first admission were included in the study. Readmission was defined as hospitalization for > 24 hours either in the emergency room or hospitalization unit within the first 90-days after discharge. Base line characteristics were compared using Chi-squared test. Univariate and multivariate analysis (MVA) of risk factors for readmission were performed using logistic regression.
Results: A total of 152 patients (93% of the 163 transplanted patients) were discharged during the study period (85 auto-HCT and 67 allo-HCT). Median age at HCT was 55 years (range 17-70) and median follow-up for survivors was 15 months (range 3-48). Patients were mainly transplanted for acute leukemia (AL) (n= 43, 28%) and NHL (n= 41, 27%) in complete remission (n=84, 55%). Sixty-five patients (43%) were readmitted within 90 days (18 [27%] auto-HCT and 47 [73%] allo-HCT) at a median of 15 days (range 1-89) [1 day (range 1-9) for auto-HCT, and 7 days (range 1-127) for allo-HCT] after first discharge. The most common complications for readmission were fever (n=41, 63%), gastrointestinal disorders (n= 11, 17%) and renal abnormalities (n=5, 8%). Median duration time of second hospitalization was 5 days (range 1-127) (2 days for auto-HCT and 7 days for allo-HCT). Among the 65 readmitted patients, 27 (41%) had a microbiological documented infection, including bacterial or viral respiratory infections (n=17, 26%), urinary tract infections (n= 6, 9%) and others (n=4, 6%). Among patients receiving allo-HCT, 15 patients (32%) were diagnosed with acute GVHD during readmission and seven (14%) had CMV infection. ICU admission was required in 7 patients (11%) during readmission, 5% of all patients who had received an HCT. Eight patients (12%) (7 allo-HCT) died during second admission and 57 (88%) were discharged. Among them, 22 patients (38%) had a third hospitalization at a median of 21 days (range 3-87), mainly because of fever (n=10, 42%). Risk factors for readmission in the MVA for the whole cohort were allo-HCT (vs auto-HCT) (HR 8.5 [95%CI 4.2-16.6], P<0.001), diagnosis of AL (HR 2.1 [95%CI 1.1-3.8], P=0.02) and HCT Comorbidity Index (HCT-CI) >2 (HR 1.7 [95%CI 1.1-2.9], P=0.03). For the allo-HCT patients, risk factors for readmission were male gender (HR 2 [95%CI 1.1-3.9], P=0.03), diagnosis of AL (HR 2.3 [95%CI 1.2-4.3], P=0.01) and HCT-CI >2 (HR 2 [95%CI 1.1-3.8], P=0.02). Overall survival at 2 years for the whole cohort and the allo-HCT patients were 71% (95%CI 76-66) and 66% (95%CI 59-73). NRM at 2-years for the allo-HCT patients were 29% (95%CI 22-36). Ninety-day readmission was not significantly associated with lower OS or NRM.
Summary / Conclusion: Hospitalization within 90 days after HCT discharge is frequent, especially after allo-HCT. Patients with acute leukemia and comorbidities seem to have higher risk for readmission.

P359

UNRELATED CORD BLOOD TRANSPLANTATION FOR CENTRAL NERVOUS SYSTEM RELAPSE IN HIGH RISK ACUTE LYMPHOBLASTIC LEUKEMIA
C Zheng[1,*] B Tang[1], J Tong[1], H Liu[1], Z Sun[1]
[1]Department of Hematology, Anhui Provincial Hospital, Hefei, China

Background: Few clinical studies have investigated the role of unrelated cord blood transplantation (CBT) for central nervous system (CNS) relapse of acute lymphoblastic leukemia (ALL) patients with high risk factors.
Aims: The aim of this report was to identify the potential benefits of unrelated CBT in high risk ALL with CNS relapse who had been treated on CNS directed prophylaxis and relapse strategy treatment in the current era.
Methods: Total of 16 childhood (n=10) and adult (n=6) ALLpatients with CNS relapse who underwent unrelated CBT enrolled in our study between 2001 and 2010, and all of the patients had features associated with poor outcomes, such as high WBC at diagnosis, ph+ chromosome, or a history of bone marrow relapse. All transplants were performed with myeloablative conditioning therapy (BU/CY2 or TBI/CY) plus highly CNS-active agents (carmustine or high-dose cytarabine).
Results: All patients achieved neutrophil engraftment and platelet engraftment. A total of 12 patients (75.0%) developed pre-engraftment syndrome (PES) at a median of 8.5 days, and 5 patients developed acute graft-vs-host disease (GVHD) at a median of 19 days. The median follow-up after CBT was 33.6 months. Six patients died at a median of 154 days (range 85- 327) after CBT. In 4 patients, the causes of death were transplant-related: acute GVHD of gastrointestinal (n=1), refractory autoimmune hemolytic anemia (AIHA) and pulmonary infection (n=1), and viral encephalitis (n=2). Two patient died due to disease relapse on day 109 and day 536 after transplantation. No patients received CNS prophylaxis after transplantation and no patients experienced a CNS relapse. The probability of overall survival at 8 years was 69.4%.
Summary / Conclusion: Our experience suggests that unrelated CBT appears to be an effective treatment option for CNS relapse of childhood and adult ALL patients associated with poor outcome features.

P360

LENOGRASTIM FROM DAY +7 AND PEGFILGRASTIM ARE EQUALLY EFFECTIVE IN REDUCING TIME TO NEUTROPHIL ENGRAFTMENT, ANTIBIOTIC USE AND INPATIENT STAY IN PATIENTS WITH MYELOMA UNDERGOING AUTOLOGOUS TRANSPLANT
B Bailiff[1,*] V Murthy[1], L Bratby[1], J Lancashire[1], B Kishore[1], E Nikolousis[1], R Lovell[1], S Paneesha[1]
[1]Hematology department, Heart of England NHS trust, Birmingham, United Kingdom

Background: High dose chemotherapy and Autologous peripheral blood stem cell transplantation (APBSCT) following induction therapy is the standard of care for patients with myeloma with good performance status. Busy haematology centres require safe and effective strategies to hasten neutrophil engraftment, decrease inpatient stay and ease financial burden. GCSF has been proven helpful in this regard. We describe our experience with the use of daily lenograstim from day +7 autograft versus one off pegfilgrastim.
Aims: To identify whether once daily lenograstim given at day + 7 following stem cell infusion is as efficacious as one dose of pegfilgrastim at day +1 with regards to neutrophil engraftment, inpatient stay, days of antibiotic and survival outcomes as compared no G-CSF use.
Methods: Our retrospective study included 113 patients (41 female; 72 male) with a median age at transplantation of 61 years (range 38-72) with myeloma between January 2006 and December 2012. APBSCT was carried out by patients receiving high dose melphalan on day -1 and thawed stem cell reinfusion on day 0. First cohort (35%) was of patients not receiving any G-CSF, second cohort (19%) received pegfilgrastim and third cohort (46%) received lenograstim. Statistical analysis was carried out using Graphpad Prism 4 for windows and SPSS 19 for windows. Sixty five patients had IgG, 22 IgA, 19 light chain and 4 non secretory myeloma. At transplant 7% patients were in complete remission, 21% in partial remission and 72% in very good partial remission.
Results: Median time for neutrophil engraftment in the pegfilgrastim and lenograstim cohorts was 12 days and 12.74 days (Mann Whitney test; p value: 0.1078). Median inpatient stay for the pegfilgrastim and lenograstim cohort was 16 days (Mann Whitney test; p value: 0.2112). Median days of broad spectrum intravenous antibiotic use in the pegfilgrastim and lenograstim cohort was 4.51 days and 3.90 days (Mann Whitney test; P value: 0.4150). Time for neutrophil engraftment, length of inpatient stay and antibiotics use was significantly more in the no G-CSF cohort. There was no difference in the progression free sur-

vival or overall survival between the three cohorts (Log Rank test; p value: 0.455).
Summary / Conclusion: Our data suggest that the use of daily lenograstim from day +7 is an effective strategy in patients with myeloma undergoing APBSCT. It is equally effective as pegfilgrastim in reducing the time to neutrophil engraftment, duration of inpatient stay and antibiotic use. Both daily lenograstim from day+7 and pegfilgrastim are superior to no G-CSF use.
Our data confirms daily lenograstim from day +7 is a cost effective alternative strategy to pegfilgrastim in patients undergoing APBSCT making lenograstim a valuable commodity in the time pressured and cost aware tertiary haematology centres.

P361

TWO DIFFERENT PLERIXAFOR STEM CELL MOBILIZATION STRATEGIES. A MULTICENTER EXPERIENCE.
C Lopez[1,*] R Rodríguez[2], S Pérez[3], E Rubira[4], A Loureiro[5], Juan Carrete[2], M Villamayor Alvarez[3], C Gómez[1], J Carreira[4]
[1]Hematology, Complexo Hospitalario Universitario De Vigo, Vigo, [2]Hematology, Complexo Hospitalario Universitario De A Coruña, A Coruña, [3]Hematology, Complexo Hospitalario Universitario De Santiago, Santiago De Compostela, [4]Hematology, Complexo Hospitalario Lucus Augusti, Lugo, [5]Hematology, Complexo Hospitalario De Pontevedra, Pontevedra, Spain

Background: Autologous stem-cell transplantation (ASCT) has became a widely applied treatment for hematologic malignancies. The vast majority of ASCT are performed with the support of peripheral blood stem cells (PBSC). A significant proportion of patients with non-Hodgkin's lymphoma (NHL), Hodgkin's disease (HD) or multiple myeloma (MM) are hard-to-mobilize with conventional mobilization regimens. Depending on disease 5-25% of patients considered for high-dose therapy failed to mobilize or have a suboptimal mobilization. Plerixafor is a novel drug used to improve mobilization of blood stem-cells.
Aims: We present our experience in patients who failed a previous mobilization attempt and compare then with patients who plerixafor was added if poor first mobilization was demonstrated.
Methods: We retrospectively collected data from 5 spanish centres on 54 patients affected by NHL, HD, MM or amyloidosis while receiving plerixafor in mobilization. From January 2008 to March 2012 44 patients received plerixafor associated G-CSF in a second attempt at mobilization when they have already failed a first mobilization. From march 2012 to February 2013 10 patients preemptively received plerixafor who seem mobilize poorly: (1) blood CD34+ cells/μL <10 on the programmed day to initiate aphaeresis after G-CSF or (2) <1x10^6/kg after the first aphaeresis process. All patients provided written informed consent.
Results: Plerixafor in second mobilizations: 44 patients received plerixafor in this setting. The median age was 61y (25-70). 26 had NHL, 13 MM, 3 HD and 2 amyloidosis. 43 received standard plerixafor dosage, 1 patient received adjusted dosage by renal insufficiency, and all of patients received G-CSF with a median dose of 10 μg/kg/d (10-20). Median number of plerixafor injections was 2 (1-4) and median CD34+ cells count after the first plerixafor injection was 14/μL (7-113). 37 (84%) of them initiated aphaeresis. A median of 2.23x10^6/kg (0-10.71) CD34+ cells were collected with a median of 1 (1-4) aphaeresis. >2x10^6/kg CD34+ cells were achieved in 28 (63%) patients (61.53% in NHL, 66.6% in HD and 84.61% in MM). Pre-emptive use of plerixafor was administered to 10 patients (5 had NHL, 4 MM and 1 HD) with a median age of 68y (40-69). The reason to use plerixafor pre-emptively where low blood CD34+ counts in 9 patients an poor yield collection in 1. All received standard plerixafor dosage before 4-day G-CSF therapy with a median dose of 10 μg/kg/d (10-20). Median number of plerixafor injections was 2 (1-4). Median CD34+ cells count the programmed day to initiate aphaeresis was 7/μL (0.84–11.39). Thus 8 (80%) of the 9 patients began aphaeresis due to delay the start of harvest to the first plerixafor administration when the peripheral CD34+ count has increased to a median of 13.42/μL (6.23-127.5). A median of 2.58x10^6/kg (0.6-4.81) CD34+ cells were collected with a median of 1 (1-4) aphaeresis. >2 x10^6/kg CD34+ cells were achieved in 7 (72%) patients.
Summary / Conclusion: Results from this study showed that plerixafor is a safe and active mobilising agent in the two strategy arms with 63% efficacy using it in remobilization and 72% as pre-emptive strategy. Although pre-emptive use may not be able to completely eliminate the need for a second attempt to mobilize, this strategy seems more efficient and should be considered in patients judged as poor mobilizers using it to optimize patient outcome and reduce of other hospital resources.

Stem cell transplantation - Clinical 2

P362

LOW PRE-TREATMENT MIR-181A-1 AND MIR-181A-2 EXPRESSION ASSOCIATE WITH RELAPSE IN INTERMEDIATE RISK ACUTE MYELOID LEUKEMIA (AML) AFTER REDUCED-INTENSITY CONDITIONING (RIC) ALLOGENEIC TRANSPLANTATION
S Schwind[1,*] M Jentzsch[1], T Lange[1], W Pönisch[1], S Heyn[1], V Vucinic[1], G Franke[1], R Krahl[1], N Jäkel[1], H Al-Ali[1], Michael Cross[1], G Behre[1], G Marcucci[2], C Bloomfield[2], D Niederwieser[1]
[1]Hematology, Oncology and Hemostaseology, University of Leipzig, Leipzig, Germany, [2]Comprehensive Cancer Center, The Ohio State University, Columbus, United States

Background: AML patients (pts) with higher pre-treatment *miR-181a* expression have better outcomes following standard chemotherapy (Marcucci *et al.* NEJM 2008; Schwind *et al.* JCO 2010; Li *et al.* Blood 2012). Clinical attempts to increase *miR-181a* expression in AML patients to improve outcomes have been initiated. Mature *miR-181a* originates from two precursor molecules (*miR-181a-1* & *miR-181a-2*) which may impact on AML biology & outcome differently. Allogeneic hematopoietic cell transplantation (HCT) represents a post-remission therapy offering potential cure for AML pts. RIC, with a therapeutic approach mainly based on immunological graft-versus-leukemia effects, is increasingly used in AML pts undergoing HCT.
Aims: In this analysis we concentrated on the clinical characteristics & prognostic impact associated with *miR-181a-1* & *miR-181a-2* pre-treatment expression in AML pts treated with RIC-HCT.
Methods: *miR-181a-1* & *miR-181a-2* expression were assessed by real-time PCR and normalized to an internal control (*ABL*) in pre-treatment bone marrow (BM). The respective median expression defined high & low *miR-181a-1* & *miR-181a-2* expressers in 39 consecutive AML pts (median age, 62 [range 27 – 67] years) with intermediate cytogenetic risk (according to the Medical Research Council [MRC] Classification), who received RIC-HCT at the University of Leipzig & who had adequate material available. The preparative regimen for all pts was Fludarabine 30 mg/m^2 from day -4 to -2 followed by 200cGy total body irradiation at day 0. Donors were human leucocyte antigen (HLA)-matched related (n=5), matched unrelated (n=29) and mismatched unrelated (≥1 antigen; n=5) to the recipients. Acute graft-versus-host disease (GvHD) grade 2-4 was observed in 12 pts & limited/extensive chronic GvHD in 24 pts. Median follow-up was 6.5 years for pts alive (n=21). Informed consent for the study was obtained from all pts.
Results: *miR-181a-1* & *miR-181a-2* expression correlated well (R^2=.83), but 31% (n=12) of pts had a discordant *miR-181a-1* & *miR-181a-2* expresser status. At diagnosis low *miR-181a-1* associated with higher white blood count (P=.03), while low *miR-181a-2* associated with normal cytogenetics (CN; P=.03) & with higher % BM blasts by trend (P=.08). In univariate analysis pts with both low *miR-181a-1* & low *miR-181a-2* had a higher probability of relapse (P=.008, Gray's test; Figure A). Low *miR-181a-1* & low *miR-181a-2* expression also associated with shorter overall survival (OS) by trend (P=.06, Log-Rank test; Figure B). When limiting our analysis to CN-AML pts (n=28) low *miR-181a-1* & *miR-181a-2* also associated with a higher probability of relapse (P=.007). In multivariable analysis low *miR-181a-1* & low *miR-181a-2* associated with a higher probability of relapse (P=.01) & shorter OS (P=.01) in all intermediated risk pts.
Summary / Conclusion: In conclusion, expression of *miR-181a-1* & *miR-181a-2* is not fully concordant & associates with different clinical characteristics at AML diagnosis, indicating a distinct impact on disease biology. However, low expression of both seems to impact outcome after RIC-HCT. Low pretreatment *miR-181a-1* & *miR-181a-2* expression associated with a higher probability of relapse & shorter OS in AML pts with intermediate cytogenetic risk. Increasing *miR-181a-1* and/or *miR-181a-2* levels either pharmacologically (eg Hickey *et al* Blood 2013) or by synthetic miR-replacement therapy may improve outcomes of AML pts receiving RIC-HCT.

INTRABONE CORD BLOOD TRANSPLANT (IB-CBT) IN HAEMATOLOGICAL MALIGNANCIES: A CLINICAL AND BIOLOGICAL STUDY ON EARLY HEMATOPOIETIC RECONSTITUTION.

F Bonifazi[1],* E Dan[1], M Labopin[2], V Guadagnolo[1], G Storci[3], M Ferioli[1], S Rizzi[1], B Sinigaglia[1], A Bontadini[4], M Motta[1], G Martinelli[1], G Bandini[1], M Bonafè[3]

[1]S. Orsola-Malpighi University Hospital, Institute oh hematology "Seràgnoli", Bologna, Italy, [2]Hôpital Saint-Antoine , 184 rue du Faubourg Saint-Antoine , 75571 Paris, France, [3]Department of Experimental, Diagnostic and Specialty Medicine, , University of Bologna, [4]S. Orsola-Malpighi University Hospital, Immunogenetics, Bologna, Italy

Background: Intrabone route of CB-HSC administration is a safe and efficient way to overcome the main impediment to the extensive use of CB transplant in adults, i.e. the insufficient amount of HSC in CB units. The "Intrabone effect" is speculatively elicited by the hypoxic bone marrow niche microenvironment, which primes CB-HSCs prior to set off the repopulation of the whole hematopoietic compartment.

Aims: Here we report on a phase II prospective study approved by the local EC and registered at http://clinicaltrials.gov/, with the primary endpoint of engraftment rate. From the biological side, we investigated hypoxia-induced genes whose expression can be correlate with engraftment.

Methods: 23 patients (median age 36 yrs, mean weight 63 kg -52 to 93-) were enrolled: 17 were AML, 4 ALL, 1 MM and 1 CML. Phase at transplant was mainly advanced stage (10 primary refractory or resistant relapse AL, 6 beyond first and 5 first cariotypic response; 1 progression for MM and 1 CB for CML). 3 patients had previously undergone allotransplant and 4 autotransplant. CB units were matched 4/6, except for three cases (5/6). Infusion on both iliac crests was performed in operating room with monitored care sedation. Conditioning regimens were Busulfan- or TBI- based; GVHD prophylaxis was Ciclosporin-A, Micophenolate Mofetil 15 mg/kg/bid and ATG-F (15-30 mg/kg).To follow-up hematopoietic reconstitution, peripheral blood was examined daily and bone marrow aspirates were performed at day 10, 20 and 30 after transplant. The samples were used to immune-magnetically separate CD34+ cells under hypoxia condition and to assess the mRNA level of target genes by Real Time PCR.

Results: Hematologic recovery: the cumulative incidence of ANC recovery (>0.5x10^9/L) was 82±9% at day+60; the cumulative incidence of plt recovery (>20 or 50x10^9/L) was 82±9% and 70±10% at day+90, respectively. In multivariate analysis, the number of infused CD34 cells was a prognostic factor for haematologic recovery. Importantly, haematological recovery was highly correlated with post-transplant day 10 mRNA level of c-mpl (TPO receptor) even when the number of infused CD34 cells were included in the multivariate analysis. Two patients failed to engraft and were IB infused with a second CB unit. One year OS and NRM were 66±11% and 20±9%, respectively. aGVHD was 39% with only one patient at grade III. Three limited and one extensive cGVHD were recorded. All but two patients achieved complete response. CMV reactivation occurred in 13/23 pts.

Summary / Conclusion: from the clinical point of view, we confirm, in a prospective study, that the intrabone route of CB transplant is feasible and leads to a remarkably fast platelet recovery. On the biological side, we show that the c-mpl/thrombopoietin receptor system contributes to the "intrabone effect" on hematologic recovery. These data provide hints about the strategy to improve early seeding and expansion of CB in the hypoxic HSC niche.

P364

DONOR AND RECIPIENT STR ANALYSIS BEFORE ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION: POSSIBLE CORRELATION WITH POST-TRANSPLANT OUTCOME

S Giammarco[1],* S Bellesi[1], E Metafuni[1], F Sorà[1], L Laurenti[1], S Sica[1], G Leone[1], P Chiusolo[1]

[1]Hematology, Università Cattolica del Sacro Cuore, ROMA, Italy

Background: The chimerism analysis after allogeneic haematopoietic stem cell transplantation (HSCT) is a useful tool to monitor the engraftment of donor cells and to early predict graft failure or disease relapse. Among several available methods to perform chimerism study, multiplex fluorescent short tandem repeat (STR) analysis represent a sensitive, accurate and reproducible technique. It provide a high rate of discrimination between donor and recipient cells since that fluorescent signal is proportional to the cells number, obtaining a quantitative assessment of chimerism.

Aims: Evaluation of a possible correlation between basal donor/recipient allelic discrepancies and post-transplant outcome in terms of GvHD development, neutrophil engraftment, relapse, DFS and OS.

Methods: We enrolled 111 patients (pts) affected by onco-haematological diseases, consecutively submitted to HSCT at our division between February 2005 and December 2012. Pts were 67 males and 44 females with a median age of 51 years (range 14-70). Underlying diseases were: 58 AML, 10 MDS, 16 ALL, 8 CLL, 6 MM, 2 HL, 9 NHL, 1 IMF, 1 MPD. Myeloablative conditioning regimen was used in 26 pts while a reduced conditioning regimen was used for the other 85 pts. Graft was obtained from sibling donor and unrelated donor in 65 and 46 pts, respectively. GvHD prophylaxis was performed with cyclosporine (CSA) and methotrexate in 61 pts, CSA and mycophenolate mofetil in 43 pts and CSA in 7 pts. Donor and recipient allelic status was performed using a multiplex PCR amplification of ten STR loci: Amelogenin alleles X/Y, D3S1358, FGA, D8S1179, D18S51, D13S317, vWA, D21S11, D5S818, D7S820. We evaluated the donor/recipient (D/R) match or mismatch for each locus and the following variables: GvHD development and onset time, time to neutrophil engraftment, relapse, DFS and OS. Statistical analysis was performed by Kaplan Meier analysis using IBM SPSS Statistics 20 Core System.

Results: Pts with D/R mismatch for D8S1179 locus achieved neutrophil engraftment (ANC>1x10^9/L) at a median time of 18 days (CI 95% 17.202-18.798) compared with 21 days (CI 95% 17.328-24.672) of pts with D/R match for the same locus (P=0.007) (Figure 1A).

Pts with D/R mismatch for D3S1358 locus developed acute GvHD at a median time of 20 days (CI 95% 15.781-24.219) compared with 29 days (CI 95% 15.421-42.579) of pts with D/R match for the same locus (P=0.031) (Figure 1B).

Pts with D/R mismatch for D3S1358 locus showed an OS of 16 months (CI 95% 11.016-20.984) compared with 41 months (CI 95% 25.420-56.580) of pts with D/R match for the same locus (P=0.025) (Figure 1C).

Pts with D/R mismatch for D8S1179 locus showed an OS of 16 months (CI 95% 8.528-23.472) compared with 56 months (CI 95% 11.254-78.057) of pts with D/R match for the same locus (P=0.012) (Figure 1D).

No relationships were found with relapse, DFS neither for the other loci.

Summary / Conclusion: Our results highlight that pts who presented a D/R mismatch for D8S1179 locus showed an earlier neutrophil engraftment but a worse OS compared with the others. Moreover, for D3S1358 locus, D/R mismatch was associated with an earlier onset of acute GvHD after HSCT and with a shorter OS than the D/R match ones. STRs are highly polymorphic di-, tri- and tetra-nucleotide repeat non-coding sequences, which are interspersed throughout the genome. Whether or not discrepancies between donor and recipient basal allelic status could be considered useful in predicting post-transplant outcome will require validation in a large sample of pts.

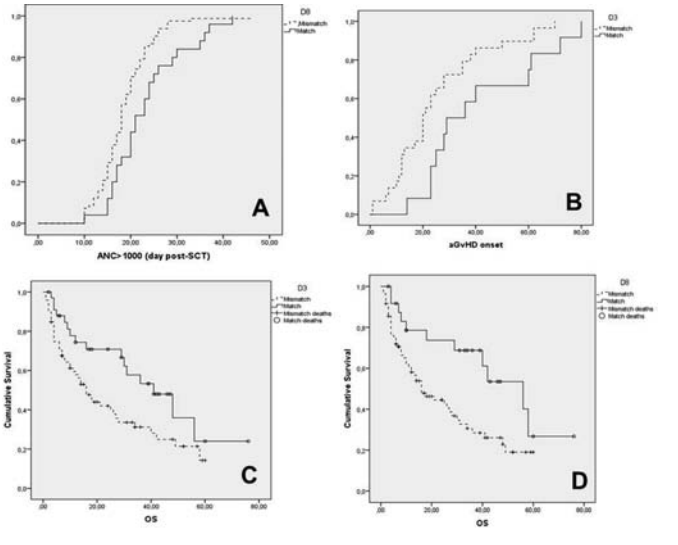

Figure 1.

P365

COMPARISON BETWEEN LONG-TERM AND SHORT-TERM ADMINISTRATION OF ITRACONAZOLE FOR PRIMARY ANTIFUNGAL PROPHYLAXIS IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION: A MULTICENTER, RANDOMIZED TRIAL

R Lin[1], X Xu[2], Y Li[3], J Sun[1], Z Fan[1], Q Jiang[1], F Huang[3], H Zhou[1], D Nie[4], Z Guo[2], Y Mao[1], Y Xiao[3], Q Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou , [2]Department of Hematology, Zhongshan Hospital, Sun Yat-sen University, Zhongshan, [3]Department of Hematology, Guangzhou General Hospital of Guangzhou Command, [4]Department of Hematology, SUN Yat-sen Memorial Hospital, SUN Yat-sen University, Guangzhou , China

Background: Although antifungal prophylaxis has been demonstrated effective for prevention of IFI after allogeneic haematopoietic stem cell transplantation (allo-HSCT), optimal agents and duration of prophylaxis remain a matter of discussion.
Aims: To investigate the effect of prophylaxis duration for IFI after transplantation, this multicenter, randomized, open-label study was conducted to compare the efficacy and safety between long-term and short-term administration of itraconazole for primary antifungal prophylaxis in recipients of allo-HSCT.
Methods: A total of 128 patients without a history of IFI were enrolled in this study. The primary antifungal prophylaxis was initiated when WBC count < 1.0×10^9/L or on day 0 (the day of allo-HSCT). Itraconazole was administered intravenously with a loading dose of 400 mg/d for 2 days followed by 200 mg/d and switched to oral solution of itraconazole on day +14 or when WBC count > 1.0×10^9/L until 30 days after transplantation in short-term arm or 90 days in long-term arm. The trough serum concentrations of itraconazole and its active metabolite hydroxyitraconazole were measured on days 3 and 8 after the beginning of administration, and then once every week during the period of prophylaxis. The primary endpoint was the incidence of IFI within 90 days after transplantation.
Results: Of the 128 patients enrolled in study, data of 121 cases were used to determine the primary endpoint in the intent-to-treat population (59 for long-term and 62 for short-term). The baseline demographic and transplanted characteristics were similar in the two arms. Within 90 days post-transplantation, 8 patients developed IFI including 1 probable and 7 possible cases. No significant difference in the incidence of IFI between long-term and short-term arm was shown by analysis of the intent-to-treat (6.78% vs. 6.45%, 95%CI of difference: 0.24% to 0.42%), indicating the noninferiority of long-term administration against short-term administration. The incidence of breakthrough IFI during the period of prophylaxis in patients with long-term and short-term administration were 6.78% and 0%, respectively. Between 30 days to 90 days after transplants, the incidence of IFI was not significant different in the two arms (0% in long-term arm vs. 6.45% in short-term arm,P=0.11 by analysis of the intent-to-treat; 0% in long-term arm vs. 6.67% in short-term arm, P= 0.12 by analysis of the per protocol set). After 2 days of treatment with intravenous itraconazole, the mean trough serum concentration of itraconazole was 520.72±483.26ng/mL and maintained greater than 500ng/ml throughout administration. Eleven patients were withdrawn from prophylaxis because of adverse events. The incidence of withdrawal in patients with long-term and short-term prophylaxis was 6.78% and 0%, respectively (P=0.054). The incidences of drug-related adverse events in the two arms were similar (18.6% in long-term arm vs. 12.9% in short-term arm, P=0.386).
Summary / Conclusion: Itraconazole with 90 days administration was as effective as that with 30 days administration in preventing fungal infection after transplantation. Prolonged-term prophylaxis might not increase side effect of itraconazole. The pharmacokinetics of itraconazole in the recipients of allo-HSCT is coincident with that in non-recipients of allo-HSCT.
This trial was registered at www.clinicaltrials.gov as NCT01160952.

P366

BENDAMUSTINE, ETOPOSIDE, CYTARABINE AND MELPHALAN (BEEAM) FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION INDUCE LONG-LASTING COMPLETE REMISSIONS IN A HIGH PROPORTION OF RESISTANT/RELAPSED LYMPHOMA P

A Isidori[1,*] P Maria Stefani[2], S Capria[3], L Malerba[1], P Galieni[4], F Gaudio[5], G Specchia[5], G Meloni[3], F Gherlinzoni[2], C Giardini[6], S Falcioni[4], F Cuberli[7], M Gobbi[7], B Sarina[8], A Santoro[8], F Ferrara[9], M Rocchi[10], E Ocio[11], M Dolores Caballero[11], P Picardi[1], T Ricciardi[1], F Loscocco[1], G Visani[1]
[1]AORMN, Hematology and Stem Cell Transplant Center, Pesaro, [2]Ca'Foncello Hospital, Hematology, Treviso, [3]La Sapienza University, Biotechnologies and Hematology Unit, Roma, [4]Ascoli Piceno Hospital, Hematology, Ascoli Piceno, [5]AOU Policlinico of Bari, Hematology, Bari, [6]AORMN, Hematology and Hematopoietic Stem Cell Transplant Centre, Pesaro, [7]San Martino Hospital, Hematology, Genova, [8]Humanitas Institute, Oncology and Hematology, Milano, [9]Cardarelli Hospital, Hematology and Stem Cell Transplantation Unit, Napoli, [10]Urbino University, Institute of Biomathematics, Urbino, Italy, [11]University of Salamanca, Hematology, Salamanca, Spain

Background: We previously demonstrated (Visani *et al*, Blood 2011) the safety of a new conditioning regimen with bendamustine, etoposide, cytarabine, and melphalan (BeEAM) prior to autologous stem cell transplant (ASCT) in resistant/relapsed lymphoma patients (EUDRACTnumber2008-002736-15). Furthermore, this regimen showed significant anti-lymphoma activity (80% CR), specially in patients with chemosensitive disease and non-Hodgkin lymphoma (NHL). However, median follow-up for surviving patients was short (18 months) at the time of publication. Therefore, it was not possible to draw final conclusion on the efficacy of the BeEAM regimen.
Aims: We evaluated the efficacy of the BeEAM regimen in terms of disease-free (DFS) and overall survival (OS) after a median follow-up of 32 months.
Methods: Forty-three patients (median age 47 years, range 18-70) with resistant/relapsed NHL (28) or Hodgkin lymphoma (HL, 15) were consecutively enrolled in the study. Twenty-one patients had primary refractory disease, whereas 22 had relapsed disease, 5 of whom where in second or subsequent relapse, at the time of enrolment. At transplant, 14/43 patients (34%) were in CR, 22/43 (50%) were in partial response (PR) and 7/43 (16%) were either resistant or in progression. At the time of publication, after a median follow-up of 18 months, 35/43 patients (81%) were in CR, and only 2 patients with HL died. Disease type (NHL versus HL) and disease status at transplant (chemosensitive versus chemoresistant) were the only statistically significant variables influencing PFS (P=0.01;P=0.007). Disease status at transplant (chemosensitive versus chemoresistant) had a significant impact also on OS (P=0.004).
Results: we updated the follow-up at 32 months after transplant. Thirty-one out of 43 patients are still in CR (72%), as documented by both PET and CT scan. Two patients with HL were refractory and rapidly died, whereas 10/43 patients (23%) relapsed after a median time of 7.5 months (range:3-35) from transplant. Five patients died (3 NHL, 2 HL), whereas 5 patients are still alive after relapse. Median PFS and OS were still not reached. Interestingly, disease type at transplant is no longer influencing PFS (P=0.4), and still does not influence OS (P=0.3). On the other hand, disease status at transplant (chemosensitive vs chemoresistant) is still a strong predictor of both PFS and OS (P=0.03 and P=0.04, respectively). At present, one patient developed myelodisplasia after transplant. No other late effects were observed up to now.
Summary / Conclusion: The new BeEAM regimen confirms its safety, even after 32 months of follow-up from transplant. Furthermore, these data confirm the high efficacy of this regimen in heavily pretreated lymphoma patients. Interestingly, the statistical difference between NHL and HL patients in terms of both PFS and OS was not confirmed in the long run.
Acknowledgements: supported in part by AIL Pesaro Onlus.

A CONDITIONING PLATFORM WITH FLUDARABINE, BUSULFAN AND ATG CONDUCTS TO IDENTICAL PROMISING RESULTS IN PATIENTS UNDERGOING ALLOGENEIC TRANSPLANTATION FROM BOTH MATCHED AND MISMATCHED UNRELATED DONOR

R Devillier[1,2,3,*] S Fürst[1], R Crocchiolo[1], J El-Cheikh[1], L Castagna[4], S Harbi[1,2], A Granata[1], C Chabannon[1,2,3], B Calmels[5], C Lemarie[5], R Bouabdallah[1], N Vey[1,2,3], D Blaise[1,2,3]
[1]Hematology, Institut Paoli Calmettes, [2]Aix Marseille Université, [3]Centre de Recherche en Cancérologie de Marseille, Marseille, France, [4]Hematology, Instituto Clinico Humanitas, Milano, Italy, [5]Cell therapy, Institut Paoli Calmettes, Marseille, France

Background: Reduced-toxicity conditioning (RTC) regimen containing fludarabine (FLU), intravenous busulfan (Bx) and 5 mg/kg total dose of rabbit antithymocyte globulin (ATG) (FBx-ATG) showed low incidences of graft-versus-host disease (GVHD) and non-relapse mortality (NRM) after allogeneic stem cell transplantation (Allo-SCT) from HLA-matched related or unrelated donors (MUD). It is not known if this FBx-ATG RTC could provide such a safety used

in the setting of one-locus-HLA mismatched unrelated donor (MMUD).
Aims: The objective was to evaluate the mortality and toxicity of the FBx-ATG RTC in the setting of Allo-SCT from MMUD in a comparison with patients transplanted from MUD.
Methods: We retrospectively selected patients younger than 65 years, transplanted in our institution from 2008 and 2012 for hematological malignancies, from MUD or MMUD peripheral blood stem cells and prepared with FBx-ATG RTC (FLU 30 mg/m²/d over 5 days, Bx 3.2 mg/kg/d over2, 3 or 4 days, ATG 2.5 mg/kg/d over 2 days). GVHD prophylaxis consisted of Cyclosporine A (CsA) alone or in association with mycophenolate mofetil (MMF). We then compared outcome of MUD (n=88) vs. MMUD (n=45) patients. Primary end point was the incidence of NRM. GVHD incidences and survivals were analyzed as secondary end points.
Results: Median age was 54 years [range: 19-64] and patients characteristics were without difference between MUD and MMUD patients. Sixty patients (45%) were transplanted for AML or MDS. Remaining patients were transplanted for lymphoma and myeloma. According to institutional guidelines and treatment protocols, MMUD patients received more frequently CsA + MMF as GVHD prophylaxis (89%) than MUD patients (16%) (P<0.001). Repartition of HCT-CI score adapted from Sorror *et al*. and disease risk index adapted from Armand *et al*. were similar in the 2 donor groups. Median follow up was 25 months [range: 5-73].
Early NRM at day 100 was low in MUD (6%) patients as well as in MMUD (7%) patients. One-year NRM was similar in the 2 donor groups (MUD: 17% vs. MMUD: 18%, P=0.533). There was no difference in the cumulative incidence of grade II-IV acute GVHD (MUD: 31% vs. MMUD: 36%, P=0.745) but MMUD patients developed more grade III-IV acute GVHD (MUD: 6% vs. MMUD: 16%, P=0.020). There was no difference in the cumulative incidences of overall chronic GVHD (MUD: 35% vs. MMUD: 29%, P=0.644) and extensive chronic GVHD (MUD: 21% vs. MMUD: 27%, P=0.540). Progression-free survival (MUD: 59% vs. MMUD: 55%, P=0.334) and overall survival (MUD: 61% vs. MMUD: 61%, P=0.748) were not different between MUD and MMUD patients. With a median follow up of 25 months, 42 of the 88 MUD patients (47%) and 20 of the MMUD patients 45 (44%) were free of both disease progression and immunosuppressive treatment (P=0.597).
Summary / Conclusion: We confirm that FBx-ATG RTC regimens provides low incidence of NRM in patients younger than 65 years transplanted from MUD, and equally from MMUD. This kind of RTC could safely extend the use of Allo-SCT to patients for whom only an MMUD is identified.

MOLECULAR MONITORING AND STEPWISE PREEMPTIVE THERAPY FOR EPSTEIN-BARR VIRUS VIREMIA AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Q Liu[1,*] L Xuan[1], H Liu[1], F Huang[1], H Zhou[1], Z Fan[1], K Zhao[1], M Wu[1], L Xu[2], X Zhai[1], F Zhang[1], C Liu[1], J Sun[1], X Huang[2]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, [2]Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Epstein-Barr virus (EBV)-associated diseases progress rapidly and are severe complications after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Despite various therapeutic options being developed, the optimal preemptive therapy forEBV-associated diseases remains under discussion. We developed a stepwise preemptive therapy (antiviral agents andreduction of immunosuppressants [RI] followed by rituximab) for EBV viremia based on duration of EBV-DNA positive and changes of viral loads.
Aims: To explore the efficacy of stepwise preemptive therapyand the optimal preemptive therapy forEBV-associated diseases after allo-HSCT.
Methods: The blood EBV-DNA loads were regularly monitored by quantitativereal-time polymerase chain reaction in251 recipients undergoing allo-HSCT. Stepwise preemptive therapy was administeredin patients experiencingblood EBV-DNA positive (more than 500 copies/ml) twice consecutively. Administration of antiviral agents and RI were first taken. If EBV-DNA was continuously positive four times with a rising trend, rituximab was administered weekly until EBV-DNA was negative or for a total of 4 times. The patients who were diagnosed as EBV-associated diseases orappeared the signs and symptomsof EBV-associated diseases within three days after preemptive therapy were withdrawn from the study of preemptive therapy.
Results: Seventy-two patientsdeveloped EBV viremia and 35 developed EBV-associated diseases, including 22 post-transplant lymphoproliferative diseases (PTLD)and 13 EBV-associated other diseases (8 EBVfever, 1 pneumonia, 1 encephalitis, 1 myelitis, 1 encephalitis with lung involvement as well as 1 encephalitis with lung and liverinvolvement). Univariate analysis revealed that antithymocyte globulin, HLA-mismatched, unrelated donor and intensified conditioning constituted the risk factors of EBV viremia and EBV-associated diseases, as none of the grafts were T-cell-depleted.The 3-year cumulative incidence of EBV viremia and EBV-associated diseases were 5.0%±2.8%, 13.3%±4.2%, 50.0%±10.2%, 63.1%±8.3%, 63.1%±10.0% (EBV viremia) and 3.5%±2.4%, 2.9%±2.0%, 28.3%±9.3%, 25.9%±6.2%, 46.4%±10.8% (EBV-associated diseases) for patients with 0, 1,2, 3 and 4 major risk factors, respectively (P<0.001, P<0.001). The blood EBV-DNA loads exceeded the thresholdfor 0 to 17 (median 7) days before the clinical manifestations of EBV-associated diseases emerged.Of the 64 patientsreceiving the first-step preemption,24(37.5%) cases achieved complete response (CR)and 40 showed no response, including 25 progressing to EBV-associated diseases duringthe first-step preemption. Fourteen (93.3%) achieved CR and one progressed toPTLD in the15 patients undergoing rituximab preemption. Of the 26 patients progressing to EBV-associated diseases during preemptive therapy,20 obtained CRin the 23 cases with rituximab-basedtreatments. Patients with ineffective preemption had more major risk factors than those with effective preemptive therapy (3.15 ±0.73 versus 2.53±1.06, P=0.007). B-cell reconstitution was significantly delayed for at least 6 months in patients with rituximab preemption. The risk of herpesvirus infection was similar in patients with effective first-step and rituximab preemption (P=0.094).
Summary / Conclusion: The strategy of stepwise preemptive therapy to prevent EBV-associated diseases is worthy further exploring. It is shown that the efficacy of preemptive therapy is associated with the numbers of major risk factors for EBV infections. To avoid over-treatment, RIplus antiviral agents could-begiven priorityto low-riskpatients; whereas considering the rapid and aggressive evolution of EBV viremia toward EBV-associated diseases, more frequent monitoring of blood EBV-DNA and earlier preemptive rituximab should be advocated inpatientsat high risk of EBV-associated diseases.

P369

BONE MARROW VERSUS PERIPHERAL BLOOD STEM CELL GRAFTS FOR UNRELATED DONOR TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING IN ADULTS WITH HIGH-RISK ACUTE LYMPHOBLASTIC LEUKEMIA

S Lee[1,*] S Shin[1], J Yoon[1], S Yahng[1], S Lee[1], B Cho[1], K Eom[1], Y Kim[1], N Chung[1], H Kim[1], C Min[1], D Kim[1], J Lee[1], W Min[1], C Park[1], J Kwak[2], J Kim[1], S Park[3]
[1]Catholic BMT Center, College of Medicine, The Catholic University of Korea, Seoul, [2]Chonbuk National University Medical School, Chonju, [3]Soonchunhyang University Medical School, Bucheon, Korea, Republic Of

Background: In the setting of matched sibling donor transplantation, several randomized trials showed that peripheral blood stem cells (PBSC) resulted in faster engraftment but increased the risk of acute and chronic graft-versus-host disease (GVHD), as compared with bone marrow (BM). In addition, some studies showed a decreased rate of relapse and better survival with PBSC, especially in patients with more advanced hematologic malignancies. However, these results may not be applicable to unrelated donor (URD) transplants, given the greater risk of GVHD due to the greater genetic diversity. In the setting of URD transplantation, few data are available comparing PBSC and BM, especially in patients with adult high-risk acute lymphoblastic leukemia (ALL).
Aims: To determine which graft source is superior in patients with adult high-risk ALL, we compared the long-term outcomes of URD transplantation using PBSC and BM.
Methods: To maximize the homogeneity of the patient population, only patients who received a uniform strategy of pre-transplant chemotherapy, myeloablative conditioning (total body irradiation [≥12 Gy]-based), and an identical GVHD prophylaxis (tacrolimus plus methotrexate) were included in this analysis. Between 2000 and 2009, 106 patients with high-risk ALL underwent myeloablative conditioning URD transplantation with PBSC (n=38) or BM (n=68) grafts. The main presenting clinical and biological features between the two groups

were comparable. The median follow-up of survivors was 60 months (range, 38 to 81 months) for PBSC transplants and 102 months (range, 49 to 147 months) for BM transplants.
Results: PBSC transplants showed faster time to recovery of neutrophil (12 days vs. 14 days; P<0.001) and platelet (12 days vs. 21 days; P<0.001) counts than BM transplants. No difference was observed in the cumulative incidence of acute GVHD between the two groups (76.3% for PBSC transplants vs. 63.2% for BM transplants), but PBSC transplants showed higher incidence of chronic GVHD than BM transplants (68.4% vs. 41.2%, P=0.009). At 5 years, PBSC transplants showed comparable outcomes to MAC transplants in terms of relapse risk (26.8% vs. 35.1%), nonrelapse mortality (19.8% vs. 26.6%), disease-free survival (57.9% vs. 48.5%), and overall survival (57.9% vs. 50.0%). In multivariate analysis, graft source had no impact on transplantation outcomes. Regardless of graft source, transplants without chronic GVHD had higher relapse risk (53.2% vs. 14.4%; HR, 4.88; 95% CI, 2.04-11.66; P<0.001) and poorer disease-free survival (41.5% vs. 70.4%; HR, 2.62; 95% CI, 1.38-4.98; P=0.003) and overall survival (43.9% vs. 70.4%; HR, 2.20; 95% CI, 1.14-4.23; P=0.018). In addition, transplants in CR1 had lower relapse risk (62.8% vs. 22.8%; HR, 3.51; 95% CI, 1.62-7.58; P=0.001) and better disease-free survival (60.2% vs. 21.7%; HR, 3.02; 95% CI, 1.57-5.80; P=0.001) and overall survival (61.4% vs. 21.7%; HR, 2.92; 95% CI, 1.49-5.73; P=0.002).
Summary / Conclusion: Our data suggest that long-term outcomes are similar between PBSC and BM in the setting of URD transplantation in adults with high-risk ALL.

P370

LONG-TERM OUTCOMES OF REDUCED-INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION FOR ADULT HIGH-RISK ACUTE LYMPHOBLASTIC LEUKEMIA

S Lee[1,*] K Eom[1], S Shin[1], H Yoon[1], S Yahng[1], S Lee[1], B Cho[1], Y Kim[1], N Chung[1], H Kim[1], C Min[1], D Kim[1], J Lee[1], W Min[1], C Park[1], S Park[2], J Kwak[3], J Kim[1]
[1]Catholic BMT Center, College of Medicine, The Catholic University of Korea, Seoul, [2]Soonchunhyang University Medical School, Bucheon, [3]Chonbuk National University Medical School, Chonju, Korea, Republic Of

Background: The role of reduced-intensity conditioning (RIC) allogeneic stem cell transplantation (SCT) in adult acute lymphoblastic leukemia (ALL) remains unclear because of the small sample size, short follow-up duration, various regimens for conditioning and graft-versus-host disease (GVHD) prophylaxis, and the heterogeneity of the criteria used to select patients for transplantation. Previously, we conducted a phase 2 trial of RIC-SCT in adults with high-risk ALL in complete remission (CR). Our interim analysis data showed the potential role of RIC-SCT (Leukemia. 2009;23:1763-1770).
Aims: We report on the updated results of RIC-SCT by analyzing 60 consecutive adult high-risk ALL transplants in CR1 (n=52; 86.7%) or CR2 (n=8; 13.3%) with a sufficient median follow-up duration of 67 months (range, 32 to 148 months).
Methods: The indications for RIC-SCT were advanced age (≥50 years; n=26; 43.3%) and the presence of organ dysfunction or active infections (n=34; 56.7%). All patients were given a uniform strategy of pre-transplant chemotherapy and an identical RIC regimen consisting of fludarabine (150 mg/m^2) and melphalan (140 mg/m^2). GVHD prophylaxis was attempted by administering calcineurin inhibitors (cyclosporine for all sibling donor transplants and tacrolimus for all unrelated donor transplants) plus methotrexate (10 mg/m^2 on days1,3, 6, and 11). If residual leukemia was detected in the absence of GVHD at 3 months after transplantation, calcineurin inhibitors were rapidly discontinued.
Results: Neutrophil recovery occurred in all patients at a median of 12 days (range, 9 to 20 days), and platelet recovery occurred at a median of 13 days (range, 7 to 23 days) after transplantation. Twenty-nine patients developed grade II to IV acute GVHD (22 grade II, 3 grade III, 4 grade IV). The cumulative incidence of acute GVHD at 5 years was 48.3±6.3%. Of the 56 patients who survived for at least 100 days with sustained engraftment after transplantation, 34 developed chronic GVHD (15 limited, 19 extensive), resulting in a 5-year cumulative incidence of 56.7±6.4%. After a median follow-up of 67 months, the cumulative incidence of relapse and nonrelapse mortality at 5 years were 34.2±6.7% and 21.2±5.8%, respectively, and the 5-year disease-free survival and overall survival rates were 50.8±6.6% and 54.5±6.5%, respectively. In multivariate analysis, transplants without chronic GVHD had a higher relapse risk (68.5% vs. 14.4%; HR, 9.04; 95% CI, 2.93-27.83; P<0.001) and poorer disease-free survival (27.3% vs. 71.5%; HR, 7.62; 95% CI, 3.08-18.85; P<0.001). In addition, transplants in CR1 showed better disease-free survival (54.7% vs. 25.0%; HR, 3.96; 95% CI, 1.27-12.40; P=0.018) and tended to show a lower relapse risk (29.0% vs. 66.7%; HR, 2.79; 95% CI, 0.97-8.03; P=0.057).
Summary / Conclusion: RIC can be considered as a reasonable choice for providing a sufficient long-term graft-versus-leukemia effect for adult high-risk ALL patients ineligible for myeloablative conditioning.

P371

REDUCED TOXICITY CONDITIONING AND ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULTS USING FLUDARABINE, BCNU, MELPHALAN, AND ANTITHYMOCYTE GLOBULIN (FBM-A): OUTCOMES DEPEND ON DISEASE RISK INDEX

J Leis[1,*] A Dueck[2], V Fauble[1], L Sproat[1], P Noel[1], N Khera[1], J Betcher[3], J Klein[1], R Adams[1], J Slack[1]
[1]Medicine, [2]Biostatistics, [3]Pharmacy, Mayo Clinic, Phoenix, United States

Background: Allogeneic hematopoietic cell transplantation (HCT) is the only curative option for many individuals with high-risk or refractory hematologic malignancies. The therapeutic benefit of allogeneic HCT ultimately derives from a graft-versus-malignancy effect that is based on immunologic disparity between recipient and donor. Until recently, allogeneic HCT was considered suitable only for younger and generally healthier patients due to increased regimen related toxicity seen with ablative doses of chemotherapy and/or radiation. Over the past decade reduced intensity conditioning (RIC) regimens have become standard of care for older and comorbid patients with high-risk hematologic malignancies who require HCT. However the optimum regimen has yet to be defined, and may differ for patients with varying pre-transplant risk factors. In 2008, Marks *et al*. reported results in 133 patients transplanted between 1998 and 2003 who were conditioned with a reduced toxicity regimen of fludarabine, BCNU (Carmustine), and Melphalan (FBM). Given that patients in that study were ineligible for standard ablative conditioning, older (median age 55.6), and often had active disease at transplant, the long-term results were very favorable (5-year EFS of 42%). We incorporated this regimen for treatment of hematologic malignancies, added rabbit antithymocyte globulin (Genzyme), and report results here.
Aims: 1. Confirm the safety, tolerability, and efficacy of the FBM regimen in patients with hematologic malignancies. 2. Assess the impact of patient characteristics, comorbidities, and CIBMTR disease risk assessment on HCT outcomes. 3. Determine the impact or rabbit antithymocyte globulin (Genzyme) on the incidence of acute and chronic GVHD.
Methods: We report results in 100 consecutive adults age 18-69 who received RIC with fludarabine, BCNU, melphalan, and rabbit antithymocyte globulin (FBM-A). Patients had high risk myeloid (AML, n=41; MDS, n=23, MPD, n=14, systemic mastocytosis, n=1) or lymphoid (ALL, n=8; NHL, n=8, Hodgkin lymphoma, n=4, CLL, n=1) malignancy. Median age was 55 (range 19 – 69), and most patients were ineligible for standard myeloablative conditioning due to age, organ dysfunction, or prior autologous HCT (45 had an HCT-CI score of >/=3). Donors were unrelated in 74, of which 34 were mismatched at one or 2 HLA loci; grafts were PBSC in 98 patients, and bone marrow and cord blood in 1 patient each. Outcomes were stratified using disease risk index (DRI) (Armand et. al. 2012).
Results: Overall survival (OS), event-free survival (EFS), non-relapse mortality (NRM), and relapse at 2 years were 68%, 66%, 20%, and 18%, respectively. Using the DRI, 68 patients were classified as low (n=1) or intermediate risk (n=67; DRI Low/Int), and 32 as high (n=28) or very high risk (n=4; DRI High/VH). With a median follow-up of surviving patients of 18 months, the Kaplan-Meier estimate of OS at 2 years for patients in the Low/Int risk group is 79%, compared to 61% in the High/VH group (P=.098). Two-year cumulative incidence estimates of relapse and NRM in the Low/Int group are 9.9% and 17%, respectively, vs. 25% and 21% in the High/VH group (P=0.057 and 0.69, respectively). The incidence of acute GVHD (grades III-IV) at 6 months was 9.8%, and the incidence of NIH-defined moderate-to-severe chronic GVHD was 22% at 2 years. Outcomes were not influenced by age, HCT-CI score, donor type, donor gender, or presence of mismatch.
Summary / Conclusion: The FBM-A regimen is safe, well-tolerated, and effective in patients up to age 69 with a wide array of hematologic malignancies. FBM-A may be most suitable for patients with low/intermediate risk disease by the DRI who have otherwise incurable hematologic malignancies. Despite advanced age and often high comorbidity scores, the 2-year OS was 79% for the low/int risk group and incidence of severe chronic GVHD was small. Curative strategies for very advanced or higher-risk hematologic malignancies will require additional pre- or post-transplant approaches to reduce disease burden or eradicate minimal residual disease. The FBM-A regimen offers a safe and effective platform to investigate such approaches.

P372

PREVALENCE OF METABOLIC SYNDROME AND METABOLIC PROFILE IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

G Mometto[1,*] L Airaghi[2], A Orsatti[2], F Onida[1], E Tagliaferri[1], F Grifoni[1], G Saporiti[1], C Olivares[1], C Bucelli[1], A Cortelezzi[1], C Annaloro[1]
[1]Hematology 1 - BMT Center, [2]Internal Medicine 1/B, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico - University of Milan, Milan, Italy

Background: In a previous paper (Airaghi L, J Endocrinol Invest 2011,34:6), we retrospectively observed an increased prevalence of metabolic syndrome (MS) in long term survivors after hematopoietic stem cell transplantation

(HSCT). In comparison to patients (pts) with spontaneous MS, we observed a difference in the clinical features, with hyperleptinemia rather than hyperinsulinemia being the key finding in HSCT recipients with MS

Aims: In pts referred for HSCT, we monitored prospectively the appearance of MS features and the evolution of laboratory parameters possibly involved in its pathogenesis. Here we present data from baseline pre-HSCT evaluation compared with those of 29 spontaneous MS, 29 post-HSCT MS pts and 29 healthy subjects derived from the above-mentioned retrospective study.

Methods: From May 2011 to February 2013 sixty-eight consecutive pts undergoing HSCT (M/F 35/33, median age 47.5, range 20-67 yrs; autologous 34, allogeneic 34) were enrolled in the study. For each patient, clinical history, physical examination, routine laboratory tests, endocrine profile, adipokines and TNF values were recorded. The comparison according to above criteria was performed univariately.

Results: A diagnosis of MS was established in 15 pre-HSCT cases; 10 had hypertension, 13 obesity, 4 hyperglycemia, 8 low HDL-cholesterol and 9 high triglycerides; 7 were candidate to autologous and 8 to allogeneic HSCT. Irrespective of having MS, 9 pts had double dyslipidemia. Pts pre-HSCT had significantly higher leptin (median 11.9 vs 7 ng/mL, P>0.01) and lower adiponectin (12.4 vs 18 mcg/mL, P<0.05) levels, in comparison with healthy subjects. Leptin levels in pre-HSCT pts were comparable with those of spontaneous MS (11.9 vs 15.3 ng/mL, P=n.s.) and significantly lower than those of HSCT survivors (11.9 vs 22 ng/mL, P<0.01). In pts pre-HSCT, adiponectin levels were similar to those of post-HSCT MS (12.4 vs 16 mcg/mL, P=n.s.), significantly lower than those of healthy subjects (12.4 vs 18 mcg/mL, P<0.05) and significantly higher than those of spontaneous MS (12.4 vs 9.4 mcg/mL, P<0.05). No difference among the separate groups was recorded in resistin levels. Insulin blood levels were comparable (11.5 vs 26 vs 26.5 mcU/mL, P=n.s.) in pre-HSCT pts, post-HSCT MS and spontaneous MS, whereas healthy subjects had significantly lower values in comparison with the three groups (10.1 mcU/mL, P<0.01). TNF levels were similar in pre-HSCT and in spontaneous MS (1.3 vs 2.8 pg/mL, P=n.s.), but significantly higher in post-HSCT MS (1.3 vs 11 pg/mL, P<0.05); fibrinogen was also significantly higher in post-HSCT MS than in pre-HSCT pts (402 vs 305 mg/dL, P<0.01).

Summary / Conclusion: Our data show a rather high prevalence of MS in pts referred to undergo HSCT, with a high prevalence of double dyslipidemia. Pts undergoing HSCT seem to comprise a self-standing population, characterized by high leptin, high insulin and low adiponectin levels, analogous to those of spontaneous MS. As spontaneous MS pts, they further differ from post-HSCT MS group, since the latter shows even higher leptin levels, with an increase in fibrinogen and TNF indicating a chronic inflammatory status. Our results point out to leptin rather than insulin resistance as a key pathogenetic clue in the development of post-HSCT MS, unlike to spontaneous MS. Therefore, the development of MS in HSCT recipients may be viewed as a multi-step process where conventional chemotherapy and conditioning regimens exert an additive effect in inducing a progressive increase in leptinemia, finally leading to full blown-MS.

P373

PREDICTION OF MOBILIZATION FAILURE FOR PRE-EMPTIVE PLERIXAFOR ADMINISTRATION: THE PAMPLONA PROTOCOL

P Anton[1,*] M Antelo[1], A Zabalza[1], S Zalba[1], M Aznar[1], E Vicente[1], I Aoiz[1], E Olavarria[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: The role of Plerixafor in routine peripheral blood progenitor cells (PBPC) mobilization in Myeloma or Lymphoma patients remains to be established.

Aims: In our institution we have developed a mobilization guideline (The Pamplona Protocol) to assess the safety and efficacy of Plerixafor + G-CSF in patients predicted to be poor mobilizers (PM).

Methods: The Pamplona protocol classifies patients according to PM risk factors including: a) previous mobilization failure; b) advanced disease; c) prior extensive radiotherapy; d) prior Hyper-CVAD, Fludarabine, Lenalidomide or alkylating agents; e) extensive BM involvement; f) >2 lines of chemotherapy; and g) age > 65. Patients with 3 or more risk factors are classified as PM and a PB CD34+ cell count is taken on day 4 of mobilization. All other patients have a CD34+ cell count on day 5 immediately before the apheresis procedure.
Plerixafor is administered at 6pm subcutaneously (0.24 mg/Kg) to: a) patients with a circulating CD34+ cell count < 10/uL (on either day 4 or 5) and b) patients with a first apheresis yield <1.0x10^6 CD34+/kg. G-CSF continues at the same dose (5-10 ug/Kg) and an apheresis is scheduled for the following morning.

Results: Since October 2009, a total of 146 patients were managed according to the Pamplona Protocol. 11 out of the 13 patients (85%) who were classified as PM before mobilization (9%) had a circulating CD34+ cell count <10/uL on day 4 and received Plerixafor as planned, demonstrating the high positive predictive value of the protocol. In addition, 9 patients (6%) failed to mobilize on day 5 despite having a median of 0.77 risk factors and also received Plerixafor. The diagnosis for the 20 patients that received Plerixafor was MM (n=7), NHL (n=11), HL and Amyloidosis (n=1 each). We observed a median of 3 fold increase in the number of CD34 circulating cells. The median CD34+ cell dose harvested was 2.33x10^6/Kg (range 0.32-5.69). There were no differences between the CD34+ cell dose in patients receiving Plerixafor on day 4 (median 2.3x10^6/Kg) and day 5 (median 2.5x10^6/Kg). The median number of apheresis was 1 (1-3). Only one patient failed to mobilize sufficient CD34+ cells. G-CSF and Plerixafor treatment was well tolerated. Adverse events were grade 1 in severity and were mostly gastrointestinal.

Summary / Conclusion: The Pamplona Protocol was able to predict PM before G-CSF administration allowing for early Plerixafor administration. Despite a 13.7% of PM in our series, 145/146 (99%) patients were able to harvest sufficient CD34+ cells for autologous SCT.

P374

DOES ALLOGENEIC STEM CELL TRANSPLANTATION OVERCOME THE ADVERSE RISK OF FLT3 POSITIVIVITY IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKAEMIA?

S Loingsigh[1,*] G O'Neill[1], T Nehhozina[1], M Chonghaile[1], P Vincent Browne[2], C Flynn[1], P Hayden[1], E Vandenberghe[1], E Conneally[1]
[1]Department of Haematology, [2]Haematology, St James's Hospital, Dublin, Ireland

Background: Cytogenetic abnormalities in acute myeloid leukaemia (AML) guide risk stratification regarding the use of haemopoietic stem cell transplantation (SCT). However, many AML patients have no karyotypic abnormality detectable: Cytogenetically normal AML (CN-AML). The presence of internal tandem duplication in the FMS-like tyrosine kinase 3 gene(FLT3), which is present in 23-25% of acute myeloid leukaemias with normal karyotype, has been associated with a poor outcome in CN-AML. Growing evidence suggests that SCT may improve outcome versus chemotherapy alone. We performed a retrospective analysis in our institution of all patients who underwent SCT for CN-AML between 2003 and 2011 in whom FLT3 status was available.

Aims: To examine the outcome post SCT of patients with CN-AML in whom FLT3 status was known in our institution.

Methods: 76 patients with CN-AML were identified from our transplant database. We excluded those in whom FLT3 status was not available. Baseline characteristics, disease status, stem cell source and survival were noted.

Results: FLT3 status was available in 52/76 patients. Of these, 35/52 (67%) tested negative for FLT3 and 17/52 (33%) tested positive. Median follow up was 28 months (1 month-96 months) in the overall group. Overall survival (OS) was 57% in the FLT3 negative group and 71% in the FLT3 positive group. 88% of the FLT3 positive group were transplanted in first complete remission (CR1) compared to 60% of those in the FLT3 negative group.

Summary / Conclusion: Patients with CN-AML who were FLT3 positive had a superior survival to both the FLT3 negative group and our institution's overall survival for intermediate risk acute myeloid leukaemia (59%) notwithstanding some differences in groups, most notably the proportion of patients in CR1 prior to SCT. This survival benefit, whilst not statistically significant given small numbers, is consistent with other reports supporting the suggestion that patients with CN-AML who are FLT3 positive can benefit from SCT in CR1.

Table 1.

	FLT 3 negative, n=35	FLT 3 positive, n=17
Age (years), median (range)	44 (22-64)	50 (20-64)
Male: female	20:15	7:10
SCT in CR1	21 (60%)	15 (88%)
SCT in CR2	13 (37%)	1 (6%)
SCT other	1 (3%)	1 (6%)
Stem cell source: BM:PBSC	16:19	10:7
Sibling donor: unrelated donor	20:15	10:7
Myeloablative conditioning	19	7
Reduced intensity conditioning	16	10
Follow up, median (range) *censored at death	29.8 months (1-97)	20.3 months (2-96)
Relapse rate	10 (29%)	6 (35%)
Death (all causes)	15 (43%)	5 (29%)
Overall survival (%)	57	71

P375

NK ALLOREACTIVE DONOR IS ASSOCIATED WITH REDUCED RELAPSE IN REFRACTORY AML BUT HIGH NONRELPASE MORTALITY IN PATIENTS WITH APLASTIC ANEMIA FOLLOWING T-REPLETE HAPLOIDENTICAL PBSCT WITH POST TRANSPLANT

S Jaiswal[1,*] S Chatterjee[1], B Mishra[1], M Bhakta[1], C Goswami[2], S Chakrabarti[1]
[1]Dept Of Blood And Marrow Transplantation, [2]Medical Oncology, Apollo Gleneagles Hospital, Kolkata, India

Background: NK cell alloreactivity has been shown to positively influence the outcome of high risk acute leukemia after T deplete Haploidentical PBSCT. However its impact on non-malignant disorders has not been studied particu-

larly in T replete Haploidentical PBSCT.
Aims: We conducted a pilot study on Haploidentical HCT with posttransplant cyclophosphamide (PTCY) and PBSC graft. The donors selected were either mother or NIMA mismatched siblings irrespective of NK cell alloreactivity. Ten antigen HLA typing, KIR genotyping and NK ligand typing were carried out on all patients and donors from stored samples. NK alloreactivity was determined based on missing self theory.
Methods: The conditioning protocol was developed based on FHCRC regimen of Fludarabine and low-dose Cyclophosphamide pre-transplant with escalating dose Melphalan 70-140 mg/m^2 replacing 2 Gy TBI. PTCY was administered 72hrs after infusion of the graft at 50 mg/kg twice at 24 hrs interval followed by Cyclosporine and MMF. The ones with AML received high dose AraC and mitoxantrone from day-14 to -12, along with Alemtuzumab 0.2 mg/kg/day. Alemtuzumab at above doses was administered from D -8 to D-4 in patients with SAA. This was replaced with Antithymocyte Globulin for the last 2 patients
Results: 12 patients (median age-16, 5-43) underwent Haplo-HCT; 7 patients with refractory AML (Cohort A) had a median BM blast count of 50% (20-80%) having failed at least two lines of treatment. Five patients had severe aplastic anemia (Cohort B). There was no difference between the two groups in age, gender, number of HLA disparities and donor gender. Patients in Cohort B were more heavily transfused (median 40 vs 20 units, P=0.005). The conditioning was tolerated without any major non-hematological toxicity in both the cohorts. The median CD34 was 4.40 x 106/kg (range 3.05-11.06) and CD3 was 517x10^6/kg (range 80-735) in CohortA whereas CD34 was 6.4x10^6(range5.0-10.0) and CD3 was 165x10^6/kg (range 40- 500) in cohort B (P=ns). All patients engrafted with neutrophils > 500/µL on day +13 (range12-17) and platelet count > 20,000/µL on day +12 and +18 in cohorts B and A (range 8-22) with > 95% donor chimerism on day +30 with morphological CR in cohort A and 100% donor chimerism in cohort B. Only one patient of Cohort A developed de-novo GVHD grade 2. Three relapsed between days 100-150 and two of them achieved a CR following a second transplant from the same donor. One patient in CR died of multi-drug resistant gram-negative bacterial sepsis. Three patients remained in CR. 4/5 patients of Cohort B engrafted promptly, but developed unexpected alloreactivity. Two developed early HLH, one with GVHD and both succumbed to the complications. Other two developed acute lung injury immediately post transplant and periengraftment. The fifth patient is well and alive at 180 days postransplant. Unlike others he had received multiagent IST as part of the conditioning. 8/12 patients amongst the entire group had NK alloreactive donor. In Cohort A, 3/7 patients received graft from a NK alloreactive donor and none relapsed. All 4 patients transplanted from donors without NK alloreactivity relapsed. 4/5 patients of Cohort B with SAA transplanted from NK alloreactive donors developed severe alloreactivity which were fatal (P=0.03). KIR haplotype, presence or absence of KIR2DS1or any other activating receptors did not impact the outcome
Summary / Conclusion: In patients with AML, unmanipulated PBSC graft from a NK alloreactive donor with PTCY was associated with strong GVL effect without GVHD. However, NK alloreactivity in heavily transfused SAA patients was associated with severe alloreactivity and early mortality despite prompt engraftment. Our study highlights for the first time that NK alloreactivity might be associated with an adverse outcome in non-malignant diseases in contrast to the beneficial effect demonstrated in malignant diseases

P376

RITUXIMAB-BASED TREATMENTS FOLLOWED BY ADOPTIVE CELLULAR THERAPIES FOR POST-TRANSPLANT LYMPHOPROLIFERATIVE DISEASE IN RECIPIENTS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q Liu[1],* X Jiang[1], J Sun[1], F Huang[1], H Zhou[1], Y Zhang[1], M Dai[1], Z Fan[1], L Xuan[1], M Wu[1], C Liu[1], X Guo[1], R Feng[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou , China

Background: The introduction of rituximab has improved the complete remission(CR) rate of EBV-associated post-transplant lymphoproliferative disease(PTLD), thus the recurrence of PTLD becomes the main cause affecting long-term survival, which is closely related with the reestablishment of immune functions. Unfortunately, PTLD happens generally at the early stage of transplants and the reestablishment of fullimmune needs for 3-5 years in the recipients of allo-HSCT.
Aims: In this study, a sequential therapeutic strategy that based on rituximab followed by adoptive cellular therapies (G-CSF mobilized donor lymphocyte infusion (DLI) or EBV-specific cytotoxic T lymphocyte infusion (EBV-CTL)) was evaluated for decreasing relapse of PTLD.
Methods: Twenty-one patients with EBV-PTLD were enrolled in this prospective study. Once PTLD was diagnosed,immunosuppressants would be withdrawn in a stepwise fashion (ie, total dose reduced by 20%/week)if the condition of the patient was acceptable. The rituximab-based treatments (rituximab alone or combined with chemotherapy) were administrated based on PTLD histopathology and the blood cells counts. After CR or 2 cycles of rithuximab-based treatments, DLI or EBV-CTL therapy would be performed in this cohort. The rituximab-based treatmentswould be discontinued once patient obtained CR, and DLI or EBV-CTL infusion would be performed once monthlytill GVHD occurring or for a total of 4 doses after CR.
Results: Of the 21 patients enrolled in this study, the data of 18 cases were used to determine the primary endpoint in the intent-to-treat population and 3 patients died of PTLD progression or other causes within 2 cycles of the rituximab-based treatments, 13 patients obtained CR , 3 obtained PR, 2 were NR and 3 died after 2 cycles of the rituximab-based treatments. The CR rate of 2 cycles of rituximab-based treatments was 61.9%. The 5 patients with no CR all obtained CR after the rituximab-based treatments combined with the adoptive cellular therapies. Of the 15patients receiving the adoptive cellular therapies, 12 patients accepted DLI and 3 EBV-CTL therapy. Fivepatients developed DLI-associated aGVHD(grade II in 4) and 4 experienced cGVHD(limited cGVHD in 3 and extensive cGVHD in 1). One patient experienced the relapse of PTLD. With a median follow-up of 509 days (range,52 to 1642 days) after PTLD, the 2year cumulativeoverall survival and disease-free survivalwere 57.8±13.8% and 48.9±14.7% respectively. Till now, only one patients experienced PTLD relapse.
Summary / Conclusion: Rituximab-based treatmentscombined with the adoptive cellular therapies might elevated the CR rate of EBV-associated PTLD, and the rituximab-based treatments followed by the adoptive cellular therapy might decrease the relapse of PTLD in the recipients of allo-HSCT.

P377

EARLY-PHASE ELEVATED TUMOR NECROSIS FACTOR ALPHA RECEPTOR-1, SOLUBLE INTERLEUKIN-2 RECEPTOR, AND LEUCINE-RICH ALPHA 2 GLYCOPROTEIN PREDICT POOR PROGNOSIS FOR ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS

T Ikebe[1],* T Satou[1], K Nakaji[1], K Okuhiro[1], S Honda[1], N Yoshida[1], Y Moroga[1], K Kohno[1], M Ogata[1], J Kadota[1], K Shirao[1]
[1]Medical Oncology and Hematology, Oita University, Yufu-shi, Japan

Background: Treatment related mortality (TRM) after allogeneic stem cell transplantation (allo-SCT) remains high. Organ damage in the early phases of transplantation due to preconditioning agents, allo-immune reactions, or infectious disease is associated with subsequent mortality. Reliable biomarkers to reflect destructive inflammation or organ damage and predict prognosis or TRM of allo-SCT patients have yet to be identified. Previously, tumor necrosis factor alpha receptor-1 (TNF alpha RI) and soluble interleukin-2 receptor (sIL-2R) were considered potential indicators of graft-versus-host disease (GVHD), but their specificity for predicting GVHD is insufficient. Leucine-rich alpha 2 glycoprotein (LRG) is a novel biomarker for monitoring disease activity in inflammatory disorders.
Aims: This study investigated whether selected biomarkers predict TRM in patients receiving allo-SCT.
Methods: A total of 37 patients who underwent allo-SCT at Oita University Hospital from January 2009 to July 2012 were enrolled. Plasma TNF alpha RI, sIL-2R, and LRG levels were measured by sandwich ELISA in samples obtained weekly (n=279); median samples per patient, 8. Prognosis was compared between patients who had high (≥median) and low (<median) levels of each biomarker. Written informed consent was obtained from each patient.
Results: The cumulative incidences at day 100 of Grade II to IV and III to IV acute GVHD were 37.8% and 2.7%, respectively. Ten patients died from TRM (infectious diseases, 3; organ failure, 6, bleeding, 1), but no patients died as a direct result of GVHD. Analysis of biomarker kinetics revealed a tendency for plasma TNF alpha RI, sIL-2R and LRG to peak around 2-3 weeks after transplantation. Levels of each biomarker at both the 2nd and 3rd week after transplantation were significantly associated with subsequent mortality. One-year overall survival (OS) was 94.7% and 35.6% in patients with high and low TNF alpha RI, respectively (P<0.01); 82.0% and 49.4% in patients with low and high sIL2R, respectively (P=0.03); and 77.1% and 55.6% in patients with low and high LRG, respectively (P=0.17). The 1-year incidence of TRM was 44.4% and 5.3% in patients with high and low TNF alpha RI, respectively (P=0.002); 44.4.0% and 5.6% in patients with high and low sIL2R, respectively (P=0.002); and 38.9% and 10.5% in patients with high and low LRG, respectively (P=0.014). Poor performance status (>2), reduced intensity conditioning (especially melphalan use), and fever in the conditioning period correlated with higher levels of TNF alpha RI, sIL-2R and LRG at weeks 2 and 3.
Summary / Conclusion: Our data demonstrate that elevation of TNF alpha RI, sIL-2R and LRG at the engraftment phase strongly predict subsequent occurrence of TRM. We speculate that elevations of these markers reflect severe organ damage or existence of a vigorous immune reaction.

A GENETIC VARIANT IN THE CD53 INTRON FUNCTIONALLY PREDICTS TRANSPLANT OUTCOMES AFTER HLA-MATCHED UNRELATED BONE MARROW TRANSPLANTATION

A Takami[1],* J Espinoza[1], S Toda [1], K Matsuo [2], Y Morishima [2], M Onizuka [3], K Kashiwase [4], T Fukuda [5], Y Kodera [6], Ka Yamada [1], E Morishita [1], S Ohtake [1], S Nakao [1]
[1]Department of Hematology and Oncology, Kanazawa University Hospital,

Kanazawa, [2]Division of Epidemiology and Prevention, Aichi Cancer Center Research Institute, Nagoya, [3]Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, [4]Japanese Red Cross Kanto-Koshinetsu Block Blood Center, [5]Hematopoietic Stem Cell Transplantation Unit, National Cancer Center Hospital, Tokyo, [6]Department of Promotion for Blood and Marrow Transplantation, Aichi Medical University, Nagoya, Japan

Background: The CD 53 antigen is a member of the tetraspanin family that is expressed in the leucocytes, endothelial cells, thymus, and lung, and plays roles in the regulation of cell growth and activation, inhibition of apoptosis, and immunity. The single nucleotide variation, rs6679497 (C>G), in the intron of the *CD53* gene is associated with TNFα inducibility (Bos SD: *Eur J Hum Genet*. 2010).
Aims: This study examined the impact of donor and recipient variation in the *CD53* gene on the clinical outcomes of patients undergoing allogeneic T-cell-replete bone marrow transplantation using an HLA-matched unrelated donor.
Methods: The *CD53* variation was retrospectively analyzed in a cohort consisting 322 pairs of patients with hematologic malignancies and their unrelated donors transplanted through the Japan Marrow Donor Program. Next, the functional relevance of the rs6679497 variation was investigated using leucocytes from healthy individuals.
Results: The recipient GG genotype was found to be associated with a lower overall survival (OS) in the univariate analysis (29% *vs*. 53% at 5-y; P=0.01) and multivariate analysis (relative risk=1.97; 95% confidence interval, 1.22-3.18; P=0.01). *In vitro* stimulated leucocytes from healthy individuals possessing the G allele showed a trend toward increased TNFα secretion than those without the G allele. In the allele-specific quantitative PCR with a TaqMan probe for healthy donors with heterozygous genotypes of rs6679497, the ratio of the G allele transcripts *vs*. C allele transcripts was higher than that of DNA amplicons, suggesting that the G allele has higher transcriptional activity than the C allele.
Summary / Conclusion: These findings substantiate the functional relevance of the rs6679497 variation, and indicate that the increased TNFα secretion by individuals with the G allele likely account for their worse OS.

P379

RELATIONSHIP BETWEEN INFUSION FEVER FOLLOWING PERIPHERAL BLOOD STEM CELL AND PERI-ENGRAFTMENT SYNDROME IN PEADIATRIC PATIENTS UNDERGOING HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANTATION

Y Chen[1],* L Xu[1], X Huang[1], F Wang[1], Z Wang[1], Y Wang[1], H Chen[1], W Han[1], H Chen[1], H Liu[1], Y Liu[1]
[1]Peking University Institute Of Heamtology, Beijing, China

Background: Our previous study showed the association between infusion fever following peripheral blood stem cell(infusion fever) and subsequent allogeneic immune reactions in adults patients in haplo-identical transplantation. Similar infusion fever has been observed in some paediatric patients under our haplo-identical transplant setting.
Aims: To explore the relationship of infusion fever with peri-engraftment syndrome and acute graft-versus-host disease (GVHD) in paediatric patients under haploidentical allogeneic hematopoietic stem transplantation (Allo-HSCT).
Methods: Clinical data of 59 peadiatric patients received haploidentical Allo-HSCT from Jan,2012 to Dec,2012 was invetstigated. Infusion fever was defined as unexplained fever>38°C not assocaited with infection within 24 hours following the infusion of allogeneic peripheral harvest. Peri-engraftment syndrome was defined as febrile reaction almost with skin rash and/or other immune reactions within 5 days of engraftment. The patients were classified into 2 groups as infusion fever group and none-fever group.
Results: Paediatric patients (median age,12 years;range,2-17 years) received myeloablative conditioning as previous reports from Peking University Institute of Hematology. Primary diseases included acute myeloid leukemia (n=23), acute lymphoblastic leukemia (n=23), chronic myeloid leukemia (n=3) and other diseases (n=10). 22 (37.3%) out of all the patients had infusion fever. The median times to neutrophil recovery and platelet recovery were 12 (10-19) days and 16 (7-83) days. Both of neutrophil and platelet reconstitution were were similar between 2 groups.32(54.2%) out of all the patients had peri-engraftment syndrome. The median of peri-engraftment syndrome was 11 (7-20) days. Infusion fever group developed significantly high incidence of peri-engraftment syndrome compared to none-fever group.The incidence rate of peri-engrafment syndrome in infusion fever group and none-fever group were 90.9% and 32.4%, respectively (P=0.000). The incidences rate of grades I–IV,II-IV and III-IV aGVHD among the whole patients were 44.1% (26/59), 30.5%(18/59) and 8.5%(5/59),respectively. The incidence rates of grade I-IV, II-IV and III-IV aGVHD were similar in fever group and none-fever group were 45.5%(10/22) versus 43.2%(16/37),36.4%(8/22) versus 27.0%(10/37) and 13.6%(3/22) versus 7.4% (2/27), respectively (P>0.05).The day-100 treatment related mortality (TRM) and survival were not significantly different in infusion fever group and none-fever group.
Summary / Conclusion: Infusion fever, as a new clinical feature belongs to haploidentical allogeneic stem transplant, was associated with the occurrence of peri-engraftment syndrome in paediatric patients.Our results suggested the potential role of infusion fever as predictor of early allogeneic immune reaction.

P380

BISPHOSPHONATES DO NOT DELAY ENGRAFTMENT AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH NEWLY DIAGNOSED MYELOMA

M Oksman[1],* M Kauppila[1], M Putkonen[1], M Itälä-Remes[1], K Remes[1]
[1]Hematology, Turku University Central Hospital, Turku, Finland

Background: Several factors have been found to affect the engraftment after autologous stem cell transplantation (ASCT) in multiple myeloma (MM), including e.g. use of blood stem cells, amount of infused CD34+ cells, prior use of myelotoxic agents and use of haematopoietic growth factor. Recently, bisphosphonates were shown to delay haematological recovery after ASCT in mice when compared to untreated controls (Lymperi *et al*. 2011). To the best of our knowledge, this issue has not been studied in the clinical setting.
Aims: The aim of this study was to evaluate the impact of bisphosphonates on haematological recovery after ASCT in patients with MM.
Methods: 221 myeloma patients transplanted 1993-2010, whose data were prospectively collected in our institutional ASCT registry, were analyzed. There were 176 patients who had received bisphosphonate treatment before ASCT and 45 who had not.
Results: There were no difference in the recovery times of blood neutrophil and platelet counts between these two groups: blood neutrophils reached the count of $1.0x10^9$/L on days 11 and 11, and platelet the count of $20x10^9$/l on days 14 and 13, respectively (Table 1). Similarly, no differences in engraftment times were seen in patients who had received either clodronate, pamidronate or zoledronate. The patients were also divided into two other groups, those who had received Thal-Dex (n=40, 74 % bisphosphonate users) or VAD (n=147, 77% bisphophonate users). It appeared that the Thal-Dex group had a significant delay in their engraftment by a median of three days (Table 1).
Summary / Conclusion: In opposite to the bisphosphonate effect on engraftment after ASCT in mice, these drugs seem not to have a similar effect in myeloma in man. Regarding the impact of the initial treatment on engraftment post-ASCT, controversial results have been published (Ghobriel *et al*. 2003, Breitkreutz *et al*. 2007). In our study, a delayed engraftment in patients previously treated with Thal-Dex was observed.

Table 1.

	All	Bp	W/o bp	VAD	Thal-Dex
Number of patients	221	175	46	147	40
CD34+ (E6/kg)	5,02	4,85	5,79	5,38	4,45
G-CSF (n)	214	170	44	147	37
VAD (n)	147	113	33	147	7
Thal-Dex (n)	40	31	8	-	40
Neutrophils ≥ 1,0 x10^9 (days post-transplant)	11	11	11	11	12
Platelets ≥ 20 x 10^9 (days post-transplant)	13	14	13	13	15
Both neutrophils and platelets (days post-transplant)	14	14	13	13	16

P381

STENOTROPHOMONAS MALTOPHILIA INFECTION IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION — RISK FACTORS AND THERAPEUTIC STRATEGIES

S Shiratori[1],* K Akizawa[2], J Sugita[1], A Shigematsu[1,2], K Fujimoto[1], T Endo[1], T Kondo[1], S Hashino[1], J Tanaka[1], T Teshima[1]
[1]Department of Hematology , Hokkaido University Graduate School of Medicine., [2]Hokkaido University Division of Laboratory and Transfusion Medicine, Hokkaido University Hospital, Sapporo, Japan

Background: *Stenotrophomonas maltophilia* (*S. maltophilia*) is aglucose non-fermentative Gram-negative bacillus, which can be isolated from humectant environments. *S. maltophilia* has multi-antibiotic resistance because of the natural possession of metallo-β-Lactamase. *S. maltophilia* infection is rare, but can develop a fatal bloodstream infection or hemorrhagic pneumonia. There are some reports about *S. maltophilia* infection in patients undergoing allogeneic hematopoietic stem cell transplantation (allo-SCT).
Aims: To clarify the risk factors and the effective therapeutic strategies for *S. maltophilia* infection in allo-SCT.
Methods: We retrospectively analyzed medical records of 259 patients under-

went allo-SCT between January 2004 and December 2011 in Hokkaido University hospital, Sapporo, Japan. We also analyzed the patients with hematologic diseases who did not be underwent allo-SCT at the same period.
Results: *S. maltophilia* were detected by culture-based identification methods in 39 patients (15%), and 25 patients of those were developed *S. maltophilia* infection. Of all 52 colonization events, *S. maltophilia* infections occurred in 33 events (63%): sepsis (n=20), pneumonia (n=8), were developed as pneumonia, multiple infection (n=5). We compared with 32 non-allo-SCT patients with *S. maltophilia* at the same period. Neutropenia was more severe in allo-SCT patients compared to non-allo-SCT patients at the time of detection of *S. maltophilia*, and consequently, the rate of onset of *S. maltophilia* infection was significantly higher in allo-SCT patients (63% vs 29%, P <0.01). Moreover, fatal cases from *S. maltophilia* infection were observed in only allo-SCT patients. Next, we compared the period detected *S. maltophilia* during allo-SCT. In the period from the initiation of conditioning therapy to neutrophil engraftment, the rate of infection onset of was higher, neutropenia was more severe, and max CRP values were more elevated compared to other periods. Especially, the onset of infection in early periods from SCT was suggested as a risk factor of *S. maltophilia* related mortality (Figure 1). In such the period of neutropenia, we frequently transfuse granulocytes from healthy donors. Indeed, the efficacy of Granulocyte transfusion (GTX) was observed in several cases of *S. maltophilia* infection. According to the analysis of 4 fatal cases from *S. maltophilia* infection, 3 cases were underwent cord blood transplantation (CBT), and in all cases, only one antibiotic with sensitivity was administered after the identification of *S. maltophilia*. Additionally, none of fatal cases removed central venous catheter (CVC), but only changed to new CVC after the onset of infection. We examined the difference of the efficacy between "CVC removal" and "CVC change". Compared to "CVC removal", the efficacy of "CVC change" was limited, especially in the period of neutropenia, the efficacy of "CVC change" was only 17%.
Summary / Conclusion: *S. maltophilia* colonization in allo-SCT was higher risk for infection development among hematologic treatments, and onset of infection in early periods from SCT (especially CBT) was the risk for *S. maltophilia* related mortality. For the treatment of *S. maltophilia* infection, 1. Removal of CVC, 2. Administration of multiple antibiotics sensitive to *S. maltophilia*, 3. GTX may be considered.

Variable	Prerengraftment		Other		Pvalue

CALM LINKS CYTOKINE SIGNALS TO HEMATOPOIETIC CELL GROWTH AND SURVIVAL BY REGULATING INTRACELLULAR TRAFFICKING OF RECEPTOR TYROSINE KINASES

S Rai[1],* H Tanaka[1], M Suzuki[2], A Tanimura[3], K Matsui[3], T Watanabe[2], Y Kanakura[3], I Matsumura[1]
[1]Hematology and Rheumatology, Kinki University Faculty of Medicine, Osakasayama, Osaka, [2]Biological Science, Graduate School of Humanities and Sciences, Nara Women's University, Nara, [3]Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan

Background: Clathrin Assembly Lymphoid Myeloid leukemia protein (CALM) was originally cloned at the brakepoint of t(10;11)(p13;q14-21) translocation as CALM/AF10 fusion protein, which is observed in 8-10% of T-ALL and a smaller percentage of AML. CALM is ubiquitously but highly expressed in hematopoietic and neuronal systems. CALM is implicated in the formation of clathrin-coated vesicles and plays an essential role in clathrin-dependent endocytosis (CDE), which mediates the entry of growth factor receptors and nutrients into the cells. However, the physiological role of CALM has yet to be elucidated.
Aims: The present experiments were designed to clarify the role of CALM in hematopoiesis, especially how CALM can regulate cytokine signaling events and biological responses in hematopoietic cells**.**
Results: To elucidate the physiological role of CALM, we established CALM-deficient ($^{-/-}$) mice through gene targeting. Although CALM$^{-/-}$ mice were obtained at the expected Mendelian ratios, they were growth retarded with about 35% weight compared with wild-type mice. Also, more than 90% of CALM$^{-/-}$ mice died during the weaning period. CALM$^{-/-}$ mice exhibited severe anemia (mean of RBC count 268x10^{10}/L; Hb 3.7 g/dl) due to the impairment of erythroid maturation. As for this reason, we found that CDE of transferrin receptor was impaired in CALM$^{-/-}$ erythroid cells, which leads to the iron deficiency in these cells. To further clarify the role of CALM in hematopoiesis, we isolated Lin^{-}Sca-1^{+}c-Kit^{+} hematopoietic stem/progenitor cells (LSKs) from the bone marrow of wild-type and CALM$^{-/-}$ mice. When we cultured these cells with SCF, FLT3 ligand, and TPO, the growth of CALM$^{-/-}$ LSKs was severely impaired, which was partly cancelled by the addition of IL-3. This result suggests that SCF- and/or FLT3-mediated signaling might be perturbed by CALM deficiency. However, an apparent difference was not observed in SCF-induced phosphorylation of c-Kit between CALM$^{-/-}$ and wild-type LSKs. Also, CALM-deficiency didn't influence the internalization of SCF/c-Kit complex in LSKs. In contrast, SCF-induced phosphorylation of Akt and extracellular regulated kinase (ERK)1/2 was enhanced and prolonged in CALM$^{-/-}$ LSKs as compared with wild-type LSKs, while CALM-deficiency did not affect IL-3-induced JAK/STAT signaling. These results suggest that appropriately regulated c-Kit signaling is required for the normal growth of LSKs. To further elucidate the role of CALM in the clathrin-mediated intracellular trafficking of c-Kit, we isolated and immortalized murine embryonic fibroblasts (MEFs) from CALM$^{-/-}$ and wild-type mice. Then, we introduced c-Kit into these MEFs. In response to the stimulation with SCF, c-Kit was found to be incorporated into the cytoplasm and then located around the nucleus in wild-type MEFs by confocal microscopy. In contrast, loss of CALM resulted in the predominant accumulation of c-Kit in the enlarged early endosomes, which was canceled by the retroviral transduction of wild-type CALM. These results indicate that the trafficking of c-Kit from the early to the late endosome or the endosomal recycling compartment is disrupted by CALM deficiency.
Summary / Conclusion: Our results raise the possibility that CALM might be a critical regulator of the intracellular trafficking of cytokine receptors in hematopoietic cells, thereby controlling normal and abnormal hematopoiesis.

SMAC MIMETICS ENABLE INTACT APOPTOSIS SIGNALING IN FORMER APOPTOSIS RESISTANT PRIMARY ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

M Schirmer[1],* M Queudeville[1], L Trentin[1], F Seyfried[1], S Eckhoff[1], L Meyer[1], K Debatin[1]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Although multiagent chemotherapy regimens have led to improvement of remission induction and long-term survival, patients with high risk ALL or relapse do not respond well to current treatments and still have a poor prognosis. Defects in apoptosis signaling pathways e.g. overexpression of "Inhibitor of Apoptosis" (IAP) proteins might be one reason for treatment failure and relapse of acute leukemia since they are associated with poor prognosis. Therefore, new small molecules targeting IAP proteins, so called SMAC mimetics, present a suitable new strategy for therapeutic intervention.We already showed that neutralizing IAP proteins by small molecule IAP inhibitors is an effective approach to sensitize childhood acute leukemia cells for death

receptor- or chemotherapy-induced apoptosis.
Aims: This study identifies the capability of SMAC mimetics to induce cell death in acute leukemia cell lines and primary acute lymphoblastic leukemia cells and demonstrates the activated signaling pathways.
Results: Here, we report that small molecule SMAC mimetics alone induce apoptosis at nanomolar concentrations in acute leukemia cells. Cell lines which are sensitive for apoptosis induction by SMAC mimetics show rapid degradation of cIAPs, activation of NF-kappaB and secretion of TNFalpha, leading to an autocrine, apoptosis-inducing TNFalpha-loop. Further analysis of signaling pathways reveals that IAP inhibition causes TNFalpha-dependent loss of mitochondrial membrane potential, caspase activation and apoptosis. Whereas the inhibition of RIP-Kinases has no effect on apoptosis-induction upon SMAC mimetic treatment, knockdown of RIP1 results in significant reduction of SMAC mimetic-induced loss of mitochondrial membrane potential, caspase activation and apoptosis. Thereby, the availability of RIP1 in the TNFalpha-receptor complex plays a decisive role for subsequent apoptosis signaling. Furthermore, we tested small molecule SMAC mimetics on a variety of 36 primary ALL samples isolated from ALL bearing mice of established patient derived NOD/SCID/huALL xenograft leukemias. Treatment with SMAC mimetics at nanomolar concentrations clearly induces cell death also in the vast majority of primary ALL samples (25/36). Since cell death induction by SMAC mimetics in primary ALL cells could also be inhibited by the soluble TNF-alpha receptor Etanercept we assume a TNFalpha-loop upon treatment with SMAC mimetics in primary ALL cells too. We previously described that rapid engraftment of ALL cells transplanted onto NOD/SCID mice analyzed as weeks from transplantation to onset of leukemia related morbidity in the recipients (short Time To Leukemia, TTL^{short}) is associated with deficient apoptosis signaling in the cells and is indicative for early patient relapse. Importantly, primary xenograft ALL samples with a TTL^{short}/early relapse phenotype showed increased cell death upon treatment with SMAC mimetic BV6 and activation of the constitutive deficient apoptosis signaling pathway, demonstrating that SMAC mimetics enable intact apoptosis signaling in former apoptosis resistant primary ALL cells. Thereby, intact apoptosis signaling was functionally analyzed assessing mitochondrial cytochrome c release and activation of the effector caspase-3.
Summary / Conclusion: Thus, induction of apoptosis by the new generation of small molecule SMAC mimetics provides a promising novel strategy for targeted therapy of high risk acute lymphoblastic leukemia.

P384

IDENTIFICATION OF A NOVEL CANDIDATE GENE CAUSING AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS)-III-LIKE DISEASE
S Nabhani[1,*] S Ginzel[1,2], S Revel-Vilk[3], D Harlev[4], H Miskin[4], R Thiele[2], H Laws[1], A Borkhardt[1], P Stepensky[3], U Fischer[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, University Children´s Hospital, Heinrich-Heine-Universität , Duesseldorf, [2]Department of Computer Science, Bonn-Rhein-Sieg University of Applied Sciences, Sankt Augustin, Germany, [3]Department of Pediatric Hematology-Oncology , Hadassah Hebrew University Medical Center, [4]Pediatric Hematology Unit , Shaare Zedek Medical Center, Jerusalem, Israel

Background: Patients suffering from the Autoimmune Lymphoproliferative Syndrome (ALPS) typically harbour germline or somatic mutations in genes involved in the CD95 death receptor signalling pathway. In ALPS type I and II patients, disease causing mutations of CD95, CD95 ligand or Caspase 10, respectively, have been identified. For 20-30% of patients, collectively classified as ALPS-type III cases, the genetic cause is still unknown.
Due to defective apoptotic signalling via the CD95 death receptor mainly T-lymphocytes are inefficiently cleared. ALPS is thus characterized by lymphadenopathy, hepatosplenomegaly, autoimmune cytopenias and an elevated number of double negative T-cells (DNT; $CD3^+$, $TCR\alpha/\beta^+$ $CD4^-CD8^-$).
Aims: The objective of this study was to employ next-generation-sequencing to search for novel gene candidates underlying ALPS-type III. The list of potential candidates should be narrowed down using an in-house developed bioinformatic analysis pipeline for patient-based gene prioritization based on protein-protein interaction networks. Resulting candidates should be validated and their impact on CD95 signaling studied.
Methods: Peripheral blood samples were collected from three patients diagnosed with ALPS based on clinical phenotype and accumulation of DNT cells. Their DNA was analyzed for germline and somatically acquired CD95, CD95L and Caspase-10 mutations by PCR/Sanger sequencing. Apoptosis was checked employing flow cytometry. Whole exome sequencing was carried out for all three patients and their parents. Single nucleotide variations (SNVs) were called, annotated using NGS-SNP and mapped to a protein-protein-interaction network using STRING. A random walk algorithm was employed to identify functional modules and gene candidates. SNVs were verified by PCR and Sanger sequencing. Candidates' protein expression and impact on CD95L expression was tested by FACS and ELISA.
Results: 216,948 sequence nucleotide variations (SNVs) were called from three ALPS type III patient samples. 59,957 SNVs remained after removing variations also present in the healthy relatives.4,749 of these SNVs were homozygous and affected exonic regions. Application of the newly developed interaction analysis pipeline reduced this number to 29 candidate genes. One of the three patients harboured a homozygous mutation in the gene for the Interleukin 12 receptor beta 1 (IL12RB1), a subunit of the IL12 receptor. The mutation led to a premature stop at codon 212 (exon7, R212stop). IL-12RB1 is a protein comprising 662 amino acids. 17 exons encode a peptide leader sequence (exon 1), extracellular domain (exons 2-13), transmembrane domain (exon 14) and an intracellular domain (exons 15-17). The mutation led to a complete loss of IL12RB1 expression on the cell surface of the patient cells and downmodulation of CD95L expression. In this patient IL12RB1 was the only identified gene with an impact on CD95 signaling.
Summary / Conclusion: IL12RB1 was identified as a candidate gene underlying an ALPS type III case. Our and previous studies confirm that IL12RB1 affects apoptotic signalling via the CD95 receptor, a prerequisite for an ALPS causing gene. Loss of IL12RB1 has also been shown to predispose for mycobacterial infections. However, the patient analyzed here had a distinct ALPS phenotype (lymphadenopathy, splenomegaly, hepatomegaly, various autoimmune symptoms, elevated DNT cell numbers) and never suffered from mycobacterial infections. Further investigation of IL12RB1 deficient patients may reveal more cases with ALPS-like symptoms.

P385

ONCOGENIC PHOSPHORYLATION OF NIPA IS MEDIATED BY ERK2
A Illert[1,*] C Klingeberg[2], M Zech[3], C Albers[4], C Peschel[4], F Bassermann[3], J Duyster[2]
[1]Department of Internal Medicine I, [2]University of Freiburg, Freiburg, [3]Department of Internal Medicine III, [4]Technical University of Munich, Munich, Germany

Background: Regulated oscillation of protein expression is an essential mechanism of cell cycle control. We previously reported cloning of NIPA (Nuclear Interaction Partner of ALK) in complex with constitutively active oncogenic fusions of the tyrosine kinase ALK, contributing to the development of lymphomas and sarcomas. Subsequently we characterized NIPA as a F-Box protein that defines an oscillating ubiquitin E3-ligase. The SCF^{NIPA} complex targets nuclear cyclin B1 for ubiquitination in interphase while phosphorylation of NIPA in late G2 phase and mitosis inactivates the complex to allow for accumulation of cyclin B1, a critical event for proper G2/M transition. Thus, SCF^{NIPA} executes an important G2/M checkpoint control.
Aims: Within our stuies, we aim to identify the kinases involved in G_2/M transistion as well as the kinases involves in pathologic signalling via oncogenes like NPM-ALK.
Results: We recently specified a sequential NIPA phosphorylation at G2/M, where initial Ser 354 and 359 phosphorylation is most crucial for SCF^{NIPA} inactivation by dissociating the SCF^{NIPA} complex. Using *in vitro* kinase assays we identified both ERK1 and ERK2 to phosphorylate NIPA with high efficiency. By combining cell cycle synchronization with stable expression of shRNAs targeting either ERK1 or ERK2, we show that ERK 2 but not ERK1 mediates NIPA inactivation at G2/M. ERK2 knockdown led to a delay at the G2/M transition, a phenotype also observed in cell expressing a phosphodeficient mutant of NIPA. NIPA has been shown to be constitutively phosphorylated in NPM-ALK expressing cells and the serine kinase responsible for this S354 phosphorylation remains unknown. We thus asked whether ERK2 is also involved in the oncogenic, cell cycle independent phosphorylation of NIPA in NPM-ALK positive cells. Therefore we treated HEK 293T cells coexpressing NPM-ALK and NIPA with different MEK/ERK inhibitors. NPM-ALK induced phosphorylation of NIPA could be completely abrogated by pharmacological inhibition of the MEK/ERK pathway. To further substantiate these data in human lymphoma cells we analyzed the effects of ERK inhibition in a human T-cell lymphoma cell line (KARPAS 299). Indeed, treatment of KARPAS 299 with U0126 abolished the phosphorylation of NIPA at S354.
Summary / Conclusion: These results indicate an involvement of ERK-kinases not only in cell cycle dependent NIPA phosphorylation but also in oncogene mediated cell cycle independent phosphorylation of NIPA. Since checkpoint proteins such as NIPA are constitutively inactivated in tumor cells ERK2 might represent an interesting target to reconstitute important cell cycle checkpoint control in malignant cells.

P386

TYROSINE PHOSPHATASE SHP-1 MODULATES LFA-1-MEDIATED ADHESION IN PRIMARY T CELLS
C Kardinal[1,*] J Herbst[1], U Diekmann[2], M Sauer[1]
[1]Pediatric Hematology/Oncology, [2]Institute of Clinical Biochemistry, Hannover Medical School, Hannover, Germany

Background: The potential of transplantation is often restricted by T cell-mediated alloresponses that in patients cause graft rejection or graft versus host disease. Besides the engagement of the T cell receptor, the adhesive interaction between potentially alloreactive T cells and antigen presenting cells of allogeneic origin is essential for alloresponses to occur. So far, the molecular processes underlying signaling events between T cell receptor activation and

cellular adhesion are not fully understood. The vast majority of published studies was done with various tumor-derived cell lines, thus producing controversial results depending on the cell line used.
Aims: To overcome these drawbacks, we used *in vitro* generated and expanded polyclonal primary T cells to study the lymphocyte function-associated antigen 1 (LFA-1)-mediated adhesion.
Methods: Primary T cells based on the priming of naïve T cells from B10.A mice (responder) with denditic cells from C57BL/6 mice (allogeneic stimulator) or from B10.A mice (syngeneic stimulator) were examined by using biochemical and cellular techniques such as protein tyrosine phosphatase activity assays, adhesion assays or immunofluorescence microscopy.
Results: We identified a novel role of the protein tyrosine phosphatase SHP-1 in the regulation of LFA-1-mediated adhesion: SHP-1 activity is significantly reduced upon alloactivation, in turn resulting in an enhanced ability of alloactivated T cells to adhere to MHC-mismatched tissues. In addition, SHP-1 impairs the adhesion-associated signaling cascade SLP-76 → ADAP → LFA-1 by modulating the tyrosine phosphorylation of ADAP.
Summary / Conclusion: The novel and decisive role of SHP-1 in the regulation of LFA-1-mediated adhesion may be of importance for a better understanding of T cell-mediated alloresponses, and provides evidence to the development of new immunosuppressive pharmaceutical agents.

P387

ERYTHROPOIETIN IMPROVES BRAIN DEVELOPMENT IN SHORT-TERM HY0POXIA IN RAT EMBRYO CULTURES

Y Torun[1,*] M Ozdemir[2], H Ulger[3], M Nisari[3], H Akalin[4], T Patiroglu[2], Y Ozkul[4], M Onal[4], M Karakukucu[2]
[1]Pediatric Hematology, Kayseri Education and Research Hospital, [2]Pediatric Hematology, [3]Anatomy and Clinical Research Institute, [4]Genetics, Erciyes University, Kayseri, Turkey

Background: Erythropoietin (EPO) is a primary regulator of erythropoiesis and is fundamentally produced by the kidney in adults and by hepatocytes in the fetus in response to hypoxia. Besides its established function in erythropoiesis, EPO is currently also appreciated for its neuroprotective effects.
It has been shown that both VEGF and EPO exert neuroprotective effects in both *in vitro* and *in vivo* experimental models, probably through the common oxygen-sensing pathway stimulated by hypoxia. However, to date, the exact molecular mechanisms by which EPO might mediate its actions in the central nervous system, and the possible implications for VEGF in this regard are not well understood.
Aims: The aim of the present study was to investigate the effects of EPO on hypoxia-induced growth retardation and embryo brain development during the organogenesis period and to determine whether VEGF has an effect on the action mechanism of EPO.
Methods: Two sets of experiments were carried out. First, the culture of rat embryos with different gassing concentrations was evaluated, and second, the culture of rat embryos in rat serum with increasing concentrations of EPO was studied; VEGFR expressions were measured in all rat embryo brains.
The five pregnant rats were humanely killed by ether overdose at 9.5 days of gestation, and the embryos (approximately 10 embryos from each pregnant rat) were removed from the mother by the explantation procedure described by New (1978). Using a dissection microscope, the decidual mass was split to expose the conceptus, which was gently teased free and immediately immersed in Hank's balanced salt solution. Four embryos were placed in each culture bottle of 4 ml volume, and the bottles were placed on a roller incubator at 37^0C. WRS was used in the control groups. Fifty embryos were used in total: 10 for 0 h controls, 10 for controls in which EPO (100 U/mL) was administrated in control cultures without hypoxia, 10 for 24 h hypoxia, and 20 for EPO supplementation (50 and 100 U/mL). The control group embryos were cultured in WRS and WRS+EPO (100 U/mL). Different gas concentrations were tested to obtain hypoxia. At the of the procedures, all embryos were gassed for 1 min in the culture bottles using a mixture of 5% O_2, 5% CO_2, and 90% N_2 and then incubated at 37^0C in an incubator. During incubation, the culture bottles were continuously rotated at 30 rpm and re-gassed after 24 hours. Embryos were gassed for 1 min with 20% O_2, 5% CO_2, and 75% N_2 in the control (only WRS) and WRS+EPO groups, and with 5% O_2, 5% CO_2, and 90% N_2 in the hypoxia group after 24 h. Embryos were gassed for 1 min with 40% O_2, 5% CO_2, and 55% N_2 in all groups at hour 44, 4 hours before the morphological evaluation. The experimental groups were cultured in hypoxic medium, 50 and 100 U/mL EPO per bottle after hypoxia, for 24h. In order to assess the effect of EPO on total embryonic growth and brain development, the embryos were cultured in different concentrations of EPO (50-100 U/mL) to produce the appropriate concentration required for the embryos to develop.After 48-h culture, the embryos from each group were harvested to be analyzed according to a morphological scoring system and also genetically to measure brain VEGFR expression.
Results: The results showed that the embryos had severe growth retardation in the hypoxia and in the 50U/mL EPO in WRS groups when compared with control embryos cultured in only WRS and in the presence of 100U/mL EPO. Compared with the control groups (normal and with EPO), the experimental groups displayed higher morphological scores and somite numbers.
The mean brain development of embryos was also significantly lower in the hypoxia and 50U/mL EPO groups when compared to the controls and the 100 U/mL EPO group. Development of the neural tube was also similar in the control groups and 100 U/mL EPO group, but developmental retardations were found in the other EPO and hypoxia groups ($P<0.05$). The mean brain development of embryos was also significantly lower in the hypoxia and 50U/mL EPO groups when compared to the controls and the 100 U/mL EPO group.
Development of the neural tube was also similar in the control groups and 100 U/mL EPO group, but developmental retardations were found in the other EPO and hypoxia groups ($P<0.05$).RT-PCR showed that all three VEGF (VEGFR-3 included) receptors expressed mRNAs. The levels of VEGFR-1, R-2, and R-3 expression were significantly elevated in the 100U/mL EPO group compared to the hypoxia group ($P<0.05$)
Summary / Conclusion: In conclusion, our results suggest that EPO may contribute to early developmental processes including the proliferation, differentiation and maturation of specific neuronal populations via specific VEGF receptors in the developing rat brain. EPO treatment can be used to prevent intrauterine brain injury, especially under conditions of hypoxia. Further studies should be performed on the use of EPO in in-utero hypoxia and neural tube closure defects in clinical practice.

P388

DISULFIRAM/COPPER COMPLEX COULD ELIMINATE RAJI CELLS IN VITRO AND VIVO THROUGH ACTIVATION OF OXIDATIVE STRESS AND INHIBITION OF NRF2 AND NF-KB

B Xu[1,*] J Zha[1], F chen[1], P Shi[1], X Guo[1], S Wang[1], R Li[1], H Dong[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Disulfiram (DS), an antialcoholism drug, demonstrates strong antitumor activity in a copper (Cu)-dependent manner. Our previous study showed that it was highly cytotoxic in doxorubicin resistant leukemia cells and enhanced cytotoxicity of doxorubicin. DS/Cu induces reactive oxidative stress (ROS) which activates stress related signaling pathway (c-Jun-amino-terminal kinase, JNK). Cancer cells possess higher ROS activity and some antiapoptotic factors. Therefore cancer cells may be effectively targeted by simultaneously inducing ROS and inhibiting antiapoptotic factors.
Aims: To determine the cytotoxicity of DS/Cu complex on human Burkitt's lymphoma cell line Raji *in vitro* and *in vivo* with mechanism being explored.
Methods: Cytotoxicity of DS/Cu complex on Raji cells was detected using MTT assay *in vitro*. Subcutaneously lymphoma animal model was established using nude mice to explore the potentiality of DS/Cu complex to eliminate Raji cells *in vivo*. Annexin-V/PI and DCFH-DA were employed for apoptosis and intracellular ROS level analysis by flow cytometric analysis. Western blotting was used to determine the change of anti-oxidative transcription factor Nrf2 (NF-E2-related factor 2), JNK as well as p65 expression. Statistical analysis was carried out with a one-way ANOVA followed by Dunnett's test to assess statistical significance (*$P<0.05$).
Results: MTT assay showed that with a low concentration (1 μM) of Cu^{2+}, DS exerted cytotoxicity to Raji cells with IC_{50} of 0.085±0.015 μM. *in vivo* experiment using subcutaneously lymphoma animal model also demonstrated the cytotoxicity of DS/Cu complex to Raji cells. Annexin-V/PI staining assay showed that the DS/Cu induced apoptosis was time-dependent. The apoptotic proportion of Raji cells increased from 18.89±5.86% to 81.03±7.91% when exposed to DS (3.3 μM) and Cu (1 μM) for6, 12 and 24h. Nrf2 is a key antioxidant factor. Western blot indicated that anti-oxidative transcription factor Nrf2 nuclear translocation changed in a time-dependent manner after cells being treated by DS/Cu. Nrf2 expression increased when Raji cells were treated for less than 12h and decreased after 18h or 24h treatment. ROS levels were closely related to Nrf2. Flow cytometric analysis showed that DS/Cu induced ROS generation. Western blot manifested that DS/Cu complex induced phosphorylation of JNK expression and inhibited P65 activity. N-acetyl-L-cysteine (NAC), an antioxidant, can partially attenuate DS/Cu complex-induced apoptosis, restore Nrf2 nuclear translocation, reactivate P65 activity and block JNK activation.
Summary / Conclusion: DS/Cu complex could induce apoptosis in Raji cells both *in vitro* and *in vivo*. Generation of ROS might be the core step in DS/Cu induced apoptosis. Moreover, ROS-related activation of JNK pathway as well as inhibition of NF-κB and Nrf2 may also contribute to the induced apoptosis.

P389

THE EXPRESSION OF TOLL-LIKE RECEPTORS IN PATIENTS WITH ACUTE MYELOID LEUKEMIAS.

J Dzietczenia[1,*] T Wrobel[1], A Butrym[1], B Jazwiec[1], E Stefanko[1], O Dobrzynska[1], R Poreba[1], K Kuliczkowski[1]
[1]Medical University Wroclaw, Wroclaw, Poland

Background: Toll-like receptors (TLRs) play an important role in the host defense against microorganisms. TLRs are mainly expressed in human immune related cells such as monocytes, neutrophils, macrophages, dendrit-

ic cells, T cells, B cells and NK cells. Theireffect is connected with secretion of cytokines and chemokines which recruit immune cells death that limits microbe expanding. The expression or up-regulation of TLRs has been demonstrated in some tumors and tumor cell lines but the role of TLRs in pathogenesis and development of acute leukemias remains unclear.

Aims: The aim of this study was to evaluate the expression of TLR2, TLR4 and TLR9 and their significance as prognostic factors in patients with acute myeloid leukemias.

Methods: 103 patients with newly diagnosed acute myeloid leukemia (AML) were evaluated (47 females and 56 males). The median age of patients was 51 years. The diagnosis was established according to the WHO criteria for AML. There were 57 patients (55%) with acute myeloid leukemias: minimally differentiated, without maturation and with maturation (M0,M1 and M2 acc. FAB classification) and 46 patients (45%) with acute mielomonocytic and monoblastic leukemia (M4 and M5 acc.FAB classification). The healthy control group included 20 age-matched individuals (9 females and 11 males). Bone marrow samples were taken before induction therapy. Using quantitative reverse transcriptase PCR, the mRNA expression of genes TLR2, TLR4 and TLR9 was measured. The relative quantitation was indicated by cycle threshold (Ct) values. The Ct value of the target genes was normalized (ΔCt) to the Ct value of the GUS gene of the samples. The results were statistically analysed using 'STATISTICA 8,0'. Statistical analysis was performed by means of Mann-Whitney's U-test and P<0,05 indicated a significant difference.

Results: 60 patients (58%) with AML achieved complete remission (CR) after induction therapy, 7 patients (7%) achieved partial remission (PR) and 36 patients (35%) had no response. TLR2, TLR4 and TLR9 mRNA were expressed in all samples. The mRNA expression of TLR2 and TLR4 was significant higher in patients with NR after induction therapy than in patients with CR and PR. Moreover we observed that mRNA expression of TLR2 and TLR4 were significantly higher in patients with mielomonocytic and monoblastic acute leukemia. In comparison to control groupTLR2 and TLR4 mRNA expression was higher in AML patients than in healthy individuals although there was no statistically significant difference (ΔCt TLR2 0,9±0,85 vs 0,82±0,87 and ΔCt TLR4 0,29±0,32 vs 0,33±0,23). The results are shown in Tables 1 and 2.

Summary / Conclusion: Our results demonstrate that increased TLRs expression is related with reduced efficacy of induction chemotherapy in AML patients. We postulate that TLRs could be an independent prognostic factor for response rate after induction therapy in patients with acute myeloid leukemias. This observation should be validated by larger study.

Table 1. Correlation between mRNA expression of TLRs and response to induction therapy.

	CR+PR n=67	NR n=36	p
ΔCt TLR2	0,78±0,82	1,31±0,87	<0,01
ΔCt TLR4	0,28±0,29	0,35±0,35	<0,01
ΔCt TLR9	0,003±0,002	0,003±0,003	ns

n=number of patients ns=not significant

Table 2. Correlation between mRNA expression of TLRs andtype of AML.

	M0-M2 n=57	M4-M5 n=46	p
ΔCt TLR2	0,66±0,51	1,14±1,05	<0,01
ΔCt TLR4	0,19±0,18	0,40±0,39	<0,01
ΔCt TLR9	0,003±0,003	0,002±0,001	ns

THE SAFETY PROFILE OF DEFERASIROX REMAINS CONSISTENT AS NON-TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS APPROACH THE TARGET LIVER IRON CONCENTRATION OF <3 MG FE/G DW FOR INTERRUPTING CHELATION

A Taher[1,*] J Porter[2], V Viprakasit[3], A Kattamis[4], S Chuncharunee[5], P Sutcharitchan[6], N Siritanaratkul[7], R Galanello[8], Z Karakas[9], D Habr[10], Z Zhu[10], M Cappellini[11]

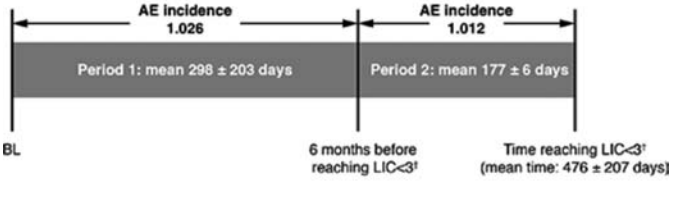
[1]American University of Beirut, Beirut, Lebanon, [2]University College London, London, United Kingdom, [3]Department of Pediatrics and Thalassemia Center, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]First Department of Pediatrics, University of Athens, Athens, Greece, [5]Ramathibodi Hospital, Mahidol University, [6]Chulalongkorn University and King Chulalongkorn Memorial Hospital, [7]Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [8]Ospedale Regional Microcitemie, Cagliari, Italy, [9]Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [10]Novartis Pharmaceuticals, East Hanover, United States, [11]Universita di Milano, Ca Granda Foundation IRCCS, Milan, Italy

Background: Non-transfusion-dependent thalassemia (NTDT) patients can develop clinically worrisome iron overload, putting them at risk of iron-related complications. The THALASSA 1-year extension study showed continued efficacy and safety in patients receiving deferasirox up to 2 years with more patients achieving the chelation stopping target of liver iron concentration <3mg Fe/g dw (LIC<3) compared with the core study. Given the potential concern with overchelation, it is important to determine the safety profile of deferasirox as LIC approaches3, a level at which it is recommended to interrupt chelation and monitor LIC for recurrent iron overload.

Aims: To characterize the safety profile of deferasirox as patients approach their chelation stopping target of LIC<3.

Methods: Study design/inclusion-exclusion criteria have previously been described (Taher *et al. Blood* 2012). Patients randomized to deferasirox during the core (starting dose 5 or 10 mg/kg/day) and those receiving placebo had the option to enter a pre-planned, 1-year, open-label extension. Deferasirox starting doses in the extension were based on LIC at the end of core and prior chelation response. Patient number reaching LIC<3 was one of the study endpoints. Treatment was interrupted in patients with LIC<3. Safety profile was assessed between baseline and 6 months before reaching LIC<3 (Period 1), and in the 6 months before reaching LIC<3 (Period 2). Given the difference in exposure between Periods 1 and 2 an exposure-adjusted adverse event (AE) characterization was carried out.

Results: 24/166 (14.5%) patients achieved LIC<3 during study (18 received deferasirox in core + extension; 6 switched from placebo to deferasirox in the extension). Baseline characteristics (12 β-thalassemia intermedia, 6 α-thalassemia, 6 HbE/β-thalassemia) were similar to the overall population. At baseline, mean ±SD LIC was 8.1 ±3.2 mg Fe/g dw and median serum ferritin (SF) was 825 ng/mL (range 393–2169), both lower than for the overall population (LIC: 14.5±8.8 mg Fe/g dw; SF: 992 ng/mL [304–6419]). Mean ±SD LIC at the end of Period 1 and 2 was 5.2 ±2.9 (range 3.2–16.8) and 2.2±0.5 (range 1.2–2.9)mg Fe/g dw, respectively (average deferasirox dose 9.7 mg/kg/day). Median SF at the end of Period 2 (or nearest assessment) was 363 ng/mL (range 74–773). Exposure-adjusted AE incidence regardless of drug causality did not differ between Periods 1 and 2 (Figure 1).



*Exposure-adjusted incidence = number of patients with new/worsened AE during period/ [total number of days patient was on treatment summed for all patients/365.25 days]
†LIC assessed by MRI-Ferriscan

Figure 1. Exposure-adjusted incidence* of AEs.

AE type regardless of drug causality reported in these 24 patients did not differ from that in the overall population. Only 1 AE of special interest was reported (blood creatinine increase in Period 1). Creatinine, creatinine clearance and ALT near the time of LIC<3 assessment were no different to those at the previous LIC assessment. 3 patients reported >33% increase in creatinine from baseline and >ULN on 2 consecutive visits (1 patient in Period 1 where creati-

nine returned to baseline levels on dose interruption but subsequently elevated in Period 2 and the remainder of the study; 2 patients during Period 2 [near the time that LIC<3 was reached] where increases were reversible and baseline levels reached at study end).
Summary / Conclusion: In NTDT patients receiving deferasirox, exposure-adjusted AE incidence did not differ from baseline to 6 months before reaching LIC<3 compared to the immediate 6 months prior to reaching LIC<3. These results indicate the safety profile of deferasirox remains constant as patients approach their chelation stopping target of LIC<3 mg Fe/g dw, indicating that with appropriate monitoring and dose adjustments this target may be reached without increased risk of overchelation.

P392

PROGNOSTIC CMR PARAMETERS FOR HEART FAILURE AND ARRHYTHMIAS IN A LARGE COHORT OF WELL TREATED THALSSEMIA MAJOR PATIENTS

A Pepe[1],* A Meloni[1], L Gulino[1], G Rossi[2], M Gamberini[3], A Quarta[4], G Giannotti[5], S Macchi[6], G Restaino[7], V Positano[1], M Lombardi[1]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, [2]Epidemiology and Biostatistics Unit, Institute of Clinical Physiology, CNR, Pisa, [3]Pediatria, Adolescentologia e Talassemia, Arcispedale "S.Anna", Ferrara, [4]Ematologia, Osp. "A. Perrino", Brindisi, [5]U.O.C. di Immunoematologia e Medicina Trasfusionale, A.S.P. n° 3 di Catania, Catania, [6]Servizio Trasfusionale, Ospedale Santa Maria delle Croci, Ravenna, [7]Department of Radiology, Catholic University of the Sacred Heart, Campobasso, Italy

Background: Cardiac complications are the main cause of death in thalassemia major (TM) patients. Cardiovascular Magnetic Resonance (CMR) plays a key role in the management of TM, allowing to assess cardiac iron burden, biventricular dimension and function, atrial dimensions, and myocardial fibrosis.
Aims: The aim of this study was to determine the predictive value of CMR parameters for heart failure and arrhythmias in TM.
Methods: We followed prospectively 537 white TM patients enrolled in the MIOT network. Fifty patients were excluded from the analysis because a cardiac complication was present at the time of the first CMR. The prognostic variables analyzed were retrieved from the MIOT database. All variables showing an association with the outcome at the univariate Cox proportional hazards model were placed in the multivariate model and were ruled out only if they did not significantly improve the adjustment of the model.

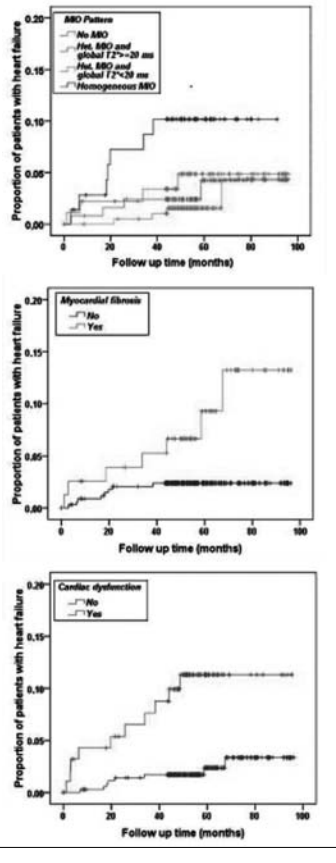


Figure 1.

Results: At baseline the mean age of the patients was 29.5±9.0 years, 222 were males and the mean serum ferritin level were 1742.49±1592.72 ng/l. The mean follow-up time was 58±18 months. After the first CMR scan only the 37.8% of the patients did not change the chelation regimen or the frequency/dosage of the chelators. We recorded 19 episodes of heart failure, diagnosed by clinicians based on symptoms, signs and instrumental findings (electrocardiogram, echocardiography and CMR) according to the current guidelines. Male sex, heart iron,ventricular dysfunction, ventricular dilation, atrial dilation, and myocardial fibrosis were significant univariate prognosticators. In the multivariate analysis the independent predictive factors were an homogeneous pattern of myocardial iron overload (compared to no MIO) (HR=5.81, 95%CI=1.42-23.74, P=0.014), global heart T2*<10 ms (compared with >20 ms) (HR=6.19, 95%CI=1.95-19.67, P=0.003), myocardial fibrosis (HR=4.76, 95%CI=1.69-13.46, P=0.003) and ventricular dysfunction (HR=3.21, 95%CI=1.13-9.12, P=0.029) (Kaplan–Meier survival curves in Figure 1). Arrhythmias occurred in 19 patients and all were supraventicular hyperhyperkinetic. Male sex, atrial dilatation and ventricular dysfunction were significant univariate prognosticators. In the multivariate analysis the independent predictive factors were male sex (HR=3.17, 95%CI=1.02-9.87, P=0.047) and atrial dilation (HR=3.07, 95%CI=1.14-8.23, P=0.026).
Serum ferritin and liver iron were not predictive factors for heart failure or arrhythmias.
Summary / Conclusion: We detected few cardiac events thanks to a CMR-guided, patient-specific adjustment of the chelation therapy. Severe and homogeneous myocardial iron overload, myocardial fibrosis and ventricular dysfunction identify patients at high risk of heart failure. Heart T2* doesn't have any power in predicting arrhythmias while male sex and atrial dilation are independent prognosticators.

P393

IMPACT OF MONITORING WITH LIVER MRI-R2 ON LIVER IRON BURDEN AND DEVELOPMENT OF ENDOCRINOPATHIES: A RETROSPECTIVE AUDIT

S Ko[1],* F Shah[2], E Prescott[2], S Sheth[1], B Davis[2]
[1]University College London Medical School, [2]Department of Haematology, Whittington Hospital, London, United Kingdom

Background: Monitoring of body iron stores continue to be a challenge in patients with transfusion-dependent β-thalassaemia major. Liver MRI-R2 is a noninvasive scanning method which using standard clinical MRI instruments and analysed telemedically. Published data suggest a strong correlation (r=0.98) between liver iron concentration measured by biopsy and that derived from the R2 scan (St Pierre, Blood, 2005).
Aims: Having recently adopted the use of MRI-R2 in liver iron monitoring, a major tertiary thalassaemia unit in London evaluates the relationship between liver iron concentration measured by MRI-R2 and serum ferritin, compliance to chelation, chelation regimen and new endocrinopathies developed between 2008-2012.
Methods: Clinical records of the 124 patients who had at least two MRI-R2 scans during the study period were reviewed to obtain demographic and clinical data. Patients were risk-stratified based on their liver iron concentration – low risk (<7 mg/g dry weight, target according to UK Thalassaemia Society guidelines), moderate risk (7-15 mg/g dry weight and risk of endocrine complications) and high risk (>15 mg/g dry weight and risk of cardiac damage) (Olivieri, Blood, 1997). Healthcare providers responsible for the patients were asked to rank the patients' compliance to chelation therapy as optimal or sub-optimal.
Results: The study group had a mean age of 32 (range 5-57) with a mean time of 2.2 years (range 8 months - 3.9 years) between the scans. 1 patient died within the study period due to sepsis unrelated to thalassaemia or iron overload. *Ferritin:* There was a weakly positive linear correlation between liver iron concentration measured by MRI-R2 and serum ferritin within three months of the scan (n=319, r^2=0.447). *Continuous monitoring:* Mean liver iron concentration decreased from 11.36±1.06 mg/g dw at initial scan to 6.10±0.55 mg/g dw at final scan (n=121, P<0.001). The proportion of patients in moderate and high risk categories nearly halved, from 48.7% to 27.3%. A continuous decrease was also shown in patients with 3 successive scans (n=56, P<0.05), where the number of patients in the high risk category decreased steadily from 28.6% to 23.2% to 12.5%. *Compliance:* 14.9% of patients were rated by their healthcare provider as sub-optimally compliant to chelation therapy. Patients who were rated as optimally compliant to therapy had better control of their liver iron concentration than those who were suboptimally compliant (P<0.001). In both optimally compliant and suboptimally compliant groups, liver iron concentration decreased from initial to final scan (P<0.01). *Chelation:* At final scan, 17.4% patients were on desferoxamine, 47.9% on desferasirox, 14.0% on deferiprone and 19.8% on combination therapy of desferroxamine and deferiprone. The chelation regime made no difference to the mean initial or final liver iron concentration (P>0.05). *Endocrinopathies:* 35 patients developed new endocrinopathies within the study period. There was no significant difference in the mean liver iron concentration in the group which developed endocrinopathies and those which did not (P=0.695). The relative risk of devel-

oping new endocrinopathies at moderate and high risk levels of liver iron compared to low risk levels was found to be insignificant at 1.04.
Summary / Conclusion: A significant improvement in liver iron concentration was demonstrated with the use of sequential MRI-R2 scans for monitoring iron overload. This is attributed to both better titration of chelation regimen and to encouraging compliance, as liver iron concentration improved even in the suboptimal compliance group. Our results emphasise the importance of optimising compliance to chelation rather than favouring any particular regime. As short-term monitoring of liver iron concentration does not predict development of further endocrine complications, we suggest the early adoption of regular MRI-R2 monitoring, routine screening for endocrinopathies regardless of scan results and re-evaluation of current targets for liver iron concentration.

P394

MYOCARDIAL FIBROSIS BY CMR LGE IN A LARGE COHRT OF PEDIATRIC THALASSEMIA MAJOR PATIENTS

A Pepe[1],* A Meloni[1], M Casale[2], L Gulino[1], B Pagano[3], S Pulini[4], A Ciancio[5], R Mattei[6], P Preziosi[7], V Positano[1], M Lombardi[1], A Filosa[2]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, [2]UOC Pediatria - DH Talassemia AORNA, Cardarelli, Napoli, [3]Centro Microcitemico. U.O. di Pediatria e Neonatologia, Presidio Ospedaliero - A.S.L. n. 9, Locri (RC), [4] U.O. Ematologia Clinica, Osped. Civile "Spirito Santo", Pescara, [5] Day Hospital di Talassemia, Ospedale "Madonna delle Grazie", Matera, [6]U.O. Pediatria, U.L.S.S. 19, Adria (Ro), [7] U.O.C. Diagnostica per Immagini e Interventistica, Policlinico "Casilino", Roma, Italy

Background: Cardiovascular Magnetic Resonance (CMR) by late gadolinium enhancement (LGE) allows to detect myocardial fibrosis. Myocardial fibrosis was shown to be a relative common finding in large cohort of Italian thalassemia major (TM) patients mainly related to HCV infection, but specific studies involving only pediatric patients are not available.
Aims: Our aim was to investigate the prevalence and clinical-instrumental correlates of myocardial fibrosis in pediatric TM patients.
Methods: We studied retrospectively 76 pediatric patients with TM (44 boys, 4.2 -17.9 years old, mean age 13.6±3.4 years) enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. All patients were well transfused and chelated since the early childhood. LGE images were acquired to detect myocardial fibrosis. Myocardial iron overload (MIO) was measured by T2* multislice multiecho technique. Biventricular function parameters were quantitatively evaluated by cine images.
Results: Myocardial fibrosis was detected in 12 (15.8%) patients. In all patients the location of the fibrosis was epi-mesocardial, with no ischemic pattern. The youngest patient showing myocardial fibrosis had 13 years of age.
Table 1 shows the comparison between patients with and without myocardial fibrosis. A significant higher MIO was detected in patients with myocardial fibrosis. The left atrial area, all the left ventricular (LV) indexed volumes, the LV mass index, and the right ventricular (RV) stroke volume index were significantly higher in the fibrosis group than in the no-fibrosis group.
Summary / Conclusion: In pediatric TM patients myocardial fibrosis is not a rare finding to keep in mind in the cardiological management. When appropriate treatment has been administered since early childhood, CMR LGE can be postponed until 13 years of age. By the natural history of this large cohort of pediatric patients where HCV infection has been appropriately prevented, myocardial fibrosis seem to be associated with MIO and high cardiac output.

Table 1.

	Fibrosis group (N=12)	No-fibrosis group (N=64)	P
Sex (M/F)	10/2	34/30	0.062

CMR SURVEY IN A LARGE COHORT OF TI PATIENTS CATEGORIZED IN DIFFERENT TRANSFUSIONAL REGIMENS

A Pepe[1],* A Meloni[1], S Vacquer[2], L Gulino[1], D De Marchi[1], N Romano[3], A Carollo[4], G Roccamo[5], G Valeri[6], V Positano[1], M Lombardi[1], M Lai[2]
[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, [2]Centro Talassemici Adulti, Ospedale microcitemico, Cagliari, [3]S.C. Medicina Trasfusionale, AO Arcispedale "S. Maria Nuova", Reggio Emilia, [4]Servizio Talassemia-U.O. Pediatria Talassemia, Az. Osp. "Sant'Antonio abate", Trapani, [5]Unità di Prevenzione e Cura delle Mictrocitemie, Presidio Ospedaliero di S.Agata di Militello, S.Agata di Militello, [6]Dipartimento di Radiologia, Azienda Ospedaliero-Universitaria Ospedali Riuniti "Umberto I-Lancisi-Salesi", Ancona, Italy

Background: Little is known about cardiac involvement in thalassemia intermedia (TI) using cardiovascular magnetic resonance (CMR). This survey is particularly significant considering the debate on the opportunity to transfuse the TI patients.
Aims: Our aim was to investigate myocardial iron overload (MIO), biventricular parameters, and myocardial fibrosis in a large cohort of TI categorized in different transfusional regimens.
Methods: We studied retrospectively 252 adult TI patients (119 females, 39.5±10.4 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. MIO was assessed using a multislice multiecho T2* approach. Cine sequences were obtained to quantify biventricular function parameters. Myocardial fibrosis was evaluated by late gadolinium enhancement (LGE) acquisitions.
Results: 188 (74.6%) patients showed no MIO in any segment, fifty-six (22%) patients had an heterogeneous myocardial iron distribution (52 with a global heart T2*<20 ms), and 8 (0.3%) showed an homogeneous MIO. Left ventricular (LV) and right ventricular (RV) dilatations were present in 113 (45%) and in 49 (19%) patients, respectively. LV dysfunction was present in the 18.0% of the cases while RV dysfunction in the 3.63%. High LV mass indexes were present in 22 (8.7%) patients. LGE acquisitions were made in 227 patients and 52 (22.9%) showed myocardial fibrosis. Myocardial fibrosis was associated only with LV dysfunction (P=0.001) and high LV mass indexes (P=0.038). 48 (19.0%) patients were no transfused, 66 (26.2%) were sporadically transfused and 138 (54.8%) were regularly transfused (mean time of the regular transfusional regimen 22.6±13.3 yrs). Among the CMR parameters considered the 3 group were significantly different for the LV volume indexes, the LV mass indexes, the cardiac output and the myocardial fibrosis (Figure 1).
Summary / Conclusion: CMR plays a key role in the management of TI patients. Heart iron was not absent in although the majority of the patients showed an heterogeneous distribution. A consistent number of the TI patients had the stigmata of the high cardiac output state cardiomyopathy and myocardial fibrosis seems to be related to the high cardiac output state. The signs of the high cardiac output state were controlled in the regular transfused patients. Conversely, in our cohort the regular transfused regimen seems to be started too late for preventing myocardial fibrosis.

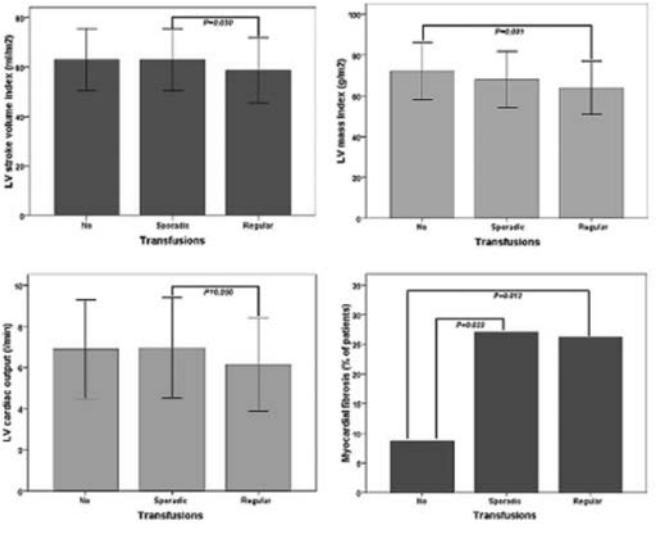

Figure 1.

P396

EVALUATION OF GLYCAEMIC ABNORMALITIES IN BETA THALASSEMIA MAJOR USING CONTINUOUS GLUCOSE MONITORING SYSTEM AND ORAL GLUCOSE TOLERANCE TEST

M Yassin[1,*] a soliman[2], s alazawi[1], h elayoubi[1], V Desanctis[3]
[1]Hematology/BMT, National centre for cancer care and research, [2]pediatric endocrinology, HMC, Doha, Qatar, [3]pediatric and adolescent, Quisisana Hospital, Ferrara, Italy

Background: Glycaemic abnormalities have been reported in patients with β thalassemia major (TM). The use of continuous blood glucose monitoring system (CGMS) for early detection of glycaemic abnormalities has not been studied thoroughly in these patients. The aims of this study were to evaluate glycaemic abnormalities, in young adult TM patients using oral glucose tolerance test (OGTT) and 72-h CGMS, and to determine whether glycaemic abnormalities are due to insulin deficiency and /resistance.
Aims: Fourteen TM patients were selected randomly. All patients were investigated using a standard 75 gm oral glucose tolerance test (OGTT) and 72-h CGM by Medtronic system. Fasting serum insulin and ferritin concentrations were also measured. HOMA-B, HOMA-IR and QUICKI index were calculated using basal glucose and insulin levels.
Methods: OGTT fasting and 2hours postprandial as well as CGMS were done in all patients, all patients with abnorml OGTT has repetition for confirmation, CGMS were fixed for three days american college of Diabetes criteria were used to interpret the results, HOMAB,HOMAIR were calculated using equation
Results: Using OGTT, 2 patients had impaired fasting glucose (IFG) only, 2 had both IFG and IGT (glucose <11.1 mmol/L) and 1 had diabetes. In contrast, by CGMS 6 patients had (IGT) only, 3 patients had had both IFG and IGT, and 4 patients were Diabetics with glucose level ≥11.1 mmol/L. The mean values of HOMA and QUICKI in patients with TM were (1.6±0.8) and (0.36±0.03) respectively. Ferritin concentrations were positively correlated with the fasting BG r= 0.69, P<0.01, serum ferritin correlated with the average (r=0.75; P<0.01) and the maximum BG recorded by CGM (r = 0.64, P<0.05). Using OGTT, 2 patients had impaired fasting glucose (IFG) only, 2 had both IFG and IGT (glucose < 11.1 mmol/L) and 1 had diabetes. In contrast, by CGMS 6 patients had (IGT) only, 3 patients hadhad both IFG and IGT, and 4 patients were Diabetics with glucose level ≥11.1 mmol/L. The mean values of HOMA and QUICKI in patients with TM were (1.6± 0.8) and (0.36±0.03) respectively. Ferritin concentrations were positively correlated with the fasting BG r= 0.69, P<0.01, serum ferritin correlated with the average (r=0.75; P<0.01) and the maximum BG recorded by CGM (r = 0.64, P<0.05).
Summary / Conclusion: Our data suggest that CGMS is more sensitive than OGTT in detecting glycaemic abnormalities in young adult TM patients .It seems that defective β-cell function rather than insulin resistance is the most likely explanation for glycaemic abnormalities in these patients

P397

HEMATOLOGIC DETERMINANTS OF CARDIAC REMODELLING AND CARDIAC INDEX IN SICKLE CELL DISEASE PATIENTS.

T Damy[1], S Rappeneau[2], A Habibi[3], S guendouz[4], J Dautremer[3], D Bachir[3], L Hittinger[1], J Randé[1], F Galactéros[5], P Bartolucci[5,*]
[1]HEART FAILURE UNIT / Department of Cardiology, CHU Henri Mondor. APHP. UPEC. INSERM, [2]HEART FAILURE UNIT / Department of Cardiology, CHU Henri Mondor. APHP, [3]Unité des maladies génétiques du globule rouge. IMRB U955 équipe2, [4]HEART FAILURE UNIT / Department of Cardiology, CHU Henri Mondor. APHP. UPEC., [5]Unité des maladies génétiques du globule rouge. IMRB U955 équipe2, CHU Henri Mondor. APHP. UPEC. INSERM, Créteil, France

Background: In sickle cell disease (SCD), relationship between cardiac remodeling, cardiac index(CI) and hemoglobin (Hb), red blood cell count (RBC) and fetal hb (HbF) have not been well characterized.
Aims: Our aims were to study biological determinants of cardiac involvement in SCD and to describe cardiac characteristics during SCD in a large cohort of patients
Methods: We interrogated our hospital database including 1780 adult SCD patients to provide new insights on biological determinants of cardiac characteristics in SCD. Inclusion criteria were: homozygous or S-β_0Thalassemia patients having an echocardiography and steady state biological values before hydroxyurea or blood transfusion. Exclusion criteria were patients less than 18 years old and pregnancy. SCD patients were compared with 25 age-matched black healthy subjects. Echocardiography included M-mode, 2D, pulsed Doppler and Left Ventricular tissue Doppler.
Results: 656 SCD patients were included in the analysis with a mean age of 31 years (25; 40).Compared to control, SCD had significant higher left ventricular diastolic diameter indexed to body surface area (LVEDDind), left atria diameter indexed (LADind), Cardiac Index (CI), and lower left ventricular ejection fraction (LVEF). Systolic pulmonary artery pressure (sPAP) was not different between the two last groups. In SCD, LVEF was not correlated with Hb (P=0.74) whereas CI and LVEDDind were (both R:0.25, P<0.0001). Systolic dysfunction (LVEF<50%) was observed in only 3.4%. There was poor relationship between LVEDD and CI (R=0.15, P=0.01). Patients were divided in quartiles of CI and LVEDDind. Patients in the fourth quartiles (Q4) of LVEDDind (median/range : 35 (34; 37)) and of CI (4.7 (4.5; 5.3)) versus the three others quartiles (Q1-3) had significantly lower Hb, HbF and RBC, and higher lactate dehydrogenase, bilirubin and Dense Red Blood Cells (DRBC). Determinants of Q4 LVEDDind and CI using multivariate binomial regression analysis were respectively lower Hb and HbF and lower RBC and HbF. Patients with two alpha-thalassemia gene deletions had a significant lower CI and LVEDD.
Summary / Conclusion: In SS and S-β_0Thalassemia SCD, cardiac remodeling and elevated cardiac output are determined by hematologic variables associated with the "hyper-hemolytic phenotype".

P398

EFFECTS OF THE ANTI RANK LIGAND DENUSOMAB ON BETA THALASSEMIA MAJOR-INDUCED OSTEOPOROSIS

M Abdeldaem Yassin[1,*] A Soliman[2], S Alazawi[3], H elayoubi[3], r kamzoul[3], V De Sanctis[4]
[1]Hematology/BMT, National centre for caree and research, [2]Pediatric endocrinology, HMC, [3]Hematology/BMT, National centre for cancer care and research, Doha, Qatar, [4]pediatric and adolescent, Quisisana Hospital, Ferrara, Italy

Background: Osteoporosis is defined as a metabolic bone disease characterized by low bone mass and microarchitectural deterioration of bony tissue leading to enhanced bone fragility and a consequent increase in fracture risk.Some drugs proved effective to reduce vertebral and non-vertebral fracture risk. Denosumab is a fully human monoclonal antibody to the receptor activator of nuclear factor-κB ligand (RANKL), However the efficacy and safety of Denosumab in BTM-induced osteoporosis has not been tested. This is the first study addressing this issue
Aims: To evaluate the efficacy and safety of anti RANK ligands on the biochemical and radiological parameters of bone mineralization in patients with BTM-induced osteoporosis. Radiological evaluation was done by DEXA scan (using WHO criteria) and biochemical evaluation of bone turnover markers included bone specific alkaline phosphatase and type 1 collagen carboxy telopetide (1CCT).
Methods: we studied 30 patients with BTM-induced osteoporosis as per WHO criteria (T score of less than -1.0 being defined as osteopenic and a T score of less than -2.5 being referred as osteoporotic). 19 males and 11 females aged between 17 and 32 years, with full pubertal development (Tanner's stage 5) at the time of the study(T-scores between -2.5 and -4.0 at the lumbar spine [LS] or total hip [TH]) . Their serum ferritin levels ranged from 500 to 5922 ng/mL (mean= 2686 ng/ml). Every patient underwent DEXA scan as baseline and after 12 months of Denosumab therapy. All patients were evaluated biochemically by checking their serum calcium, phosphorus, bone specific alkaline phosphatase and 1CCT with the use of enzyme-linked immunosorbent assay (ELISA) (Nordic Bioscience Diagnostics A/S) at baseline and 12 months after starting Denosumab. Fasting serum samples were collected before and 1 and 6 months after the injection. Follicle stimulating hormone(FSH) ,Luteinizing hormone (LH) and testosterone (T) in males were measured at baseline and repeated every 3months. Renal function and electrolytes including calcium and phosphorus were measured at baseline and every two months. Circulating parathyroid hormone (PTH) levels were checked at baseline and then every 3months. Patients with renal impairment, hypocalcaemia or hyperparathyroidism were excluded from the study. 60 mg of Denosumab was administered subcutaneously twice yearly for a year. The mean bone mineral density T scores were −2.7 at the lumbar spine, −1.8 at the total hip, and −2.1 at the femoral neck.
Results: Denosumab therapy for a year was associated with a significant increase in bone mineral density of 9.2% (95% CI, 8.2 to 10.1) at the lumbar spine and 6.0% (95% CI, 5.2 to 6.7) at the total hip. Denosumab treatment decreased serum TICCT levels by 56% at 1 month and normalized them in all patients at 1 year. Significant correlations were found between bone mineral density T score before and 1year after Denosumab in vertebral (r=0.752, P<0.001) and both hips (r=0.758 respectively P<0.001). The most common side effects were pain in the extremities (12%) and nausea (10%) of patients. Hypocalcaemia was not reported in any patient.
Summary / Conclusion: Denosumab therapy for a year significantly decreased bone resorption and increased bone mineral density through inhibition of RANKL and is associated with a rapid and sustained reduction in bone turnover markers, a continuous marked increase in bone mineral density at vertebral and hips of patients with BTM. However further studies are required to confirm long-term effects of this therapy.

P399

REFERENCE RANGES FOR BIVENTRICULAR VOLUMES AND EJECTION FRACTION AND FOR LEFT VENTRICULAR MASS IN ADULT THALASSEMIA INTERMEDIA PATIENTS WITHOUT MYOCARDIAL IRON OVERLOAD

[1]Cardiovascular MR Unit, Fondazione G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, [2]P.O."Giovanni Paolo II" Sciacca , Distretto AG2 ASP Agrigento, Agrigento, [3]Ospedale Microcitemico, Centro Talassemici Adulti, Cagliari, [4] Ematologia II con Talassemia , Ospedale "V. Cervello", Palermo, [5]Oncoematologia Pediatrica, Policlinico di Modena, Modena, [6]Department of Radiology, Catholic University of the Sacred Heart, Campobasso, Italy

Background: Thalassemia intermedia (TI) patients were shown to have significantly higher cardiac output and cardiac volumes with respect to thalassemia major (TM) patients. So, to compare biventricular parameters in TI patients with established ranges from TM may be misleading.
Aims: The aim of this study was to establish the ranges for normal biventricular volumes and ejection fraction (EF) and for left ventricular (LV) mass assessed by cardiovascular magnetic resonance (CMR) in TI.
Methods: Among the 294 TI patients with >18 years of age enrolled in the Myocardial Iron Overload (MIOT) network who underwent CMR, we selected 68 patients with no known risk factors or history of cardiac disease, normal electrocardiogram, no myocardial iron overload (all the cardiac segments with a normal T2* value) and no myocardial fibrosis. Biventricular parameters were quantitatively evaluated in a standard way by SSFP cine images using MASS® software. LV and right ventricular (RV) end-diastolic volume (EDV), end-systolic volume (ESV) and stroke volume (SV) were normalized by body surface area (EDVI, ESVI, SVI), as well as the LV mass.
Results: The selected patients had a mean age of 36.5±9.2 and 37 were males. Biventricular volumes indexes were significantly larger in males than in females, with the exception of the RV ESVI. The LV mass was significant higher in males while the LV and the RV EFs were not different between the sexes. No significant differences among TI regularly (N=36), sporadically (N=16) and no transfused (N=16) were found in biventricular parameters, so no division was made on the basis of the transfusional regimen.
The biventricular parameters are detailed in Table 1 with differentiation for sex. Table 1 reports also the cut-off of normality defined as mean - 2 standard deviation (SD) for the volumes and the LV mass and as mean - 1 SD for the EF (considering the high cardiac output state in anemic patients).
Summary / Conclusion: Reference ranges for biventricular volumes and function specific to adult TI patients were defined. These new reference ranges are important for avoiding a misdiagnosis of cardiomyopathy in TI patients.

Table 1.

	Males			Females		
	Mean ± SD	95% CI	Normal value	Mean ± SD	95% CI	Normal value
LV EDVI (ml/m2)	101.5 ± 22.6	93.9-109.0	<147	89.4 ± 15.1	83.8 – 94.9	<120
LV ESVI (ml/m2)	38.1 ± 11.2	34.4 – 41.8	<60	32.2 ± 7.9	29.3 – 35.1	<48
LV SVI (ml/m2)	63.6 ± 13.9	58.9 – 68.2	<91	57.4 ± 12.3	52.9 – 61.9	<82
LV Mass I (g/m2)	69.2 ± 12.6	64.9 – 73.4	<94	57.7 ± 10.9	53.7 – 61.8	<79
LV EF (%)	62.6 ± 5.6	60.7 – 64.4	>57.0	63.8 ± 5.9	61.6 – 66.0	>57.9

CLINICAL PROGRESS IN FOUR CARRIERS OF BETA GLOBIN LOCUS DELETIONS

J Nieto[1,1,*] E Fontanes[1], F De La Fuente Gonzalo[1], P Gradilla[1], L Galán[1], F González Fernández[1], A Villegas[1,2], S Salazar[1], E Calderón[1], E Ramírez[1], T López[3], B de Mendiguren[3], M Durán[4], G Juan[4], B Arrizabalaga[5], S Erquiaga[5], J Mediavilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]on behalf of Spanish Erithropathology Group, Madrid, [3]Hematology, Hospital General de Burgos, Burgos, [4]Hematology, Hospital Universitario Son Espases, Mallorca, [5]Hematology, Hospital de Cruces, Bilbao, Spain

Background: The HBB locus contains several globin genes highly and specifically expressed at different human development stages. The ε and γ genes are expressed during embryogenesis and fetal development, respectively. The adult erythropoiesis occurs in the bone marrow. Here, the δ and β genes begin their expression. Located several Kb upstream the locus, the main regulatory element leading to high globin expression is known as LCR (Locus Control Region). Large DNA deletions may affect one or more of these genes, resulting in a thalassemic phenotype at the developmental stage in which the deleted gene is required. When a deletion removes all globin genes in the locus, or even when the deletion is limited to the LCR, a phenotype named εγδβ thalassemia is produced. In this case, globin gene expression in the HBB locus is abolished.
Aims: Here we present the genetic study and clinical progress of four εγδβ thalassemic patients.
Methods: Four non related patients were submitted for genetic screening of thalassemia because they showed a moderately-severe anemia at birth (patient I: Hb 10,1 gr/dl; MCV 80,1 fl; MCH 25 pg; patient II: Hb5,7; MCV 63,5; MCH 20,1; patient III: Hb 7,3; MCV 65,7; MCH 21,4; and patient IV: Hb 6,9; MCV 74,7; MCH 21,8). Patient IV was the only one requiring a sporadic blood transfusion for the treatment of the anemia. The genetic screening was performed by MLPA, with a commercial kit (P102-B2 HBB, MRC-Holland). This technique allows the detection of any large deletion in a genetic region spanning more than 80 Kb, including the HBB locus and the LCR. In order to follow the patients clinical progress it has been compared theirs hematological indices at birth versus the more recent data available (patient I at 7 years old: Hb 11,8; MCV 60,4; MCH 20,3; patient II at3,5 years old: Hb 10,6; MCV 59,8; MCH 18,6; patient III at2,5 years old: Hb 10,6; MCV 59,1; MCH 18,4; and patient IV at 2 years old: Hb 11,2; MCV 53,2 ; MCH 17,9).
Results: MLPA showed that all patients were carriers for large deletions affecting the genetic region studied here. Patients I to III have a deletion removing more than 80Kb, including the LCR and all the globin genes. Patient IV is carrier for a deletion limited to the LCR and ε gene, leaving intact the remaining globin genes in the locus. The clinical progress of all four patients is showed in Figure 1.
Summary / Conclusion: There are 15 previously known deletions causing εγδβ thalassemia. Most of these cases were *de novo* mutations. Parents of our patients I to III showed a normal hematologic profile. Thus, it is plausible that these deletions also were produced in a similar way that those cited above. In contrast, the father of patient IV presents a thalassemic trait, so he could be a carrier of the same deletion. In all our cases, the phenotypic substantially improves over time, possibly occurring in parallel to fetal to adult globin switching. Interestingly, many of the previously known heterozygote carriers for this kind of deletions have a clinical course marked by a variable moderate-severe hemolytic anemia, followed by the hematological picture of normal HbA2 β thalassemia trait in adult life. It is though that, somehow, fetal erythrocyte precursors could be more supceptible to α globin chain excess than adult precursors. However, the molecular basis responsible of both the phenotypic variability of εγδβ thalassemias in the perinatal period and the subsequently remission of the patients have not been explained so far.

P401

PITUITARY MRI IN CORRELATION WITH IRON OVERLOAD AND HYPOGONADISM IN YOUNG THALASSEMIA MAJOR PATIENTS

M Elalfy[1], A Adly[1,*] A Samir[2]
[1]Pediatrics, [2]Radiodiagnosis, Ain Shams, cairo, Egypt

Background: Iron over load is common for patients with thalassemia major and

other transfusion-dependent anemias. The toxic effects of iron include heart failure, diabetes, and hypogonadism. Hypogonadism is the most common endocrinopathy in thalassemia major, with a prevalence rate of over 50% in multicenter studies. Early recognition of pituitary iron loading is imperative because hypogonadism is only partially reversible by intensive chelation.
Aims: Our aim was to determine MRI signal intensity young beta-thalassemia patients with transfusional iron overload. And to correlate MRI findings with degree of hemosidrosis and gonadal dysfunction.
Methods: We recruited 56 patients divided into 2 groups; group 1 comprised 22 patients with hypogonadism (chronological age range :12.5-19.6 years) and group 2 comprised 34 patients with normal gonadal function (chronological age range :12 -16.6 years). Hypogonadism was defined clinically based on the timing of secondary sexual characteristics or the need for sex hormone replacement therapy. MR imaging of pituitary gland using 1.5 T unit with survey sagittal T1-weighted image and a sagittal T2-weighted image on Fast Field Echo sequence. Signal intensities were measured in consensus by the use of 3 operator-defined regions of interest . Thalassemia patients were subjected to questionnaire about data at diagnosis, age , disease duration ,chelation therapy, blood transfusion with calculation of the mean pretansfusion hemoglobin and transfusion index. Through clinical examination, weight, height standard deviation scores, Pubertal stage assessment, bone age according to Greulich and Pyle method as well as mean serum ferritin in the last 2 years prior to the study and hormonal assay (Growth hormone, Gonadotropin-stimulating hormones both basal and after stimulation). Patients were compared to 40 healthy age and sex matched subjects served as controls.
Results: All studied patients had high seum ferritin (mean=3156.25± 740.38 µg/L) and they show significant reduction in their signal intensity of pituitary MRI compared to controls (<0.001). Moreover there was significant reduction of signal intensity in group 1 compared to group 2 (P<0.005). Negative correlation was found between pituitary signal intensity and mean serum ferritin (r = -0.78, P<0.001). Thalassemic patients with hypogonadism had significantly higher serum ferritin, older age, lower height and weight SDS with lower mean pituitary MRI signal intensity. Moreover thalassemia patients with hypogonadism had significantly lower LH and GH basal levels and after stimulation (P<0.05). A negative moderate correlation between pituitary MRI SI and age (r= -0.48, P=0.002). Best cut off value for MRI signal intensity was 369 with sensitivity of 87.5%, specificity 68 %, and diagnostic accuracy of 73%. o differentiate between patients with and without hypogonadism.
Summary / Conclusion: The use of pituitary MRI signal intensity is a useful noninvasive tool for detecting adenohypophyseal iron overload in patients with transfusional hemosidrosis and for predicting the pituitary gonadal dysfunction

P402

HBH CONSTANT SPRING DISEASE (HBHCS) HAS LOWER SERUM FERRITIN RELATIVE TO LIVER IRON CONCENTRATION (LIC) COMPARED TO DELETIONAL HBH DISEASE: IMPORTANCE OF LIC MEASUREMENT IN HBHCS

A Ang[1,*] T Le[2], R Tan[2]
[1]Haematology, Singapore General Hospital, [2]Cardiology, National Heart Centre, Singapore, Singapore

Background: HbH Constant Spring disease (HBHCS) is a non-deletional HbH disease which generally has a more severe phenotype than deletional HbH disease (HBH) due to its greater ineffective erythropoiesis from alpha^{CS} chains accumulation within the erythroid precursors. Therefore, there may be differences in the correlation of serum ferritin (SF) with liver iron concentration (LIC) between HBHCS and HBH.
Aims: This retrospective study aims to investigate the difference in the correlation of SF with LIC between HBHCS and HBH.
Methods: T2* measurement by CMRtools is available to our patients (pts) as the mode of non-invasive liver iron assessment. We included all HBHCS and HBH pts within an adult haematology unit who ever had liver T2* and SF measured within 3 months of the T2*. Beta thalassemia intermedia (TI) pts were also selected for comparisons with the HBHCS pts as TI had been repeatedly shown in published studies to have lower than expected SF to LIC ratio. Pts with active hepatitis B or C and infections at the time of SF measurement were excluded. The pts selected had liver T2* and SF assessments prior to regular iron chelation. Liver T2* was converted to LIC (in mg/g dw) using calibrations previously derived by Garbowski M W *et al* [Reference: Calibration of Improved T2* Method for the Estimation of LIC in Transfusional Iron Overload. Blood (ASH Annual Meeting Abstracts), 2009; 114: 2004.]. Data on baseline characteristics and correlation of SF with LIC were retrospectively collected and compared between HBHCS and other types of thalassemia (HBH and TI). Statistical significance was taken as a two-tailed P-value of <0.05.
Results: 7 HBHCS, 13 HBH and 12 TI were included. No HBHCS and TI pts were transfusion dependent. Four HBH pts required intermittent transfusion for symptomatic anaemia while the rest did not. At the time of T2* HBHCS pts were similar in age (median 53 (18-57) years) as HBH pts (median 56 (41-78) years, P=0.251) but were significantly older than the TI pts (median 28 (18-61), P=0.035). Overall, 53% of pts were males and 25% had splenectomy. There were no significant differences in the proportion of males (P≥0.350) and splenectomy (P ≥0.270) between HBHCS and other types of thalassemia. SF was measured at a median of 17 (0-85) days within T2* assessment and were not significantly different between HBHCS, HBH and TI (P ≥ 0.663). There was a positive correlation between SF and LIC for HBHCS (R^2= 0.8, P=0.007), HBH (R^2= 0.6, P=0.001) and TI (R^2= 0.9, P=0.000). SF of HBHCS pts (median 1345 (904-1874) mcg/L) did not differ significantly from HBH pts (median 1278 (422-6322), P=0.663) and yet had significantly higher LIC (median 19.5 (6.7-30.7) mg/g dw) than HBH patients (median 9.1 (3.5-22.2) mg/g dw, P=0.022). TI pts have similar SF (1487 (299-4616) mcg/L, P =0.933) and LIC (median 18.4 (4.5-34.1) mg/g dw, P=0.966) as HBHCS pts. HBHCS pts had significantly lower SF to LIC ratio (median 65 (56-134) mcgL^{-1}/ mgg^{-1}dw) than HBH pts (median 125 (48-285) mcgL^{-1}/ mgg^{-1}dw, P=0.013). They had similar SF to LIC ratio as the TI pts (median 68 (26-136) mcgL^{-1}/mgg^{-1}dw, P=0.612). The difference in the correlation of SF with LIC between HBHCS and HBH was also reflected by the linear regression graphs which had significantly different slopes (P=0.013, Figure 1). We have shown that SF and LIC correlations are not uniform across all types of HbH disease. HBHCS has lower SF relative to LIC compared to HBH, and may be similar to non-transfusion dependent TI which has been well established to have lower than expected SF to LIC ratio. This may be explained by the greater ineffective erythropoiesis in HBHCS, resulting in more hepcidin suppression, iron absorption and iron release from the reticuloendothelial system, thereby leading to lowering of SF relative to LIC compared to HBH.
Summary / Conclusion: Iron load in HBHCS needs to be monitored differently from the more common HBH. SF may underestimate the degree of iron overload in HBHCS pts who need LIC measurement for more accurate total body iron load assessment, especially for decision-making on the initiation of iron chelation.

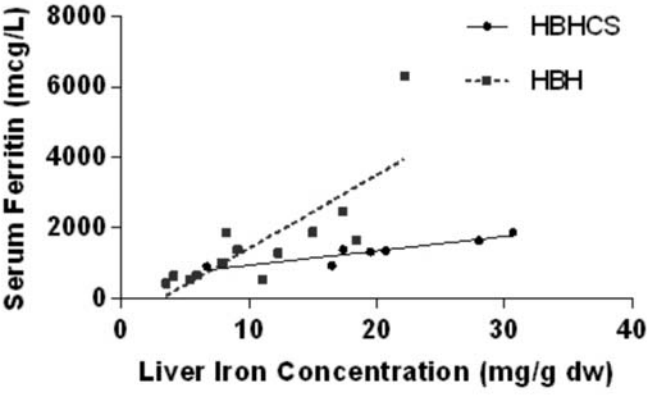

Figure 1. Serum ferritin vs liver iron concentration.

P403

AN AUTOMATIC METHOD FOR MYOCARDIAL T2* CURVE FITTING IN THALASSEMIA PATIENTS WITH SEVERE IRON OVERLOAD

V Positano[1], A Meloni[1], L Gulino[1], A Peluso[2], M Romeo[3], M Lendini[4], F Santarelli[1], L Landini[1], A Vallone[5], C Ascioti[6], M Lombardi[1], A Pepe[1,*]

Talassemie ed Emoglobinopatie , Ospedale Ferrarotto CT Az. Osp. Universitaria Policlinico Vittorio Emanuele, Catania, [4]Centro trasfusionale , Osp. Giovanni Paolo II, Olbia, [5]Istituto di Radiologia Az. Osp. "Garibaldi" , Presidio Ospedaliero Nesima, Catania, [6] Struttura Complessa di Cardioradiologia, UTIC P.O. "Giovanni Paolo II", Lamezia Terme, Italy

Background: Myocardial iron overload assessment by multislice multiecho T2* technique is used in the clinical management of thalassemia major (TM) patients. Signal decay curves are extracted from the 16 left ventricular (LV) segments and the fitting of these curves to a mono-exponential model provides the corresponding T2* values. In patients with severe cardiac iron overload, where signal will decay quickly becoming comparable to image noise, manual truncation of signal decay curves excluding later echo times (TEs) is adopted.
Aims: In this study an automatic truncation method avoiding the variability associated with the manual selection of the truncation point is introduced and validated.
Methods: Twenty patients (13 males, age 33±7 years) enrolled in the MIOT Network and diagnosed for severe iron overload (T2*<10 ms) were considered. Using a previously validated software the segmental T2* values were evaluated by the standard methodology (i.e. manual truncation). Images were independently analysed by the developed automated approach. The percentage fit-

ting error *e* was computed as the root mean square error between the signal decay curve and the mono-exponential model normalized to the mean value of the signal. If *e* was >5%, the algorithm cut-off the last TE and performed again the fitting. The procedure was iterated until the error become <5% or the number of TEs become equal to three. To assess the inter-operator variability, the dataset was processed by a second operator.

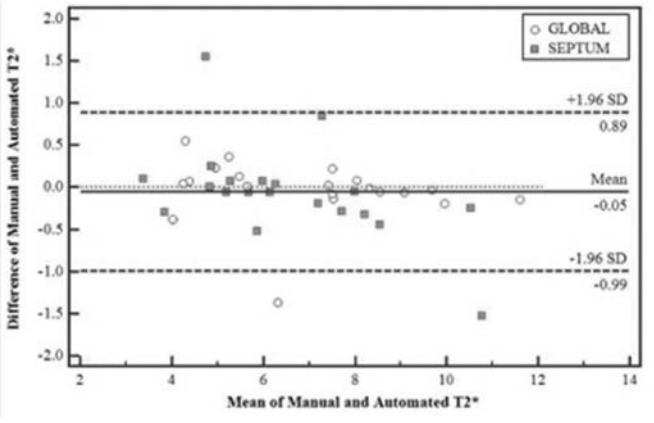

Figure 1.

Results: The Coefficient of Variability (CoV) for inter-observer variability was 6.82±4.01%. The CoV between automated and manual analysis was 6.15±3.92 %, not significantly different from inter-observer variability (P=0.332). No significant difference was detected between mid-septum and global T2* values evaluated with manual and automated procedure (P=0.26 and P=0.91, respectively). The figure shows the Bland-Altmann plots. The mean fitting error was not significantly different in manual and automated analysis (4.10±2.11 vs. 4.52±2.12, P=0.53). In segmental analysis, no significant differences were found between manual and automatic procedure (P>0.01 for all segments).
Summary / Conclusion: Truncation of signal decay curve needed to compensate for low signal in later echoes in patients with severe iron overload can be effectively automatized avoiding operator induced variability.

P404

MOVEMENT ABNORMALITIES IN THE LEFT VENTRICLE OF THALASSEMIA MAJOR PATIENTS

A Meloni[1], L Gulino[1], T Casini[2], P Sanna[3], B Piraino[4], M Smacchia[5], M Resta[6], E Chiodi[7], C Salvatori[8], V Positano[1], M Lombardi[1], A Pepe[1,*]

Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy

Background: Movement abnormalities of the left ventricle (LV) have been reported in thalassemia major (TM) patients. Movement abnormalities can be detected through a qualitative analysis of cine MR images. Moreover, MR is the gold standard technique for the evaluation of myocardial iron overload (MIO), biventricular global systolic function and myocardial fibrosis.
Aims: The aim of this study was to investigate the relationships between movement abnormalities and MIO, left ventricular (LV) function and myocardial fibrosis.
Methods: CMR (1.5T) was performed in 1092 TM patients (537 male; 30.6±8.5 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Cine SSFP images were acquired in vertical and horizontal long-axis, and in sequential 8-mm short-axis plans (gap 0 mm) from the atrio-ventricular ring to the apex. These sequence were used to evaluate the wall motion and to quantify LV volumes and ejection fraction (EF) by means of the MASS software in a standard way. For MIO assessment, three parallel short-axis views of the LV were acquired using a T2* GRE multi-echo sequence. To detect myocardial fibrosis, late gadolinium enhanced (LGE) images were acquired in the same views as used for cine images after the gadobutrol (1.0 mol/l) (0.2 mmol/kg) intravenous administration. During image analysis the 17-segment LV model of the standard AHA/ACC was taken into account. On the cine images, segmental wall motion was visually assessed by skilled observers (with at least 5 years of experience in CMR) and scored as 1=normal, 2=hypokinesia, 3=akinesia and 4=dyskinesia. The T2* value in all segments as well as the global value were calculated. Presence/absence of enhancing area was assessed for each segment.

Table 1.

	Patients with abnormal wall motion	Patients with normal wall motion	P-value
Age (years)	33.1 ± 8.3	30.4 ± 8.5	0.014
Sex (M/F)	37/29	500/526	0.248
Global Heart T2 (ms)*	22.5 ± 14.7	30.4 ± 8.5	0.001
N. of segments with T2 <20 ms*	8.6 ± 7.5	4.6 ± 6.1	<0.0001
Global heart T2 <20 ms, N (%)*	38 (57.6)	376 (36.6)	0.001
LV end-diastolic volume index (ml/m2)	99.0 ± 24.5	87.5 ± 18.9	<0.0001
LV end-systolic volume index (ml/m2)	49.3 ± 18.7	34.0 ± 11.6	<0.0001
LV mass index (g/m2)	66.3 ± 14.1	58.4 ± 13.3	<0.0001
LV ejection fraction (%)	51.1 ± 9.1	61.7 ± 6.6	<0.0001
LGE, N (%)	34 (51.5)	162 (15.8)	<0.0001

Results: Abnormal motion of LV was found in 66 (6%) patients: 60 were hypokinetic while 6 were dyskinetic. Our data demonstrated predominant involvement of wall motion abnormalities in the medium anterior, anterolateral and septal segments. Table 1 shows the comparison between patients with normal and abnormal motion. Patients with abnormal motion were significantly older, they had significantly lower global heart T2* value and a significantly higher number of segments with T2*<20 ms. Left volumes and mass indexed by body surface area were significantly higher in patients with abnormal motion while the EF was significantly lower. LGE areas were detected in 196 patients (18%) and they were predominantly located in the mid-ventricular septum. There was a significant correlation between the presence of enhancement and the abnormal motion.
Summary / Conclusion: Movement abnormalities in the left ventricle were not really frequent in TM patients but were associated with age, MIO, LV dilation and dysfunction, and myocardial fibrosis.

P405

CLINICAL CHARACTERISTICS AND EVOLUTION OF 78 DELAYED TRANSFUSION REACTION AMONG SICKLE CELL DISEASE PATIENTS

A Habibi[1,*] C Guillaud[2], M Michel[2], K Razazi[3], C Rieux[4], P Bartolucci[1], D Bachir[1], J Gellen-Dautremer[1], A Mekontso-Dessap[3], B Godeau[2], F Noizat-Pirenne[5], F Galacteros[1]
[1]Unité des Maladies Génétiques du Globule Rouge, [2]Médecine Interne, [3]Réanimation médicale, [4]Hémovigilance, [5]Etablissement français du sang, Ile de France INSERM U955, Hopital Henri Mondor, Créteil, France

Background: Patients with sickle cell disease (SCD) are exposed to delayed hemolytic transfusion reaction (DHTR), which is a life-threatening complication The diagnosis is based on the analysis of the post transfusional hemoglobin A level.
Aims: Our objective was to describe the clinical characteristics and outcome of DHTR episodes among adults with SCD.
Methods: We retrospectively analyzed 78 episodes of DHTR that have occurred in 54 patients with SCD (52 hemoglobin S/S, 1 S/C and 1 S/ ß) followed in our national referral center over a 12 years period.
Results: Transfusions were indicated to treat an acute complication such as an acute chest syndrome in 46.2% of the cases, or to avoid any complication (cerebral vasculopathy, during pregnancy..) in 53.8% of the cases (see table). Regarding the characteristics of the DHTR episodes, in 52 over 78 cases (66.6%), a secondary hospitalization after discharge was required, while the other patients stayed hospitalized beween the transfusion and the DHTR. The diagnosis was seldom made at the emergency department. The clinical presentation was a painful vaso-occlusive crisis in 75% of cases, an acute chest syndrome in 34% of cases. The median delay between transfusion and the first clinical sign of DHTR was 11 days [3-22]. The most frequent clinical manifestation was the presence of reddish urine (73/78). The mean lower hemoglobin level was 5.5 +/- 3.5 g/dl observed on average at 12 +/- 5 days after the transfusion. The mean highest level of lactico-dehydrogenase level was 1715 +/- 1283 UI/l at day 11+/-4. A management in intensive care unit was required in 34 (43%) cases and five patients died. In 30 cases (38%), another transfusion was decided, including 21 patients for whom the diagnosis of DHTR was not initially made. Five transfusions were decided because of multiple organ failure. The analysis of the hemoglobin A level revealed that 80% of the transfusions were ineffective at day 15. An allo-antibody was identified in 41% of cases. In term of management, recombining erythropoietin (Epo) either alone was used in 36

cases (46%) cases, intravenous immunoglobulin in 4 cases (combined with Epo in 2 cases), corticosteroids and Epo in 3 cases and rituximab + Epo in a single case.

Summary / Conclusion: DHTR is a severe and often misdiagnosed complication of transfusion in SCD patients with a high mortality rate. The indication for transfusion in patient with a history of DHTR must be highly restricted taking carefully into account the risk/benefit ratio. The early identification of DHTR is of major importance in order to rapidly start supportive care measures and to avoid any other harmful transfusion. Studies are ongoing to find the best therapeutic approach for DHTR.

P406

RELATIVELY LOW MORTALITY OF SICKLE CELL PATIENTS WITH ELEVATED TRICUSPID REGURGITANT JET FLOW VELOCITY AFTER EXTENDED FOLLOW UP IN A DUTCH COHORT

M Schimmel[1,2,*] E van Beers[1], C van Tuijn[1], E Nur[1], A Rijneveld[3], M Gillavry[4], A Duits[5], D Brandjes[2], J Schnog[6], B Biemond[1]

[1]Hematology, Academic Medical Center, [2]Internal Medicine, Slotervaart Hospital, Amsterdam, [3]Hematology, Erasmus Medical Center, Rotterdam, [4]Cardiology, Slotervaart Hospital, Amsterdam, Netherlands, [5]Red Cross Blood Bank Foundation, [6]Hematology/Oncology, Sint Elisabeth Hospital, Willemstad, Curaçao

Background: Elevated tricuspid regurgitant jet flow velocity (TRV) is reported to be an independent risk factor for early death in patients with sickle cell disease (SCD) with mortality rates as high as 40% after a median follow up of 40 months. We previously reported a mortality rate of 8% in a Dutch cohort of 85 ambulatory sickle cell patients with an elevated TRV (≥2.5 m/s) using trans-thoracic echocardiography after a follow up of 53 months.

Aims: The aim of the current study was to determine the mortality rate after an extended follow-up period and to investigate the relation between baseline elevated TRV and mortality in this well described cohort.

Methods: After obtaining informed consent, consecutive patients with SCD (HbSS, HbSC, HbSβ^0 or HbSβ^+) were included in a prospective observational study and were followed by regular outpatient visits, including laboratory testing and repeated echocardiography. Baseline TRV, as well as laboratory values, were related to outcome. For statistical analysis, patients were divided in patients with relatively severe genotypes (HbSS/HbSβ^0-thalassemia) and patients with relatively milder genotypes (HbSC/HbSβ^+-thalassemia). The study protocol was approved by the local medical ethical committee.

Results: In 81 of 85 patients baseline echocardiography was performed. In 25 patients (31%) a TRV ≥ 2.5 m/s was measured (39% in HbSS/HbSβ^0-thal patients and 12% in HbSC/HbSβ^+-thal patients). A TRV >2.9 m/s was measured in 2 patients (both HbSS). Median follow-up for the whole group was 82 months (IQR: 75-85). Four patients were lost to follow-up, including 1 patient with a baseline TRV ≥ 2.5 m/s (2.65). During follow-up twelve patients (11 HbSS and 1 HbSβ^0-thal) died. The death rate for patients with a TRV ≥2,5 m/s was 20% versus 12.5% for patients with a TRV <2.5 m/s (Hazard Ratio of 1.6 (CI 0.5-5.2, P=0.4). In two of the patients who died without an elevated TRV at baseline, a TRV ≥2.5 m/s was measured during follow-up. Median age at death was 53 years (37-60) as compared to a median age of 34 (28-47) in survivors. NT-proBNP and BNP levels were significantly higher at baseline in patients who deceased (177 pg/mL; 77-871 and 179 pg/mL; 40-340) versus levels in survivors (52 pg/mL; 34-108, P<0.001 and 31 pg/mL; 17-71, P<0.001 respectively). Hazard ratio for patients with NT-proBNP ≥160 pg/mL at baseline was 10 (CI 2.9-34.4, P<0.001) versus patients with NT-proBNP levels <160 pg/mL at baseline. No difference in baseline HbF%, leukocyte count, or total bilirubin level was observed between survivors and non-survivors while haemoglobin concentration (P=0.005), LDH (P=0.017) and ferritin (P<0.001) differed significantly.

Summary / Conclusion: After a median follow-up of 82 months, we observed a mortality rate of 20% in patients with a TRV ≥2.5 m/s which, in contrast to previous studies, appeared not to be a risk factor for death in our study. NT-proBNP plasma level > 160 pg/mL appeared to be a strong risk factor for early death.

PRASUGREL IN CHILDREN WITH SICKLE CELL DISEASE: PHARMACOKINETIC AND PHARMACODYNAMIC CHARACTERISTICS FROM AN OPEN-LABEL, ADAPTIVE-DESIGN, DOSE-RANGING STUDY

L Styles[1,*] J Jakubowski[2], D Heiselman[2], L Heath[2], C Zhou[2], R Redding-Lallinger[3], M Heeney[4], C Quinn[5], C Parikh[6], S Rana[6], Ju Kanter[7], D Small[2], B Moser[2], K Winters[2]

[1]Children's Hospital and Research Center, Oakland, [2]Eli Lilly and Company, Indianapolis, [3]University of North Carolina, Chapel Hill, [4]Boston Children's Hospital, Boston, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, [6]Howard University, Washington, DC, [7]Tulane University School of Medicine, New Orleans, United States

Background: There are few approved treatments for children with sickle cell disease (SCD) who experience painful vaso-occlusive crises (VOC). Evidence suggests a pathophysiologic role of platelets in VOC. Thrombocytosis is common and markers of platelet activation are elevated in SCD. Platelet activation is partially mediated by adenosine diphosphate (ADP) released as a result of inflammation induced by chronic hemolysis in SCD. Therefore, platelets are a possible therapeutic target to decrease the frequency and severity of VOC. We studied prasugrel, an irreversible $P2Y_{12}$ platelet ADP-receptor antagonist that reduces platelet reactivity and aggregation, in children with SCD.
Aims: The primary aim was to characterize the relationship between prasugrel dose, exposure to prasugrel active metabolite (Pras-AM), and platelet inhibition in children with SCD.
Methods: We conducted a two-part Phase2, open-label, multi-center, adaptive-design, dose-ranging, pharmacokinetic (PK) and pharmacodynamic (PD) study of prasugrel in children (2–17 years) with SCD (HbSS and $HbS\beta^0$-thalassemia genotypes). PD was assessed using vasodilator-associated stimulated phosphoprotein (VASP) and VerifyNow® (VN) P2Y12 assays. PK analysis of Pras-AM was performed by calculating area under the concentration-time curve. Part A: Patients received up to 3 single doses of prasugrel, separated by 14±4 days. Treatment was initiated with prasugrel doses expected to be sub-therapeutic, and doses were then modified based on PD responses to previous doses. Part B: Doses were administered once daily for 14±4 days. The initial dose was chosen to target ~30% platelet inhibition at steady state. The second dose was titrated up or down for each patient based on the response to the first dose.

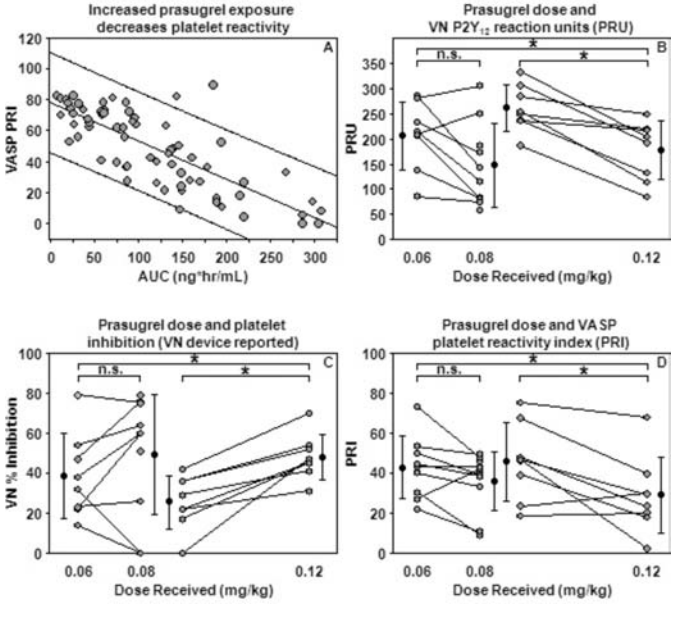

Figure 1. (A) regression analysis with 95% PI. (B,C,D) comparison with mixed model analysis for all treatments.

Results: Data were collected from a total of 24 patients in Part A and 18 patients in Part B. In Part A, a single-dose range of 0.30–0.50 mg/kg led to a VN $P2Y_{12}$ reaction units (PRU) of 197±96 (mean±SD), VASP platelet reactivity index (PRI) of 41±22, and platelet inhibition (VN device reported) of 41±27%. Pras-AM exposure increased with dose and correlated significantly with PRU (r=-0.72) and PRI (0.-78; Figure 1A). In Part B, first dose produced ~30–60% platelet inhibition for 6 patients (~33%), and over the 2 dosing periods with the titration strategy, no patient failed to meet the minimum PD response of 30% on the 0.12 mg/kg dose, and only 1 patient exceeded the maximum PD response of 60% on the lowest dose of 0.06 mg/kg. PRU and PRI were significantly decreased and platelet inhibition was significantly increased in patients given 0.12 mg/kg compared to 0.06 or 0.08 mg/kg (Figure 1B-D;* P<0.05). Overall, six serious adverse events related to SCD occurred in 4 patients. There were 3 mild hemorrhagic adverse events in Part B (epistaxis, eyelid bleeding, wound hemorrhage); 2 were possibly related to prasugrel. No patients discontinued study participation due to an adverse event.
Summary / Conclusion: Prasugrel appeared to be safe and well tolerated in this small patient sample. The trend toward higher exposure and platelet inhibition with increasing dose and variability in PD responses was generally consistent with previous studies in adult subjects. A majority of patients (11/18; 61%) were titrated to a prasugrel dose that resulted in 30–50% platelet inhibition. These results support the initiation of a Phase 3 trial designed to assess efficacy of prasugrel in reducing VOC in children with SCD.

P408

A MONOCENTRIC, PROSPECTIVE, OBSERVATIONAL STUDY ON VASO-OCCLUSIVE CRISIS (VOC) IN ADULT SICKLE-CELL DISEASE (SCD). CHARACTERISTICS AND PREDICTIVE SCORE OF SECONDARY ACUTE CHEST SYNDROME (PRESEV STUDY)

P Bartolucci[1,*] A Habibi[1], M Khellaf[2], F Roudot-Thoraval[3], S Moutereau[4], A Lascaux[5], A Santin[6], Y Levy[5], F Galactéros[1], b godeau[2]

UPEC., [5]Service d'Immunologie Clinique, CHU Henri Mondor. APHP. UPEC. INSERM, [6]Service d'Accueil des Urgences, CHU Henri Mondor. APHP. UPEC., Créteil, France

Background: Vaso-Occlusive Crisis (VOC), the most common manifestation of SCD, is the first cause of death, particularly when complicated by an acute chest syndrome (ACS). However, no data are available on follow-up differences between patients hospitalized for uncomplicated VOC and those who will develop ACS. We report results on hospitalization for VOC from patients enrolled in the PRESEV study.
Aims: Our aims were to better characterize hospitalized VOC and find a predictive score of secondary ACS
Methods: This prospective, monocenter, observational trial included homozygous SCD patients, ≥18 years old with severe VOC requiring admission to our university hospital's Adult Sickle-Cell Referral Center. This study was conducted in accordance with the Declaration of Helsinki principles, Good Clinical Practice guidelines, and local laws and regulations. Severe VOC was defined as pain or tenderness, affecting at least 1 part of the body, e.g. limbs, ribs, sternum, head (skull), spine and/or pelvis, that required opioids and was not attributable to other causes. ACS was defined as the association of 2 criteria among chest pain, radiologic infiltrate and auscultatory abnormality. Patients could be enrolled in the trial more than once if their hospitalizations were separated by ≥1 months. Exclusion criteria were: ACS on day of inclusion, pregnancy, hospitalization for >24 h, chronic blood-exchange transfusion (BET), transfusion impossibility, severe complication requiring transfusion at admission, proven sepsis, surgery <15 days earlier. Patients were divided into 2 groups: VOC (without ACS) and those with secondary ACS; all were treated according to the French guidelines. Steady state was defined as a consultation ³1 months after an acute clinical event (VOC, infection, ACS, or any other clinical event requiring hospitalization and/or blood transfusion) and ³3 months after last blood transfusion. Results are expressed as mean±SD.
Results: 250 VOC were included. Among them, 18.8% developed a secondary ACS which appeared a mean of 3.2±2.75 days after admission. For the VOC and ACS groups, respectively, mean ages were comparable (30.8±7.1and 31.1±8 years), as were F/M sex ratios (1 and 1.18). The percentage of patients treated with hydroxyurea at inclusion in the two groups was similar (31.5% in VOC group, 38.3% patients in ACS group). Lengths of hospitalization were respectively 5.24±3.9 and 9.98±5.8 for the VOC and ACS groups. BET was required in 2.5% VOC and 44.6% ACS, according to French guidelines. Patients were readmitted within 2 weeks after hospitalization discharge in 12.3% VOC and 10.6% ACS (6.9±3.4 and 8.8±2.9 days respectively). No patient died. The multivariate analysis provided a predictive score for ACS at admission with a negative predictive value of 94.6%.This composite score includes one clinical and two easily available biological parameters.
Summary / Conclusion: This observational prospective trial on adult SCD patients gives new insights in ACS incidence during hospitalization for VOC and provides for the first time a predictive score for secondary ACS. This score should be to validate in an international study.

FINAL RESULTS FROM THE MULTICENTER COMPACT STUDY OF COMPLICATIONS IN PATIENTS WITH SICKLE CELL DISEASE AND UTILIZATION OF IRON CHELATION THERAPY: A RETROSPECTIVE MEDICAL RECORDS REVIEW

L Jordan[1,2], P Adams-Graves[3], J Kanter-Washko[4], P Oneal[5], M Sasane[6,*] F Vekeman[7], C Bieri[8], A Marcellari[6], M Magestro[6], Z Gorn[8], M Duh[9]

[1]Sickle Cell Disease Association of America, Baltimore, [2]Miller School of Med-

icine, University of Miami, Miami, [3]College of Medicine, University of Tennessee, Memphis, [4]School of Medicine, Tulane University, New Orleans, [5]Department of Medicine, Howard University, Washington, [6]Novartis Pharmaceuticals Corporation, East Hanover, United States, [7]Analysis Group, Inc., Montreal, Canada, [8]Analysis Group, Inc., Washington, [9]Analysis Group, Inc., Boston, United States

Background: The life expectancy of individuals with SCD is increasing. As these individuals age, they are at risk of developing significant morbidities and SCD-related complications. Throughout their course of care, individuals with SCD may receive acute, episodic and chronic blood transfusions, which may result in multi-organ iron burden. Substandard treatment of iron toxicity is directly related to increased morbidities and complications in all age groups. Early detection and appropriate intervention may prevent or delay the onset of damaging health outcomes associated with iron overload.
Aims: Describe the SCD complication rates, blood transfusion patterns, iron chelation therapy (ICT) use, and associated resource utilization in SCD patients ≥16.
Methods: Medical records of SCD patients ≥16 were retrospectively reviewed between 08/2011 and 07/2012 at three US tertiary care centers. Patients were observed from their first visit after age 16 until the earliest of death, loss to follow-up, or last patient record. Three patient cohorts were defined based on cumulative units of blood received and ICT history: <15 units of blood and no ICT (Cohort 1 [C1]), ≥15 units of blood and no ICT (Cohort 2 [C2]), and ≥15 units of blood and ICT (Cohort 3 [C3]). SCD complications recorded from patient charts per patient per year (PPPY) were reported and compared among cohorts using rate ratios (RRs). For the young adult subset, only complications and resource utilization observed between ages 16 and 30 were analyzed.
Results: Cohorts1,2, and 3 consisted of 69, 91, and 94 patients, respectively. Mean (range) age at index date was similar across cohorts (27 years [16-65]). Mean length of observation was shorter among patients in C1 (years, C1: 6.6; C2: 8.2; C3: 8.1). The rate (95% CI) of any SCD complications PPPY was highest in C2: 3.02 (2.89-3.14), followed by C3: 2.26 (2.16-2.37), then C1: 1.66 (1.54-1.77). For all patients, pain was the most frequent SCD complication (74%) and the most common reason for IP (76%) and ER (82%) SCD complication related visits. Among transfused patients (C2, C3), those not receiving ICT were more likely to experience any SCD complication (RR [95% CI] C2 vs. C3: 1.33 [1.25-1.42]), and pain (RR [95% CI] C2 vs. C3: 1.55 [1.44-1.68]) than those who did. Similar trends were observed in ER and IP visits associated with any SCD complications (RR [95% CI], C2 vs. C3, ER: 1.94 [1.70-2.21]; IP: 1.61 [1.45-1.78]) and pain (RR [95% CI], C2 vs. C3, ER: 2.05 [1.78-2.37]; IP: 1.89 [1.67-2.13]), but not in outpatient visits. These trends were more pronounced in young adults (any SCD complications: RR [95% CI], C2 vs. C3, ER: 2.45 [2.10-2.87]; IP: 1.93 [1.69-2.21]; pain: RR [95% CI], C2 vs. C3, ER: 2.48 [2.08-2.97]; IP: 2.14 [1.82-2.50]). Similarly, pain was the most frequent SCD complication (71%), and the most common reason for ER (80%) and IP (77%) SCD complication related visits; followed by infections [ER (8.3%), IP (7.0%)].
Summary / Conclusion: SCD complication rates, including pain, and associated IP and ER visits were higher among young adult transfused (C2, C3) SCD patients. Among transfused patients, those receiving ICT were less likely to experience complications than those without ICT. This trend, pronounced in young adults, underscores the necessity to avoid an interruption in the management of care as they transition from a pediatric to an adult doctor. Our results reinforce the importance of screening and treatment for iron overload in transfused individuals.

Table 1. Rate and rate ratio of SCD complications by type of setting.

	All Patients			Rate Ratio (RR) – Cohort 2 vs. Cohort 3				
				All Complications		Pain Only		
	Cohort 1 n = 69	Cohort 2 n = 91	Cohort 3 n = 94	All Patients	Patients 16–30	All Patients	Patients 16–30
Total SCD Complications								
Mean PPPY ± SD	11 ± 13	25 ± 53	18 ± 38	RR	1.33	1.63	1.55	1.89
Median PPPY [range]	8 [0 - 61]	7 [0 - 308]	4 [0 - 225]	[95% CI]	[1.25 - 1.42]	[1.50 - 1.78]	[1.44 - 1.68]	[1.65 - 2.08]
Rate PPPY [95% CI]	1.66 [1.54 - 1.77]	3.02 [2.89 - 3.14]	2.26 [2.16 - 2.37]					
Outpatient/Clinic								
Mean PPPY ± SD	4 ± 6	7 ± 14	6 ± 16	RR	1.01	0.85	1.00	0.89

Rate PPPY [95% CI]	0.65 [0.57 - 0.72]	0.80 [0.74 - 0.87]	0.80 [0.73 - 0.86]					
Hospitalization								
Mean PPPY ± SD	3 ± 4	10 ± 22	6 ± 13	RR	1.61	1.93	1.89	2.14
Median PPPY [range]	1 [0 - 19]	2 [0 - 135]	1 [0 - 81]	[95% CI]	[1.45 - 1.78]	[1.69 - 2.21]	[1.67 - 2.13]	[1.82 - 2.50]
Rate PPPY [95% CI]	0.43 [0.36 - 0.49]	1.22 [1.14 - 1.30]	0.76 [0.70 - 0.82]					
Emergency Room								
Mean PPPY ± SD	3 ± 6	7 ± 23	4 ± 13	RR	1.94	2.45	2.05	2.48
Median PPPY [range]	1 [0 - 29]	0 [0 - 154]	0 [0 - 85]	[95% CI]	[1.70 - 2.21]	[2.10 - 2.87]	[1.78 - 2.37]	[2.08 - 2.97]
Rate PPPY [95% CI]	0.51 [0.45 - 0.58]	0.88 [0.82 - 0.95]	0.46 [0.41 - 0.52]					

Notes:
IP = Per Patient.
PPPY = Per Patient Per Year.
Cohort 1: Patients who have received < 15 units of blood in their lifetime and have not received ICT treatment in their lifetime.
Cohort 2: Patients who have received ≥ 15 units of blood in their lifetime and have not received ICT treatment in their lifetime.
Cohort 3: Patients who have received ≥ 15 units of blood in their lifetime and have received ICT treatment in their lifetime.

P410

NEWBORN SCREENING FOR SICKLE CELL DISEASE IN BRUSSELS, A PROGRAM WITH AN ONGOING CLINICAL OUTCOME IMPROVEMENT

P Quoc Le[1,*] B Gulbis[2], L Dedeken[1], A Vanderfaeillie[3], C Heijmans[1], C Vermylen[4], S Huybrechts[1], C Devalck[1], F Cotton[2], B Nguyen[5], F Vertongen[6], M Mujinga[1], A Ferster[1]
[1]Hemato-Oncology, Hôpital Universitaire Des Enfants Reine Fabiola, ULB, [2]Clinical Chemistry, Hôpital Erasme, ULB, [3]Pediatrics, Hôpital Saint Pierre, ULB, [4]Hemato-Oncology, Cliniques Universitaires Saint Luc, [5]Scientist Computer, [6]Clinical Chemistry, Hôpital Saint Pierre, ULB, Brussels, Belgium

Background: Early identification of sickle cell disease (SCD) by newborn-screening (NS) is well established to be an efficient and practical tool in enhancing the health care of affected patients with SCD.
Aims: The aim of our study, conducted in Brussels Region, was to assess whether there is an ongoing improvement of clinical outcome of children with SCD detected by the NS program.
Methods: Universal NS was progressively implemented in Brussels starting within a few maternity wards in 1994 and extending to all maternity wards in 2000. Children identified with SCD progressively benefited from comprehensive expert medical care in three dedicated reference centers. Care included education, prevention, emergency and specific out-patient and in-patient treatments. To evaluate the improvement in comprehensive care, we reviewed data of children born from January 1st 2000 to December 31st 2003 (group A) and from January 1st 2005 to December 31st 2008 (group B). All data were recorded from January 1st 2000 to December 31st 2005 for group A and from January 1st 2005 to December 31st 2010 for group B. Both groups had the same follow-up period accounting for 118 patient-years in group A and 259 patient-years in group B. Median follow-up was 3.5 yrs (range 2.06-5.83 yrs) and 4.1 yrs (range 2.08-5.96 yrs) in group A and B respectively. The major events such as septicemia, anemia, dactylitis, vaso-occlusive event (VOC), acute chest syndrome (ACS), symptomatic neurological events and hospital days were reviewed and compared during the study follow-up between the two groups. The reasons for hospitalization that were selected were: septicemia, pneumonia, urinary tract infection, osteomyelitis, gastroenteritis, VOC crisis, dactylitis, ACS, acute splenic sequestration, aplastic episodes and neurologic events. Several biological parameters were also reviewed.
Results: Among the 98 patients identified with SCD at birth, 33 (16 girls and 17 boys) and 65 (37 girls and 28 boys) belonged to group A and B, respectively. In group A, 25 children were HbSS, 2 HbSβ$^+$ and 6 HbSC. In group B, 53 were HbSS, 5 HbSβ°, 5 HbSβ$^+$ and 2 had an other genotype. Most of the patients developed at least one major adverse event during the study period. The proportion of patients having presented severe anemia and acute chest syndrome was significantly lower in group B than in group A. The higher rate of septicemia in group A could be due to the delayed implementation of national vaccination for *Streptococcus pneumonia* or to the poor prophylactic penicillin compliance. No difference was observed between both groups for dactylitis, VOC and clinical neurological event. No patient died during the study period. Hematological parameters at one year of age were not different between both groups.
Summary / Conclusion: In conclusion, newborn screening is obviously recognized as a precious tool to identify patients with SCD. However, it must be part of a comprehensive care program. Our results demonstrated that its sustained effectiveness is really and clearly proven when it is coupled with a comprehensive and dedicated treatment program including close and regular parent education. This ongoing assessment should be performed to monitor and improve the screening program. Thereby the progressively implementation of comprehensive care has improved over time the quality of SCD management and then the outcome of patients in Brussels Region.

P411

ENDOTHELIAL NITRIC OXIDE SYNTHASE GENE INTRONE4 VNTR POLYMORPHISM IN SICKLE CELL DISEASE AND TRANSFUSION-DEPENDENT B-THALASSEMIA MAJOR: RELATION TO CARDIO-VASCULAR COMPLICATIONS

A Tantawy[1,*] A Adly[1], I Ismail[2]
[1]Pediatric Department, [2]Clinical Pathology Department, Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background: Impaired nitric oxide (NO) bioavailability represents the central feature of endothelial dysfunction, and is a common denominator in the pathogenesis of vasculopathy in sickle cell disease (SCD) and thalassemia. Endothelial NO synthase (eNOS), an enzyme that generates NO, is encoded by a gene located on chromosome 7q35-36 and expressed constitutively by vascular endothelium. Some evidence indicates the contribution of 4a allele of the eNOS gene to cardiac disease. However, eNOS gene polymorphism has not been explored in SCD or thalassemia.
Aims: We aimed to study the 27 base pair tandem repeat polymorphism in intron4 of eNOS gene in young patients with SCD and β-thalassemia major patients and to assess its potential relation to cardio-vascular complications.

Methods: The study is a cross sectional study done in the Pediatric Hematology Unit , Children's Hospital,Ain Shams University,Cairo,Egypt.It included 30 patients with SCD and 50 transfusion-dependentβ-thalassemia major patients aged 12-18 years,compared with 60 age- and sex-matched healthy controls.Data were collected including: transfusion history, splenectomy, sickling crisis, thrombotic events, chelation/hydroxyurea therapy.Investigations included hematological profile ,serum ferritin, study the 27 base pair tandem repeat polymorphism in intron4 of eNOS gene by polymerase chain reaction , as well as Doppler echocardiography and assessment of carotid intima media thickness by Doppler ultrasound.
Results: SCD patients had significantly higher frequency of aa genotype and eNOS4a allele compared with healthy controls (P<0.001). We found that 13.5% of SCD patients had history of cerebral thrombosis, 35% had pulmonary hypertension defined as pulmonary artery pressure ≥25 mm Hg and 15% had cardiomyopathy defined as cardiac functional impairment with ejection fraction ≤50%. The frequency of the eNOS4a allele (aa and ab) was significantly higher in SCD patients with history of cerebral thrombosis, pulmonary hypertension or cardiomyopathy compared with bb genotype (P<0.001). SCD patients with frequent history of sickling crisis (≥5 attacks in the last year prior to the study) showed higher frequencies of the eNOS4a allele(P<0.05). In β-thalassemia, 29% of patients had pulmonary hypertension and 33% had cardiomyopathy. β-thalassemia patients had significantly higher frequency of aa genotype and eNOS4a allele compared with healthy controls (P<0.001) and the frequency of the eNOS4a allele (aa and ab) was significantly higher in those with pulmonary hypertension and cardiomyopathy compared with bb genotype (P<0.001). There was no significant difference between the SCD and thalassemia patients as regards aa genotype (P>0.05).
Summary / Conclusion: We suggest that eNOS intron4 gene polymorphism is potentially related to endothelial dysfunction and cardiovascular complications observed in SCD and β-thalassemia patients .Its value as a possible genetic marker for prediction of increased susceptibility to cardio-vascular diseases in those patients needs further confirmation by large longitudinal studies.

P412

ANTENATAL SCREENING PROGRAMME FOR HAEMOGLOBINOPATHY IN A LOW PREVALENCE AREA: IS IT EFFECTIVE?

A Liyanage[1,*] V Ratnayake[1], C Pocock[2], J Sedgewick[3], H Horne[4], R Bajoria[5]
[1]Departement of Haematology, East Kent Hospital Trust, Ashford, [2]Departement of Haematology, East Kent Hospital Trust, Canterbury, [3]Departement of Haematology, East Kent Hospital Trust, Margate, [4]East Kent Hospital Trust, Ashford, [5]Institute of womens health, University College London, London, United Kingdom

Background: In England Sickle cell & thalassaemia are among most commonly inherited serious genetic disorders. Recent data confirms that in England, Sickle cell disease affects more people than Cystic Fibrosis. To reduce the burden of the disease, the National Health Service plan in England published in 2000 recommended implementation of a linked antenatal and newborn haemoglobinopathy and sickle cell disease screening programme by 2004. The NHS Sickle Cell and Thalassaemia Screening Programme were set up as a consequence of this policy statement to target offering antenatal screening by 10 weeks' gestation. Antenatal screening is intended to identify pregnancies that are at risk of an affected fetus. If the mother is identified as a carrier, testing is offered to her partner, with a view to offering prenatal diagnosis (PND). The recommendations depend on whether the antenatal unit is in a high or low prevalence area. For low prevalence areas (fetal prevalence of sickle cell disease <1· 5 per 10 000 pregnancies), screening is based on determining the family origin of the woman and her partner.
Aims: The aim of our analysis was to confirm the effectiveness and to identify deficiencies of the current antenatal screening programme.
Methods: This was a screening test evaluation study of a group of patients undergoing a selective antenatal screening programme, which was conducted at East Kent Hospitals NHS Foundation Trust. The Trust serves a population of around 750,000 in Kent and has a well-established haematology department providing a selective antenatal screening programme. East Kent has a low prevalence of residents from ethnic minorities and within this population there were approximately 7225 births/year, and according to the 2011 census 11.6% of the population were from ethnic minorities. We retrospectively analysed data from 49,700 antenatal patient samples booked between June 2007 and February 2013. As per the BCSH guidelines all women had a family origin questionnaire for her and the baby's father along with a full blood count at booking. All samples were analysed with a full blood count and red cell indices as an initial screening test for thalassaemia. Haemoglobin variants were analysed in those in whom red cell indices were abnormal (MCH <27 pg) or based on their family origin (confined to those women whose own or the baby's father's family origin is not Northern European or is unknown). The initial test used in the lab was HPLC and if an abnormal variant was identified samples were sent to Kings College Hospital (KCH) for confirmation.
Results: Out of 49,700 antenatal patient samples, 10,974 samples were identified for screening. Of these, nine women refused screening and 10,965 samples were analysed. 124 women had a significant haemoglobinopathy. Thirty of them were diagnosed with Beta thalassaemia trait and thirty seven women were diagnosed with possible alpha 0 thalassaemia from high risk ethnic groups; thirty two women were diagnosed with sickle cell trait (AS), twelve women were diagnosed with suspected HbD Punjab trait, six women diagnosed with HbC trait and seven with HbE trait. Hospital notes were available for analysis in 119/124 women, and sufficient documents could not be found in 5/124. 111/119 partners underwent testing, 8/119 had no partner result as the partners either moved to a different area or a different country, no longer with the partner or refusal to disclose partner's details. Seven couples had results indicating the fetus was at risk of a major haemoglobinopathy. Three accepted pre natal diagnosis which confirmed that the fetus was not at a risk of a significant haemoglobinopathy. Two women did not have PND due to late booking, one woman declined PND and one woman had moved to another area. No follow up data were available for these four women.
Summary / Conclusion: This data confirms that we fail to targ*et all* the screen-positive women and fail to implement follow up. In addition we doubt the value of a screening programme in a low prevalence area as only 3 out of 10,965 of women screened had PND of which none had a significant haemoglobinopathy.

P413

FG4592, A NOVEL INHIBITOR OF THE PROLYL HYDROXYLASE OF HYPOXIA-INDUCIBLE FACTOR (HIF-PH) ELICITED LINEAR-EXPONENTIAL DOSE-RESPONSE PROFILE ON PLASMA ERYTHROPOIETIN (EPO) LEVELS

X Chen[1,*] X Zheng[1], J Jiang[1], Q Zhao[1], T Liu[1], W Zhong[1], H Liu[1], D Ni[2], F Volane[3], J Chou[3], T Neff[3], Pei Hu[4]
[1]Clinical Pharmacological Research Center, Peking Union Medical College Hospital, Beijing, [2]FibroGen Company, Shanghai, China, [3]FibroGen Company, SanFrancisco, United States, [4]Peking Union Medical College Hospital, Beijing, China

Background: Hypoxia stimulates hemoglobin (HgB) production. FG4592 is a HIF-PH inhibitor that simulates hypoxia and is being developed to treat anemia associated with chronic kidney disease (CKD).
Aims: Two studies were performed in Chinese healthy male/female volunteers to investigate the pharmacokinetics (PK) and pharmacodynamics (PD) of FG4592 after single dose (study A) and repeated doses (study B).
Methods: Both were double-blind, randomized, placebo-controlled studies. After provision of informed consent, four cohorts of 10 subjects received single oral doses of FG4592 (40 mg, 100 mg, 160 mg, and 200 mg) or placebo in an 8:2 ratio in study A; three cohorts of 15 subjects received FG4592 (40 mg, 160 mg, or 200 mg) or placebo thrice-weekly (TIW) for two weeks in a ratio of 13:2 in study B. Plasma and urine samples were collected for bioassays of FG4592 and EPO after dosing in study A and following the first and the sixth doses in Study B. Safety and laboratory measures such as hemoglobin (HgB) were evaluated throughout each study.

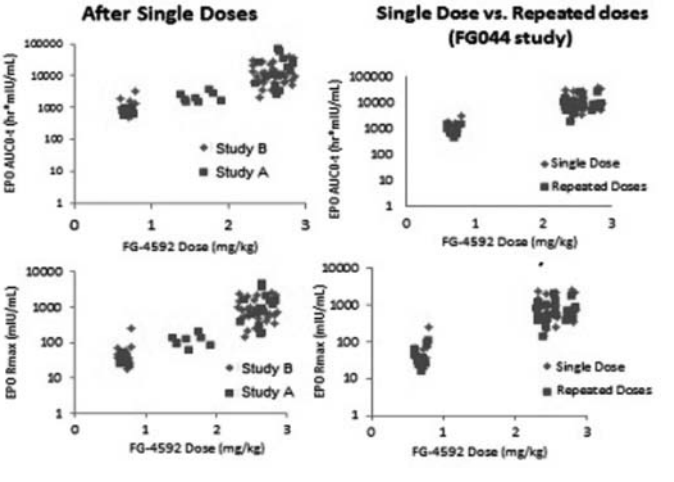

Figure 1. Semi-log-linear plotting between EPO exposure parameters and weight-adjusted FG4592 dosed by dose and dosing regimens, respectively.

Results: FG4592 reached a mean±standard deviation peak plasma concentration (C_{max}, μg/mL) of 3.48±0.81 (40 mg, N=21), 8.11±1.65 (100 mg, N=8), 13.65±2.93 (160 mg, N=21), and 14.81±2.65 (200 mg, N=21) within a median time of 2-3 hours after oral administration and had a mean elimination half-life of 7.4-8.5 hours among the groups. The plasma exposure of FG4592 increased

dose-proportionally from 40 mg to 200 mg (point estimate (90% confidence intervals)) for both AUC_{0-t} (0.936 (0.828,1.045)) and C_{max} (0.938(0.847,1.028)). TIW dosing in Study B did not lead to significant accumulation. The average urinary -recovery of FG-4592 was 5.14% (for 160 mg) to 6.22% (for 40 mg) of the administered dose in study A. Plasma EPO levels rose to maximal increments from baseline (R_{max}, mIU/mL: 40mg: 34.1±9.7; 100mg: 119.0±45.3; 160mg: 615.0±475.1; 200mg: 2110.0±1341.9; placebo: 18.1±6.4) at 16:00hr to 20:00hr of the day after either FG4592 or placebo and returned to baseline by hour 48. The exposures of EPO (AUC_{0-48h}, hr*mIU/mL) increased with doses of FG4592 (40 mg, N=21: 1019.7±619.8; 100 mg, N=8: 2103.7±726.1; 160 mg, N=21: 11390±8310; 200 mg, N=21: 20729±16918) and were all higher than that after placebo (N=14: 622.6±200.2). Plotting of EPO responses against weight-adjusted FG4592 doses suggested an exponential-linear relationship (Figure 1). The differences of EPO response between single dose and multiple doses seemed minimal in the semi-log-linear graphs although some subjects had lower EPO responses after repeated doses of FG4592. In Study B, overall HgB changes from baselines were significantly more positive with FG4592 160 mg (P=0.054) and 200 mg (P=0.034) compared to placebo between day 8 and day 21. A number of 6 (incidence, 46.2%), 4 (30.8%), 2 (15.4%) and 1 (16.6%) subjects had at least two consecutive higher-than-baseline post-dose HgB measurements in the group of 160mg, 200mg, 40mg FG4592 and placebo, respectively. FG4592 was safe and well tolerated in both studies.

Summary / Conclusion: Oral doses of FG4592 between 40mg and 200mg resulted in linear pharmacokinetics and an exponential-linear EPO-dose profile. FG4592 appeared to be safe and induced slight increase of HgB with short-term dosing in non-anemic healthy volunteers. These results support further exploration of the clinical effects of FG4592 in patients with CKD.

P414

THE NATURAL HISTORY OF COLD AGGLUTININ DISEASE

P Swiecicki[1,*] L Hegerova[1], R Kyle[1], M Gertz[1]
[1]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Cold agglutinin disease (CAD) is a rare and poorly understood disorder accounting for 15% of patients with autoimmune hemolytic anemia. Treatment has been controversial with few studies addressing safety and efficacy of various treatment regimens.

Aims: This study aimed to elucidate the clinical features, prognosis and management of cold agglutinin disease.

Methods: A retrospective analysis of Mayo Clinic medical records since 1970 was performed to identify all cases of CAD. Initial appraisal identified 89 patients after which an in depth review of clinical notes, laboratory evaluations, and treatment regimens was performed. Statistical analysis was performed via descriptive statistics and Kaplan-Meier survival.

Results: Eighty-nine patients with cold agglutinin disease were identified. The median age at symptom onset was 65 years (range, 41-83 years), whereas the median age at diagnosis was 72 years (range, 43-91 years). Median survival of all patients was 10.6 years, and 68 patients (76%) were alive 5 years after the diagnosis. The most common symptom was acrocyanosis (44%), and many had symptoms triggered by cold (39%) or other factors (22%). The most common disorder identified was monoclonal gammopathy of undetermined significance in 49%. Thirty-six patients (40%) received red blood cell transfusions during their disease course and 82% received drug therapy. Seventy-three patients (82%) required treatment for CAD and the median time from diagnosis to treatment was 11.4 months (range, 0-375 months). Treatment characteristics and responses are displayed in Table 1.

Table 1.

Characteristic	Single Agent Prednisone	Rituximab	Purine Analog	Alkylating Agent
Patients treated	24	44	8	37
Duration of therapy, median (range), mo	3.0 (0.1-13.9)	1.0 (0.1-107.7)	4.0 (1.0-24.5)	3.2 (0.0-46.4)
Tolerated therapy, (%)	83	92	90	83
Confirmed response to therapy, (%)	42	79	63	46
Duration of response, median (range), mo	51.6 (7.0-210.8)	24.0 (1.0-135.6)	18.5 (12.0-41.7)	11.3 (0.4-146.8)
Further treatment required, (%)	69	55	60	68

Summary / Conclusion: This is the largest study of patients with cold agglutinin disease to date. Symptoms were frequently ill-defined resulting in delay of diagnosis. Although drug therapy was frequently indicated, many patients were successfully observed without treatment. New treatment agents including Rituximab demonstrate promising response rates higher than seen with corticosteroids, especially in patients with underlying hematologic abnormalities. These results support consideration of CAD as part of the differential diagnosis in the setting of new onset anemia and re-enforces the importance of evaluation for underlying B Cell abnormality in this patient population.

P415

DEVELOPMENT OF A LABORATORY PATHWAY TO ASSIST THE DIAGNOSIS OF HEREDITARY HAEMOCHROMATOSIS IN PRIMARY CARE

C Ogilvie[1,*] D Gaffney[1], H Murray[2], A Kerry[1], B Heather[1], G Cuthbertson[1], S Wickremesinghe[1], R Spooner[1], E Fitzsimons[1]
[1]Department of Haematology and Biochemistry, NHS Greater Glasgow and Clyde, [2]Robertson Centre for Biostatistics, University of Glasgow, Glasgow, United Kingdom

Background: Hereditary Haemochromatosis (HH) is a common, treatable condition. Large population studies have determined global distribution of the C282Y and H63D mutations with highest prevelance in North European populations: 0.5% C282Y homozygotes. Clinical penetrance, defined by biochemical evidence of iron overload, is around 50%. HH is however poorly recognised and there is a need to improve the detection of clinically relevant HH. The aim of this study was to develop a hospital laboratory pathway to improve the diagnosis in Primary Care. Serum ferritin (SF) is a reliable marker of body iron stores and is sensitive to iron overload in HH. Greater Glasgow and Clyde (GG&C) is the largest Health Board in Scotland, annually processing some 70,000 SF samples from Primary Care. These samples provided the study population.

Aims: The aim of this study was to utilise samples sent from Primary Care to develop a hospital laboratory pathway to improve the diagnosis of HH.

Methods: Samples were recruited from laboratories across GG&C from Jan 2011 to August 2012. Samples were selected from patients aged ≥30years with serum ferritin >200µmol/l (normal range 20-300µmol/l). Transferrin saturation was performed on all samples. HFE genotyping was carried out on samples with Tsat >30%.

Results: At final analysis, 3734 samples had been recruited. Males n=1657 (44%), median values; age 63yrs, SF 578 µmol/L, Tsat 36%. Females n=2077 (56%), median values; age 68yrs, SF 421 µmol/L, Tsat 31%. 1745 samples had Tsat >30% and were submitted for HFE genotyping.134 patients were homozygous C282Y (7.7% of those genotyped). Males; 878 samples were genotyped. 594 (68%) Tsat >30-50%; 284 (32%)Tsat >50%. 58 C282Y homozygotes were detected. 52 (90%) of these C282Y homozygotes had Tsat >50%. The detection rate was 18.3% (52/284) for patients with Tsat >50% and 1% (6/594) for Tsat >30-50%. 98.3% of C282Y homozygotes had SF >300 µmol/l. Females; 867 samples were genotyped. 657 (76%) Tsat >30-50%; 210 (24%) Tsat >50%. 74 C282Y homozygotes were detected. 57 (77%) of these C282Y homozygotes had Tsat >50%. The detection rate was 27.1% (57/210) for patients with Tsat >50% and 2.6% (17/657) for Tsat >30-50%. The detection rate was 5% (11/205) for Tsat >40-50% and 1% (6/452) for Tsat >30-40%. The detection rate is 16.3% (68/415) for Tsat >40%. 28% of C282Y homozygotes had SF 200-299 µmol/L and 78% had SF >300 µmol/L. Serum Ferritin; 1180 patients (31.6%) had SF 200-299 µmol/L. 148 males (12.5%) and 1032 females (87.5%). 22 C282Y homozygotes were detected in this group; 1 male and 21 females. 150 (39%) female patients with SF 200-299µmol/l had Tsat >40%. 21 C282Y homozygotes were detected in this group. Detection rate 14% (21/150).

Summary / Conclusion: 807 male patients had SF ≥300 µmol/L. HFE genotyping of samples with Tsat >50% revealed 18.3% C282Y homozygotes i.e 1 in 5.5 patients genotyped was affected; a 73 fold enrichment over population screening (0.5% C282Y homozygotes with 50% clinical penetrance). In female patients with SF ≥200 µmol/L and Tsat >40% the detection rate was 14% (56 fold enrichment).We would now propose: The standard normal range for SF in female patients should not exceed 200 µmol/L. The large number of SF requests sent from Primary Care can be utilised to improve the diagnosis of HH. The following algorithm should be applied to samples sent from Primary Care in areas with a North European population. Patients ≥30yrs; females SF >200 µmol/, males SF >300µmol/l should have iron studies performed. If Tsat >40% (females) or Tsat 50% (males) samples should be referred for HFE genotyping.

P416

DIRECT AGE EFFECT ON B12 DEFICIENCY IN HOSPITALIZED PATIENTS: A SINGLE INSTITUTION STUDY ON 14.904 SAMPLES.

S Giraudier[1,*] A Meziere[2], S Vairelles[1], M Dicko[2]
[1]Hematology, [2]Geriatry , APHP, CRETEIL CEDEX, France

Background: B12 deficiency was considered as a rare pathology for a long

time, but more recently, the recognition of "middle" deficiencies with low-intermediate range of Cobalamin concentrations in the blood individualized a more frequent disorder. The high proportion of such B12 deficiency found in several studies performed in outpatients underlines a public health problem. However, identification of such deficiencies in large cohorts of hospitalized patients as well as correlations with other blood parameters just like hemoglobin level, MCV, homocystein or folate concentrations have not yet been reported.
Aims: The aims of this study were to screen a large cohort of inpatients for which B12 concentration measurement was performed in order to i-analyze population distribution according to age and the different biological values, ii-evaluate potential correlation between B12 and homocystein concentrations, iii-compare subjects according to B12 and folate profiles and iv-compare biological values distributions and metabolic profiles according to age.
Methods: The studied population included all consecutive patients admitted from January 1st2011 to December 31th2011 in 5 hospitals and who had centralized serum B12 concentration measurement during this period. Duplicate blood measurements for a given patient were excluded, thus the final analytic sample consisted of 14904 measurements of different subjects.
Results: Patients were aged 70.3+/-19.5 years. Low B12 concentration (<200 ng/L) was observed in 4.6% of cases, 24.2% had middle B12 (200 to 350 ng/L), 11.4% were true B12 deficient (B12<350ng/L associated to tHcy>17 microM/L), 20.4% had low folate concentration (folate<4 microg/L), 9.8% were true folate deficient (folate<4 microg/L associated to tHcy>17 microM/L) and 4.1% of patients were both B12 and folate deficient. Anemia and macrocytosis were not predictive factors of B12 deficiency. Significant increase in MCV and tHcy concentrations with age and decrease in B12, folate and hemoglobin levels with age were observed. At least, frequencies of true B12 deficiency and patients with low B12 concentration without true cellular deficiency increased significantly with age ranging respectively from 9.61% (patients aged 30 to 60 years) to 14.19% in patients over 90 years (P<0.05) and from 3.44% to 6.38% respectively (P<0.05).
Summary / Conclusion: This study demonstrates clearly an increase in true B12 deficiency according to age and demonstrates also that this increase is directly correlated to age decade. We also found a high rate of double deficiency (B12+Folates). It also suggest that B12 (or folates) deficiencies have a direct impact on MCV but not in hemoglobin level for a long period of time. It also confirm that about half the low B12 concentrations measured in routine practice are not "true" B12 deficiency since tHcy is normal but correspond probably to transcobalamin I deficiency. Moreover, we found that this sub-group of possible transcobalamin I deficient patients (B12<200 ng/L associated to normal tHcy level) was stable with age after 30 years. This suggests that tHcy measurement in clinical practice could be used only in the context of low B12 measurement to confirm the cellular deficiency and eliminate transcobalamin I deficiency that do not need to be treated with B12 supplementation.

P417

EPOETIN BIOSIMILARS IN THE MANAGEMENT OF CHEMOTHERAPY-INDUCED ANAEMIA (CIA) IN PATIENTS WITH LYMPHOMA AND MYELOMA: A SUBANLYSIS OF THE ORHEO STUDY

M Michallet[1],* E Luporsi[2], P Soubeyran[3]
[1]Hematology, Centre Hospitalier Lyon Sud, Pierre Bénite, [2]Oncology, Centre Alexis Vautrin, Vandoeuvre-les-Nancy, [3]Oncology, Institut Bergonié and Université Bordeaux , Bordeaux, France

Background: Chemotherapy may induce anaemia with potentially serious consequences, leading to discontinuation or interruption of the chemotherapy agents. The treatment of these CIA requires transfusion or epoetin administration. The ORHEO (place of biOsimilaRs in the therapeutic management of anaemia secondary to chemotherapy in HaEmatology and Oncology) study examined the post-marketing efficacy and safety of epoetin alpha biosimilars for the treatment of CIA.
Aims: To evaluate the efficacy and safety of epoetin alfa biosimilars (EAB) for the treatment of CIA in oncology and haematology in the clinical setting.
Methods: ORHEO was a French observational, prospective, multicentric study. CIA (Hb <110g/l) patients (pts), >18 years old, with solid tumors, lymphomas or myelomas and eligible for Epoetin Alpha Biosimilars (EAB) treatment were included to receive EAB according to drugs approval recommendations. Baseline patient characteristics and anaemia-related data including baseline Hb level, target Hb level, prescribed EAB brand and dose, any other concomitant treatments prescribed, were recorded. The primary study endpoint was the rate of responders (defined as increase in Hb levels to 100 g/L or at least 10 g/L since inclusion visit, or reaching target Hb level set by the physicians at start of study, without any blood transfusions in the 3 weeks prior to measurement) at +3 months (M+3). Other endpoints included rate of responders at +6 months (M+6) and safety (NCI-CTC V2.0) evaluation. A total of 2310 patients were included in the study. Here we present data for pts with lymphoma and myeloma.
Results: 472 pts (301 with lymphoma and 171 with myeloma) were included in this analysis. 100% of these pts received epoetin zeta (median dose 30 000 IU / week). 1.3% of pts with lymphoma and 1.2% of pts with myeloma received iron supplementation in addition. In the 301 pts with lymphoma, the mean age was 68.6 years; 62.7% of them had stage IV lymphoma. At baseline, 34.2% of pts had grade 2 anaemia and the mean Hb level was 95.5 g/l. For 71.3% of patients the target Hb level wasset between 120 and 129 g/l by the physicians. At M+3 and M+6, respectively 29.4% and 34.2% of patients reached the target Hb level, 80.8% and 86.0% were respondersand the average increase in Hb level was 17.2 and 21.2 g/L. At M+6, the transfusion rate was 10.3% and 15.4% of pts with lymphoma reported adverse events (AE); the most frequent was infection (8.8%), whereas the rate of thrombotic events was 1.1%. No EAB-related death was reported. In the 171 pts with myeloma, the mean age was 70.7 years; 88.6% of them had stage III myeloma. At baseline, the majority of patients (37.4%) had grade 2 anaemia and the mean Hb level was 95.7 g/l and. For 70.8% of patients the target Hb was set between 120 and 129 g/l. At M+3 and M+6, respectively 35.8% and 26.1% of patients achieved the target Hb level, 86.2% and 83% had a response to treatment and the average increase in Hb level was 20.3 and 15.7 g/l. At M+6, the transfusion rate was 7.5% and the rate of reported AE was 18.8%; themost frequent was also infection reported in 6.9% of patients, whereas the rate of thrombotic events was 5%. No EAB-related death was reported.
Summary / Conclusion: EAB therapy is effective and well-tolerated in the management of CIA in pts with lymphoma and myeloma.

P418

INTRAVENOUS IRON THERAPY FOR TREATMENT OF ANEMIA DURING PREGNANCY IS ASSOCIATED WITH IMPROVED MATERNAL QUALITY OF LIFE, LESS POSTNATAL DEPRESSION AND LONGER BREASTFEEDING

A Khalafallah[1,2],* A Dennis[3]
[1]Haematology, Launceston General Hospital, [2]School of Human Life Sciences, University of Tasmania, [3]Obstetrics and Gynaecology, Launceston General Hospital, Launceston, Australia

Background: Currently, there are no data available concerning quality of life outcomes and other long-term effects of intravenous versus oral iron therapy of anaemia during pregnancy, particularly the physical impact of iron deficiency anaemia (IDA) on pregnant women as well as the impact of iron therapy on wellbeing and health-related quality of life (HRQoL) during and after pregnancy. IDA is a potential risk factor for many complications during and after pregnancy, and may be associated with inferior maternal and neonatal health.
Aims: To assess the long-term effect of iron therapy on HRQoL during and after pregnancy, in particular postnatal depression and duration of breastfeeding.
Methods: We conducted a follow-up study between January 2010 and January 2011 of an earlier randomized open-label clinical trial of intravenous and oral iron versus oral iron for pregnancy-related iron deficiency anemia. We useda modified version of the SF-36 questionnaire together with the original prospective HRQoL data collected during and after pregnancy. This study is approved by the Tasmanian Human Ethics Committee, Australia. The study was registered prospectively in the Australian New Zealand Clinical Trial Registry (http://www.ANZCTR.org.au) under ACTRN 12609000177257 and in the World Health Organization Clinical Trials Registry (http://*www.who.int/trialsearch/trial. aspx?trialid=ACTRN12609000596202)*. We assessed HRQoL data on 126 pregnant Caucasian women randomized to receive oral iron or a single intravenous iron polymaltose infusion during pregnancy followed by oral iron maintenance. The participants were followed-up 4 weeks after treatment, pre-delivery, and post-delivery for a median period of 32 months (range, 26-42) with a wellbeing and HRQoL questionnaire using a modified SF-36 QoL-survey and child growth charts as set by the Australasian Paediatric Endocrine Group (APEG).
Results: Patients who received intravenous iron demonstrated significantly higher hemoglobin and serum ferritin levels (P<0.001). There were strong associations between iron status and a number of the HRQoL parameters, with improved general health (P<0.001), improved vitality (physical energy) (P<0.001), less psychological downheartedness (P=0.005), less clinical depression (P=0.003), and overall improved mental health (P<0.001). The duration of breastfeeding was longer (P=0.046) in the intravenous iron group. The babies born in both groups recorded similarly on APEG growth chart assessments.
Summary / Conclusion: Our data suggest that HRQoL is improved during and after pregnancy in anemic pregnant women by repletion of their iron stores during pregnancy. About 80% of the intravenous iron group showed a maintained normal ferritin until delivery with long-term benefits such as prolongation of the breastfeeding period and less postnatal clinical depression. this study reports a novel finding in terms of a correlation between both postnatal depression and the breastfeeding period with iron status. There are no data available concerning the quality of life during and after pregnancy, which makes the scientific input of the current study important. Further studies to confirm these findings are warranted.

P419

ESTIMATION OF THE RELATIONSHIP BETWEEN SERUM FERRITIN AND LIVER IRON CONCENTRATION IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

N Gattermann[1,*] P Greenberg[2], A Urabe[3], A El-Ali[4], N Martin[4], J Porter[5]
[1]Heinrich-Heine-Universität, Düsseldorf, Germany, [2]Stanford University Medical Center, Stanford, United States, [3]Kanto Medical Center, Tokyo, Japan, [4]Novartis Pharma AG, Basel, Switzerland, [5]University College London, London, United Kingdom

Background: As magnetic resonance imaging (MRI) is not widely available to assess liver iron concentration (LIC), serum ferritin (SF) can be used as a surrogate marker of liver iron overload. In a previous pooled analysis of iron-overloaded patients with myelodysplastic syndromes (MDS) nearly half of patients had SF<2500ng/mL. A similar proportion of patients overall had severe liver iron accumulation with LIC≥15mg Fe/g dw (Gattermann *et al. Haematologica* 2012). These data suggest that, in this selected patient sample, liver iron burden appears to be more severe than indicated by SF in some patients with MDS.
Aims: To better understand patterns of iron accumulation in MDS patients and to evaluate the predictive value of various SF cutoffs to estimate severe liver iron burden.
Methods: Data were pooled from iron-overloaded MDS patients having Low/Int-1 risk or a life expectancy >1 yr and who completed 1-yr deferasirox treatment in four open-label single-arm studies. Patient distribution by baseline iron loading categories LIC < and ≥15 mg Fe/g dw was summarized descriptively. A receiver operating characteristic (ROC) analysis was conducted on all patients with available SF and LIC at baseline, for the LIC threshold of 15mg Fe/g dw. Positive predictive values (PPV; the percentage ratio of true positives; ie % patients with LIC≥15 in all patients whose SF>cutoff) and negative predictive values (NPV; the percentage ratio of true negatives; ie % patients with LIC<15 in all patients whose SF≤cutoff) were generated. SF cutoff values were tested at 500 ng/mL intervals. Accuracy was the proportion of accurate assessments, either true positive or true negative.
Results: 71 patients with both SF and LIC measurements were included in this assessment. Patient distribution by baseline iron loading categories is shown (Table 1). Overall, in patients with SF≥1000ng/mL, 58.0% had LIC≥15 mg Fe/g dw. The largest proportion of patients had SF 2500–<5000ng/mL (36.6%); among these patients 65.4% had LIC≥15mg Fe/g dw. The ROC analysis identified that a SF level of 2000ng/mL was the strongest predictor of an LIC of 15mg Fe/g dw, with an accuracy of 70.4% (PPV 68.6 & NPV 75.0). The probability of a patient having an LIC≥15 mg Fe/g dw when SF>2000ng/mL was 68.6% (PPV). SF<2000ng/mL was 75% predictive of an LIC<15mg Fe/g dw (NPV).
Summary / Conclusion: Patients with MDS in this pooled analysis showed severely elevated LIC despite only moderately elevated SF levels. Evaluating patient distribution by iron loading categories, over half of patients with SF≥1000 ng/mL showed evidence of severe liver iron accumulation in excess of 15 mg Fe/g dw. ROC analysis showed that SF levels of 2000 ng/mL can effectively predict an LIC of 15mg Fe/g dw, although a quarter of patients with SF<2000 ng/mL would have LIC≥15mg Fe/g dw. Underestimation of LIC by SF in this heterogeneous MDS patient population may be connected to variability in hepcidin production with the underlying disorder (Santini *et al. PLoS One* 2011). Ineffective erythropoiesis leads to inhibition of hepcidin production, thereby increasing iron absorption from the gut with periportal hepatocellular iron accumulation, but with depletion of macrophage iron. Consequently, SF levels, which mainly reflect macrophage iron, can be low relative to total LIC, with underestimation of hepatic iron overload. This analysis is limited by low patient numbers in other iron burden categories, which precluded assessment at different thresholds. SF remains a good marker of iron overload in MDS, but liver iron appears to accumulate more quickly than previously understood.

Table 1. Summary of MDS patient distribution by LIC an SC categories at baseline.

SF categories (ng/mL)	LIC categories (mg Fe/g dw), n (%)*		All patients, n (%)†
	<15	≥15	
<1000	2 (100.0)	0	2 (2.8)
≥1000 to <1500	9 (75.0)	3 (25.0)	12 (16.9)
≥1500 to <2000	4 (66.7)	2 (33.3)	6 (8.5)
≥2000 to <2500	6 (42.9)	8 (57.1)	14 (19.7)
≥2500 to <5000	9 (34.6)	17 (65.4)	26 (36.6)
≥5000	1 (9.1)	10 (90.9)	11 (15.5)
All patients, n (%)†	31 (43.7)	40 (56.3)	71 (100.0)

*% refers to the proportion of patients within each SF category
†% refers to the proportion of patients overall

P420

STUDY OF IRON STATUS AS A CONTRIBUTING FACTOR TO ANEMIA IN PEDIATRIC CANCER PATIENTS

A Tantawy[1,*] I Ragab[1], I, Ismail[2], R Bashkar[1]
[1]Pediatric Department, [2]Clinical Pathology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background: The prevalence of anemia approaches 50% in patients with cancer and may increase to more than 90% in patients with certain types of cancer and in those undergoing chemotherapy or radiation therapy. *The* term functional iron deficiency (FID) has been applied to the situation characterized by iron-restricted erythropoiesis in the presence of iron stores. This is an additional cause of anemia in patients with various chronic diseases including cancer.
Aims: The study aimed to evaluate the etiology of anemia in cancer patients in relation to the iron status and the prevalence of iron restricted erythropoeisis.
Methods: All patients with childhood cancer on chemotherapy regularly following at the Pediatric hematology-oncology unit, Children's hospital ,Ain-Shams university ,in the period from June 2012 to January 2013, were screened by routine blood picture for the presence of anemia. Patients with hemoglobin level ≤10.5 gm/dL were subjected to history and revision of hospital records for collecting data including their age, sex, symptoms of anemia, dietary recall, bowel habits, any blood loss and/or blood transfusion, date at diagnosis of cancer, its type and chemotherapy protocol; then physical examination were done for signs of anemia and any evidence for infection. Laboratory investigations included complete blood picture, reticulocyte count, Iron profile: serum iron, serum ferritin, transferrin, total iron binding capacity, CRP , and reticulocyte hemoglobin content(**CHr**). Patients with malignant bone marrow infiltration, patients admitted for infection or having febrile neutropenia , and patients infected with hepatitis C virus were excluded from study. Cut-off level for CHr was 28pg and transferrin saturation (Tsat) 20% [1]. Patients were classified into 4 categories according the level of transferrin saturation (Tsat) and CHr content [1]. Category 1: with no iron deficiency (Tsat >20%)and no FID (CHr >28pg); category 2 : iron deficiency (Tsat<20%) and no FID(CHr>28pg); Category 3: replete iron (Tsat>20%) and FID (CHr ≤28pg) and category 4 both levels below cutoff: Iron deficiency anemia.
Results: Forty patients were included in the study, 22 males(55%) and 18 females (45%). Their mean age was 4.9± 3.9 years (range 1.3-17). Twenty two (55%) had acute leukemia and 18 (45%) had solid tumors and lymphomas. Their mean hemoglobin level was 9.8± 1.7 gm/dL(range 8.2-10.4). The mean serum ferritin was 904.1±723 ng/mL, Median 757 ng/ml (Range 55-2420 ng/mL). Nine (22.5%) patients had CHr ≤28 pg/mL.Patients had the following iron status categories: no ID and no FID were 29(72.5%), Mild ID and no FID was only 1(2.5%), Replete iron stores and FID was present in 8 patients (20%), and IDA was present in 2 patients (5%).Patients with FID were successfully treated with combined EPO and iron, while iron therapy was offered for the three patients with ID anemia.
Summary / Conclusion: Functional iron deficiency represents an appreciable etiology for anemia in childhood patients with cancer on chemotherapy. Serum ferritin level is not a reliable marker for assessment of iron status in children with cancer.The transferrin saturation and assessment of the reticulocyte hemoglobin content are accurate indicators of true and functional iron deficiency in cancer patient.

P421

A PHASE I, DOSE ESCALATION, PLACEBO-CONTROLLED STUDY IN HEALTHY INDIVIDUALS TO ASSESS THE SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF FBS0701, AN IRON CHELATOR IN DEVELOPMENT

B Boutouyrie-Dumont[1,*] P Zhang[2], F Rombout[3], S Krishnan[2], H Rienhoff Jr[4]
[1]Shire AG, Nyon, Switzerland, [2]Shire Pharmaceuticals Inc., Wayne, United States, [3]Shire-Movetis NV, Turnhout, Belgium, [4]FerroKin BioSciences Inc., San Carlos, United States

Background: Chronic iron overload in patients with transfusion-dependent anemias can lead to organ failure if not effectively treated. Parenteral dosing, frequent daily dosing and side effects of current therapies reduce adherence and compromise clinical benefit. FBS0701 is an orally administered, tridentate, iron chelator in clinical development. Previous studies showed that once-daily FBS0701 (3–40 mg/kg) was well tolerated in healthy volunteers and iron-overloaded patients.
Aims: To characterize the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics of FBS0701 in healthy volunteers across the anticipated therapeutic dose range.
Methods: This was a phase I, single-dose, randomized, double-blind, placebo-controlled, dose escalation study of FBS0701 in healthy volunteers. Healthy

individuals 18–50 years of age with body mass index of 18–30 kg/m^2, serum ferritin of >20 ng/mL and ≤300 ng/mL, and erythrocyte indices within the normal range were eligible for inclusion. All participants provided written, informed consent. Oral FBS0701 was administered at 6 dose levels (30, 40, 50, 60 and 75 mg/kg once daily [q.d], and 20 mg/kg twice daily [b.d.]) with at least 4 participants per dose and an additional individual randomized to placebo. Dose escalation occurred in the absence of serious adverse events (SAEs). Blood samples were collected pre-dose on day 1 and at 15 intervals post-dose (15 min to 96 h). For twice-daily dosing, samples were collected pre-dose and at 6 time points up to 12 h following the first dose; blood sampling following the second dose was as per once-daily dosing. Urine volume and concentrations of FBS0701, creatinine and protein were measured at pre-dose and up to 24 h post-dose. The assay measured the total of free and Fe(III)-bound FBS0701.

Results: Thirty participants were enrolled with 5–8 per cohort; 5 participated in 2 cohorts. Mean age was 26 years (range, 18–47 years). FBS0701 plasma concentrations indicated dose-related but less than dose-proportional increases in exposure from 30–60 mg/kg; the 75 mg/kg exposures (mean C_{max}, 84 575 ng/mL) were lower than expected based on linearity (Table 1). Mean FBS0701 plasma concentrations for 40 mg/kg q.d. and 20 mg/kg b.d. were consistent with the different dosing regimens. Terminal half-life and renal clearance of FBS0701 20 mg/kg at 12 h intervals (i.e. twice daily) were consistent with those from the single-dose cohorts. No clinically significant urine creatinine or urine protein results were noted. AEs that were possibly/probably treatment related were reported in 4 of 30 participants (13%) and included dysgeusia, hyperchromic urine, loss of appetite, fatigue and headache, which were all mild. AEs were also reported in 1 of 5 individuals receiving placebo. There were no SAEs, deaths or withdrawals due to AEs, and no relationship between drug dose and incidence, severity or causality of AEs.

Summary / Conclusion: The bioavailability of oral FBS0701, based on the total of free and Fe(III)-bound plasma concentrations, appeared dose-related as reported for lower doses. PK parameters were consistent when FBS0701 was administered as either a once-daily or twice-daily dose. The half-life was similar to that observed in a previous study of healthy volunteers. FBS0701 was generally well tolerated and warrants further investigation in treating transfusional iron overload.

Table 1. PK results.

Parameter	Once-daily dosing	Twice-daily dosing
FBS0701 doses, mg/kg	30, 40, 50, 60, 75	20
Mean C_{max} per dose group, ng/mL	68 171, 87 900, 91 714, 82 325, 84 575	52 900
Mean C_{max} at same total daily dose, ng/mL	87 900 (40 mg/kg q.d.)	52 900 (20 mg/kg b.d.)
Range of mean T_{max}, h	1.0–1.5	0.75
Range of mean $t_{1/2}$, h	8.4–18.6	9.6
Range of mean urinary recovery of FBS0701 over initial 24 h, %	~38–55	NA

P422

THE SAFETY, TOLERABILITY, PHARMACOKINETICS AND PHARMACODYNAMICS OF FBS0701, AN IRON CHELATOR IN DEVELOPMENT, IN PHASE I STUDIES OF HEALTHY VOLUNTEERS AND PATIENTS WITH TRANSFUSIONAL IRON OVERLOAD

B Boutouyrie-Dumont[1,*] F Rombout[2], S Krishnan[3], H Rienhoff Jr[4]
[1]Shire AG, Nyon, Switzerland, [2]Shire-Movetis NV, Turnhout, Belgium, [3]Shire Pharmaceuticals Inc., Wayne, [4]FerroKin BioSciences Inc., San Carlos, United States

Background: Despite advances in chelation therapy, the effective treatment of chronic iron overload is compromised in many patients. Parenteral dosing, frequent daily dosing and side effects of current therapies reduce adherence and limit clinical benefit. FBS0701 is an orally administered, tridentate, iron chelator in clinical development.

Aims: To characterize the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of FBS0701 in healthy volunteers and in patients with transfusional iron overload.

Methods: Two studies were conducted in distinct populations. Study 1 was a phase I, randomized, dose-escalation, double-blind, placebo-controlled study in healthy volunteers. Participants were randomized to a single-dose of oral FBS0701 at 4 dose levels (3, 6, 10 and 16 mg/kg) or placebo (cohorts 1–4). Healthy males aged 18–45 years with body mass index 18–27 kg/m^2, serum ferritin >20 ng/mL and ≤250 ng/mL, and erythrocyte indices within the normal range were eligible for this study. Study 2 was a phase I, dose-escalation study assessing FBS0701 in patients with chronic transfusional iron overload. Patients received a single oral dose of FBS0701 (6, 10, 16 or 32 mg/kg). Male patients with β-thalassemia aged 18–50 years with iron overload requiring treatment with an iron chelator (serum ferritin >300 ng/mL and ≤5000 ng/mL) were eligible for this study. In study1, blood samples were collected up to 96 h post-dose for PK and PD analyses; blood samples were collected up to 72 h post-dose in study 2. In both studies, urine samples were collected up to 24 h post-dose for PK and PD analyses. The total of free and Fe(III)-bound FBS0701 was measured in both studies. All participants provided written, informed consent.

Results: Seventeen individuals were enrolled into study 1; 12 received FBS0701 and 5 received placebo across the dose cohorts. Mean age was 23.5 years (range, 19–36 years). Mean AUC_{0-24} and C_{max} were linear across the dose range (Table 1). Nine treatment-emergent adverse events (AEs) were reported in 5 of 17 participants (29%); all 5 participants had received FBS0701. There were no AEs deemed to be probably/definitely related to FBS0701, and there were no deaths or withdrawals due to AEs. Four AEs were possibly related to the study drug and included moderate gastroenteritis, flatulence and headache. There was no evidence of a relationship between drug dose and the incidence, severity or causality of AEs. In study2, 4 patients were enrolled with 1 patient per dose. Mean age was 36.3 years (range, 33–41 years). AUC_{0-24} and C_{max} seemed dose-related but less than dose-proportional (Table). Three treatment-emergent AEs were reported in a single patient (bruising at venepuncture and cannula sites); none were related to the study drug. There were no deaths, SAEs or withdrawals due to AEs.

Summary / Conclusion: The bioavailability of FBS0701 seemed dose-related in both healthy individuals and patients with β-thalassemia. It is anticipated that there would be minimal accumulation of FBS0701 with repeated once-daily dosing. FBS0701 was generally well tolerated. Further investigation of FBS0701 in patients with transfusional iron overload is warranted.

Table 1. PK results across dose cohorts.

Parameter	Study 1 (n=12)	Study 2 (n=4)
Population	Healthy volunteers	Patients with β-thalassemia
FBS0701 doses (mg/kg)	3, 6, 10, 16	6, 10, 16, 32
Mean C_{max} per dose group (ng/mL)	5413, 12 233, 16 633, 34 833	14 900, 35 400, 38 500, 47 600
Mean AUC_{0-24} per dose group (h*ng/mL)	12 104, 24 720, 42 692, 74 620	45 664, 69 216, 121 781, 157 183
Mean T_{max}, h (range)	1.1 (0.9–1.3)	0.9 (0.8–1.0)
Mean $t_{1/2}$, h (range)	12.8 (3.8–35.2)	21.6 (16.0–30.0)
Plasma concentration 24 h post-dose, % of C_{max}	<0.5	<1
Mean urinary recovery of FBS0701 over initial 24 h, % (range)	59 (19–83)	39 (28–51)

LONG TERM EFFICACY AND SAFETY OF DEFERASIROX IN TRANSFUSION DEPENDENT MYELODYSPLASTIC SYNDROME (MDS) PATIENTS WITH IRON OVERLOAD: RESULTS FROM THE EPIC EXTENSION STUDY

N Gattermann[1,*] G Sanz[2], C Finelli[3], G Forni[4], F Nobile[5], M Schmid[6], D Vassilieff[7], A Guerci-Bresler[8], A Ganser[9], A El-Ali[10], Ni Martin[10], C Rose[11]
[1]Heinrich-Heine-Universität, Düsseldorf, Germany, [2]Hospital Universitario y Politecnico La Fe, Valencia, Spain, [3]Policlinico S. Orsola-Malpighi, Bologna, [4]Ospedale Galliera, Genova, [5]Az. Osp. Bianchi Melacrino Morelli, Reggio Calabria, Italy, [6]Stadtspital Triemli, Zurich, Switzerland, [7]Assistance Publique-Hôpitaux de Paris, Hôpital Cochin, Paris, [8]CHU Brabois, Vandoeuvre Cédex, France, [9]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany, [10]Novartis Pharma AG, Basel, Switzerland, [11]Hôpital Saint-Vincent de Paul, Lille, France

Background: The prospective, 1-year EPIC study conducted in a large cohort of patients with transfusion-dependent anemias (including 341 MDS patients) demonstrated the efficacy and safety of iron chelation therapy with deferasirox (DFX) by reducing serum ferritin (SF) levels and proving a manageable safety profile. This EPIC extension study was conducted to further evaluate the long term efficacy and safety of DFX in these patients.

Aims: The objective of this sub group analysis was to evaluate the long-term efficacy and safety of DFX in MDS patients enrolled in the EPIC extension study.

Methods: Patients who had completed the core EPIC study continued to receive DFX for a maximum of an additional 18 months or until the drug was locally available, whichever came first. The inclusion and exclusion criteria were

earlier defined in Cappellini *et al.,* 2010. Initial extension dose was based on the last dose they received during the core period and dose adjustments were made based on safety and efficacy markers. The primary efficacy endpoint was change in SF from baseline (BL) to the end of extension (EOE), analyzed using the Student's *t-test.* Safety assessments consisted of monitoring and recording all adverse events (AEs), serious adverse events (SAEs) with their severity and relationship to drug, study discontinuation, and deaths.
Results: Of the 341 MDS patients enrolled in the core study, 175 patients completed the core and 166 patients discontinued, of which 47% were due to AEs (n=78) and were mainly gastrointestinal (GI) related (n=25). From the core study, 45 patients continued into the extension phase for an additional 18 months or until the drug was locally available. Cumulative data, core plus extension, is being reported here. In this cohort, 51% of patients were ≥65 years old (n=23). The average daily dose of DFX was 20.6 mg/kg/day and mean duration of exposure was 74 weeks (SD: 19). Compliance >80% was noted in most of the patients (n=29, 64%). Overall, significant reductions in median SF levels from BL to EOE were observed with DFX treatment in MDS patients (n=44, median change -393.5 ng/mL, P= 0.0161). Maximum reduction in SF levels (-736 ng/ml) was observed in patients receiving average daily dose of DFX 25 - <35 mg/kg/day. AEs related to study treatment were reported for 55.6% of patients from BL to EOE, similar to the rate observed in the core MDS patients (66.3%). The most frequently reported drug-related AEs were GI disorders (n=14, 31.1%), of which 64% were mild in severity and none lead to discontinuation of treatment. Increases of >5 x ULN for AST or ALT were not reported with exception of one patient with an elevated BL ALT who subsequently experienced two consecutive ALT increases of >5 x ULN post-BL values. At BL, the majority of patients had normal levels of serum creatinine (SCr) (n=35, 77.8%). In this cohort of 45 patients, 11 (24.4%) had two consecutive values >33% increase and >ULN of SCr. Increases in SCr or liver transaminases reported were mainly mild in severity, transient, non-progressive, and were effectively managed with dose adjustment. None of the 45 patients reported SAEs related to study drug and two patients had non-drug related AEs leading to discontinuation (acute myeloid leukemia, respiratory failure).
Summary / Conclusion: This extended follow up showed that DFX significantly reduced SF levels from BL in the MDS patients who completed core and extension phases of the EPIC study. DFX treatment had a manageable safety profile. This additional extension analysis confirms the overall safety and efficacy of DFX treatment in transfusion dependent MDS patients.

Infectious diseases, supportive care

P424

FOUR MEASURES TO REDUCE THE RATE OF HEALTH CARE-ASSOCIATED BLOODSTREAM INFECTIONS RELATED TO THE USE OF NEEDLESS MECHANICAL VALVE CONNECTORS IN LONG-TERM CENTRAL VENOUS CATHETERS
L Cláudio Leite[1,*] J Martinez[1], R Capela[1], D França[1], N Varajão[1], L Viterbo[1], Â Martins[1], I Oliveira[1], I Moreira[1], N Domingues[1], A Espírito-Santo[1], F Trigo[2], J Mariz[1]
[1]Serviço de Onco-Hematologia, [2]Serviço de Microbiologia, Instituto Português de Oncologia do Porto, Porto, Portugal

Background: Mechanical valve needless connectors (MVC) are devices known to be associated with augmented risk for bloodstream infections (BSI). This risk is even superior when positive pressure MVC (PP-MVC) are compared with neutral pressure MVC (NP-MVC). One reason for this augmented risk seems to be related with the formation of a biofilm on the surface of the MVC, so measures taken with to reduce this biofilm could probably decrease BSI rate.
Aims: To compare the BSI rates registered in onco-haematological patients with long-term central venous catheter (CVC), before and after the introduction of measures aimed at reducing biofilm formation on the MVC.
Methods: We analysed the BSI rates for a period of 18 months after adoption of new rules for MCV manipulation: 1-changed the use of a PP-MVC to a NP-MCV; 2- replaced the MVC two times a week instead of just one time; 3- replace the MVC after each blood cultures collection to study a new episode of fever; 4- changed the cleaning solution from alcohol 70% to chlorhexidine 2%/alcohol). The rates obtained were compared with the rates registered in the 6 months immediately preceding this change of procedures.
Results: The number of CVC days analysed before and after the introduction of the MCV manipulation measures was 2111 and 6756, respectively. The evaluation of the number of blood cultures collected between the two groups revealed a reduction of 35% with the introduction of the measures (107 vs. 70 blood cultures/1000 CVC). The mean rate of BSI in the control group (without measures) was 35.5 / 1000 CVC days, whereas in the study group was 9.4 / 1000 central venous catheter days, corresponding to relative risk of 0.27 (CI 95%, 0.27-0.37; P<0.001). Using differential time to positivity to identify bacteraemias originating from CVC, the BSI rate decrease from 17.5 to 4.7 / 1000 CVC days after adopting the measures, relative risk of 0.27 (CI 95%, 0.16-0.43; P=0.006). We also found that the reduction in BSI rates was essentially at the expense of gram positive microorganisms (51 vs. 21%), indicating that the measures taken have affected mainly infections originating in catheters.
Summary / Conclusion: We have shown in this study that measures taken with the objective of reducing biofilm formation, including the substitution of PP-MCV with NP-MCV, can result in a significant decrease of BSI related with long-term CVC in haematological patients.

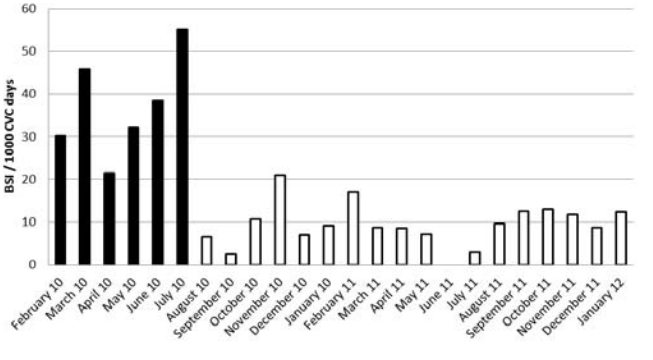

Figure 1.

P425

CHANGING PATTERN OF INFECTION DURING TREATMENT OF PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)
E Audisio[1,*] C Frairia[1], S D'Ardia[1], S Aydin[1], B Nicolino[1], A Busca[1], B Allione[1], C Dellacasa[1], M Falda[1], F Marmont[1], U Vitolo[1]
[1]Haematology, Haematology, AO Città della Salute e della Scienza, Turin, Italy, Torino, Italy

Background: Acute myeloid leukemia (AML) patients during chemotherapy

induced neutropenia are at high risk of bacterial and fungal infections. The first induction course is associated with high susceptibility to infectious complications leading to increased morbidity and mortality.
Aims: In the present study, the incidence and pathogenesis of neutropenic fever were analyzed during the first induction therapy and compared with the following post-remission courses.
Methods: 223 consecutive newly diagnosed AML patients with a median age of 51 yrs (18-70) were treated with standard induction chemotherapy with Idarubicin, Citarabine and Etoposide (ICE). A complete remission (CR) was achieved in 169 pts (76%), whereas 40 pts (18%) were resistant and 14 (6%) died because of infections. Patients entering CR were treated with a second induction course with Idarubicin and Citarabine followed by a third cycle of intermediate Cytarabine (IDAC) with peripheral blood progenitor cells harvest. The post-remission therapy consisted in repeated (up to three) cycles with high-dose Cytarabine (HDAC) and PBSC rescue. Sixty-seven (30%) non low-risk patients with a suitable donor received an allogeneic stem cell transplant and were censored at the time of transplantation. A total of 774 neutropenic episodes was analyzed. All patients received anti bacterial and antifungal prophylaxis with levofloxacin and itraconazole or posaconazole. Four (1.8%) pts died in the post-remission phase due to infections.
Results: During the first induction course 19 patients (8%) had no infections whereas 87 (39%) developed a fever of unknown origin (FUO), 40 (18%) had clinically documented infections (CDI), 62 (28%) microbiologically documented infections (MDI) and 15 (7%) probable or proved invasive fungal infections (IFI). In the post-remission courses febrile episodes were significantly reduced compared to the first induction course. Analysis of post-remission neutropenic episodes showed no infection in 301 (54.6%), FUO in 87 (15.8%), CDI in 17 (3.1%), MDI in 139 (25.2%) and IFI in 7 (1.3%) (P=.0000). Forty-eight(21.5%) pts developed pneumonia during induction vs. 33 (6%) in the post-remission phase (P=.0000). Gram-positive bacteriemia (s. epidermidis 50%, enterococcus 16,6%, s. aureus 7%) was significantly predominant in induction, while Gram-negative bacteriemia (e. coli 76%, p. aeruginosa 5.5%, enterobacter 4%, k. pnemoniae 2.2%, s. maltophilia 2%) was mostly detected in post-remission. Gram positive vs Gram negative isolates were 65% vs 33% in induction and 35% vs 67% in post-remission (P=.00003). During induction in 15 (6.7%) pts a respiratory support with continuous positive air pressure (CPAP) ventilation was required. CPAP support was necessary in 8 (1.4%) out of 551 post-remission aplasias (P=.0000). Eight (3.6%) of 223 inductions were complicated by severe sepsis/septic shock vs 8 (1.45%) of 551 post-remission aplastic periods. Two pts required ICU admission in induction and 4 in post-remission.
Summary / Conclusion: The results of the present study show a significantly changing pattern of infection during treatment of AML patients. This observation should be considered in the choice of empiric antibiotic therapy during consecutive neutropenic episodes.

P426

PNEUMOCOCCAL VACCINE RESPONSES IN B CELL MALIGNANCIES AND DYSFUNCTIONS

J Karlsson[1,2,3,*] H Hogevik[4], K Andersson[2], L Roshani[4], B Andréasson[3,5], C Wennerås[2,3]
[1]Department of Infectious Diseases, NU Hospital Organization, Trollhättan, [2]Department of Clinical Bacteriology, [3]Department of Hematology and Coagulation, Sahlgrenska University Hospital, Göteborg, [4]Department of Research and Development, NU Hospital Organization, Trollhättan, [5]Department of Hematology/Internal Medicine, NU Hospital Organization, Uddevalla, Sweden

Background: Pneumococcal infections are a common cause of disease and death in patients with B cell malignancies. Vaccination with the 23-valent polysaccharide vaccine has been clinical praxis among these patients; however, more recent vaccination schedules suggest the use of conjugate pneumococcal vaccines.
Aims: To compare antibody responses and functional antibody activity as measured by opsonophagocytosis after vaccination with either polysaccharide or conjugate pneumococcal vaccine in elderly patients with multiple myeloma (MM), Waldenstrom's macroglobulinemia (WM) and monoclonal gammopathy of undetermined significance (MGUS).
Methods: Fifty-six patients > 60 years of age with a diagnosis of MM (*n* = 24), WM (*n*=15) and MGUS (*n*=17), and 20 age-matched controls were randomized to receive a single dose of either the 23-valent pneumococcal polysaccharide vaccine (PPV) or a 7-valent conjugated vaccine (PCV7). Sera were collected prior to and 4-8 weeks after immunization and analyzed with a serotype-specific ELISA for IgG antibodies to pneumococcal serotypes4, 6B, 9V, 14, 18C, 19F, and 23F, and with an opsonophagocytosis killing-type assay (OPA) for functional antibody activity towards serotypes 4 and 14. Written informed consent was obtained from all study participants.
Results: Pre- and post-vaccination sera revealed the lowest antibody and OPA titers among MM patients, followed by WM patients, MGUS patients and healthy controls. Statistically significant increased levels of IgG antibodies were seen for one pneumococcal serotype among MM patients, three serotypes among WM patients and four serotypes among MGUS patients and healthy controls post-vaccination. Geometric mean IgG and OPA titers did not differ significantly between the vaccine subgroups for any of the study groups although there was a tendency towards higher IgG antibody fold increases in PCV7 vaccinees among MM and WM patients. A few MM patients had very high IgG antibody levels to pneumococci in ELISA. However, corresponding OPA titers were low, indicating the presence of cross-reactive non-functional antibodies.
Summary / Conclusion: A suboptimal response to pneumococcal vaccination was confirmed in MM patients in particular. However, also WM and MGUS patients had lower IgG and OPA titers than healthy controls. No obvious difference between PPV and PCV7 given in single dosage was observed. OPA analysis seems to be a more reliable method than ELISA for evaluation of humoral pneumococcal vaccine responses in MM patients.

P427

A RETROSPECTIVE STUDY OF THE RELATIONSHIP BETWEEN VITAMIN D SUPPLEMENTATION AND THE RISK OF FEBRILE NEUTROPENIA(FN) IN ADULTS WITH HEMATOLOGICAL MALIGNANCIES IN EAST KENT HOSPITALS(EKUFHT)

S Alhassan[1,*]
[1]Haematology, East Kent University Foundation Hospitals NHS Trust, Canterbury, United Kingdom

Background: Prior studies (1950-2000) regarding the use of vitamin D as part of treatment/prevention of infections opened the door to intensive scientific and clinical research, over the past decade, into the non-endocrine (autocrine/paracrine) role(s) of vitamin D, particularly its impact on the function and maintenance of both the innate and adaptive parts of the immune system. None of these studies looked specifically at the relationship between vitamin D supplementation and the risk of infections amongst adults with haematological malignancies (or with a diagnosis of cancer), an increasing cohort of patients who are particularly vulnerable to FN. Vitamin D deficiency is common in adults in the United Kingdom (UK). The UK National Diet and Nutrition Survey (NDNS), in the key findings from years one and two (2008/2009 – 2009/2010) of its rolling programme, states that there is evidence of low vitamin D status in UK adults, both male and female. The NDNS collected fasting blood samples. The UK Department of Health recommended daily allowance (RDA) for vitamin D is 10 micrograms (400 IU) for people over 65 years and those with limited exposure to sunlight. Between 01/01/2009 and 31/12/2010, there were 585 episodes of admissions with FN in patients who also have a diagnosis of cancer to EKUFHT (serving a population of 0.72 million) with an average hospital stay of 8.03 days. These episodes were caused by 297 patients. Of those 122 patients (41.2%) had hematological malignancies, which breaks into 65 patients (53.3%) with Lympho-Proliferative Neoplasms (LPNs) and 57 patients (46.7%) with Myelo-Proliferative Neoplasms (MPNs). *[FN is defined by the presence of fever (38 degrees Celsius or higher for at least 1 hour) and a peripheral blood neutrophil count of less than 0.5x10^9/L (high risk category) / 0.5-1.0x10^9/L (low risk category) as per EKUFHT guidelines].* The NHS UK, estimates the average cost of one day stay in secondary health care facilities at £670 for the financial year 2010/2011(>£1.5 million/year for EKUFHT).
Aims: To test the hypothesis; that regular vitamin D supplementation at the UK RDA reduces the risk of FN in adults with Haematological malignancies.
Methods: This is a follow-on sub-study from a large retrospective, single centre, hospital based, case-control study to assess the relationship between exposure to prescribed daily vitamin D and the risk of developing FN, in adults with cancer in EKUFHT(William Harvey, Queen Elizabeth Queen Mother, and Kent and Canterbury hospitals).*(The main study was submitted and accepted as the thesis part of a MSc. degree in clinical oncology issued to the author by the school of cancer sciences-CRUK, University of Birmingham, UK, in July 2012 - full Thesis available on request*). The risk of developing FN in adults with haematological malignancies was estimated by calculating the Odds Ratio (OR), with 95% Confidence Interval(CI), for prescribed daily vitamin D3(Yes/No).
Results: Vitamin D supplementation in adults with haematological malignancies was associated with a clinically significant reduction in the risk of developing FN with an unadjusted OR of 0.690 (95% CI, 0.159, 2.524).*[For those with a diagnosis of myeloma the unadjusted OR was 0.656 (95% CI 0.037, 2.877)]. [In the main study including all adults with a diagnosis of cancer the unadjusted OR was 0.44 (95% CI, 0.26, 0.74), with a p-value of 0.003, which equals a reduction in the risk of developing FN from 11.4% in those not taking vitamin D to 5.4% in those on regular vitamin D].*
Summary / Conclusion: These results suggest that vitamin D supplementation may significantly reduce the risk of FN in adults with haematological malignancies. Large double-blinded randomised controlled clinical trials for specific cancer sub-types, are necessary to further study the relationship between vitamin D supplementation and the risk of FN. The potential for preventative and therapeutic use of vitamin D to boost the human innate immune responses is exciting and warrants further studies.

P428

INFECTIONS CAUSED BY CARBAPENEMASE PRODUCING KLEBSIELLA PNEUMONIAE IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

M Stamouli[1,*] P Tsirigotis[1], S Vourli[2], P Tofas[3], A Antoniadou[3], C Girkas[1], E Ioannidou[1], A Bouhla[1], N Papanikolaou[1], M Atta[1], C Roubakis[1], N Gardikas[1], A Konstantinou[4], I Alafis[3], G Tzebetzi[5], M Tzima[1], A Mamoureli[1], V Pappa[1], A Megalakaki[4], S Papageorgiou[1], G Dimitriadis[1]
[1]2nd Department of Internal Medicine, [2]Microbiology Laboratory, [3]4th Department of Internal Medicine, Attikon University Hospital, Haidari, [4]Department of Hematology, Metaxa Hospital, Piraeus, [5]Infection Control, Attikon University Hospital, Haidari, Greece

Background: Carbapenemase producing *Klebsiella pneumoniae* (KPC) is an increasingly prevalent pathogen in Greek hospitals. The mortality rates are very high in patients with hematologic malignancies who are infected by this microorganism. This is partly due to the fact that initial empiric antibiotic therapy is inappropriate. There is a need for new diagnostic and preventive strategies to control KPC infections in this vulnerable population.
Aims: The aim of this study was to assess the prevalence of KPC colonization among hematologic patients as well as the impact of weekly colonization screening for KPC in combination with adapted empiric treatment on a. the frequency of KPC infections among hematologic patients and b. the outcome of these infections.
Methods: Infections caused by multiresistant pathogens have been recorded in our hospital for approximately a three year period (March 2010-January 2013). Since March 2012 perianal swabs were obtained weekly from 204 consecutive patients with hematologic malignancies and cultured in meropenem supplemented Mac Conkey agar plates. The patients who were KPC+ were isolated or cohorted. Patients who were colonized or infected by KPC after being transferred to the Intensive Care Unit were excluded from the study.
Results: KPC colonization was present in 36 out of 204 screened patients at some time during their (often multiple) hospitalizations (17.6%). In a 3-year period 40 KPC related infections have been recorded. Thirty infections occurred in 21 patients before the commencement of weekly screening for KPC (during a 24-month period). Ten infections were reported in 9 patients after the commencement of weekly screening for KPC (during a 9-month period). Five deaths due to KPC were reported before the screening period while only one death occurred after screening was implemented (in a patient with relapsed disease). Most patients who recovered from KPC infection or were just colonized by KPC went on to receive additional chemotherapy without any life threatening KPC infection occurring. Furthermore, four patients who were previously found to be colonized by KPC received allogeneic stem cell transplantation without any life threatening KPC infection.
Summary / Conclusion: The prevalence of KPC colonization in our hospital is high among patients with hematologic diseases. Weekly screening and cohorting of KPC+ patients didn't reduce the rate of infections so far. Prompt initiation of adapted empiric therapy could reduce the mortality caused by KPC infection.

P429

MANAGEMENT OF HBV INFECTION IN ONCOHEMATOLOGIC IMMUNOSUPPRESSED PATIENTS: LAMIVUDINE PROPHYLAXIS AND RESCUE THERAPY OF OCCULT HBV INFECTION REACTIVATION.

A Marrone[1,*] M Esposito[2], C D'Amore[1], L Siniscalchi[1], L Rinaldi[1], L Mastrullo[2]
[1]Internal Medicine and Hepatology, Second University of Naples, [2]Hematology Unit, San Gennaro Hospital of Naples, Napoli, Italy

Background: Hepatitis B virus (HBV) overt and occult infection reactivation in oncohematologic patients (OHPs) is a frequent event and it can lead to severe hepatitis and to liver acute failure even. The reactivation can occur from 5 to 36 months (m) after the start of chemotherapy. Patients with serological markers of resolved HBV infection (HBsAg-, HBcAb+, HBsAb -/+) which receive highly immunosuppressive chemotherapy are at high risk of viral reactivation. Antiviral prophylaxis is recommended but the optimal length, monitoring and the mechanisms of reactivation in these patients are still uncertain.
Aims: 1) to evaluate the efficacy and safety of lamivudine (Lam) prophylaxis given for 18 m after discontinuation of chemotherapy; 2) the efficacy of antiviral standard treatment in OHPs chronic HBV carriers; 3) we also report 11 cases of HBV reactivation who had not received Lam prophylaxis and were treated with antiviral rescue therapy.
Methods: 1) Forty-eight OHPs (M/F:33/15; median age yrs:65; range 29-82) were studied: 28 non Hodgkin lymphoma (NHL), 1 Hodgkin lymphoma (HL), 9 chronic lymphocytic leukemia (CLL), 10 multiple myeloma (MM). At the Hematology Unit admission, before starting chemotherapy, all were screened for HBsAg, HBsAb, HBcAb, HCV-Ab, HAV-Ab and ALT values. HBsAg and ALT were monthly monitored and serum HBV-DNA was tested every 3 m after the start of chemotherapy. 2) Eleven pts. with ongoing HBV reactivation were hospitalized in the Liver Unit. Patients received standard highly immunosuppressive chemotherapic protocols for the hematologic malignancies.
Results: Following serological screening pts. were distinguished in two groups. *Group A* including 9/48 (18%) pts. (M/F:7/2; median age: 67 yrs (34-71) which resulted HBsAg/HBV-DNA pos (2 HBeAg+, 7 HBeAg-). One of these was HCV-Ab/HCV-RNA pos and all were HAV-Ab (IgG) pos. *Group B* including 39/48 (82%) HBsAg neg pts. (M/F: 26/13; median age yrs:65; range 29-82). Nine of 39 (23%) presented isolated HBcAb positivity and 29/39 (74%) HBsAb/HBcAb positivity. Five of 39 (13%) were HCV-Ab positive and 38/39 (99%) HAV-Ab (IgG) positive. *Group C*: 11 pts. (M/F: 7/4; median age 68 yrs), 6 with severe clinical reactivation (jaundice and high ALT levels) and 5 with mild/moderate disease. 4 pts. were HBsAg neg/HBV-DNA pos. *Standard therapy: Group A* pts. (4 inactive and 5 active carriers) received antiviral therapy (5 entecavir (Ent) 0.5 mg/d, 3 Lam 100 mg/d, 1 Lam/adefovir combination); all cleared HBV-DNA (antiviral median time months:11; range 4-24), normalized ALT and completed chemotherapy but are still HBsAg+. *Lam prophylaxis: Group B* pts. started Lam 100 mg/d for 18 m after the last chemotherapy cycle. Twenty of 39 (51%) pts. have completed 18 m of Lam prophylaxis and, among these, 14/20(70%) have passed 12 m after discontinuation of Lam prophylaxis. Median time after discontinuation of chemotherapy and Lam is 30 (1-58) and 19 (1-54) m respectively. None case of HBV reactivation has been observed. Five pts. of Group B died because hematologic malignancy. *Rescue therapy:* Group C pts. received Ent (6) and Lam (5). One died because liver failure, 3 because hematologic disease but were still HBV-DNA pos. 7/11 cleared HBV-DNA.
Summary / Conclusion: HBV reactivation is life threatening condition and must be prevented. These preliminary data show that: 1)prolonged 18 months of Lam prophylaxis is safe and effective in preventing HBV reactivation and in permitting the completion of chemotherapy; 2)Standard anti-HBV treatment is effective to treat chronic HBV carrier with hematologic disease.

P430

CLINICAL CORRELATIONS AND MOLECULAR ANALYSIS OF HUMAN CYTOMEGALOVIRUS (HCMV) INFECTION IN BRAZILIAN PATIENTS WITH SICKLE CELL DISEASE, BETA-THALASSEMIA MAJOR, AND BLOOD DONORS

S Nanev Slavov[1], S Kashima[1], V de Deus Wagatsuma[1], A Silva-Pinto[1], D Covas[2,*]
[1]Hemocentro de Ribierão Preto, [2]Departamento de Clinica Médica, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil

Background: There is a significant lack of information regarding the impact of the human cytomegalovirus (HCMV) infection on patients with sickle cell disease, and beta-thalassemia major, despite of the serious clinical effect of this virus. For example, the knowledge of HCMV impact on patients with sickle cell disease is limited to a unique case report describing a fatal HCMV pneumonia in a young man with sickle cell disease. Such information for HCMV in patients with hemoglobinopathies can be crucial in the time when new approaches for the treatment of these diseases by stem cells are gaining ground as the most promising therapeutic tools.
Aims: To examine the molecular characteristics and clinical impact of the HCMV infection on patients with sickle cell disease and beta-thalassemia major and healthy blood donors.
Methods: Blood samples were collected from 144 patients with sickle cell disease, 39 with β-thalassemia major, and 100 healthy blood donors at the Regional Blood Center of Ribeirão Preto, Faculty of Medicine of Ribeirão Preto, University of São Paulo (the Southeast Brazil). The specimens were submitted to viral load quantitation, sequencing analysis, genotyping and phylogenetic analysis of the UL55 gene. The HCMV molecular findings were related to the clinical records of the positive patients.
Results: HCMV DNA was detected in 13.8% of the sickle cell disease patients, 7.6% of the patients with beta-thalassemia major, and 3% of the donors at a mean viral load of $3.8x10^3$ copies/mL. Nevertheless, infections with higher viral load and accompanied by a different hematological findings, and even retinopathy were also observed. HCMV genotype gB2 was detected predominantly (90.9%), followed by genotype gB1 (9%).
Summary / Conclusion: This study examines for the first time the clinical impact and the molecular characteristics of HCMV in patients with hemoglobinopathies. The high rates of HCMV detection among patients with sickle cell disease compared to the patients with beta-thalassemia major could be due to their relative immune suppression. The extensive spread of genotype gB2 among patients with hemoglobinopathies is probably due to geographic characteristics and could not be related to higher virulence, specific patient group or clinical symptoms. Nevertheless, special attention should be paid for the monitoring of the HCMV infection in patients with sickle cell disease, and β-thalassemia major, once this virus can have serious impact on them due to their altered immune surveillance and the specificity of the underlying diseases.

P431

ABNORMAL SPLEEN FUNCTION ASSESSED BY THE STUDY OF "PITS" AND SUBMEMBRANOUS VACUOLES IN ERYTHROCYTES IN PATIENTS WITH SPLENOMEGALY OF DIFFERENT ETIOLOGY

E Feliu[1], F Milla[1,*] M Xandri[1], A Oriol[1], L Berga[1], J Ma Ribera[1], M Pacha[1], B Oller[1]
[1]Laboratory Hematolgy Department, Institut Català d'Oncologia (Badalona), Badalona, Spain

Background: Patients with enlarged spleen may present a hyposplenism
Aims: To evaluate the spleen function in patients with benign and malignant blood diseases presenting splenomegaly.
Methods: 100 patients were studied (54 males 46 females, median age 39 years (range:16-84 yeas) (group I: 14 autoimmune processes, group II: 6 hereditary red cell disorders, group III: 23 lymphoproliferative disorders, group IV: 10 chronic myeloproliferative neoplasms, group V: 10 liver cirrhosis, group VI: 37 splenic traumas (22 conservative treatment and 15 splenectomy). The control group was formed by 28 "normal subjects": 12 males 16 females, median age 32 years (range: 22-50). The following clinical and analytical data were recorded: age, sex, spleen size, diagnosis, complete blood count and erythrocytic formula. The methods used were: a) study of red cell "pits" (Nomarsky optic) and b) study of the red cell submembranous vacuoles (transmission electron microscopy).
Results: There was a correlation between the measurements of "pits" and the submembranous vacuoles in the whole series (R>0.68, P<0.001). The correlation was better in the cases with pathology (R>0.82, P<0.001) than in the normal subjects. In the group of healthy people (negative control)the median percentage of red cells with "pits" was 2.1% (0.5-8.8) and with submembranous vacuoles 1.4% (0.4-3.8). The median number of "pits" per red cell was 0.02 (0.01-0.12) and of submembranous vacuoles 0.02 (0.00-0.20). In the traumatic spleen group (group IV), in patients in which splenectomy was performed without autologous transplantation (9 cases) (positive control), the median percentage of red cells with "pits" was 54.7 (extremes 29-64) and the median of "pits" per red cell 1.4 (0.6-1.8). Both median values were statistically different from those of the negative control group (P<0.001). The results of the pathological groups are depicted on the attached Table 1.
Summary / Conclusion: a) Patients with splenomegaly due to chronic lymphoproliferative and myeloproliferative disorders present a hyposplenism that may contribute to severe infections; b) An altered splenic function is also observed in patients with autoimmune diseases and with hereditary red cell disorders although with less intensity; c) Splenic congestion characteristic of patients with liver cirrhosis presents a normal spleen function; d) Spleen function is more related to the splenic red pulp infiltration than to spleen size.
In part by grant 95/00063-01 and 02/0754 from FIS, Instituto de Salud Carlos III; and Presidential grants of Josep Carreras Foundation P-EF 01-07

NEUTROPENIC ENTEROCOLITIS AND VANCOMYCIN RESISTANT ENTEROCOCCUS AS PREDISPOSING FACTOR

E Umit[1], M Uyanik[1], F Kuloglu[2], G Pamuk[1], M Demir[1,*]
[1]Hematology, [2]Infectious Diseases, Trakya University Faculty of Medicine, Edirne, Turkey

Background: Neutropenic enterocolitis (NEC) is a life-threatening disease with high rates of morbidity and mortality, seen primarily in patients with hematologic malignancies. The frequency of NEC has increased with the use of chemotherapeutic agents causing severe gastrointestinal mucositis. Neutropenic patients with fever and abdominal symptoms (pain, distention, diarrhea, GI bleeding), should be evaluated for bowel wall thickening of ≥4 mm, the hallmark of NEC. Management includes bowel rest, correction of cytopathies and coagulopathies, and broad spectrum antibiotics and antifungal agents. Surgical intervention may be necessary to manage complications such as hemorrhage and perforation and should be delayed, if possible, until recovery from neutropenia. Vancomycin resistant enterococci (VRE) are an increasingly common and difficult to treat cause of hospital-acquired infection. Long hospitalization periods, use of broad-spectrum antibiotics and immunosuppression are major risks for VRE colonization.
Aims: The aim of our study is to evaluate our patients' characteristics and factors which may contribute to VRE colonization as well as the role of colonization for the development of NEC
Methods: 140 patients who have been hospitalized in the Hematology inpatient clinic between April 2012 and September 2012 were enrolled in the study. Ages of the patients ranged between 19 and 84 years (mean 54.81) and gender of the patients were 63 female (45%) and 77 male (%55). Diagnosis of the patients were grouped as acute leukemias, lymphomas (both Hodgkin's and non-Hodgkin's), chronic leukemias an myeloproliferative disorders and benign hematological disorders. Leucocyte count, initial questioning for gastrointestinal problems and the presence of hypogammaglobulinemia were recorded. After discharge, VRE status and neutropenic enterocolitis and diarrhea were also recorded.
Results: VRE colonization was observed primarily in patients with acute leukemias. Initial leucocyte count was not related with VRE status, thus VRE colonization was significantly related with the presence of hypogammaglobulinemia. History of previous gastrointestinal problems were significantly related with VRE colonization. And last o all, Both neutropenic enterocolitis and neutropenic diarrhea were significantly related with VRE status.
Summary / Conclusion: VRE colonization is a fast spreading, not easily managed problem especially in Hematology clinics. Patints with hypogammaglobulinemia is observed to be susceptible for colonization. Serious and life-threatening complications of hematological malignancies and their treatment such as neutropenic diarrhea and enterocolitis are observed to be more frequent in patients who have VRE colonization.

Table 1.

Parameters		VRE positive (# of patients)	VRE negative (# of patients)	Total (# of patients)	P values
Total number of patients		28	112	140	
Hypogammaglobulinemia at the time of diagnosis		27	20	47	0.000
Complaints about gastrointestinal system at the time of diagnosis		13	9	22	0.000
Diagnosis	Acute leukemias	20	26	46 (32.9%)	
	Lyphomas	6	36	42 (30.0%)	
	Chronic leukemias and myeloproliferative disorders	2	40	42 (30.0%)	
	Benign hematological disorders	0	10	10 (7.1%)	
Neutropenic diarrhea		23	7	30	0.000
Neutropenic enterocolitis		14	2	16	0.000

P433

ANAEROBIC BLOODSTREAM INFECTIONS AMONG HAEMATOLOGICAL CANCER PATIENTS: EPIDEMIOLOGY AND OUTCOME. RESULTS OF AN 8-YEAR SURVEILLANCE PROGRAM AT A SINGLE INSTITUTION

C Cattaneo[1,*] F Antoniazzi[1], M D'Adda[1], F Schieppati[1], E Cerqui[1], C Pagani[1], S Fogazzi[1], E Borlenghi[1], A Re[1], G Rossi[1]
[1]Hematology, Spedali Civili di Brescia, Brescia, Italy

Background: Anaerobic bloodstream infections (BSI) are a rare event among haematological cancer patients (pts). Due to its low incidence, few large studies have been published concerning cancer pts as a whole, but only few small series referring to haematological cancer pts. Frequent association with polymicrobic BSI, oral/gastrointestinal mucositis and life-threatening complications were reported.
Aims: In order to better define the clinical characteristics of anaerobic BSI (AnBSI) among haematological pts, we analyzed all BSI occurring to consecutively admitted haematological pts to our Institute during a period of 8 years.
Methods: Since June 2004 a program of active epidemiological surveillance is ongoing at our Institute. Levofloxacin prophylaxis was given to pts with a ≥7day-expected neutropenia. All pts showing fever or signs/symptoms of infection underwent at least two sets of blood culture; empiric antibiotic treatment consisted of beta-lactam+amynoglycoside association. Data concerning anaerobic BSI occurring were analysed.

Results: From June 2004 to December 2012, 691 cases of BSI were recorded. Gram-negative (G-) pathogens accounted for 395 cases (57.2%), Gram-positive (G+) for 235 (34%), fungi (all *Candida* spp) for 11 (1.6%). In 50 cases (7.2%) BSI etiology was polymicrobic (PMB). In 17/691 (2.5%) cases an anaerobic pathogen was isolated, in 4 cases they were observed in PMB BSI. Incidence of AnBSI was constant over time. G+ anaerobic bacteria were observed in 9 cases (6 *Clostridium* spp, 1 *Gemella* spp, 1 *Eubacterium* spp, 1 *Lactobacillus* spp), whereas G- in 8 cases (5 *Bacteroides* spp, 2 *Campylobacter* spp, 1 *Prevotella* spp). Enterococci were the most frequent bacteria associated with anaerobic pathogens in PMB AnBSI. AnBSI were associated with uncontrolled underlying haematological disease (13/328, 4.0% vs 4/363, 1.1%; OR 3.72 [IC 1.2-11.51]) and PMB BSI (4/50, 8% vs 13/641, 2%; OR 4.19 [IC 1.31-13.38]), whereas neither type of disease (acute leukaemia or not) nor neutropenia or prophylaxis with levofloxacin were considered risk factor for AnBSI. Antibiotic susceptibility profile was available in 11/17 cases. None of the *Clostridium* and *Bacteroides* spp bacteria showed metronidazole resistance (4 and 3 cases, respectively), whereas fluoroquinolone resistance was observed in the *Campylobacter* susceptibility available test. Overall, 30-days mortality was 54/691 (7.8%). AnBSI mortality was significantly higher (4/17, 23.5%) in comparison with G- (32/395, 8.1%) (P=0.05) and G+ (5/235, 2.1%) (P=0.0015); it was similar to mortality due to other PMB BSI (9/46, 19.6%) and fungal BSI (4/11, 36.3%) (P=ns). Life-threatening complications was observed in two cases, 11.1% (admission to ICU for respiratory distress and compartment syndrome in 1 case each).
Summary / Conclusion: Incidence of AnBSI was similar in our study to those reported by literature in unselected series. Anaerobic pathogens are frequently associated to other bacteria, particularly enterococci, also among haematological cancer patients, and typically occur with an uncontrolled underlying disease. Our data also confirm that incidence of complications is high as well as mortality rate, which is similar to those of candidemia and other PMB BSI. Further studies are warranted in order to better clarify predisposing factors for AnBSI among haematological cancer pts.

P434

COMPARISON OF THE BD GENEOHMVANR ASSAY TO CULTURE FOR IDENTIFICATION OF VANCOMYCIN-RESISTANT ENTEROCOCCI IN RECTAL AND STOOL SPECIMENS IN PEDIATRIC MALIGNANCY PATIENTS
F Devrim[1], G Gülfidan[1,*] Y Yaman[2], G Özek[2], Ö Cartı[2], B Tatlı[2], B Demirağ[2], E Albudak[2], İ Devrim[3], C Vergin[2]
[1]Dr.Behçet Uz Children Hospital, izmir, Turkey, [2]Pediatric hematology, [3]pediatric infectious disease, Dr.Behçet Uz Children Hospital, izmir, Turkey

Background: Active screening for vancomycin-resistant enterococci (VRE) in rectal and stool specimens has been recommended to limit the spread of antimicrobial resistance within certain high-risk populations including oncology-hematology wards.
Aims: The aim of this study is to compare the diagnostic performance of the rapid real-time PCR test; BD GeneOhmVanR assay (BD Diagnostics,SanDiego, CA) BD with the conventional screening cultures for VRE
Methods: Direct swab specimens were tested by the molecular assay and compared with direct culture. 306 rectal swabs and stool specimens were evaluated with BDGeneOhmVanR assay (BD GeneOhm,SanDiego, CA) that detects the presence of vanA and/or vanB genes. The rectal swaps were inoculated directly to ChromID VRE agar (Biomerieux-France) and enterococci were identifiedusing standard biochemical tests and VITEK 2 automated microbiology system (Biomerieux-France). The susceptibility of the enterococci to vancomycin and teicoplanin was determined using an Etest (Biomerieux-France).
Results: VRE were initially isolated from 37 cultures, and the RT-PCR assay was positive in detected 37 of the 306 samples. The sensitivity and spesificity of RT-PCR was 91.8%(34/37) and 93.6%(252/269) respectively. The positive and negative predictive values for GeneOhmVanRassay was 66.6% and 98,8%.
Summary / Conclusion: VRE colonization is an important health-care problem however infections were mostly common in high-risk patients. Early diagnosis of VRE colonization will help cohorting the patients, transmission of VRE patients and improving infection control measures. In our study; GeneOhmVanR assay is an useful tool for this usage; however its specifity was found to be more impressive compared to its sensitivity.

P435

REASONS FOR TREATMENT SEEKING DELAY IN NEUTROPENIC SEPSIS
M Talbot[1,*] P Yates[2], A Todd[3]
[1]Clinical Psychology, [2]School of Psychology, Exeter University, [3]Haemotology, Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom

Background: Treatment seeking delay (TSD) may be divided into emergency medical services delay, hospital delay and patient presentation delay. In the United Kingdom hospital delay has been a recent focus of guidelines and standard development for the common and potentially fatal chemotherapy complication of neutropenic sepsis (NS). However, studies of TSD in other settings suggest most TSD is due to patient, not medical service delay. Since NS commonly arises in the out-patient setting, patient factors in TSD represent a substantial but under-researched clinical issue
Aims: To identify the patient processes involved in seeking medical treatment for potential NS in chemotherapy patients and identify a model for TSD which could inform future efforts to improve outcome.
Methods: Between May 2011 and April 2012, all patients receiving chemotherapy at our haematology service received the same written and verbal instructions, consistent with national guidance with 24 hour contact details and advice to seek immediate medical attention for any self-recorded temperature exceeding 38C or after 2 hours of being unwell without fever. Patients admitted with suspected NS who had not followed these instructions were invited to participate in the study. This involved an audio-taped semi structured interview with a psychologist. A social constructionist version of grounded theory was used to explore the processes underlying patient experiences, emotions and identity and to contextualise theory development for this clinical scenario.
Results: 50% (16) of patients admitted with suspected NS had not followed the instructions given to them. 12 agreed to participate in the study. Six theoretical constructs were generated from interview: Recall of Treatment Advice, Symptom Monitoring Behaviour, Symptom Interpretation, Impact of Emotions, Influence of Social Networks and, finally, Preparation and Journey Time. TSD appeared to be shaped by a complex interplay between these constructs comprising 3 stages (Figure 1): 1) Adherence to treatment advice (monitoring signs and symptoms), 2) Contacting hospital, 3) Presenting at hospital. Only in stage 1 is patient recall of advice and instructions a dominant factor, combined with the degree of acceptance that the concept of neutropenic sepsis is relevant to them. In the more complex stage2, monitoring behaviour, interpretation of symptoms – in turn driven by understanding and prior experience of illness – emotion (e.g. fear, denial) and social network influence (e.g. opinion and advice of family or friends) are the key decision making modifiers. Stage3, Presenting at Hospital, centres on practical considerations around the journey such as transport, packing and preparing the rest of the family.
Summary / Conclusion: This study permits a provisional 3 Stage Model of TSD for NS in chemotherapy patients to be developed (Figure 1). There are implications at two levels: Health policy / clinical practice - there is often poor recall of FN information. Future guidelines on NS could recognise that information provision is insufficient and this provision should be structured to maximise recall, for example at different stages rather than during one outpatient visit. Lay population - contextual social factors and social networks heavily influence help seeking behaviour. Patients are more likely to seek treatment for NS if they view it as a real danger and accept previous health beliefs may not apply. Chemotherapy patients also need to believe that seeking treatment would not inconvenience family/friends and healthcare staff.

Background: Cefepime is a widely used antibiotic for patients with hematological malignancies (HM). It can cause encephalopathy, which has been increas-

ingly described in the literature, occurring mainly in patients with impaired renal function. However, the risk factors and characteristics have not been fully elucidated in patients with HM.
Aims: The primary objective of this study was to measure the incidence of cefepime-induced encephalopathy and determine potential risk factors and clinical characteristics.
Methods: We conducted a retrospective cohort study in 222 patients using cefepime with HM at our hospital in the period from August 2011 to February 2013. Other causes of encephalopathy were excluded for all patients with clinically suspected encephalopathy. Head CT, MRI, cerebrospinal fluid examination, and electroencephalography (EEG) were performed to assist in the diagnosis. We also investigated the clinical features of patients with cefepime-induced encephalopathy. We used univariate analysis and assessed the risk factors for the development of cefepime-induced encephalopathy in HM patients. Statistical analysis included two-sampled *t* test and Fisher's exact tests. All calculations were performed using the program R 2.12.1.
Results: Among 222 HM patients using cefepime, 9 were diagnosed with cefepime-induced encephalopathy, thus indicating a cumulative incidence of approximately 4%. These cases corresponded to 4 men and 5 women with an average age of 70 years. With respect to underlying disease, 2 patients had myeloma, 4 had lymphoma, one had leukemia, and 2 had other hematological malignancies. Of 9 patients with encephalopathy, 7 patients had impaired renal function (4 on maintenance hemodialysis), and 1 had impaired liver function when cefepime was prescribed. The average creatinine level at the beginning of treatment was 5.02 mg/dL (range: 0.60-19.85) and the initial dose of cefepime was 3.66 g/day (range: 1.0-6.0). The average time between commencement of treatment and symptoms was 3.4 days (range: 1-5).The most common clinical manifestations were decreased level of consciousness (100%) and myoclonus (30.0%). The EEG was pathological in 6 cases where it was carried out, demonstrating periodic short-interval diffuse discharges with a predominance of triphasic waves in 4 cases, and slowed global activity with repetitive paroxysm in 2 cases. The head CT scan and MRI were normal in all cases. After diagnosis of encephalopathy, treatment with cefepime was discontinued immediately. Symptoms improved fully in all patients, and the average period between symptoms and recovery of encephalopathy was 5.4 days (range: 2-23). Univariate analysis showed that impaired renal function (creatinine, eGFR) ,acute worsening of renal function was significantly associated with development of cefepime-induced encephalopathy (P=0.0001, P=0.025, respectively). Age, sex, weight, liver function abnormality, hypertension, diabetic mellitus, total dose of cefepime per day and unadjusted cefepime dose were not identified as potential risk factors. Receiver operating characteristic (ROC) curves demonstrated that the threshold level of eGFR for cefepime-induced encephalopathy was 31.82 (area under the curve=0.849).
Summary / Conclusion: This study indicated that the development of cefepime-induced encephalopathy was associated with severely impaired renal function (eGFR<30 mL /min/1.73 m^2) in patients with HM. We should be aware of cefepime-induced encephalopathy, especially in HM patients with impaired renal function, and early withdrawal is needed when there is clinical suspicion of encephalopathy.

P437

DIVERSE CLINICAL PICTURE AND ORIGIN OF HEMOPHAGOCYTIC SYNDROME IN ADULT PATIENTS. SINGLE CENTER EXPERIENCE OF 18 PATIENTS

W Wiktor-Jedrzejczak[1,*] R Machowicz[1], P Boguradzki[1], J Dwilewicz-Trojaczek[1], A Waszczuk-Gajda[1], J Drozd-Sokolowska[1]
[1]Hematology, Oncology and Internal Diseases, Medical University of Warsaw, Warsaw, Poland

Background: Hemophagocytic syndrome also called hemophagocytic lymphohistiocytosis (HLH) is a rare but devastating clinical syndrome characterized by fever, splenomegaly, cytopenias, hyperferritinemia, hypofibrinogenemia and hemophagocytosis leading to fatal outcome if untreated. It is frequently misdiagnosed as sepsis because resemblance of the symptoms and frequent secondary bacterial infection. For long time it was considered to be disease of children, where it occurs in mainly primary form produced by mutations affecting function of cytotoxic lymphocytes. In reported cases of adolescent and adult patients it was related either to infection (mainly aberrant EBV) or malignancy. However, the knowledge on its occurrence, diversity and course in adult patients is very limited.
Aims: The aim of the study was to describe relatively large group of patients with this condition referred to our Department.
Methods: For this patients records were evaluated and results reported.
Results: Since 2006 17 patients were referred to our Department, who fulfilled majority of criteria for this syndrome and additionally 1 patient who died in 2000 was retrospectively included. For majority of patients it was not possible to test them at diagnosis for soluble IL-2R and NK cells, so diagnosis was made in 12 patients after fulfilling 5 out of 6 remaining diagnostic criteria and in 6 patients after fulfilling 4 out of 6 diagnostic criteria of HLH. There were 9 cases of EBV-associated HLH, 8 cases of malignancy-associated HLH and 1 case where both PTCL and confirmed recurrent EBV infection contributed to the syndrome. Regarding malignancy-associated HLH there were 2 more cases of PTCL, 2 T-LGL, 1 ALCL ALK (-), 1 DLBCL, 1 AML, 1 CML-BC, and 1 with cancer of unknown origin. Eight patients have been referred in so advanced status that there was not possible to initiate treatment and they died early after admission. Out of 7 EBV-associated HLH patients who have received combination of etoposide, cyclosporine A and steroids (HLH 2004 protocol), 5 are alive and well up to 5 years after treatment. Two patients died of infection day 14 and day 18 of therapy with significantly alleviated symptoms. Patient suffering from both PTCL and EBV-associated HLH died of unrelated cause while in remission of both conditions after CHOP and DHAP treatment. Out of 8 malignancy associated HLH patients, 2 are surviving: one with DLBCL treated with R-CHOP and one with T-LGL treated with methotrexate + G-CSF. The most prominent features in all patients were hyperferritinemia (18/18), fever (17/18), and splenomegaly (18/18) with less regularly observed red cell, platelet and neutrophil deficiencies (18/18 but variable), hemophagocytosis (10/18) and hypofibrynogenemia (7/18) or hypertriglicerydemia (11/18). Many patients suffered from prominent mixed coagulapathy (16/18) with D-dimer level up to 24,6, decreased albumin (11/18) and increased liver enzymes: LDH (16/18), ASPAT (13/18), ALAT (13/18) and hyperbilirubinemia (11/18). Frequent were pleural and peritoneal effusions and skin changes such as panniculitis. Only one patient demonstrated severe neurologic deficits that resolved completely after HLH 2004 treatment.
Summary / Conclusion: Adult patients demonstrating fever, splenomegaly and deficiencies in complete blood count should be tested for ferritin level and if increased further followed for confirmation or exclusion of HLH. Since disease is fatal when untreated, therapy with either HLH 2004 protocol or other disease specific protocol should be initiated as promptly as possible.

P438

USEFULNESS OF GALACTOMANNAN ASSAY IN BRONCHOALVEOLAR LAVAGE SAMPLES IN PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES AND RISK OF INVASIVE PULMONARY ASPERGILLOSIS.

R Del Orbe[1,*] I Olazabal[1], M Zamora[1], M Olivares[1], I Amarika[1], E Landeta[1], A Iglesias[1], A Balerdi[1], L Lopez-Soria[2], E Amutio[1], J García-Ruiz[1]
[1]Hematology, [2]Microbiology, Hospital Universitario Cruces, Barakaldo, Spain

Background: Invasive pulmonary aspergillosis (IPA) is a major cause of morbidity and mortality in patients with haematological malignancies. Definitive diagnosis of IPA is based on demonstration of the fungus in lung tissue by culture and / or histopathology. Clinical status of these patients makes so difficult to get a diagnosis with certainty and is where the role of biomarkers, such as galactomannan (GM) can be useful. GM is a wall component of fungal cell polysaccharide which is released during invasion by *Aspergillus* spp. and can be detected in body fluids. Its determination in serum of patients with haematological malignancies at risk of invasive fungal infection is useful in the early diagnosis of aspergillosis, but its presence in bronchoalveolar lavage (BAL) remains unclear in diagnosing IPA.
Aims: To determine the usefulness of galactomannan assay in bronchoalveolar lavage specimens and its value in clinical practice.
Methods: We conducted a retrospective and observational study, during 32 months (February 2010-November 2012). We got 33 BAL samples from 32 patients diagnosed with hematological malignancies in context of fever and suspected lung infection. Cases were categorized into low, intermediate and high risk of IPA; also diagnostic of IPA were made in base of EORTC/MSG criteria. A chest CT scan was performed in all patients prior to bronchoscopy and BAL. A serum galactomannan antigen (AGA) assay, prior and / or subsequent to the completion of BAL was measured. All patients were receiving or had recently received beta-lactam antibiotics or carbapenems. Samples obtained from BAL were conducted to determine galactomannan (GM), Gram stain, culture of aerobic bacteria and fungal, antigen *P. jirovecii*, PCR [respiratory syncytial virus (RSV), parainfluenza, adenovirus, rhinovirus, coronavirus, bocavirus, metapneumovirus, Influenza and Enterovirus], cytomegalovirus (CMV) Shell-Vial, CMV culture, auramine staining and culture of mycobacteria. The results of GM in BAL, were expressed as ratio, considering positive a value greater than 0.5 (GM +) extrapolating from serum values and its significance.
Results: Of the 33 cases studied, 6 were classified as IPA (5 probable and 1 proven). The proven IPA was based of identification by culture and histopathology of *A. fumigatus* in BAL and lung tissue. 22 cases (66%) were at high risk of IPA, 8 intermediate risk (23%) and 4 (11%) low risk. GM + was observed in 76% of cases (25/33) (range 0.62-6.60). In all cases of IPA, GM had elevated values >3 (range 3.02 - 6.25). In 19/33 cases of GM + BAL were not evidence of *Aspergillus* spp. in the diagnostic screening. In 12/33 cases was isolated an infectious agent, *Candida* spp. (1 case), *P. jirovecii* (2 cases), *E. faecium* (2 cases), CMV (2 cases), RSV (1 case), rhinovirus (2 cases), coagulase-negative *Staphylococcus* (1 case) and *Penicillium* spp. (1 case). CT scan showed variable findings in all patients, being pulmonary infiltrates and cavitation the most frequent radiological pattern in patients with IPA (4/6). Positive and negative predictive values of determination of GM in BAL was 24% (95% CI 11.5-43.4) and 100% (95% CI 67.6-100) respectively. Sensitivity and specificity of the test was 100% (95% CI 61-100) and 29.6% (95% CI 15.9-48.5).
Summary / Conclusion: In our experience determining galactomannan in BAL specimens using a ratio ≥ to 0.5 is useful to identify a group of patients at risk

for aspergillosis with very low probability of getting the infection. This limited series does not allow establishing other cutoff value to improve the specificity of the test, although it is noted that all IPA cases in this study, proven or probable, showed elevated levels of GM in BAL (ratio> 3). It is necessary to carry out studies with larger series to clarify these issues.

P439

RISK FACTORS RELATED TO MORTALITY IN HEMATOLOGICAL PATIENTS ADMITTED TO INTENSIVE CARE UNIT (ICU)

S Iraheta[1,*] J Raya[1], L Lorente[2], S Lakhwani[1], M Fernández[1], L Hernández-Nieto[1], M Mora[2]
[1]Haematology and Hemotheraphy , [2]Intensive Care Medicine, Complejo Hospitalario Universitario de Canarias, Tenerife, Spain

Background: Patients admitted into the intensive care unit (ICU) because of complications in the treatment of a hematological malignancy have a poor prognosis classically. However, recent studies indicate that advances in managing critically ill cancer patients and in selecting them for ICU admission have improved their outcome.
Aims: To assess the main clinical features of this group of patients at discharge from the ICU in a tertiary university hospital and to identify possible risk factors associated to mortality such as invasive mechanical ventilation (IMV) requirement.
Methods: We retrospectively collected data of all patients with a hematological disease admitted to the ICU between January-2009 and April-2012. Recorded variables included: sex, age, hematological diagnosis, disease status, type of treatment received, evidence of sepsis criteria, major reason for ICU admission, need for IMV, use of vasopressors agents, ICU lenght of stay, laboratory values at admission, and APACHE II and SAPS II scores calculated within the first 24 h. Predictors for in-hospital mortality were evaluated using uni- and multivariate analysis.
Results: A total of 21 patients (median age 55, inter-quartile range IQR 15-80, and male 66.6%) were analyzed. Of these, 95.2% had a hematological malignancy, 47.6% with a recent diagnose, and only in two cases ICU admission coincided with disease progression. The main causes of admission were pneumonia associated with acute respiratory distress syndrome (ARDS) and sepsis of any origin (28.6% each). The average stay in the ICU was 12.4 days (IQR 1-60). Globally, 71% had received chemotherapy during the 2 weeks prior to admission. Severe neutropenia was present in 38% of patients, and 50% of them died during ICU stay. IMV requirement was recorded in 66.6% of patients, of which 50% died; however, only 14.3% of patients who did not require IMV were exitus. No statistically significant relationship was found between IMV and mortality (P=0.133). Fourteen patients (66.6%) required vasopressor drugs, of which 57% died; by contrast, all patients who did not need amines (33.3%) survived (P=0.018). The mean scoring systems APACHE II and SAPS II were 18.7 and 46.1 respectively, and a relationship between them and mortality was not observed (P=0.804). The overall mortality rate during ICU stay was 38%. Of the 13 patients alive at discharge from ICU (62% of total), two (15.4%) died of ARDS within a week, both in situation of hematologic disease progression. The overall in-hospital mortality was 47.6%, and overall survival at 6 months after ICU discharge was 47.6%.
Summary / Conclusion: The overall mortality rate in our population is slightly below average described in the literature. Regarding prognostic factors associated with mortality, we observed only statistically significant association between this and the need of vasopressor amines administration. Finally, although the sample size is small, mortality was not significantly associated with IMV, the degree of neutropenia or the haematological disease type.

P440

AUDIT OF POSACONAZOLE USAGE IN THE HAEMATO-ONCOLOGY UNIT AT ST BARTHOLOMEW'S HOSPITAL

A Nizam[1,*] A Heath[2], M Fanous[3], L Dark[1], S Agrawal[4,5]
[1]Pharmacy, Barts Health NHS Trust, London , [2]Medical School, Imperial College, London, [3]Haemato-Oncology, Barts Health NHS Trust, [4]Blizard Institute, Academic Haematology, Queen Mary University of London, London , [5]Haemato-Oncology, St Bartholomew's Hospital, London, United Kingdom

Background: Posaconazole, a triazole antifungal, is indicated for use in the prophylaxis and treatment of invasive fungal disease (IFD) in adults. In 2007, our antifungal management protocol was changed to include posaconazole for IFD prophylaxis in patients with graft versus host disease (GVHD) receiving high dose steroids (≥1mg/kg/day of prednisolone or equivalent) and to stop posaconazole at a steroid dose of <0.25 mg/kg/day.
Aims: To establish compliance with the protocalised use of posaconazole.
Methods: Data was collected retrospectively with posaconazole use identified from an existing database, F.A.T. (fungal audit tool) and pharmacy records. 67 patients received posaconazole between January 2006 and December 2011. Review of their records revealed 100 episodes of posaconazole prescriptions. Toxicity was assessed from the clinician reported information, as well as laboratory parameters.
Results: Data was captured for 99 prescriptions, of which 63% were for prophylaxis in the setting of GVHD, 19% for suspected IFD, 8% for prophylaxis during chemotherapy, 6% for previous IFD (secondary prophylaxis) and in the remaining 3% episodes indications were not documented. In terms of the dosing schedule, 68% (n=66) were prescribed 600mg per day for prophylaxis as per protocol in GVHD; 28% (n=28) were prescribed 800mg per day, which included all "treatment" use, but also prophylactic use in 9% of episodes. The average duration of a posaconazole prescription was 61.5 days, which was longer in the outpatient setting (69.9 days) than for inpatients (13.5 days). Steroids were prescribed in 55 episodes, all for GVHD management. Posaconazole was discontinued appropriately in 32 episodes as per protocol. No stop date was available in 3 episodes. In the remaining 20 prescriptions, 7 prescriptions were for the treatment for IFD and hence not stopped at the same time as steroids; however, the protocol was not followed in 13 cases and prophylactic posaconazole was continued, representing a cost of £34.533. Evidence of symptomatic toxicity was seen in 8% of episodes, which included tiredness, visual disturbances and vomiting, none of which required discontinuation. In 13 episodes, posaconazole was started despite hyperbilirubinaemia and/or transaminitis (>5x upper limit of normal): at the cessation of posaconazole, liver function had improved/returned to normal in 10; was stable in 1; and worse in 2 cases. Posaconazole induced hepatoxicity was documented in only one episode and led to cessation of treatment. Posaconazole was changed to a new antifungal in 13 episodes without evidence of toxicity, liver impairment or intolerance: Ambisome in 6 cases; caspofungin in 3; voriconazole in 4. Although this is indirect evidence, it suggests a maximal breakthrough rate of suspected IFD of 13%.
Summary / Conclusion: The greatest use of posaconazole was for IFD prophylaxis in the setting of GVHD as per protocol. Posaconazole use appeared to be safe even with significant liver impairment. One third of posaconazole use was non-protocolised, mainly prophylaxis for chemotherapy. Overall, this audit highlights appropriate prescribing by clinicians. However, the failure to stop posaconazole prophylaxis in the GVHD setting on reduction/stopping of steroids has a significant budgetary impact. The results of this audit have led to the design of a specific request form for all outpatient prescriptions for posaconazole (and voriconazole), with monthly monitoring to ensure appropriate management in terms of indications and duration of therapy.

P441

CHILDREN WITH MACROPHAGE ACTIVATION SYNDROME: A SINGLE CENTER EXPERIENCE

S Aytac[1,*] S Ozen[2], S Unal[1], G Balta[1], M Cetin[1], F Gumruk[1]
[1]Pediatric Hematology, [2]Pediatric Rheumotology, Hacettepe University, Ankara, Turkey

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatining complication of childhood systemic inflammatory disorders. Recognition of MAS in patients with JIA and SLE is often challenging because MAS may mimic all signs and symptomps even laboratory features of the underlying disease.
Aims: We aimed to document all relevant clinical and laboratory features, treatment and outcome of MAS in our center.
Methods: This report presents a retrospective review of 22 patients diagnosed as MAS in Hacettepe University Ihsan Dogramaci Childrens Hospital. Our group (17 JRA and 5 SLE) included 12 girls and 10 boys and the median age of MAS onset was 11,5 years(range 16 months-16 years). The mean duration of underlying disorder was2,5. months(range 0-156,5 months) for the whole group however median duration was 0 months(range 0-156,5 months) for JIA and 12 months(10-24 months) for SLE. Patients with JIA were diagnosed to have MAS when they developed prolonged fever with organomegaly and worsening blood values especially platelet count which is progressively decreasing, decreased sedimentation rate, deranged liver functions, elevated ferritin level, elevated Vit B12 and LDH level, hyponatremia, hypoalbunemia, coagulopathy, encephalopathy and other diagnostic criterias for HLH -2004 with or without eveidence of hemophagocytosis in the bone marrow.
Results: Twelve patients with JIA were presented with MAS. At the time of the diagnosis fever at ≥38 C was observed 93% of the patients. Leucopenia, anemia and thrombocytopenia was found in 12%, 81% and 75% ,respectively. Median Hb, WBC and platelet count were 9,4 g/dL (range 6,4-15), 5100/mm^3 (range 900-70200) and 88500/mm^3 (range 21000-536000),respectively. When compare SLE with JIA at the time of MAS episode , it seems that patients with SLE had lower blood counts (median Hb, WBC and platelet count 7,6 g/dl(range 7-13,6), 1450/mm^3(1100-5000) and 65000/mm^3 (21000-99000/mm^3)) than JIA(median Hb, WBC and platelet count 10 g/dL (range 6,4-15), 10800/mm^3(900-70200) 995000/mm^3 (27000-536000/mm^3) respectively. Median ferritin level was 16728 µg/L (range 3747-150099). Vit B12 is available for 14 patients and 6(43%)of them were found to be elevated. The overall mortality rate was 40% in our group. Mortality rate for SLE was 60% (3 died, 2 alive) and it was 35% for JIA(6 died, 11 alive).
Summary / Conclusion: Literature review did show that we have relatively a large number of cases with MAS in single center experience beside there is an

accumulating case series in the recent years. According to our experience we can say that some of those patient has a very silent MAS clinic perhaps to due to underlying genetic feautures. On the other hand some of those patients rapidly worsened beside a prompt recognition and immediate therapeutic intervention. There were 3 patient presented in this study had consanguinity and none of them revealed specific mutations caused by primary HLH. In conclusion, MAS patients may presented with almost within a normal limit of blood values, however clinician kept in mind that platelet and sedimentation decrease will give a very important diagnostic clue. Bone marrow aspiration does not necessarily show hemophagocytosis at the first admission, serial examination with checking ferritin level regularly is helpful to put the diagnosis. Patient clinical status is also very important during these follow up period, in case of unexpected worsening of the patient even in the absence of any MAS criteria, prompt evaluation probably will be life saving.

P442

DIAGNOSTIC EFFICACY OF GALACTOMANNAN ASSAY AND COMPUTERIZED CHEST TOMOGRAPHY IN INVASIVE ASPERGILLOSIS OF FEBRILE NEUTROPENIC CHILDREN

G Aydogan[1],* N Celik1, D Tugcu[1], A Akcay1, F Akici[1], Z Salcioglu[1], M Demirkaya[1], M Gökce[1], N Ayaz[1], H Sen[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Invasive pulmonary aspergillosis (IPA) is a leading cause of morbidity and mortality in children with haematological malignancy and it can result in various clinical presentations due to the characteristics of fungus. Early diagnosis is quite important for better prognosis, however it is difficult to achieve this through the conventional methods Detection of IPA represents a formidable diagnostic challenge and, in the absence of a 'gold standard', a combination of clinical data and microbiology with histopathology is helpful. Culture-based approaches rely on the availability of biopsy samples, but these are not always accessible in sick patients, Blood and radiologic tests are frequently used for diagnosis of invasive pulmonary aspergillosis, but it remains unknown which is more useful for its early diagnosis.
Aims: In our study, we aimed to evaluate the diagnostic methods, that are based on measurement of galactomannan levels and imaging with computerized chest tomography of neutropenic patients with persistent fever (> 5 days duration) and to evaluate the incidence of aspergillus infection depending on these methods.
Methods: In this study, children with haematological malignancies and fever were enrolled prospectively. Fifty-three febrile neutropenic episodes of 32 patients, who have been followed up because of hematologic malignancies in Pediatric Hematology and Oncology Department of Kanuni Sultan Süleyman Education and Research Hospital were eveulated. Microbiological sampling was performed to determine the etiology. Clinical samples were assessed through culture and direct microscopy. Aspergillus antigen was detected with serum galactomannan (GM) levels. Blood sample for GM was drawn on the day of admission; levels were measured with Platellia Aspergillus enzyme immunoassay. Computerized chest tomography is used for determining invasive pulmonary aspergillosis. Invasive fungal infection was diagnosed according to the latest EORTC/MSG criteria. Proven, probable and possible episodes were considered as the disease groups.
Results: The mean age was 7.52±3.82 years. Thiry-one patients were treated for acute lymphoblastic leukemia,seventeen patients for acute myeloid leukemia and five patients for solid tumors. Twenty-one of 53 (39.6%) episodes were diagnosed with IFI, while six of them were probable, fifteen of them (28.3%) were possible IFI . No IFI was detected in 32 of the patients. It is observed, that prolonged neutropenia is a risk factor for invasive aspergillosis (P<0.05). The coincidence of pulmonary lesions seen at X-rays and computerized tomography was only 42%. The findings on chest CT were halo sign (7.5%), cavitation (3.8%) and nodules (22.6%) and other nonspesific findings (49.1%). For the diagnosis of invasive aspergillosis halo sign is more sensitive than other findings (P<0.05). The progression of CT findings is a sign of poor prognosis (P<0.05).Thirty-nine of 228 (17.1%) samples were positive for galactomannan. The false positive results were present in 29.4%. A close relationship was found between CT findings and GM positivity (P<0.05). The mortality rate due to fungal infection was 14.3%.
Summary / Conclusion: Serologic follow up with galactomannan levels and chest CT are important for the successful diagnosis and management of invasive aspergillosis in febrile neutropenic children associated with hematological malignancies.

Transfusion medicine

P443

VESICLES OBSERVED IN LEUCOREDUCED AND NON LEUCOREDUCED CONCENTRATED RED BLOOD CELLS BY MEANS OF ADVANCED MICROSCOPES: POSSIBLE RELATION TO THE STORAGE LESION

D Stamopoulos[1],* N Mpakirtzi[2], G Nikolaou[1], S Valsami[3], M Politou[3], M Pissas[1]
[1]Institute of Advanced Materials, Physicochemical Processes, Nanotechnology and Microsystems, National Center for Scientific Research, Demokritos, [2]Department of Nephrology, General Hospital of Athens, Gennimatas, [3]Department of Haematology, Areteion University Hospital, Medical School of Athens, Athens, Greece

Background: Red Blood Cells (RBCs) constitute the basis of probably the most important blood product that is widely used in transfusions in clinical practice. Processed RBCs (pRBCs), leucoreduced (LR) or not (nLR), are isolated from the plasma, redispersed in a storage solution in concentrated form and finally stored at 2-6 ºC under sterile conditions. Normally, the storage duration does not exceed 42 days due to the pRBCs biochemical degradation that is accompanied by morphological modification of their membrane, a sequel of processes that is termed 'storage lesion'. Specifically, the morphological modification of the pRBCs membrane is established by a gradual reduction of both surface and volume that is commonly ascribed to the exocytosis of cytoplasm and membrane parts through the releasing of *spherical* micro/nano-vesicles (SmnVs).
Aims: To investigate the morphological characteristics of the released vesicles and deduce detailed information on their dimensions at the nanometer level we employed advanced microscopes.
Methods: Samples were drawn and investigated progressively (day 0, 1, 10, 20, 30, 40, 42 and 50) from two units (CPDAM: citrate, phosphate, dextrose, adenine and mannitol), one LR-pRBCs and one nLR-pRBCs both stored at 2-6 ºC. The imaging techniques employed in this study were the conventional Optical Microscope (OM) and the advanced Atomic-Force Microscope (AFM) and Scanning-Electron Microscope (SEM) that both have extreme spatial resolution. These microscopes except for the overall morphological characteristics of the complete cell at the micrometer level (1 μm=10^{-6} m) can reveal specific details of the cell membrane at the nanometer level (1 nm=10^{-9} m). We stress that both LR-pRBCs and nLR-pRBCs were investigated in their *intact* form with only minimum processing, carefully avoiding mechanical stress (intense centrifugation) and or biochemical shock (washing with any kind of solution). Specifically, for the AFM measurements the smears were completely *intact*, while for the SEM investigations a thin metallic overlayer was unavoidably deposited to the otherwise *intact* smear.
Results: SmnVs, but most importantly *cylindrical* mnVs (CmnVs), were observed in both LR-pRBCs and nLR-pRBCs by means of AFM (upper Figure 1) and SEM (lower Figure 1). The CmnVs most commonly had spherical ends. The cylindrical part had length within 0.2-10.0 μm and diameter within 70-400 nm. Regarding the spherical ends of the CmnVs they had diameter in the range 100-700 nm. The CmnVs were detected even during the early stages of storage (day 1), but exhibited a pronounced increase (two orders of magnitude) with storage duration (threshold day 10).
Summary / Conclusion: The observation of CmnVs in pRBCs is reported here for the first time. This finding raises questions on the origin of the relative SmnVs that are only observed by means of scanning/transmission electron microscopy in samples produced after intense processing such as centrifugation, fixation etc. The incompatibility of the morphological and geometrical characteristics of the extended CmnVs with the RBCs and the lack of microscopy snapshots that prove the releasing of the former from the later are against the scenario of CmnVs direct releasing from RBCs. Extra studies are surely needed to clarify the origin of the CmnVs reported here and the possible relation with the SmnVs that are commonly reported in the literature.

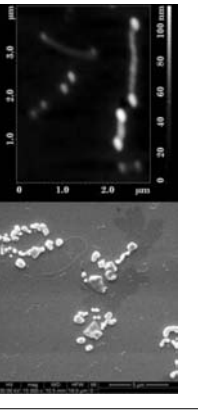

Figure 1.

P444

SUCCESSFUL STEM CELL RE-MOBILIZATION AND HARVEST IN PATIENTS WITH MULTIPLE MYELOMA RELAPSED AFTER A PREVIOUS MYELOABLATIVE AUTOLOGOUS TRANSPLANT.

F Zallio[1,*] A Baraldi[1],V Montefusco[2], F Cavallo[3], L Depaoli[4], P Minetto[5], G Catania[1], M Rapetti[6], G Gaidano[4], F Salvi[1], A Levis[1]
[1]Onco-hematology, Hematology Division, Alessandria, [2]Hematology Division, Milano, [3]Hematology Division, Torino, [4]Hematology Division, Novara, [5]Hematology Division, Genova, [6]Pharmaceutical Institution, Alessandria, Italy

Background: Background: Autologous stem cell transplantation (ASCT) still remains a necessary component of a therapeutic program in patients affected by multiple myeloma and younger than 65 years. However, in relapsed patients, despite the improvements reported with novel drug therapies, outcome remains not satisfactory. Recently it has been shown that a second ASCT represents a viable option in individuals with chemosensitive relapse after a first ASCT; however in a proportion of patients an adequate storage of PBSC had not been planned at diagnosis in order to ensure a second salvage transplantation. Melphalan (MEL) is traditionally considered the best anti-myeloma drug and furthermore it is extensively used at myeloablative doses (200 mg/sm) in the conditioning regimen; however pretreatment with high dose of melphalan is a known risk factor for poor mobilization of PBSC, because it can damage bone marrow microenvironment and stem cell hematopoiesis, finally impairing future attempts of mobilization rate.
Aims: Aims: Aim of this study was to analyze retrospectively whether there was the possibility to perform a stem cell mobilization in a relatively rare category of multiple myeloma patients, who have already undergone a first myeloablative ASCT and do have an indication for a second one.
Methods: Methods: A research was carried on in the database of five italian hematologic centres between 1998 and 2012 and 9 patients (median age 59 years) were found with those charactheristics, namely with a chemosensitive disease, prolonged remission after a prior autograft, exclusion from an allogeneic transplant for older age at relapse (4 patients), patient's refusal (2 patients) or inability to find a matched donor (3 patients). The recommended schedule for mobilization included: 1) intermediate doses of chemotherapy at day 0 (4 patients) followed by daily injection of G-CSF (10 mcg/kg) starting from day 5 or 2) daily injection of G-CSF (10 mcg/kg) for four consecutive days. Peripheral CD34+ blood monitoring was started from the fifth day of G-CSF and in case of low blood count of circulating CD34+ (< 20/mcl), a single injection of Plerixafor was planned in order to prevent a mobilization failure
Results: Results: All patients have a chemosensitive relapse after a previous ASCT performed with MEL 200 mg/sm as conditiong regimen. Median time of remission after first ASCT was 5 years (range 2-12). Median circulating CD34+ at the day of starting leukapheresis was 30/mcl (range 25-500 CD34+/mcl). The collection goal of at least 2×10^6 CD 34/kg was achieved in all patients (median yeld of 3×10^6 CD34+/kg, range 2-19). Allowing for the small number of patients, there were no differences in terms of number of circulating and harvest of CD34+ cells, except for the number of aphereses requested for patients mobilized with G-CSF only (median 2 aphereses), compared with the addition of Plerixafor (1 apheresis for all patients).
Summary / Conclusion: Conclusions: To date, there is a very limited number of reports about successful stem cell mobilization and harvest in patients with multiple myeloma who have undergone a previous ASCT. In our retrospective analysis, we demonstrate that: i. Melphalan administered as conditioning regimen at myeloablative doses is no longer to be considered a limiting factor for future stem cell re-mobilization in patients without CD34+ back-up and in whom there is the need for a second ASCT. ii. Addition of Plerixafor could provide an increase of circulating CD34+ in order to assure stem cell yield while maximizing the cost and time effectiveness.

P445

ALLOANTIBODY FORMATION IN PATIENTS WITH SICKLE CELL DISEASE

J Sins[1,2,*] S Zalpuri[3,4], M Cnossen[5], A Rijneveld[6], J Kerkhoffs[7], A van Meurs[8], Y de Rijke[9], M Peters[2], B Biemond[1], A van der Bom[3,10], K Fijnvandraat[2,11]
[1]Department of Hematology, [2]Department of Pediatric Hematology, Academic Medical Center, Amsterdam, [3]Sanquin Research, Center for Clinical Transfusion, [4]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, [5]Department of Pediatric Hematology and Oncology, Erasmus Medical Center-Sophia Children's Hospital, [6]Department of Hematology, Erasmus Medical Center, Rotterdam, [7]Department of Hematology, [8]Department of Pediatrics, Haga Hospital, the Hague, [9]Department of Clinical Chemistry, Erasmus Medical Center, Rotterdam, [10]Clinical Epidemiology, Leiden University Medical Center, Leiden, [11]Sanquin Blood Supply Foundation, Amsterdam, Netherlands

Background: Sickle cell disease (SCD) is a hereditary hemoglobinopathy, characterized by chronic anemia, recurrent pain and irreversible organ damage. Transfusion of red blood cells (RBC) is a common intervention to treat and prevent these complications. However, frequent transfusions may lead to erythrocyte alloimmunization, thereby complicating donor matching procedures and posing patients at risk for hemolytic transfusion reactions.
Aims: The primary aim of this study is to evaluate the cumulative incidence of first alloantibody formation in a Dutch cohort of transfused SCD patients, and to compare this with a general Dutch RBC-transfused population. In addition, potential clinical determinants of alloimmunization and the effectiveness of extended RBC matching protocols in reducing the incidence of alloantibody formation in SCD will be assessed.
Methods: We conducted a retrospective cohort study and collected data on SCD patients (genotypes HbSS, HbSC, $HbS\beta^0$ and $HbS\beta^+$ thalassemia), diagnosed in the Academic Medical Center, Erasmus Medical Center and Haga Hospital in the Netherlands, that received non-extended matched (ABO, RhD) RBC transfusions between 1984-2004 and extended matched (at least ABO, Rhesus phenotype, Kell) RBC transfusions between 2004-2011.
In addition, we compared this population with a general population of 3 042 patients that received non-extended matched (ABO, RhD) RBC transfusions between 2005-2009 in the Leiden University Medical Center (Zalpuri *et al*. 2012). Cohorts were not matched for ethnicity. Alloimmunization incidences and potential associations with clinical determinants were respectively estimated by Kaplan-Meier and Cox-regression analyses.
Results: A total of 294 SCD patients received 7 961 RBC units. Alloantibody formation occurred in 52 (17.7 %) patients. The cumulative incidence of alloimmunization was 9% after 5 RBC units, 17% after 10, 24% after 20 and 34% after 40 RBC units. Multivariate analysis, correcting for the number of transfusions received, demonstrated a significantly increased risk of alloantibody formation in our SCD cohort when compared to a general population of transfused patients (HR 7.5 (95% CI: 5.06-11.13), where the cumulative incidence of alloimmunization was 1.1% after$_5$, 2.4% after 10, 3.4% after 20 and 6.5% after 40 RBC units. No association was found between alloantibody formation and clinical determinants such as gender, SCD-phenotype or ethnicity. However, a significant reduction in alloimmunization was observed in SCD patients that received their first transfusion from the year 2004 onwards, after preventive matching for Rhesus phenotype and Kell was introduced for SCD patients (HR 0.51 (95% CI: 0.258-0.989). (Figure 1)
Summary / Conclusion: The overall rate of first RBC alloantibody formation in our SCD cohort was 17.7% and the risk of alloimmunization increased substantially with an increasing number of RBC transfusions. A unique comparison with a general cohort of Dutch transfused patients demonstrates a significantly higher risk of alloantibody formation in SCD, acknowledging earlier findings. Partially, this can probably be explained by the differences in RBC antigens between patients of African descent and the predominantly Caucasian donors. Besides the number of RBC units, no other clinical risk factors for alloimmunization in SCD could be identified. The effectiveness of extended RBC matching protocols in the prevention of alloimmunization for chronically transfused patients in the participating centers was confirmed.

P446

THE ROLE OF BLOOD TRANSFUSION IN BETA-THALASSEMIA: AN EX VIVO STUDY OF HEMOSTATIC PARAMETERS

A Trinchero[1,*] M Marchetti[2], E Celega[2], C Balduini[1], A Falanga[2]
[1]Università degli Studi di Pavia, Pavia, [2]Ospedale Papa Giovanni XXIII, Bergamo, Italy

Background: Blood transfusion is one of the main therapeutic strategy for ß-thalassemia. Splenectomy is often required. In the last decades clinical trials report on a high rate of thromboembolic events, particularly in ß-thalassemia intermedia and in splenectomized patients. Regular transfusions seem to significantly reduce the relative risk of thrombosis.
Aims: To describe the post-transfusional modifications of hemostatic parameters in ß-thalassemia.

Methods: Consecutive patients followed-up at the Center of Immunohematology and Transfusion Medicine of Bergamo were screened. Inclusion criteria: ß-thalassemia requiring regular blood transfusions and acquisition of written informed consent. Exclusion criteria: ongoing therapy with anticoagulant or antiplatelet drugs. Seven thalassemia carriers (trait) and nine healthy donors were enrolled as a control group. Blood samples were obtained before the monthly scheduled blood transfusion and 60 minutes post-transfusion. The following tests were performed: hemocromocytometry by fully automated hematology analyzer XE-2100 (Sysmex); platelet function by Multiplate® platelet function analyzer with Adenosine DiPhosphate, arachidonic acid (ASPI), COLLagen or Thrombin Receptor Activating Peptide 6; flow cytometry to detect platelet activation (as a percentage of cells expressing surface P-Selectin, Tissue Factor, and/or Fibrinogen) by FACS Canto™ II (BD Biosciences) before and after ADP-stimulation. In addition, thrombin generation (TG) was performed by calibrated automated thrombography (CAT assay, Thrombinoscope™) in platelet-rich plasma spiked with 1 pM Tissue Factor or ADP (1.6 and 8.3 µM). TG results were described in terms of lag-time, peak height, time-to-peak and endogenous thrombin potential.
Results: Nine ß-thalassemia patients were enrolled from May to August 2012 (mean age 28.9, age range 5-48, ß-thalassemia intermedia 33%, splenectomy 44%, prior history of thrombosis 22%). Before blood transfusion, splenectomized patients had a higher increase of platelet surface TF expression upon ADP-stimulation (by flow cytometry) compared to healthy controls (P<0.05). In the same patients the platelet function was significantly higher than healthy donors (ADP P<0.01, COLL P<0.001, TRAP P<0.05, ASPI P<0.001), thalassemic trait subjects (ADP P<0.05, COLL P<0.01, ASPI P<0.05) and non-splenectomized patients (ADP P<0.05, COLL P<0.001). In splenectomized patients we observed a decrease (not statistically significant) in platelet aggregation capacity to all agonists after blood transfusion. In the same group of patients, the lag-time and time-to-peak of TG performed in the presence of TF or ADP were significantly shorter than in controls both before (lag time TF P<0.01, ADP P<0.05; time to peak TF P<0.001, ADP P<0.01) and after blood transfusion (lag time TF P<0.05, ADP P<0.05; time to peak TF P<0.05, ADP P<0.05). Differently, the hemostatic profile of non-splenectomized patients was similar to controls.
Summary / Conclusion: In routinely transfused ß-thalassemia patients, splenectomy is associated with a prothrombotic shift of hemostatic parameters (i.e. thrombocytosis, enhanced platelet reactivity and function, and earlier thrombin generation), which are not influenced on the short term by blood transfusions.

P447

AN EVALUATION OF PREDICTIVE SCORES FOR MASSIVE TRANSFUSION IN A TRAUMA COHORT CLINICALLY JUDGED TO BE AT HIGH RISK OF MAJOR HAEMORRHAGE

R Gregg[1,*] T Boutefnouchet[2], J Steadman[1], J Tidman[1], H Doughty[3]
[1]Haematology, [2]Trauma & Orthopaedics, University Hospital Birmingham, [3]Haematology, NHS Blood and Transplant, Birmingham, United Kingdom

Background: Major Transfusion Protocols (MTPs) provide a timely and co-ordinated response to traumatic Major Haemorrhage (MH). MTPs aim to prevent coagulopathy and must be activated during the early stages of resuscitation. The decision to activate an MTP is complex. Although predictive models for Massive Transfusion (MT) exist they are not widely employed. A senior clinician's judgment remains the most common trigger for MTP activation and de-escalation. Under-recognition of MH has grave consequences, however use of MTP in non-massive haemorrhage is associated with adverse outcomes. One pragmatic solution to balance these opposing risks is to escalate transfusion support early, but promptly de-escalate when the MTP is not required.
Aims: We sought to evaluate whether predictive scores for MT can determine the likelihood of progressing to an advanced phase of a MTP (> 6 red cell concentrates) in patients judged to be at risk of MH and already initiated on a MTP.
Methods: This work was undertaken at a single academic UK major trauma centre. The department's MTP is ratio-based and activated at the discretion of a senior trauma clinician. MTP pack 1 consists of 4 units of red cell concentrate (RCC) and 4 units of fresh frozen plasma (thawed from frozen). Prior to MTP pack 1 arrival, 2 units of group O RhD-ve RCC are available in the emergency department for immediate transfusion. MTP pack 2 and subsequent packs contain an additional adult dose of platelets. Data about blood component usage were prospectively recorded during every MTP activation. To derive the Trauma Associated Severe Haemorrhage (TASH) score and Assessment of Blood Consumption (ABC) score for each patient, data were retrospectively collected from the patient's electronic record, written notes, laboratory system and the regional trauma audit research network. Sensitivity, specificity and receiver operating characteristic (ROC) analysis were performed by defining a positive outcome as use of > 6 RCC units. This figure was chosen as it marked progression to an advanced stage of the MTP i.e. to MTP pack 2.
Results: A total of 118 trauma MTP activations were reviewed. The mean age of trauma cases was 40.8 years, 73% were male. The mean injury severity score was 27. Blunt injury accounted for 81% of cases, the remainder (19%) were due to penetrating trauma. The ABC and TASH scores were strongly associated with the total number of RCC transfused. Linear regression analysis confirmed that both the TASH score (R^2=0.63, P=< 0.0001) and ABC score (R^2=0.28, P=0.004) remained predictive of total RCC usage. A TASH score of ≥7 provided a sensitivity of 90% for progression to MTP pack two with a specificity of 67%. The TASH score had an area under ROC (AUROC) of 0.88 in our cohort (Figure 1). An ABC score of ≥2 had a sensitivity of 25% with a specificity was 96% for the same outcome. The AUROC was 0.8 for ABC.
Summary / Conclusion: We have demonstrated that both the TASH and ABC scores retain an association with the total volume of RCC transfused in a cohort of trauma patients at high risk of MH. The TASH AUROC analysis demonstrated that this model may be useful to predict the need to progress to MTP pack two (>6 RCC units) and beyond. Our data suggest that, in addition to MTP activation, the TASH score can objectively guide clinical decisions about continuation of a major transfusion protocol.

TRANSCRIPTIONAL PROFILING OF HUMAN ERYTHROID PROGENITORS FROM G-CSF MOBILIZED AND NONMOBILIZED PERIPHERAL BLOOD

M Diklić[1], T Subotički[2], B Beleslin-Čokić[3], G Jovčić[1], V Čokić[1,*]
[1]Laboratory of experimental hematology, [2]Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, Belgrade, Serbia

Background: Progenitor cells from a variety of sources including bone marrow, cord blood, and peripheral blood (PB) have been used for transplantation. Granulocyte colony-stimulating factor (G-CSF) mobilized PB (mPB) progenitor cells have been successfully used for both autologous and allogenetic transplants.
Aims: The functional and genomic characterization of primitive and more mature populations of mPB can be very useful in examining the role of these progenitors in engraftment following transplantation.
Methods: We correlated gene expression patterns of highly enriched steady-state PB- and mPB-CD34$^+$ cells by cDNA array technology, to identify molecular causes underlying the functional differences during *in vitro* erythroid differentiation. To better understand the transcriptional program that accompanies erythroid differentiation, we performed oligonucleotide microarray analysis of erythroid CD71$^+$ progenitors harvested after 6 days of culture.
Results: The total gene expression is almost doubled in mPB-derived (4417) compared to PB-derived erythroid progenitors (2246). The genes only present in PB-derived erythroid cells are NUP85, NOP10, SLC30A5, and CHD1L genes, while only present in mPB-derived erythroid cells are ESRRB, DTX4, and KIT genes. Comparative analysis of transcript levels shows differential expression of 88 genes between mPB- and PB-derived erythroid progenitors. We identify 13 genes (CRTC3, VIM, SERPINH1) that are downregulated in both pools of cells; per 7 genes (TM9SF2, TCP1, TGIF2) are downregulated in PB- and mPB-derived cells respectively, while 61 genes (ERAF, MTSS1, VAMP7) are upregulated in both pools of cells. Using Ingenuity pathways analysis we describe the network of genes linked to cancer, hematological diseases, cell growth and proliferation. The G-CSF receptors CSF2RA and CSF2RB are linked to STAT3 transcription factor influenced by upregulated erythroid-specific ALAS2, CLC and GATA2 genes preferentially more expressed in mPB-derived erythroid progenitors. GATA2 and ALAS2 transcription factors are linked to NUDC and GTF3A genes upregulated in PB-derived erythroid progenitors.
Summary / Conclusion: As expected, the G-CSF stimulated network has predominantly increased total gene expression in mPB-derived erythroid progenitors. This report provides an extensive transcriptional profile of erythroid progenitors and leads to a better understanding of diversity among the hematopoietic progenitor sources.

P449

IMPACT OF HLA ANTIBODY LEVELS ON PLATELET TRANSFUSION REFRACTORINESS

E Juvonen[1,*] T Linjama[1], R Niittyvuopio[2], J Tuimala[1], M Pyörälä[3], H Rintala[4], J Rimpiläinen[5], M Kauppila[6], J Peräsaari[1]
[1]Finnish Red Cross Blood Service, [2]Helsinki University Central Hospital, Helsinki, [3]Kuopio University Hospital, Kuopio, [4]Tampere University Hospital, Tampere, [5]Oulu University Hospital, Oulu, [6]Turku University Hospital, Turku, Finland

Background: Poor post-transfusion platelet increment, PPI, (post-transfusion platelet count minus pre-transfusion platelet count) may be fatal in high dose treatments of malignant disorders. In most cases the poor increment is secondary to non-immune causes such as infections, splenomegaly or medications. Immunologically mediated refractoriness caused by alloantibodies against HLA-A and –B locus antigens is usually induced by previous pregnancies or non-leukocyte-reduced transfusions. In these cases the availability of HLA-matched platelets is crucial.
Aims: The aim of this study was to analyse the impact of the HLA class I antibodies on PPI.
Methods: We have analysed PPI of 270 platelet transfusions from HLA-identical or selectively mismatched donors of 40 adult patients with hematological disorder (22 AML, 6 MDS or MDS-AML, 3 ALL, 3 MM, 1 NHL, 5 SAA). 31 (78 %) of the patients were women and 9 (22%) were men. Since 2003, all blood components in Finland have been leukoreduced with filtration. One platelet transfusion comprises of 2 apheresis products, both equivalent to four units of pooled buffy coat platelet concentrates. The median number of platelet transfusions per patient was5, range 1-23. All transfusions were prophylactic. The presence of HLA class I antibodies was determined by Luminex-based IgG single-antigen-bead assay. Donors were selected with HLAMatchmaker computer program and the selection was modified with the HLA antibody profile of the patient. ABO incompatibility, an infection at the time of the transfusion, and body weight were also included in the analysis.
Results: The median pre-transfusion platelet count was $15x10^9$/l, range 1–86. PPI at one hour was available in 92 transfusions, and at 24 hours in 253 transfusions. The median PPI at one hour was $40x10^9$/L (range -16–91) and the median PPI at 24 hours was $28x10^9$/L (-61–123). The 24 h PPI was >$20x10^9$/L in 168 (65%), >$30x10^9$/L in 116 (49%) and >$40x10^9$/L in 78 (31%) out of 253 transfusions. In 103 transfusions (38 %) donors were HLA-compatible. They were either identical (54 cases) or they had no antigens against which the patent showed antibodies (49 cases). In 167 (62%) transfusions donor specific antibodies were present with the median level of 2026 mean fluorescence intensity, MIF (range 299-29203). Impact of the donor specific HLA antibody levels on PPI as an independent risk factor was highly significant (P=0.001). Antibody levels less than 1000 MIF had no negative effect on PPI. Other independent risk factors were the presence of an infection at the time of the transfusion (P=0.01) and the age of the product in days (P=0.002).
Summary / Conclusion: Simple measures, such as PPI, for platelet refractoriness are appropriate in everyday clinical practice. The availability of HLA identical platelets may be limited for patients with class I HLA alloantibodies. The selection of incompatible platelet donors using HLAMatchmaker computer program supported with the HLA antibody profile of the patient may improve PPI. In these cases, good co-operation between clinicians and blood service consultants is mandatory.

P450

MATERNAL AND FETAL OUTCOMES IN PREGNANT PATIENTS WITH SICKLE CELL DISEASE WHO APPLIED PROPHYLACTIC RED BLOOD CELL EXCHANGE PROCEDURE

S Asma [1,2], I Kozanoglu[3,4,*] E Tarım[5], M Kasar[6], N Turgut[6], M Yeral[6], C Boga[6], H Ozdogu[6]
[1]Hematology, Baskent University Adana Adult Bone Marrow Transplantation Center Clinical Unit, Adana, [2] Department of Family Medicine, Baskent University Medical Faculty, Ankara, [3]Physiology, Baskent University MedicalFaculty, Ankara, [4]Hematology and Apheresis Unit, Baskent University Adana Adult Bone Marrow Transplantation Center, Adana, [5]Obstetrics and Gynecology, Baskent University Medical Faculty , Ankara, [6]Hematology and Apheresis Unit, Baskent University Adana Adult Bone Marrow Transplantation Center Clinical Unit, Adana, Turkey

Background: Sickle cell disease (SCD) is one of the most common inherited diseases worldwide and is associated with anaemia and intermittent severe pain. Pregnant women who are affected have increased maternal and fetal mortality and morbidity. Maternal risks include painful prepartum and postpartum crises, urinary tract infections, pulmonary complications, anemia, gestational hypertension, pre-eclampsia or eclampsia, and death. Fetal complications include preterm birth and associated risks, intrauterine growth restriction, fetal distress during labor, and a high rate of perinatal mortality.
Aims: This retrospective study examines the pregnancy outcomes of SCD patients who underwent red blood cell exchange (RBCX) procedures.
Methods: A total of 45 pregnants underwent apheresis prophylaxis for mentioned complications. Exchange procedures were performed in 20 patients for prophlaxis of mentioned complications. Four patients underwent RBCX for treatment of vasoocclusive crisis. Prophylactic RBCX procedures were performed in the second or third trimester of pregnancy and before the caesarean.Two different continuous flow apheresis systems (Cobe Spectra V. 7.0, and Spectra Optia V. 7, Terumo BCT) were used to exchange 60–70% of the patients' red cells with crossmatched donor red blood cells of the same blood type with an aim of reducing the hemoglobin S level to less than 30%. Leukofiltered red cell suspensions preserved for 1–7 days by citrate-phosphate-dextrose and with a hematocrit level of about 75% were used. The target hematocrit levels were determined according to the steady-state hematocrit levels of the patients who were regularly examined as outpatients.
Results: No women and no babies died. HBS values were decreased to <30% and the hematocrit levels were increased, allowing for perfusion of the placenta as determined by Doppler USG. There was no crisis during pregnancy, among the SCD patients who underwent prophylactic RBCX procedures. After the delivery, the 5th minute apgar scores were 9.1±1.2.
Summary / Conclusion: This study shows that prophylactic RBCX during pergnancy seems to be a feasible and safe procedure for prevention of hemoglobin S associated complications in patients with SCD. Given the decrease in transfusion risks, RBCX is worthy of further study in future trials.

P451

PROSPECTIVE SCREENING FOR ANTI-PLATELET ANTIBODIES AND IMMUNE PLATELET REFRACTORINESS IN PATIENTS DIAGNOSED WITH ACUTE MYELOID LEUKEMIA

L Bonstein[1,*] R Lauterbach[1], N Haddad[2]
[1]Blood Bank and platelet Immunology Laboratory, [2]hematology institute, Rambam medical center, Haifa, Israel

Background: Acute myeloid leukemia (AML) patients are treated with intensive chemotherapeutic protocols, suffer from *protracted* pancytopenias and need prolonged transfusion support. Long-term transfusion dependency exposes these patients to allo-immunization to both leukocyte (HLA) and platelet (HPA) antigens, expressed by immune platelet transfusion refractoriness, a major risk factor for bleeding-associated morbidity and mortality. The published incidence of platelet refractoriness in patients with hematologic malignancies, ranges between 7% and 34%. The frequency of platelet transfusion failure, at least once, in multiply transfused patients is reported to reach 70%. There is no data regarding the incidence of platelet refractoriness, whether immune or non immune, in the Israeli population.
Aims: To estimate the prevalence of platelet transfusion refractoriness (both immune and non-immune) among AML patients treated according to defined treatment protocols, to evaluate the incidence and "timing" of alloimmunization during treatment protocol and to evaluate weekly antibody screening as a tool to predict the risk for immune transfusion refractoriness.
Methods: Newly diagnosed AML patients were screened for the presence of anti-platelet antibodies and anti-HLA antibodies using flow cytometry. Antibodies were identified by the MAIPA assay. All patients were followed using weekly antibody screening. Clinical parameters of patients were consecutively registered. Patients received platelet transfusions according to the local transfusion policy: random or single donor platelets with continuous PLT increment monitoring. Patients' blood counts and platelet transfusion requirement were followed weekly, platelet refractoriness was determined when no increment was documented on two consecutive platelet transfusions.
Results: 64 newly diagnosed AML patients (35 males and 29 females) with age ranging between 25-60 years of various ethnic origins were included. Platelet refractoriness was found in 30 (47%) patients (10 males and 20 females). 26 patients (41%) developed new anti HLA and/or anti HPA antibodies, 21/26 (81%) were females. Immune platelet refractoriness was defined in 22/30 (73%) refractory patients (18 females and 4 males). 22/26 (85%) patients with antibodies developed refractoriness, 10/22 had anti HPA with (8) or without (2) anti HLA antibodies. 12/22 had only anti HLA antibodies. Average time to antibody production was 20 days from the beginning of treatment protocol.
Summary / Conclusion: although all AML patients receive irradiated and leukoreduced blood products at our centre, the prevalence of platelet refractoriness, specifically immune refractoriness, was higher than expected according to published data. Anti HPA antibodies were strongly correlated with the appearance of immune platelet refractoriness. Altogether our results demonstrate that immune platelet refractoriness is in a larger extent than previously described. These interesting results need to be confirmed in a larger cohort.

P452

ANCESTIM VERSUS PLERIXAFOR FOR THE COLLECTION OF PERIPHERAL BLOOD STEM CELLS

A Tempescul[1], C Tripogney[2], J Ianotto[1], P Delepine[2], R Le Calloch[1,*] F Quivoron[2], E Hardy[2], C Berthou[1]
[1]Clinical Hematology, Teaching Hospital Brest, [2]Site de Brest, EFS Bretagne, Brest, France

Background: Autologous peripheral blood stem cells transplantation (APBSCT) has always had an important indication for patients with lymphoma or myeloma. The essential condition for this procedure is the existence of a sufficient graft, at least $2x10^6$ CD34 per kg of patient weight, according to the recommendations of the EBMT. For patients defined as 'poor mobilizers', two drugs with different mechanisms of action have been used to optimize the collection of PBSC.
Aims: We conducted a retrospective, monocentric, cohort study, to characterize and compare the effectiveness of ancestim and plerixafor, associated to G-CSF during mobilization of PBSC.
Methods: Between 2002 and 2011 we identified 48 patients who failed mobilization after classic stimulation with G-CSF. Among them, 32 patients received stimulation, in steady-state situation, by ancestim+GCSF and 16 patients with plerixafor+GCSF. We compared the successful rate of harvest, the total amount of CD34 + cells collected and the number of aphaeresis necessary to achieve the target.
Results: There were no significant differences in the initial characteristics of the patients between the two groups. The successful rate was 43% (14/32patients) for patients stimulated by ancestim+GCSF and 68% (11/16 patients) for patients with plerixafor+GCSF (P-0.0006). There were no statistically significant differences between the two groups of patients for the average number of CD34 + cells collected: $3.45x10^6$/kg for ancestim and $3.05x10^6$/kg for plerixafor (p-0.37) or the mean number of aphaeresis necessary to achieve the target 3.89 for ancestim and 3.28 for plerixafor (p-0.59). Similar results were observed in subgroups of patients according to the type of disease: multiple myeloma and lymphoma.
Summary / Conclusion: The two molecules have different mechanisms of action: ancestim is an agonist of c-kit (CD117), which allow a stimulation of cell proliferation and plerixafor is an reversible and selective chemokine receptor (CXCR4) antagonist which blocks binding of its ligand (SDF-1), enabling a break in the connection between the stem cells and their microenvironment. In situation of clinical failure to first mobilization, for PBSC harvest in view of ABSCT, in patients treated for lymphoma or myeloma, plerixafor seems superior to ancestim regarding the successful rate of harvest. By cons, there is no significant difference between the number of aphaeresis necessary to achieve the target or the number of CD34+ cells harvested.

P453

BONE MARROW ASPIRATE MORPHOLOGIC, IMMUNOPHENOTYPIC AND CYTOGENETIC EVALUATION IN RELATED DONORS PRIOR TO HEMATOPOIETIC STEM CELL DONATION

R Milani[1,*] A Palini[2], B Migliavacca[1], G Torriani[1], P Ronchi[3], L Bellio[3], M Coppola[3], S Gattillo[3], L Malabarba[3], F Ciceri[4]
[1]Hematology Cytometry, [2]Fractal, [3]SIMT, [4]Hematology, OSR, Milano, Italy

Background: The current screening for eligibility of related marrow donor volunteers comprises a complete clinical check-up, personal and familiar history, a blood cell count, biochemical analysis and serological assays.
Aims: In our center, a potentially eligible donor is requested to perform an hematopoiesis evaluation by bone marrow aspirate. The donor who provides consent undergoes a bone marrow aspiration for morphological, cytogenetic and flow cytometric evaluation.
Methods: From April 2012 to February 2013, we analyzed bone marrow samples from 34 related donor candidates. Median age, at time of evaluation, was 44 years (range 18-72) and the male:female ratio was 50:50. Morphologic evaluation included staining with May Grunwald-Giemsa, PAS and PERLS. Cytogenetic analysis was performed using conventional G-banding karyotyping. Flow cytometric analysis was performed using a whole blood lysis technique and a panel of directly conjugated antibodies. Five-color flow cytometry was performed using an FC500 cytometer (Beckman/Coulter). Data, collected in list mode, were analyzed with FCS Express (DeNovo software). An immunological gating strategy utilizing CD45 versus side scatter was used to select the populations of granulocytes ($CD45^{bright}SSC^{high}$) and lymphocytes ($CD45^{bright}SSC^{low}$). CD2 and CD19 were used to identify the T and B lymphocyte subpopulations. Myeloblasts were primarily identified and gated as $CD45^{dim}SSC^{low}$ and further qualified and enumerated with CD34, CD117 and the myeloid marker CD33. Within the CD34+ cell compartment, the myeloblast related cluster (CD33+CD10-) and the B-progenitor related cluster (CD33-CD10+) were identified. In order to apply the low-grade-MDS score (Haematologica 2012; 97(8)), we considered the lymphocyte to myeloblast CD45 MFI ratio and the granulocyte to lymphocyte side scatter (SSC) peak channel ratio. The staining patterns of CD11b versus CD16, CD13 versus CD16 and CD11b versus CD64 were used to reveal abnormal antigen expression in the granulocytic population.
Results: All evaluated donors had normal a karyotype. Six subjects showed morphologic dysplasia of one, two or three lineages and 4 revealed an abnormal antigen expression of the granulocytic population. Table 1 describes the characteristics of the six donors with detected abnormalities. The median age of donors showing bone marrow dysplasia was 51 years and no alterations of blood cell count parameters were found. The history and the clinical check-up excluded co-morbidities potentially responsible of the morphological and cytometric changes observed.
Summary / Conclusion: These donors will be followed up with future checks. We believe that bone marrow analysis should be considered for a complete evaluation of eligibility of related donors prior to hematopoietic stem cell donation.

Table 1.

donor	Age (year)	Morphology (No. of observed dysplastic lineages)	CD117+(% of CD45+)	CD34+(% of CD45+)	abnormal antigen expression in granulocytic population	FCM score for low-risk MDS
TB	65	3	1.4	1.57	no	0
AG	29	2	1.5	2.1	yes	0
BO	44	1	1.5	1.37	no	0
AM	64	2	0.4	1.67	yes	0
DC	56	3	1.5	1.55	yes	0
DM	46	2	1.8	1.65	yes	0

P454

THE USE OF PREOPERATIVE ERYTHROPOIESIS-STIMULATING AGENTS (ESAS) IN PATIENTS WHO UNDERWENT KNEE OR HIP ARTHROPLASTY

G Alotaibi[1,*] K Alsaleh[2], H Almodaimegh[3], A Aleem[1], T Kouroukis[4]
[1]Medicne, [2]Medicine, King Saud University, [3]Pharmacy, King Saud Bin Abdulaziz University for Medical Sciences, Riyadh, Saudi Arabia, [4]Medicne, McMaster University, Ontario, Canada

Background: Erythropoiesis-stimulating agents (ESAs) havebeen used preoperatively in orthopedic patients to reduce the need for allogeneic blood transfusion. However, their use for this indication is still not widely practiced.
Aims: The purpose of this review is to evaluate the efficacy of preoperative administration of ESAs on hemoglobin level at discharge and frequency of allogeneic blood transfusion in patients undergoing hip or knee surgery.
Methods: This is a systematic review of comparative randomized clinical trials that compared preoperative ESAs to other interventions or placebo in reducing the need for allogeneic transfusions and increase in hemoglobin levels at discharge.
Results: Pooled results of 26 trials with3,560 participants showed that the use of preoperative ESAs significantly reduced the need for allogeneic blood in patients undergoing hip or knee surgery [Relative Risk (RR):0.48, 95% CI: 0.38 to 0.60, P<0.00001)]. Hemoglobin mean difference between ESA and control groups was 7.16 (g/L) [95% confidence interval (CI)of 4.73 to 9.59, P=0.00001]. There was no difference in the risk of developing venous-thromboembolism between ESA group and the control groups [Risk Difference (RD): 0, 95 % CI: -1%>2%, P= 0.95; I^2= 0%].
Summary / Conclusion: ESAs offer an alternative blood conservation method to avoid allogeneic blood transfusion in patients undergoing hip or knee surgery.

P455

THE EFFICACY OF IMAGE MONITORING OF OPERATING ROOMS IN TRANSFUSION MEDICINE

H Furumaki[1,*] C Yamada[1], H Shibata[1], S Nagai[1], K Ishizuka[1], H Fujihara[1], H Watanabe[1], A Asahina[1], A Takeshita[1]
[1]Transfusion and Cell Therapy, Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: Communication between operating rooms and the transfusion unit is important to provide safe and appropriate transfusions, especially in cases with emergency and mass bleeding. However, it was difficult for the transfusion unit to understand real-time information in operating rooms only by an interphone or an intranet transfusion management system.
Aims: The efficacy of image monitoring of operations has been reported in various situations. Recently, we placed monitors on the central board of the

transfusion unit, and linked it to each operating room. We could understand the perioperative needs by integration of image, voice communication and blood transfusion management system. Here, we analyzed the efficacy of this system, and discuss its importance in transfusion medicine.
Methods: Two 40-inch screen displays (Panasonic, Tokyo, Japan) linked to 11 operating rooms, as well as to the preparation and recovery rooms, were placed on the central board of the transfusion unit in January 2010. Each screen of the monitors can be divided into 16 sections, and each section can be enlarged to a full-size screen. We analyzed the amounts of blood ordered, blood used and blood returned to the transfusion unit and compared them during the 3-year periods before and after adoption of the image monitoring system.We also analyzed the amount and frequency of expired blood after surgeons had ordered blood in the preoperative period. Statistical analyses were performed using chi-square test or Student's t-test (SAS, Tokyo, Japan). All statistical analyses were two-tailed with a significance level of 0.05.
Results: Among all operations, the number of cases with expired red blood concentrates (RCC) significantly decreased from 17 cases to 2 cases (P<0.001); the amount of expired RCC decreased from 57 units to 3 units (P<0.001); and the frequency of expiration decreased from 0.73% to 0.05% (P<0.001). In cardiovascular operations in which 10 units or more of RCC were used, the amount of RCC, that was requested initially in the preoperative period, was 7.5±2.2 (mean±SD) units and 6.8±2.4 units before and after adoption of the image monitoring system, respectively, showing a significant reduction (P=0.02). The number of cases in which more than 30 units of RCC were requested initially, decreased from 24 cases (9.1%) to 1 case (1.7%) (P=0.03). The amount of blood that was requested in the perioperative period and the amount was returned to the transfusion unit significantly decreased (P=0.03 and P<0.001, respectively). The amount of expired blood by mishandling also decreased. The serious deficiency of blood in the transfusion unit was alleviated. All of the doctors realized the importance of image monitoring in this area.
Summary / Conclusion: The efficacy of an image monitoring system, which was linked to the operating rooms, was analyzed. It in combination with the existing communication procedure was effective in improving transfusion practice. It increased the safety of transfusion, and decreased the amount of expired blood. It is useful to establish a good partnership between clinicians and the transfusion unit.

P456

FAILURE ON MAINTAINING HAEMOGLOBIN LEVEL AFTER TRANSFUSION IN TRANSFUSION DEPENDENT THALASSEMIA PATIENTS RELATED TO ERYTHROCYTE ALLOANTIBODY AND AUTOANTIBODY PRODUCTION: PROPORTION AND REL

A Kurniawan[1,*] D Atmakusuma[2], L Sukrisman[2], K Harimurti[3]
[1]Internal Medicine, University of Pelita harapan / University of Indonesia, [2]Hematology of Internal Medicine, [3]Internal Medicine, University of Indonesia, Jakarta, Indonesia

Background: In transfusion dependent thalassemia patients who has got repeated transfusion for a period of time, the haemoglobin level after transfusion could not be maintained appropriately to be expected. The production of erythroyte alloantibody and autoantibody in transfusion dependent thalassemia patients has been reported before. These antibodies were probable related to the failure on maintaning haemoglobin level after transfusion.
Aims: To find related factors of failure on maitaining haemoglobin level after transfusion in adult transfusion dependent thalassemia patients related to erythroyte alloantibody and autoantibody production.
Methods: Cross sectional study of adult transfusion dependent thalassemia patient without others autoimune disease at Haematology and Medical Oncology outpatient clinic in Cipto Mangunkusumo hospital from July to September 2012 was done. The specimen was subjected to erythroyte alloantibody and autoantibody evaluation by column gel agglutination technique. Eleven cell reagent panel were used in screening and identification of alloantibody and autoantibody respectively. Positive alloantibody is defined as positivity of indirect antiglobulin test and positive autoantibody is defined as positivity of direct antiglobulin test. Statistic analysis between erythrocyte alloantibody and autoantibody positivity and sex, type of rhesus, feritin level, type of iron chelation, and alloantibody were done.
Results: From 88 subjects, there were 37,5% thalassemia patients that did not maintain haemoglobin level after transfusion. From 33 of those subjects, there were 78,6% subjects with alloantibody and 72,7% subjects with autoantibody. From 24 patients with autoantibody, there were 25% subjects with severe hemolytic anemia that clinically significant. Positif alloantibodi related to autoantibody production (P≤0,000). Positive alloantibody [odds ratio (OR) = 26,32; P≤0,000], positive autoantibody (OR = 11,99; P≤0.011), and feritin level ≥3000 ng/mL (OR = 6,36;P≤0,042) related to failure on maintaining haemoglobin level.
Summary / Conclusion: The proportion of failure on maintaining haemoglobin level in adult thalassemia patients were 37,5%. The proportion alloantibody and autoantibody production in adult thalassemia patients that failure on maintaining haemoglobin level were 78,6% and 72,7% respectively. Related factors of those were positive alloantibody and autoantibody, and feritin level ≥3000 ng/mL. Positive alloantibody related to autoantibody production.

P457

EFFECT OF USING LEUKOSTOP FILTER DURING BLOOD TRANSFUSION ON PULMONARY FUNCTIONS IN PATIENTS WITH THALASSEMIA MAJOR

A Shoeib[1], I Ragab[1,*] T Beshry[1], A Adel-Gawad[1]
[1]Pediatrics, Ain Shams University, Cairo, Egypt

Background: Although pulmonary dysfunction is not the most significant clinical manifestation of patients with β-thalassemia major, a certain reduction in pulmonary volumes has frequently been reported.Its etiology is multifaceted including iron deposition, free radicals production and a leucocyte inflammatory reaction could be a contributing factor. In developing countries, the blood is not routinely filtered, and the use of bedside filters is limited to patients with leucocyte mediated complications.
Aims: The aim of this study was to determine the prevalence and patterns of lung dysfunction among patients with BTM after the application of the Leukostop filter during transfusion for a period of 6 months.
Methods: The study included 30 patients with transfusion dependent BTM sequentially recruited from the Hematology Clinic, Children's Hospital, Ain Shams University. They were 12 (40%) males and 18 (60%) females, their ages ranged between (7-17) years with a mean 12.4±3.2 years. They were sub divided into 2 groups according to their use of Leuckocyte filter. Group 1: included 15 patients with BTM were allocated to use the Leuckocyte filter before each blood transfusion for 6 months and group 2 (Control Group) included 15 patients with BTM using non Leuckocyte filtered blood. Patients with history of airway disease and smokerswere excluded. They were subjected to history taking and revision of hospital files recording age, sex, age at diagnosis, transfusion dependency period and frequency, previous transfusion reactions and history of Splenectomy. Chest X-Ray was done for each patient before the use of the Leuckocyte filter and after its use for 6 months .Pulmonary Function tests using spirometry was done at baseline and after 6 month-follow up. Forced expiratory maneuver was used for calculation of forced vital capacity (FVC), forced expiratory volume in one second (FEV1) , FEV1/FVC ratio(%), functional residual capacity (FRC), forced vital capacity (FVC), residual volume (RV) and Total lung capacity (TLC); then impulse oscillometry technique for assessment of small airway behavior was used.
Results: Group 1 (using leukostop) showed no significant difference at baseline evaluation in distribution pulmonary abnormalities with control group; the distribution of pulmonary disease significantly improved in group 1 (normal 40%, restrictive 33.3% and obstructive 26.67% at initial evaluation to 53.33, 33.3 and 13.33% respectively in the post-filter evaluation, P<0.05), however no change in pulmonary disease distribution in control group. A statistical significance improvement in FVC (L)1.72±0.48,1.85±0.51,P=0.043, FVC (%) 88.13±15.08,91.89±12.97, P=0.025, FEV1(L) 1.33±0.35,1.51±0.32, P=0.004, FEV1(%)79.31±14.24,88.56±12.86, P=0.001 and FEV1/FVC (%) 79.33±14.56,84.27±7.59, 0.041 in the 6 month evaluation compared to the initial evaluation in patients with BTM using bedside filter,while in the control group a decline in FEV1 (%)(87.09±12.11,80.91±8.87, P=0.001), FVC (L)(1.85±,1.55±0.33, P= 0.036) , FVC (%) (90.88±13.71,84.81±11.42, P<0.001), and no significant change in FEV1/FVC ratio. There was no correlation between Serum Ferritin and PFT results in the pre or post filter evaluation (P > 0.05).
Summary / Conclusion: Pulmonary function abnormalities mainly restrictive pattern although subclinical is not an unfrequent finding in patients with BTM. Leukofiltration although increases the cost of provided service in countries with limited health resources; yet it improves all PFTs and should be implemented to prevent long-term consequences.

P458

PLATELET TRANSFUSIONS IN HAEMATOLOGY PATIENTS

B Choufi[1,*] f Drouvin[1], R Kadiata[1], M Barry[1], I Voronina[1]
[1]Nord Pas de calais, hôpital Duchenne, Boulogne Sur Mer, France

Background: Platelet transfusion modality still constitutes an unsolved problem. The majority of hospitals routinely give prophylactic platelet transfusions to patients with long-term bone-marrow failure. Recent findings demonstrate that the platelet count threshold for prophylactic transfusion can be as low as 10,000/μL and a therapeutic rather than a prophylactic strategy of transfusion for bleeding manifestations only may be equally safe for most patients. Another recent study suggests that very low doses of platelet transfusions are as effective at preventing bleeding as much higher doses.
Aims: reduction number of platelet transfusions per subject and cost.
Methods: Our retrospective study was conducted on two groups of 15 patients each who treated for ALL or AML. We compared the quantity of platelet transfused, cost and hemorrhagic risks between both groups. Patients were given transfusion when the platelet count was ≤20×10^9/L. The first group received 0,5.10(11) platelets per 7 kg of weight, and in the second group patient received 0,5.10(11) platelets per 10 to 14 kg of weight.
Results: Among the 30 adults who were enrolled in total, only those in the second group received a decrease number of transfusions and fewer units of platelet transfusions per subject. No significant difference in the outcome and no hemorrhagic complication were detected between the two groups

Summary / Conclusion: Changes in transfusion practices such as maintain of prophylactic strategy but with the reduction of dose per transfusion is considerable potential for decreased use of platelet transfusions with a consequent improvement of cost reduction

P459

THE EFFECTIVENESS OF PLATELETS TRANSFUSIONS IN PATIENTS WITH DE NOVO ACUTE MYELOID LEUKEMIA (AML) DURING INDUCTION CHEMOTHERAPY (IC).

B Davaasambuu[1],* S Gritsaev[1]
[1]Hematology, Russian Institute of hematology and Transfusiology, St.Petersburg, Russian Federation

Background: Platelets transfusions (PT) are the main condition to save patients' lives during and after IC period. The effectiveness of PT depends on different parameters including the age of patients, variant of AML, serious infectious complications and HLA-antibodies.
Aims: To determine the factors that influenced on the effectiveness of PT in patients with *de novo* AML during IC.
Methods: Retrospective analyses of 41 patients' IC were done. All patients were treated with 7+3 regimen. FAB classification was used to determine the morphological variant of AML. The prognostic variant of karyotype was managed by ELN criteria. Platelet transfusion was effective if the 24 hours corrected count increment (24h CCI) was more than $4.5x10^9$/L.
Results: Median age of patients was 42 y. (19-84). Morphological variants of AML were next: 5 M1, 17 M2, 3 M3, 6 M4, 7 M5, 2 M6 and 1 M7. Good karyotype was determined in 11 patients, intermediate in 25 patients and poor in 5 patients. Complete response was diagnosed in 25 patients (61.0%). The IC was ineffective in 13 patients (31.7%) and 3 patients (7.3%) died from infectious complications during the period of pancytopenia. Platelets transfusions were started when the count of platelets in peripheral blood was $19.0\pm11,8x10^9$/L (0-51) and were ended when the count of platelets $57.7\pm37.6x10^9$/L. The criteria to begin PT were thrombocytopenia $\leq20.0x10^9$/L (68.2%), hemorrhagic syndrome (36.5%) and DIC (48.7%). Two or three reasons to start PT have been taken place in 26.8% patients. The total number of PT transfused to all patients including in the trail was 459 units and most of them (88.7%) were prepared by discrete apheresis. The number of platelets units transfused to one patient was 10.2±5.8. There was no any association between PT effectiveness and age of patients. We did not find the role of prognostic variant of karyotype and the response to IC on the effectiveness of PT. At the same time the dependence of effective PT rate from morphological variant of AML was determined. Patients with M1 and M2 AML have got much more effective PT than patients with M4-M5 AML; P=0.022. There was association of overall survival (OS) and the level of platelets in peripheral blood before PT. The median of OS of patients with platelet count $\leq10x10^9$/L was 10.9 mo versus 7.0 mo in patients with platelet level $>10x10^9$/L.
Summary / Conclusion: The effectiveness of PT depends on morphological variant of AML. The reason is unknown. We suppose the role of high level of anti-HLA antibody. The early start of PT is a condition to improve OS of patients with *de novo* AML during IC.

P460

MEASUREMENT OF IRON CONCENTRATION IN HAIR AS AN INDICATOR OF BODY IRON LOAD

C Pala[1], C Sahin[1], Y Torun[2],* F Kurnaz[1], S Sıvgın[1], F Sahin[1], A Cetin[3], R Saraymen[3], L Kaynar[1]
[1]Hematology, Erciyes University, [2]Pediatric Hematology, Kayseri Education and Research Hospital, [3]Biochemistry, Erciyes University, Kayseri, Turkey

Background: As in iron deficiency, iron excess in the body also precipitates metabolic disorders. Iron accumulates in tissues and organs and causes tissue damage during the course of treatment in patients with myelodysplastic syndrome and ß-thalassemia, which require regular blood transfusions. Iron accumulation, which is seen commonly in the liver, myocardium, pancreas, pituitary gland and joints, is associated with functional loss in these organs and leads to life-threatening complications. Currently, several tests including invasive laboratory evaluations are used to determine the amount of iron in the body. Blood count, serum iron concentration, total iron binding capacity (TIBC), percentage of transferrin saturation (TS) and serum ferritin levels form the basis of these evaluations, which are widely available at many centers and relatively affordable. Serum free transferrin receptor level, which shows iron deficiency at cellular level and is not affected by acute phase response, is used for investigational purposes, although it has limited use in clinical practice. Furthermore, magnetic resonance imaging and needle biopsies are alternative tests which are used to demonstrate iron accumulation in the organs. An invasive method, consisting of staining bone marrow aspirate with Prussian blue, is the best clinical test to show iron status.
Aims: In the literature, there is limited information suggesting that iron concentration in hair may be an indicator of body iron load. In a few studies, the authors failed to demonstrate a significant relationship, thus emphasizing the need for further studies. We sought an answer to the question as to whether iron concentration in hair could be used as an indicator for body iron load. We aimed to determine whether there is a relationship between the iron concentration in hair and indicators of body iron in patients with iron deficiency anemia in which body iron load varies; in those with transfusion-dependent anemia who require regular blood replacement; and in controls.
Methods: Patients being followed up at the Hematology Department of Erciyes University's, Medical Faculty and at Kayseri Teaching Hospital between September 2010 and October 2011 were included in this study. The study population was assessed in three groups. The groups consisted of patients with high and low body iron and healthy controls with levels iron with in the normal range. Twenty patients with ß-thalassemia and myelodyplastic syndrome, who received at least 30 units of erythrocyte suspension, were included in the transfusion-dependent anemia group with high body iron. Twenty three patients with a iron deficiency anemia were or included in the group with low body iron. Seventeen healthy cases with a percentage of transferrin saturation and ferritin levels with in the reference range and who did not meet anemia criteria were employed as the control group. The hair samples were then dried in an oven at 80ºC. Each hair sample, weighing 250 mg, was transferred to a digestion vessel of 10 mL capacity, and concentrated nitric acid (5 mL) was pipetted into the vessel. Hair samples were diluted with concentrated nitric oxide in a microwave oven (Berghof Speedwave Germany).
Results: Median age was 33 years (14-48) in the iron deficiency anemia group, 22 years (15-75) in the transfusion-dependent anemia group and 28 years (13-42) in the control group. Differences between groups were found to be statistically significant for all parameters other than age. The median iron concentration in hair was measured as 5.080 µg/g in the iron deficiency anemia group, whereas it was 28.886 µg/g in the transfusion-dependent anemia group and 12.986 µg/g in the control group. The differences in terms of iron concentration in hair were found to be statistically significant (P<0.001). The highest iron concentration in hair (89.41 µg/g) was found in patients with transfusion-dependent anemia, who had the highest ferritin values, while the lowest concentration (0.77 µg/g) was detected in the iron deficiency anemia group (P<0.001).
Summary / Conclusion: These findings indicate the usability of iron concentration in hair as an indicator of body iron concentration. Further studies should evaluate how iron in hair is affected in settings such as acute or chronic infection or inflammation, in which the ferritin value acts as an acute phase reactant and the relationship between iron concentration in hair and hepatic iron load should be measured by MR imaging and liver biopsy.

P461

REVIEW AND DESIGN OF A NEW BLOOD BOOKING PROTOCOL FOR EACH SURGERY AND A RESTROSPECTIVE STUDY OF THE DIRECT EXPENSE DECREASE WITH THE NEW PROTOCOL

A Vicandi[1],* C Lana[2], M López[1], B Aguirrezabal[1], I Ormategi[1], J Aguirre[1], J Guinea de Castro[1], B Larraza[2], A Abad[1], J Wong Arteta[1], E Persona[1], B Moreno De Gusmao[1], B Campeny Najara[1], M Raczka[1], I Vallejo[1], C Echevarria[1], M Eguilaz[1], F Rodriguez Eleta[1]
[1]Hematology, [2]Anesthesiology, Hospital Universitario Araba, Vitoria-Gasteiz, Spain

Background: Blood components are a limited resource with many adverse reactions and they suppose a significant economic impact in health management. Is therefore necessary to implement protocols for their optimal use.
Aims: Valoration of a new standarized transfusional protocol implementation study according to direct expense decrease.
Methods: During 2011 the potentially bleeding surgeries (n=1107) are analized in our hospital and classified according to original surgical units, blood booking application rates and blood transfusion rates during 48 hours after surgery. Urgent surgeries are not included. Transfusion probability is analized depending on employed protocol and a new protocol is defined based on transfusional probability of applied surgery procedure: If transfusion probability is < 3% a signed Informed consent is required, if transfusion probability is >3% but <10% a group analysis and indirect coombs is required, and if transfusion probability is >10% a standarized blood booking is required. Finally, patients with transfusion need, without previous blood booking but all pretransfusional laboratory tests done (ABO and RH D group, indirect coombs, blood crossmatches tests) with patients who would need a transfusion if the new protocol was applied are compared. Direct expense savings according to Osakidetza´s public rates and its retrospective application to analysed requestes are calculated.
Results: From the global analysed patients transfusion rate of requested blood (74.6%) was 16.9%. Only one surgery (0.09% 1/1107) needed blood transfusion without previous blood booking. If the new consensual protocol would have been applied 16 blood transfusions would have been done: 2.2% (8/359) from the Informed consent group and 6.4% (8/125) from the group analysis and indirect coombs group, but there would have been saved 11.447€ (6.528€ in blood crossmatches, 419 € in ABO and RH D group analyses, and 4.500 € in indirect coombs tests).
Summary / Conclusion: The developement of new surgical techniques fitted protocols carry on an increasement in human resources use efficiency, a better management of the booked blood avoiding blood blockade and direct and indirect expense decrease.

P462

A CANADIAN TALE OF TWO BLOOD GROUPS

C Mcconville[1,*] g benson[1], k morris[2]
[1]Haematology, Belfast City Hospital, Belfast Trust, [2]Blood Transfusion, NIBTS, Belfast, United Kingdom

Background: A 75 year old gentleman fron Canada presented of a cruise ship to the acute medical take with lethargy. Blood counts revealed a pancytopenia, with a normochromic, normocytic haemaglobin of 5.7 g/dL.
Aims: Investigation of an extremely rare cause for mixed field blood grouping
Methods: Given symptom of cardiac compromise, i.e. shortness of breath and chest tightness, he was cross-matched for four unit of blood. His cross match revealed two distinct population of cells, some group O, and group A; some Rh(D) positive and some Rh(D) negative. The patient denied receiving any previous blood transfusions.
Results: Bone marrow biopsy revealed myelodysplasia with trilineage cytopenia and a complex karyotype. Reference Laboratory. Red cell samples were sent to Bristol Red Cell Reference Laboratory. Samples sent for cross matching revealed mixed field grouping reactions. Samples were then analysed at the regional transfusion laboratory. Two red cell populations were confirmed - O and A, Rh(D) positive and Rh(D) negative. DiaMed gel testing indicated double populations with anti-A, anti-A,B and both anti-D's. Gel Rhesus genotyping also showed a double population with anti-C. The patient's DAT was negative. These findings were confirmed by manual tests. Additional manual phenotypes were performed: Patient phenotype: Amf; Cmf, Dmf, E-, c+, e+, K-, k+, Fy(a+b+), Jk(a+b+), M+,Nmf, Smf, s+, P1+. Transfusion recommendation was group O Rh(D) negative red cell, and group A Rh(D) negative plasma containing products. PCR assay analysis excluded a weak subgroup A, predicted that the patient's genotype is O1 O1 (probable phenotype O).
Summary / Conclusion: This interesting case illustrates the challenge faced by both medical and laboratory staff in providing appropriate, safe blood products in a very unusual situation. The most common cause of a mixed field reaction in a patient not recently transfused is a weak subgroup A. This was excluded by molecular analysis. As there are two dual populations detected on phenotyping (ABO and rhesus), the mixed field phenotype result is actually chimaera i.e. two populations and transfer of DNA because of a resorbed twin in utero.

Platelets 1

REDUCED HOSPITALIZATIONS AND BLEEDS IN ADULTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) RECEIVING ROMIPLOSTIM IN CLINICAL PRACTICE – INTERIM RESULTS FROM A LARGE, EUROPEAN, OBSERVATIONAL STUDY

M Steurer[1,*] A Janssens[2], D Selleslag[3], H Wadenvik[4], P Quittet[5], G Kaiafa[6], T Kozak[7], H Papadaki[8], J Viallard[9], L Belton[10], G Kreuzbauer[11]
[1]Division of Hematology and Oncology, Innsbruck Medical University, Innsbruck, Austria, [2]Department of Hematology, University Hospitals Leuven, Leuven, [3]Department of Hematology, A-Z Sint-Jan, Bruges-Oostende, Belgium, [4]Section of Hematology, Sahlgrenska University Hospital, Gothenburg, Sweden, [5]Hematology Department, Hôpital Saint Eloi, Montpellier, France, [6]Medical Propedeutic Department of Internal Medicine, AHEPA General Hospital, Thessaloniki, Greece, [7]Fakultni nemocnice Kralovske Vinohrady, Praha, Czech Republic, [8]Department of Hematology, University of Crete School of Medicine, University Hospital of Heraklion, Crete, Greece, [9]Hôpital du Haut Lévèque, University of Bordeaux, Pessac, France, [10]Biostatistics, LB Biostatistics, London, United Kingdom, [11]International Medical Development and Research, Amgen (Europe) GmbH, Zug, Switzerland

Background: ITP is characterized by platelet counts <100x10^9/L, with romiplostim recommended for second-line treatment of adult ITP. Patients (pts) with more severe disease may experience bleeding symptoms which require hospitalization. Such hospitalizations incur high direct and indirect economic costs.
Aims: Describe ITP-related hospitalizations in adult ITP pts receiving romiplostim in clinical practice.
Methods: Study eligibility criteria and outcomes have been described elsewhere (Wadenvik *et al*, 2012). Data on ITP-related hospitalizations were collected for up to 2 years before and after romiplostim initiation; bleeding data were collected for up to 6 months before and 2 years after initiation. Informed consent was obtained from all pts. Hospitalization and bleeding rates were calculated with adjustment for the varying observation periods.
Results: At an interim analysis conducted in September 2012, 310 pts had enrolled; 296 met the study inclusion criteria and were included in the Full Analysis Set. Of these, 44% (n=131) remained on study, 46% (136) had completed the observation period and 10% (29) had withdrawn, with death the most common reason (19 [6%]). At romiplostim initiation, median (Q1, Q3) age, weight and platelet count were 62.0 (46.0, 73.0) years, 75.00 (64.00, 85.00) kg and 19.0 (9.0, 35.0)x10^9/L. One-third (n=102) of pts were splenectomized, one-third (97) diagnosed <1 year previously (median [Q1, Q3] time since diagnosis 3.56 [0.42, 10.96] years) and 54% (161) female; 54% (159) had received ≥3 prior ITP therapies. Median (Q1, Q3) duration of romiplostim exposure was 65.0 (29.9, 104.9) weeks (maximum 109 weeks); 28% (84) of pts initiated romiplostim at doses above 1 µg/kg/week, 64% (190) received ≥1 romiplostim injection at home and 29% (86) self-administered. Median (Q1, Q3) average weekly dose was 2.8 (1.6, 4.4) µg/kg/week. Median (Q1, Q3) platelet counts rose to 86 (41, 150)x10^9/L after 4 weeks of romiplostim treatment and remained >50 x10^9/L thereafter. After romiplostim initiation, the rate of ITP-related hospitalizations, primarily for ITP treatment administration and bleeds, was 2-fold lower; the rate of all bleeds 3-fold lower; and grade ≥3 bleeds rare (Table 1).

Table 1. ITP-related hospitalizations and bleeding events.

	Full Analysis Set (N=296)	
	Before rom initiation	After rom initiation
Number of ITP-related in-pt hospitalizations* (rate/100 pt-yrs)	340 (83.3)	172 (37.1)
ITP-treatment administration	166 (40.7)	61 (13.2)
Bleeding event	102 (25.0)	66 (14.3)
Number of bleeds† (rate/100 pt-yrs)	318 (262.8)	336 (72.6)
Number of grade ≥3‡ bleeds (rate/100 pt-yrs)	16 (13.2)	8 (1.7)

pt, patient; rom, romiplostim; yrs, years; *Defined as requiring an overnight stay; collected for up to 2 yrs before and after rom initiation, with a total of 408 and 463 pt-yrs of observation, respectively. †Collected for up to 6 months before and 2 yrs after rom initiation, with a total of 121 and 463 pt-yrs of observation, respectively. ‡Defined using the WHO bleeding scale.

Ten pts reported a total of 13 serious adverse drug reactions (ADRs): 2 events each of pulmonary embolism and myelofibrosis (likely due to the underlying disease [bone marrow metastases in 1 subject each whose initial disease diagnosis was inconsistent with ITP]); 1 event each of acute myeloid leukemia (confirmed by bone marrow trephine biopsy), deep vein thrombosis, drug ineffective (clinical symptoms, thrombocytopenia), myocardial infarction, no therapeutic response (clinical symptoms, bleeding), phlebitis, platelet count decreased (platelets <20x10^9/L), retinal vein thrombosis, and (reversible)

thrombocytosis (platelets 477x10^9/L). No other thrombotic or bone marrow reticulin ADRs were reported. No fatal ADRs were reported.
Summary / Conclusion: With similar doses as reported previously (Kuter *et al*, 2008), and ADRs consistent with the known safety profile, pts with ITP of varying duration and severity receiving romiplostim in routine clinical practice achieved sustained increases in platelet counts and a reduction in ITP-related hospitalizations. The reduction in hospitalizations was likely due to fewer bleeds and less rescue medication/IVIg use, and could offer cost savings in clinical practice. Possible incomplete reporting before romiplostim initiation and imbalanced observation periods should be noted when interpreting these data.

P464

COMPLEMENT ACTIVATION IN THROMBOTIC THROMBOCYTOPENIC PURPURA

J Westwood[1],* K Langley[1], E Heelas[1], S Machin[1], M Scully[2]
[1]Haemostasis Research Unit, University College London, [2]Department of Haematology, University College London Hospital, London, United Kingdom

Background: Thrombotic Thrombocytopenic Purpura (TTP) is a microangiopathy associated with organ dysfunction and a high level of morbidity and mortality. Although dysregulation of complement is well established in the pathophysiology of atypical Haemolytic Uraemic Syndrome (aHUS), the potential role of complement in TTP has not yet been determined.
Aims: We carried out a prospective study to investigate the role of complement anaphylatoxins C3a and C5a in patients with TTP during acute episodes, and in remission, and compared these with normal controls. For both acute and remission groups we also investigated the cytokine response (Th1/Th2/Th17-involving IL-2, IL-4, IL-6, IL-10, TNF, IFN-Y and IL-17a) and association with disease state.
Methods: EDTA plasma was obtained from 21 patients (12F, 9M) with acute TTP, ADAMTS13 activity <5% and positive anti-ADAMTS13 IgG antibodies (median IgG 59%, range 8-180%). Also, EDTA Plasma from 50 patients (34F, 16M) previously treated for acute TTP, now in clinical remission (normal ADAMTS13 activity and a platelet count >150x10^9/L). Paired EDTA plasma was obtained from 12 patients (6F, 6M) for whom both acute and remission samples were available. Measurement of complement anaphylatoxins C3a (NR 32.5-56.1ng/ml) and C5a (NR 1.7-13.6ng/ml) was performed using BD™ Human Anaphylatoxin Kit, (BD Biosciences, San Jose, CA, USA) using a Cytometric Bead Array (CBA) method. Serum was obtained from acute and remission patients, enabling the measurement of cytokines, using BD™ Human Th1/Th2/Th17 Kit, (BD Biosciences, San Jose, CA, USA) also incorporating the CBA method.
Results: In acute TTP, median C3a and C5a were significantly elevated compared to patients in remission, C3a 66ng/ml vs 38.5 ng/mL (P<0.001) and C5a 17 ng/mL vs 10ng/ml (P<0.001), respectively. For the 12 patients with paired acute and remission samples, median C3a levels were significantly higher during the acute episode than in remission, C3a 45.5 ng/mL vs 35.8 ng/ml (P=0.041); there was a non-significant difference in C5a levels 15.2 ng/mL vs 10.6ng/ml (P=0.084). Compared to controls, remission median C5a levels were significantly higher 10ng/ml vs 5.81ng/ml (P=0.001); however remission C3a levels were lower than controls 38.5 ng/ml vs 43.7ng/ml (P=0.046). Within the acute TTP group, there was no significant difference in C3a or C5a levels for patients requiring ITU admission vs those not requiring ITU care or patients with or without neurological features at presentation. Both median IL-6 and IL-10 levels were significantly higher in the acute vs remission groups, IL-6: 8pg/ml vs 2 pg/ml (P=0.002), IL-10: 6pg/ml vs 2pg/ml (P<0.001). C3a levels were strongly correlated with both anti-ADAMTS13 IgG (r_s=0.731, P=0.002) and IL-10 (r_s=0.627, P=0.012) levels.
Summary / Conclusion: These results suggest complement anaphylatoxin levels are higher in acute TTP cases than in remission, and highlight the possibility that the complement response seen acutely may relate to both the degree of anti-ADAMTS13 IgG antibody level and cytokine (IL-10) levels. Factors triggering complement activation in TTP need to be elucidated. Complement inhibition at presentation in the acute phase may have therapeutic potential.

P465

A LONGITUDINAL PROSPECTIVE STUDY EVALUATING THE EFFECTS OF ELTROMBOPAG TREATMENT ON BONE MARROW IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: INTERIM ANALYSIS AT 2 YEARS

R Brynes[1], A Orazi[2], R Wong[3], K Bakshi[4], C Bailey[4], G Chan[4],*
[1]University of Southern California Keck School of Medicine, Los Angeles, [2]Weill Cornell Medical College, New York, United States, [3]Prince of Wales Hospital, Shatin, Hong Kong, [4]GlaxoSmithKline, Collegeville, United States

Background: Eltrombopag (epag), a thrombopoietin receptor agonist (TPO-RA), increases platelet counts in chronic immune thrombocytopenia (cITP) patients. TPO-RAs are associated with varying degrees of bone marrow (BM) reticulin increases.[1,2] Due to lack of pretreatment evaluations, the incidence and clinical significance of these findings are not established. Inconsistencies in specimen preparation, staining, and analysis across institutions further confound conclusions.
Aims: To assess the degree of BM fibrosis (reticulin and/or collagen) in cITP patients treated for up to 2 years with epag (NCT01098487).
Methods: BM biopsies were collected at baseline (prior to epag treatment) and 1y and 2y on treatment. Specimens were centrally processed and stained for reticulin (silver) and collagen (trichrome), and were reviewed by a central independent hematopathologist for cellularity; megakaryocyte, erythroid, and myeloid quantity and appearance; trabecular bone quality; reticulin grade (European Consensus scale-MF[3]) and presence of collagen.
Results: 167 patients were enrolled. Currently, 45 patients have completed all 3 protocol-specified BM biopsies (baseline, 1y [10-14 mo], and 2y [22-26 mo]). Median age is 39 (18-78) y; 34 (75.6%) are females; 51% Caucasian/European, 13% East Asian, and 36% South Central Asian. Median time since ITP diagnosis is 3.5 (0.6-45.7) y. All patients received prior ITP therapy, and 2 (4%) received prior TPO-RA treatment (both with epag), and the last dose was ≥6 months before enrollment. At baseline, 40 (89%) patients had reticulin grade 0 (MF-0), and 5 (11%) MF-1. At 1y, 26 (58%) patients had MF-0, 17 (38%) MF-1, and 2 (4%) MF-2. At 2y, 37 (82%) had MF-0, 6 (13%) MF-1, and 2 (4%) MF-2 (Figure 1). Compared with baseline, 33 (73%) patients had no change at 2y in MF grade, 7 (16%) a 1-grade increase, 4 (9%) a 1-grade decrease, and 1 (2%) patient had a 2-grade increase. Three patients had post-baseline MF-2; 2 (4%) patients at 1y, and 2 (4%) at 2y. One patient with MF-2 at 1y decreased to MF-0 while continuing on epag. One patient with MF-2 had collagen at 1y and 2y. None of the 3 patients with post-baseline MF-2 had adverse events or hematologic abnormalities considered related to impaired BM function, and none withdrew due to BM findings. Both patients with prior TPO-RA (epag) treatment had baseline reticulin of MF-0, and remained MF-0 at 1y and 2y.
Cellularity was normal in 86%, 71%, and 80% of patients at baseline, 1y, and 2y, respectively. No changes occurred in marrow cellular composition. In 2 of 3 patients with post-baseline MF-2, cellularity was increased from baseline. Trabecular bone thinning was found at baseline in 8 (18%) patients (most with prior steroid use), 24 (53%) patients at 1y, and 28 (62%) at 2y.
Summary / Conclusion: 11% of patients had MF-1 at baseline. After 2y of treatment, no increase or a mild increase in reticulin was observed in 73% and 16% of patients, respectively. No patient with an increase to MF-2 at 2y had clinical signs or symptoms indicative of BM dysfunction. Results were similar to those reported for EXTEND, an epag extension study (median treatment duration >2y[1]).
Conclusion: These data suggest that treatment with epag is generally not associated with clinically relevant increases in BM reticulin or collagen. The potential association of TPO-RAs and increased BM reticulin needs further study.

RECOMBINANT HUMAN THROMBOPOIETIN (RHTPO) IN COMBINATION WITH LOW-DOSE RITUXIMAB (LD RTX) IN SEVERE OR REFRACTORY PRIMARY IMMUNE THROMBOCYTOPENIA: A MULTICENTER PROSPECTIVE CLINICAL TRIAL

M Hou[1],* M Xu[1], J Peng[1]
[1]Hematology, Qilu Hospital, Shandong University, Jinan, China

Background: Adult primary immune thrombocytopenia (ITP) is an autoimmune disease characterized by autoantibody-induced platelet destruction, which affects around 1 in 10,000 people. 25%>30% of the patients achieve no response to the conventional therapy. Both rituximab and thrombopoietin are recommended as the second-line treatments. Standard-dose rituximab (SD RTX, 375 mg/m^2 ×4 weeks) is the mainstream for the treatment of ITP. Previous studies reported a response rate around 60%. Zaja *et al* evaluated LD RTX (100 mg dose×4 weeks) in 28 patients with ITP, which showed that the response rate (platelet count > 50×10^9/L) was 75%, which was similar to that with SD RTX, though the median time to response (or complete response) were longer than SD RTX. Conventional agents focused on the decrease of platelet destruction, while it was also discovered in recent years that many ITP patients had abnormalities in megakaryocyte growth and apoptosis, as well as lower level of thrombopoietin (TPO). The recombinant human full-length glycosylated TPO (rhTPO) is a TPO receptor agonist. The combination of rhTPO and rituximab could complement each other's advantages and exert powerful effect on platelet production, which may be a choice for the glucocorticosteroids-resistant/ relapsed patients.
Aims: We reported 86 adult ITP patients treated with rhTPO in combination with LD RTX from 12 centers. This trial focused on exploring novel therapeutic strategies for ITP. We assessed response rates and safety of rhTPO combined with low-dose rituximab in primary ITP who had failed to response to glucocorticosteroids or relapsed.
Methods: rhTPO was given 300U/kg in the first 14 days, with 100mg qw rituximab weekly for 4 weeks. The dose frequency of rhTPO was adjusted according to the platelet counts. Primary outcomes include response (R), complete response (CR), no response (NR) and relapse. R was defined as platelet count ≥30×10^9/L and at least two-fold increase from the baseline count and absence of bleeding; CR in case of platelet count ≥100×10^9/L and absence of bleeding; NR in case of platelet count <30×10^9/L or less than two-fold increase from baseline. Relapse was defined as a drop in platelet count to ≤30×10^9/L following an initial, partial or complete response. Secondary outcomes are listed below. Time to response and sustained time were considered as the duration from baseline to response, duration from response to relapse or the end of the study, respectively. Safety was reflected as adverse events graded according to the Common Toxicity Criteria. All of the patients were informed about the clinical trial and signed the consent forms. This clinical trial was registered at http://clinicaltrials.gov as NCT01506414.
Results: Response and complete responses were achieved in 26/86 (30.2%) and 35/86 (40.7%) patients respectively. In a follow-up of 3 months, 5 cases lost to follow-up, and 14/56 (25%) patients relapsed. Median time to response (or complete response) was 7 days (range 4-28 days). And the median sustained time was 79 days (range 3-86 days) in a total observation time of 90 days. There were several adverse effects reported, such as fatigue, pulmonary inflammatory, but almost all were below Grade 2. Two of the patients died in the process. One (>70 year old) died of cerebral embolism, however it has nothing to do with therapy of ITP, since his platelet count kept steady. The other was a patient relapse in the third month, and died of cerebral hemorrhage.
Summary / Conclusion: Our findings suggest that combination of RTX and LD RTX in ITP improves response rate and yields shorter time to response compared with monotherapy of RTX in reports. Thus, combination therapy may represent an effective treatment option for glucocorticosteroids-resistant or relapsed patients.

P467

EFFICACY AND SAFETY OF ROMIPLOSTIM IN PATIENTS ≥65 YEARS WITH IMMUNE THROMBOCYTOPENIA (ITP)

M Michel[1],* J Wasser[2], B Godeau[1], L Aledort[3], N Cooper[4], Y Tomiyama[5], M Khellaf[1], X Wang[6], P Woodard[6]
[1]Henri Mondor University Hospital, Creteil, France, [2]University of Connecticut School of Medicine, Farmington, United States, [3]Mount Sinai School of Medicine, New York, United States, [4]Catherine Lewis Centre Hammersmith Hospital, London, United Kingdom, [5]Osaka University Hospital, Osaka, Japan, [6]Amgen Inc, Thousand Oaks, United States

Background: ITP is an autoimmune disease characterized by increased platelet destruction and suboptimal platelet production. ITP prevalence increases with age, and geriatric patients (pts) may not tolerate therapy for ITP as well as younger pts. Romiplostim is a thrombopoietin (TPO) receptor agonist that can increase platelet production and is approved for treatment of chronic ITP in adults. However, little is known about the efficacy and safety of romiplostim in pts ≥65 years (yrs).
Aims: To describe the efficacy and safety of romiplostim among pts ≥65 compared to pts <65 yrs.
Methods: For efficacy endpoints, data from 2 global phase 3 trials (2005–2006) and 1 Japanese phase 3 trial (2007–2009) of romiplostim in pts with ITP were analyzed separately. Efficacy endpoints included overall platelet response (≥1 weekly platelet count ≥50x10^9/L within the study treatment period) and number of weeks with a platelet response. For safety endpoints, data from 13 clinical studies of romiplostim in pts with ITP (2003–2009) were included. Data from pts given placebo or standard of care (SOC) were pooled, and pts who received placebo in the parent study and romiplostim in the extension study were included in both the placebo/SOC and romiplostim groups. Safety endpoints included rates of adverse events (AEs), serious AEs (SAEs), fatal events, and AEs of interest (ie, bleeding events, thromboembolic events, and bone marrow reticulin events). Results were adjusted for study duration and reported as rates per 100 pt-yrs.
Results: The efficacy analysis included 159 pts who were treated in randomized, controlled trials; 54 received placebo and 105 received romiplostim. Most were Caucasian (64.2%) or Japanese (21.4%). Mean (SD) age was 53 (15.7) yrs with 24.5% ≥65 yrs and 75.5% <65 yrs. In the romiplostim group, a trend towards higher overall platelet response rates was seen among pts ≥65 vs <65 yrs in the global studies (94.4% vs 86.2%) and the Japanese study (100% vs 93.3%). The mean (SD) number of weeks with platelet responses was similar among pts ≥65 vs <65 yrs in the global studies (7.2 [3.2] vs 6.7 [4.1]) and the Japanese study (9.9 [2.0] vs 9.3 [3.9]). In the placebo group from the global studies, the overall platelet response rate was lower among pts ≥65 vs <65 yrs (7.7% vs 20.7%), and the mean (SD) number of weeks with platelet responses was similar among pts ≥65 vs <65 yrs (0.4 [1.4] vs 0.6 [1.4]). Comparisons were difficult in the Japanese study because only 1 pt ≥65 yrs was included in the placebo group. The safety analysis included 718 pts. Most were Caucasian (80.9%) or Japanese (6.4%). Mean (SD) age was 52 (18.8) yrs with 27.3% ≥65 yrs and 72.7% <65 yrs. A total of 32 fatal events were seen; 2 pts had fatal bleeding events and 5 had fatal thromboembolic events. The incidences of AEs were similar among pts ≥65 vs <65 yrs in the romiplostim (92.4% vs 92.1%) and placebo/SOC groups (92.9% vs 93.8%). Duration-adjusted rates of overall AEs were similar among age groups, and rates of SAEs and fatal AEs were greater among pts ≥65 vs <65 yrs (Table 1). Of interest, pts ≥65 yrs had a lower rate of grade ≥3 bleeding events in both the romiplostim and placebo/SOC groups and a higher rate of thromboembolic events in the romiplostim group than pts <65 yrs (Table 1).
Summary / Conclusion: Though numerical differences were seen, key efficacy outcomes were similar among pts ≥65 and <65 yrs treated with romiplostim. Safety outcomes varied among age groups with pts ≥65 yrs having greater rates of SAEs and fatal events than pts <65 yrs, regardless of treatment.

Table 1.

	Placebo/SOC[a]		Romiplostim[a]	
	≥65 yrs N = 42	<65 yrs N = 96	≥65 yrs N = 172	<65 yrs N = 481
Any AE, n (r)	397 (1046.8)	874 (1212.0)	3143 (1307.0)	9218 (1353.6)
SAE, n (r)	56 (147.7)	51 (70.7)	249 (103.5)	350 (51.4)
Fatal Event, n (r)	5 (13.2)	3 (4.2)	14 (5.8)	10 (1.5)
Grade ≥3 Bleeding Event, n (r)	2 (5.3)	17 (23.6)	20 (8.3)	83 (12.2)
Thromboembolic Event, n (r)	1 (2.6)	5 (6.9)	24 (10.0)	45 (6.6)
Bone Marrow Reticulin Event, n (r)	0 (0.0)	0 (0.0)	3 (1.2)	9 (1.3)

[a]Pts who received placebo in the parent study and romiplostim in the extension study were included in both groups.
n = number of events.
r = study duration-adjusted event rate per 100 pt-yrs (n/pt-yr x 100).

P468

EFFICACY OF ENZYME REPLACEMENT THERAPY WITH VELAGLUCERASE ALFA IN PATIENTS WITH TYPE 1 GAUCHER DISEASE AND THROMBOCYTOPENIA OR SEVERE SPLENOMEGALY

P Giraldo[1],* D Gonzalez[2], M Kabra[3], E Lukina[4], I Kisinovsky[5], D Elstein[6], D Zahrieh[7], E Crombez[7], A Zimran[6]
[1]Haematology, Hospital Universitario Miguel Servet, Zaragoza, Spain, [2]Sanatorio Español, Asunción, Paraguay, [3]All India Institute of Medical Sciences, New Delhi, India, [4]Hematology Research Center, Moscow, Russian Federation, [5]Your Health SA, Buenos Aires, Argentina, [6]Gaucher Clinic, Shaare Zedek Medical Center and Hebrew University-Hadassah Medical School, Jerusalem, Israel, [7]Shire Human Genetic Therapies, Inc., Lexington, United States

Background: The responses of type 1 Gaucher disease (GD)-related throm-

bocytopenia and splenomegaly to enzyme replacement therapy (ERT) are linked to their pretreatment severity.
Aims: To evaluate the efficacy of velaglucerase alfa in type 1 GD patients with thrombocytopenia or severe splenomegaly.
Methods: TKT032 and HGT-GCB-039 were parallel-group trials; eligible patients were ≥2 years old with untreated type 1 GD. In both trials, 1 treatment arm was allocated to velaglucerase alfa 60 U/kg ERT every other week (EOW). Patients completing either trial could enroll in a combined extension study, HGT-GCB-044. Informed consent was obtained from all adult patients and from the guardians of patients ≤17 years old.
Results: 27 type 1 GD patients received velaglucerase alfa 60 U/kg EOW in TKT032 or HGT-GCB-039 and HGT-GCB-044 over 24 months. 15/27 patients had a pretreatment (baseline) platelet count <100×10^9/L; 6 of these 15 had a platelet count <60×10^9/L. All 15 had an intact spleen. 6/27 patients had severe baseline splenomegaly (splenic volume >15 multiples of normal); all 6 had a platelet count <100×10^9/L. At 24 months, 14/15 (93%) patients had reached the platelet count therapeutic goal and 6/6 with severe baseline splenomegaly had reached the splenic goal. 5/6 (83%) patients with a baseline platelet count <60×10^9/L had a normal platelet count (≥120×10^9/L), including 2 with severe baseline splenomegaly (Table).
Summary / Conclusion: Clinically significant improvements in platelet count and splenic volume occurred in the first 24 months of velaglucerase alfa treatment among patients with type 1 GD and severe baseline splenomegaly and/or a platelet count <100×10^9/L (including those with a platelet count <60×10^9/L).

Table 1. Individual platelet and splenic responses: 24 months of study drug.

Baseline age, y	Gender	Platelet count, ×10^9/L				Splenic volume, multiples of normal			
		Baseline	12 months	24 months	24-month change, %	Baseline	12 months	24 months	24-month change, %

*Patients with spleens >15 multiples of normal in volume at baseline.
†Below goal.
Therapeutic goals by 2 years: splenic volume must decrease 50–60%; baseline platelet count 60–120×10^9/L must be ≥100×10^9/L; baseline platelet count <60×10^9/L must increase 2-fold.

P469

AN UNEXPECTED ROLE OF THE VON WILLEBRAND FACTOR-CLEAVING PROTEASE ADAMTS-13 DURING EXPERIMENTAL INFLAMMATION IN LUNGS

M Bosmann[1,2,*] K Alber[1], T Falter[1,2], K Jurk[2], M Theobald[1], I Scharrer[1]
[1]Department of Hematology and Oncology, [2]Center of Thrombosis and Hemostasis, University Medical Center Mainz, Mainz, Germany

Background: The metalloprotease ADAMTS-13 is a key factor for the development of thrombotic thrombocytopenic purpura (TTP). ADAMTS-13 cleaves ultra-large *von Willebrand* multimers into smaller fragments. The presence of ADAMTS-13 activity is essential for blood clotting homeostasis, since genetic deficiency or blockade by auto-antibodies can result in micro-thrombi formation and thrombocytopenia during TTP. Infection-associated inflammation has been described as a triggering factor for episodes of TTP in humans. Genetically targeted mice with deletion of ADAMTS-13 have only recently become available.
Aims: In this study, we sought to induce TTP-like symptoms in ADAMTS-13 deficient mice (ADAMTS-13-/-) by inducing acute experimental inflammation in mouse lungs. In addition, the dependency of the acute inflammatory response on the activity / presence of ADAMTS-13 was characterized.
Methods: Breeding colonies of ADAMTS-13-/- mice were housed and genotyped at our institution and phenotyping was accomplished using a fluorescent activity assay for ADAMTS-13 (FRETS-VWF73). Anaesthetized ADAMTS-13-/- mice and wild type mice were injected intra-tracheally with 40µg of LPS (from *E. coli*, O111:B4). Alternatively intra-pulmonal immune-complexes were induced by intra-tracheal injection of 125 µg of anti-bovine serum albumin antibody along with injection of intra-venous 1 mg bovine serum albumin. At the end of experiments broncho-alveolar lavage fluids and blood samples were harvested and analyzed using a Sysmex KX-21 N instrument or immunoassays.
Results: Intra-tracheal challenge with LPS did not induce thrombocytopenia in ADAMTS-13-/- mice or wild type mice after 8 hours. As expected, LPS intratracheally promoted the accumulation of myeloid cells (6-fold increase, mainly polymorphonuclear neutrophils) in the alveolar lung compartment as counted in broncho-alveolar lavage fluids of wild type mice. Surprisingly, the LPS-induced influx of polymorphonuclear neutrophils to the alveolar compartment was reduced by around 50% in ADAMTS-13-/- mice as compared to wild type mice (Figure 1, **P<0.01). In addition, circulating leukocytes in peripheral blood were substantially reduced in ADAMTS-13-/- mice but not wild type mice. When mice were subjected to immune-complex induced inflammation of lungs, significant lower numbers of leukocytes in broncho-alveolar lavage fluids (*P<0.05) and peripheral blood (**P<0.01) were observed in ADAMTS-13-/- mice as compared to wild type controls 8 hours after immune-complex inflammation. When the disruption of the alveolar/capillary barrier was assessed by detection of alveolar albumin concentrations in broncho-alveolar lavage fluids, no significant differences between ADAMTS-13 and wild type mice were observed in both models of lung inflammation. The molecular mechanisms underlying the observed results, including alterations of chemokine expression signatures, are currently under investigation in our laboratory.
ISummary / Conclusion: Collectively, these results reveal an unexpected role of ADAMTS-13 as a modulator of leukocyte migration in two models of acute lung inflammation. Our future studies will aim to evaluate, if targeting ADAMTS-13 activity may be a beneficial treatment strategy during acute lung diseases.

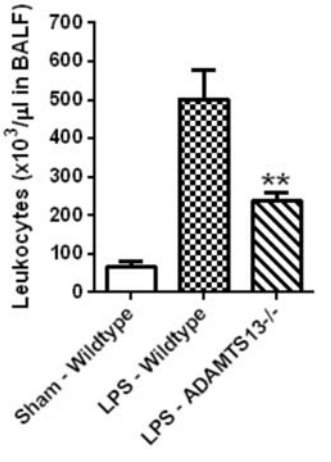

Figure 1. ADAMTS13-/- mice display reduction of leukocytes in bronchoalveolar lavage fluids following LPS-induced lung inflammation (LPS 40 mg/mouse, i.t.) 8h Sham mice received PBS i.t.)

P470

RITUXIMAB VERSUS SPLENECTOMY IN PERSISTENT OR CHRONIC ADULT PRIMARY IMMUNE THROMBOCYTOPENIA: AN ADJUSTED COMPARISON OF MORTALITY AND MORBIDITY

G Moulis[1,2,3,*] L Sailler[1], A Sommet[3], M Lapeyre-Mestre[3], D Adoue[1]
[1]Internal Medicine, Toulouse University Hospital, [2]University of Toulouse, [3]UMR INSERM-UPS 1027, Toulouse, France

Background: Splenectomy and rituximab are both recommended as second-line treatment in primary immune thrombocytopenia (ITP), while they have never been directly compared.
Aims: This study was aimed at conducting an adjusted comparison of efficacy and serious adverse outcomes (infection, bleeding and death) of splenectomy versus rituximab in persistent or chronic adult primary ITP patients.
Methods: Thanks to hospital databases, we built a retrospective monocentric cohort of 105 consecutive adult primary ITP patients exposed to either of these treatments. Outcomes were hospitalization for bleeding, overall mortality, reponse (no beleeding and platelet count >30 G/L) at 3 and 12 months, complete response (no bleeding and platelet count >100 G/L) at 3 and 12 months, loss of response and of complete response, hospitalization for infections. Outcomes were assessed by medical file reviewing and by phone interviews of the patients and their general pratictionners. Comparisons were made using Cox models. Risks were adjusted on gender, age-adjusted comorbidity Charlson score, disease duration, history of mucosal bleeding, treatments for ITP before splenectomy or rituximab.
Results: The cohort included 105 adult primary patients exposed either to splenectomy (n=62) either to rituximab as second-line treatments. Patients treated with rituximab were older and had more comorbidities than splenectomized patients. Mean follow-up were respectively 3 and 8.4 years. Response and complete response rates at 12 months were higher in the splenectomy group (87.9% *versus* 59.0% and 81.0% *versus* 35.9%, P<0.001). Splenectomy was independently associated to response at 12 months (OR 4.6, 95%CI[1.6-13.6]). Loss of response was higher in the rituximab group (P=0.02). In multivariate model, the risk of hospitalization for bleeding was associated with

a history of mucosal bleeding at diagnosis (HR 11.1, 95%CI[1.5-84.7]) and with age-adjusted Charlson score (for one point increase: HR 1.3, 95%CI[1.0-1.6]), but not with rituximab exposure (channeling bias). Two patients died by bleeding in the rituximab group and none in the splenectomy group (P=0.09). Overall mortality was increased in the rituximab group (P=0.01). In multivariate analysis, mortality was also associated to a high age-adjusted Charlson score (for one point increase: HR 2.2, 95%CI[1.6-3.0]). There was no difference between the two groups regarding hospitalizations for infection.
Summary / Conclusion: In a real life practice, older people are preferentially treated with rituximab. Age and comorbidities explain the poor prognosis of these patients. Nevertheless, splenectomy is an independant factor of reponse at 12 months and this study suggests that it should be proposed in elderly whenever possible. Prospective studies are mandatory to assess the benefit-to-risk ratio of both treatments in older people.

P471

EVALUATION OF THE IMMATURE PLATELET FRACTION IN THE DIAGNOSIS AND PROGNOSIS OF CHILDHOOD IDIOPATHIC THROMBOCYTOPENIC PURPURA

A Adly[1,*] E Ismail[2], I Ragab[1], M Farahat[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams, cairo, Egypt

Background: Idiopathic thrombocytopenic purpura (ITP) is an acquired immune-mediated disease in adults and children characterized by a transient or persistent decrease in the platelet count. A rapid assessment of platelet production would distinguish between thrombocytopenia due to bone marrow failure and thrombocytopenia due to increased peripheral platelet destruction. Immature platelet fraction (IPF%) is a measure of reticulated platelets (RPs), obtained from an automated hematology analyzer as one of the platelet parameters and represents the state of thrombopoiesis.
Aims: Therefore, we aimed to evaluate IPF as a diagnostic tool to differentiate between ITP and thrombocytopenia due to decreased platelets production and as a prognostic marker for severity of ITP patients.
Methods: Fifty patients with ITP were compared with 14 patients with hematological malignancies under chemotherapy representing a control group with thrombocytopenia due to bone marrow suppression and 30 age- and sex-matched healthy subjects served as healthy controls. Patients were studied stressing on bleeding manifestations, recent viral infection, history of drug intake, bleeding score, organomegaly/lymphadenopathy and therapy. Complete blood count (CBC) was performed using Sysmex XE-2100. The studied ITP Patients were classified into 2 subgroups: acute ITP with spontaneous resolution within 3 months from diagnosis and chronic ITP lasted ≥1 year from diagnosis.
Results: ITP patients had significantly lower hemoglobin, platelet count and plateletcrit (PCT) with higher mean platelet volume (MPV), platelet distribution width (PDW), platelet large cell ratio (P-LCR) and IPF compared with healthy controls. Similarly, MPV, PDW, P-LCR and IPF were significantly higher and PCT was significantly lower in ITP patients compared with patients having hematological malignancy under chemotherapy. However, hemoglobin level, WBC count and absolute lymphocyte count were significantly lower in those patients than ITP patients. Comparison between acute and chronic ITP showed that chronic ITP patients had significantly higher age with longer disease duration. Number of chronic ITP patients taking first line corticosteroids and second line IVIG, anti D, combined therapy or thrombopoietin was significantly increased compared with acute patients. Number of lines used and incidence of drug dependency were also elevated among chronic than acute ITP patients. Bleeding score and platelet count were negatively correlated with IPF. ITP patients taking second line IVIG, anti D, combined therapy or thrombopoietin had significantly lower IPF than untreated patients with those lines. IPF was positively correlated to number of lines used, MPV, PDW and P-LCR while negatively correlated to platelet count and PCT in ITP patients. Multiple regression analysis showed that platelet count, patient's condition, thrombopoietin intake and relapse were independently related to IPF. ROC curve analysis revealed that the cutoff value of IPF at 4.3% could be diagnostic for ITP patients with a sensitivity of 90%, specificity of 83%.
Summary / Conclusion: IPF is a rapid and inexpensive automated marker for thrombocytopenia and can be integrated as a standard parameter to evaluate the thrombopoietic state of the bone marrow. It may be considered as a diagnostic tool to differentiate between ITP and thrombocytopenia due to bone marrow pathology as well as a potential prognostic marker for disease severity in ITP patients.

P472

THALIDOMIDE CORRECTS IMPAIRED MESENCHYMAL STEM CELL FUNCTION IN INDUCING TOLEROGENIC DENDRITIC CELLS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

J Peng[1,*] J Ma[1], M Xu[1], M Hou[1]
[1]Department of Hematology, Qilu Hospital, Shandong University, jinan, China

Background: Thalidomide (THD) was first introduced as a non-barbiturate sedative-hypnotic drug in West Germany in the 1950s, but was withdrawn worldwide in 1961 due to its potential for teratogenesis, which resulted in 8000–10000 newborns with phocomelia malformation. However, it has since expanded its range of usage and was approved by the FDA in 1997 as an agent to treat erythema nodosum leprosum. Presently, thalidomide is used as an immunomodulatory agent to treat immune-mediated diseases. Immune thrombocytopenia (ITP) is an autoimmune disorder in which both T and B cells are involved. Recently a study found impaired proliferative and functional capacity of MSCs in patients with ITP.
Aims: The aim of this study was to explore whether THD could correct the defects of MSCs and to investigate its mechanism of inducing tolerance in ITP.
Methods: Thirty-three newly diagnosed primary ITP patients were enrolled and twelve samples of venous blood and nine samples of bone marrow from healthy donors were used as controls. MSC proliferation was determined by Cell Counting Kit-8 and cell-cycle analysis. The molecular changes in MSCs induced by THD were detected by microarray analysis and validated by quantitative real time polymerase chain reaction. Mixed lymphocyte reaction and cytokine production assays were performed to analyze the malfunction of MSCs in ITP patients. Interference with TGF-β inducible early-response gene 1 (TIEG1) small hairpin RNA (shRNA) (h) lentivirus was used to analyze the tolerogenic effects of dendritic cells (DCs) induced by MSCs. Phenotypic analysis of mature DCs after co-culture with MSCs was conducted by fluorescence-activated cell sorter (FACS)
Results: We demonstrated that MSCs in ITP had a reduced proliferative capacity and lost their immunosuppressive function, which could be corrected with THD treatment. According to the gene profile, the down-regulation of caspase 8, caspase10 and c-myc and up-regulation of oct 3/4 and TGF-β1 in MSCs may be associated with THD modulation. The inhibitory effects of MSCs on lymphocyte proliferation rely on the presence of DCs. The THD-modulated MSCs could regulate mature DCs by down-regulating the expression of costimulating factors and up-regulating IL-10 and TGF-β1 production. To study the functional alteration of DCs induced by MSCs, we sorted DCs after incubation with MSCs and performed T-lymphocyte reaction assays. Both the DCs induced by MSCs from healthy controls and those induced by THD-modulated MSCs from ITP patients suppressed T-cell proliferation activated by allogeneic mature DCs, whereas the DCs induced by unmodulated MSCs from ITP patients did not. When DCs were infected with TIEG1-interference lentivirus, the MSCs lost the ability to induce them into tolerogenic DCs. These results indicated that the modulatory effects of MSCs on DCs was dependent on the expression of TIEG1 in DCs.
Summary / Conclusion: The study demonstrates the inability of MSCs from ITP patients to induce mature DCs into a tolerogenic DC population. THD could restore the regulatory effect of MSCs on DCs. These findings will help us understand the pathogenesis of ITP, and further lay a foundation for a new regimen in the treatment of ITP.

P473

DISEASE PROGRESSION, TREATMENT PATTERNS, AND CO-MORBID BURDEN AMONG ADULT PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP): UPDATED RESULTS FROM THE UNITED KINGDOM ITP REGISTRY

D Bennett[1,*] U Doobaree[2], R Nandigam[2], A Newland[2], D Provan[2]
[1]WWEpidemiology, GSK, Collegeville, United States, [2]Department of Haematology, Blizard Institute, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder that is characterized by decreased platelet count ($<100\times10^9$/L). Contemporary findings on the epidemiology of ITP and treatment patterns are limited. To address these gaps the United Kingdom ITP Registry (UKITP) took up an important task to recruit an adequate sample size of patients with ITP and is conducting extensive studies on the data and biological samples that it has collected to date.
Aims: We aim to study the disease's natural progression, including longitudinal platelet counts and bleeding events, evaluate treatment patterns, and measure the prevalence and incidence of at least 25 comorbid conditions in a primary ITP cohort. In this analysis, we estimated the baseline demographics, prevalence of comorbidities at diagnosis of ITP and the natural progression of platelet counts before and after presentation with ITP.
Methods: The registry, based at the Royal London Hospital, collects data and biological samples on ITP participants locally and externally through a network of 36 collaborating regional centres. We collect study-related data at diagnosis of ITP and throughout the clinical history of enrolees. Occurrences of comorbidities are followed throughout the lifetime of participants thus permitting the estimation of their prevalence and incidence. Historical platelet counts are also collected. We described the characteristics of the ITP cohort using stratified summary statistical analyses (inc. standard deviation). Mean platelet counts were estimated based on individual counts during specified time periods before and after ITP diagnosis date.
Results: Our sample consisted of 729 adults (18+ years) who had a mean age

of 47.4 (19.4) years at diagnosis and 52.8 (18.7) years at registration. Overall, more females than males (57% vs. 43%) were diagnosed with ITP; a pattern reversed among 70+ years old (N=94; 44% vs. 56%). The prevalence of at least 1 comorbid illness for 40+ years old was 37% (N=432) compared to 19.4% (N=263) among their younger counterparts. Before or at ITP diagnosis among those 40+ years, 3.7% had cataract, 4.4% had a myocardial infarction, 5.6% had osteoarthritis, and 4.9% had a solid tumour. The mean platelet count within ±7 days of ITP diagnosis was 40.2 (50.0) [N=423]. In a small proportion of patients platelet counts were available before the diagnosis of ITP was made, in the 2 months leading to the diagnosis a decline in mean platelet counts below 100 x10^9/L was noted, which subsequently rose sharply over this threshold during a shorter time following diagnosis (Figure 1). The rise in platelet counts post diagnosis in adults was treatment related. Next analyses will look at the platelet count drop reported here in context of the diagnostic process (e.g. eliminating other potential causes) and whether decision to treat were dependent on other clinical features (e.g. platelets count<50x10^9/L). Risk of experiencing certain comorbid illnesses will also be investigated, including the role of prevalent diseases and risk factors at baseline.

Summary / Conclusion: These results are preliminary to more thorough analyses currently being undertaken and patterns identified will be explained further with additional data. The UKITP registry presents a valuable source to study ITP and future ambitions include pheno-genotypic association studies with a view to predict disease severity and likely response to treatment (especially to novel therapeutic agents).

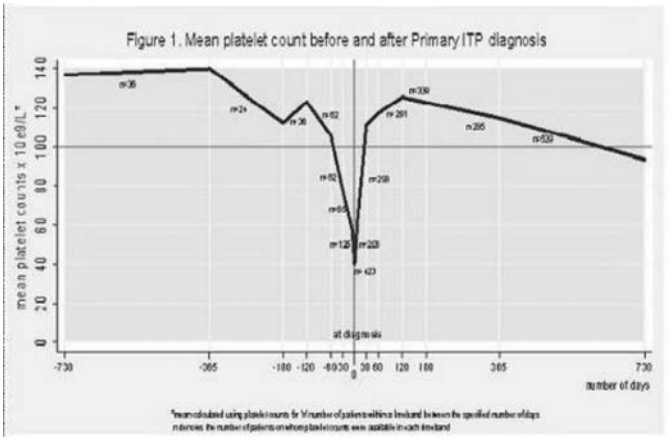

Figure 1.

P474

THROMBOEMBOLIC EVENTS IN PATIENTS WITH ADULT CHRONIC IMMUNE THROMBOCTOPENIA (ITP) TREATED WITH ELTROMBOPAG

S Takagi[1,*] S Watanabe[1], Y Ozeki[1], T Hara[1], Y Kanakura[2], Y Ikeda[3]
[1]GlaxoSmithKline K.K., Tokyo, [2]Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Suita, [3]Faculty of Science and Engineering Life Science and Medical Bioscience, Waseda University, Tokyo, Japan

Background: Eltrombopag is a thrombopoietin receptor (TPO-R) agonist, which binds to the trans-membrane region of TPO-R and promotes platelet production by inducing differentiation and proliferation of megakaryocytes. Eltrombopag has been approved in Japan for adult chronic ITP patients who are intolerant to conventional therapy, show insufficient efficacy to other therapeutic options or have high risk for bleeding. The approved initial dose of eltrombopag is 12.5 mg/day (maximum dose; 50mg/day). Post marketing surveillance (PMS) is mandatory and all patients must be registered for collection of safety and efficacy information in Japan.

Aims: To investigate the relationship between thromboembolic events and eltrombopag treatment based on interim analysis of PMS data in Japan.

Methods: PMS data of patients who were treated with eltrombopag from December 2010 to June 2012 were analyzed. In these patients ertrombopag was taken for up to 6 months. This analysis was focused on the thromboembolic events.

Results: Data were collected from 683 patients (female: 65%). For those patients with information available, 43.3% of patients had ITP for more than 3 years, 14.2% for 1 to 3 years and 19.9% for less than 1 year. In 29.3% of patients platelet count was less than 10x10^9/L at baseline. Corticosteroid was taken concomitantly by 76% of patients during eltrombopag treatment. Eltrombopag increased the mean platelet count up to more than 50x10^9/L after 2 weeks (N=656) and reached to more than 90x10^9/L at 16 weeks (N=460) from the baseline (26x10^9/L). During the 6-month observation period, 25.5% of patients reported an adverse drug reaction (ADR). Thromboembolic events were reported in 29 patients (4.2%) (median age: 70 years, female 69%). Serious ADRs was reported in 45 (6.6%) of 683 patients. As serious ADRs thromboembolic events were reported in 24 patients (3.5%). Among 29 patients associated with thromboembolic events, arterial or venous thromboembolism was seen in 11 and 15 patients, respectively. Two patients had both arterial and venous thromboembolism. In another one patient site of thromboembolic event was unknown. Concomitant corticosteroid was used in 26 (89.7%) of these 29 patients. A past history of thromboembolism, the presence of anti-phospholipid syndrome (APS), or other reported risk factor such as obesity or long-term bedridden was a significant risk factor of thromboembolic events, but concomitant use of corticosteroid or positive anti-phospholipid antibody alone was not significant. Fourteen (48.3%) of 29 patients associated with arterial or venous thromboembolic event had these risk factors. Patients who experienced venous thromboembolic event had significantly more of these risk factors than those associated with arterial thromboembolic event (73.3% vs. 27.3%) (P=0.02). Eleven (37.9%) of 29 patients showed rapid increase of platelet count (above 3 times or more from the baseline and 50x10^9/L or more) within 2 weeks before thromboembolic event. Eight (27.6%) of 29 patients had neither past history of thromboembolic events nor rapid increase of platelet count. In 30% of patients with thromboembolic event, the event was observed at lower platelet count (less than 50x10^9/L).

Summary / Conclusion: Thromboembolic events (ADRs) in eltrombopag treated ITP patients were reported in 29 (4.2%) of 683 ITP patients in Japan. Past history of thromboembolism, the presence of APS, or other reported risk factor such as obesity or long-term bedridden was identified as a significant risk factor of thromboembolic events. ITP patients with venous thromboembolic event had risk factors of thromboembolic event more frequently than those with arterial thromboembolic event.

P475

MANAGEMENT OF ADULT CHRONIC IMMUNE THROMBOCYTOPENIA IN JAPAN: PATIENT AND HEMATOLOGIST PERSPECTIVES

Y Tsukune[1,*] Y Edahiro[1], N Komatsu[1]
[1]Department of Hematology, Juntendo University School of Medicine, Tokyo, Japan

Background: Immune thrombocytopenic purpura (ITP) is an uncommon disorder and hematologists' experience is therefore limited. Although many treatments have been recommended for ITP, there are no evidence-based recommendations for when different treatments should be used, or even when any treatment should be used rather than managing a patient by observation alone. There is no absolute consensus on first line of therapy for treatment of ITO. The prognosis of individual patients with chronic refractory ITP is very variable. Patients may not always understand the disease and available treatments due to the generally mild nature of the disease

Aims: The purpose of this study is to examine the perspectives of Japanese hematologists and adult ITP patients about the disease and treatment.

Methods: A multicenter, questionnaire-based survey conducted between November 2012 and February 2013 in Japan. Both hematologists and their patients with ITP were invited to participate in this survey. The hematologists were mainly asked about their management of ITP. A survey questionnaire for patients asked about their attitudes towards applied treatments, the effects of treatments (effectiveness and safety), impacts on quality of life (QOL), and treatment satisfaction. Written informed consent was obtained from each patient. A response distribution was calculated for each item.

Results: 178 hematologists and 154 adult chronic ITP patients had completed the survey at the time of abstract submission. Regardless of the presence of bleeding symptoms, approximately 80% of hematologists started treatment based on platelet count. Treatment was considered when platelet counts are less than 20x10^9/L in patients without bleeding, and less than 30 ×10^9/L in patients with bleeding. However, in patients without bleeding symptoms whose platelet count had been 10x10^9/L, 11% of hematologists did not start their treatment. Ninety six percent of hematologists consider that platelet counts of 2 to 5x10^9/L are enough for ITP patients. Sixty nine percent of hematologists recognized that quality of life (QOL) has been disturbed in ITP patients. Corticosteroids was considered to be the most effective treatment (44.1%), but 99.4% of physicians expressed concern about its adverse events, especially hyperglycemia (40.9%). In the patient survey, 59.1% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than 10x10^9/L in 57% of patients. The most common symptom of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. Of ITP treatments, side-effects were most frequently associated with corticosteroid use (55%). Among these side effects moon face was considered as a lot of bother. 49.7% patients reported impairment of QOL impairment. No improvement of QOL was recognized in 33% of patients. For ITP patients acceptable platelet counts after ITP treatment were 50 to 100x10^9/L. Fifty one percent of patients still have feeling of vague fear to ITP.

Summary / Conclusion: This is the first survey to examine the perspectives of Japanese hematologists and adult ITP patients about ITP and treatment of the disease in Japan. Inability to balance the risk of severe bleeding against the

risk of side effects with ITP treatment is still a major cause for concern among Japanese hematologists. The gap about target platelet counts between hematologists and patients may not be well recognized. Improvement of QOL was not the major treatment target for hematologists, although the both hematologists and patients recognized QOL impairment. Awareness of the different opinions about ITP treatment between hematologists and patients may improve management decisions.

P476

D-DIMER LEVELS IN ACUTE IDIOPATHIC AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA

A Grosset[1,*] R Soutar[2], K Bailie[3], K Douglas[3]
[1]University of Glasgow, [2]Beatson West of Scotland Cancer Centre, [3]West of Scotland Blood Transfusion Centre, Glasgow, United Kingdom

Background: Prompt and accurate diagnosis of Thrombotic Thrombocytopenic Purpura (TTP) is crucial. Aggressive plasma exchange with FFP reduces an untreated mortality rate of 90% in autoimmune TTP but is ineffective in secondary TTP. Differentiating autoimmune TTP from similar disorders e.g. cancer associated TTP can be challenging.
Aims: We retrospectively reviewed our patients over the past 4 years to see if any laboratory parameters would allow differentiation of primary from secondary TTP.
Methods: Patients with suspected TTP presenting to the West of Scotland Apheresis unit (catchment population circa 3 million), presenting between April 2009 and January 2012 were included. Medical records were reviewed for the final diagnosis and laboratory parameters at presentation. Due to variation in methods between laboratories, D-Dimer levels were expressed as a multiple of the upper limit of normal. Comparison of groups was made by Mann-Whitney tests using Stata 11, Stata Corporation.
Results: 38 patients presented with a clinical picture suggesting TTP, of whom 3 did not have notes or test results available leaving 35 in the analysis group. Nine of these patients had acute idiopathic (autoimmune) TTP, and 8 had an underlying cause identified (malignancy n=5, HIV n=1, pregnancy related n=1, pancreatitis n=1). In 6 patients a definitive diagnosis was not reached and no underlying cause was identified. Twelve patients had haemolytic uraemic syndrome. The autoimmune TTP group had significantly lower levels of both ADAMTS13 (P=0.008, n=10) and D-dimer (P=0.009, n=15). Three of the six patients with D-Dimer levels greater than 5 times the upper limit of normal (approximately 1000 ng/ml) were found to have an underlying malignancy (Figure 1). Haemoglobin levels tended to be higher at presentation in the autoimmune TTP group (median 95 g/L) compared to all other cases (median 80g/l), but the difference was not significant (P=0.07, n=28). There was no difference in platelet count between the two groups (P=0.749, n=28), and no difference in body mass index (P=0.21, n=33).
Summary / Conclusion: D-Dimer levels are not commented on as a diagnostic test in the current British Committee for Standards in Haematology guideline. However, elevated levels appear to be highly indicative of the TTP being secondary. Unlike the ADAMTS13 assay, D-dimer levels are widely available, give a result within minutes and are inexpensive. Elevated D-dimer levels in patients presenting with TTP should prompt urgent search for an underlying cause and possibly delay second line therapy until this has been undertaken.

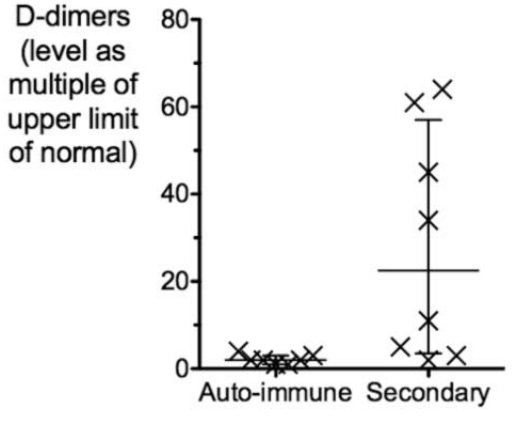

Figure 1.

P477

THROMBOCYTOPENIA IN PREGNANCY: OUR EXPERIENCE AT THE NATIONAL MATERNITY HOSPITAL

M Diaz[1,*] L Mackeogh[1], L Greenan[1], J Quigley[1], P McGarry[1], C O'Neill[1], F Hogan[1], M Anderson[1], M Culliton[1], P Cockburn[1], E Campion[1], J Byrne[1]
[1]Haematology, NMH, Dublin, Ireland

Background: The National Maternity Hospital, Dublin is a tertiary referral centre, with approximately 11,000 deliveries per annum making it one of the biggest maternity hospitals in Europe. At booking and throughout the pregnancy, a low platelet count is not unusual. The main published causes of Thrombocytopenia are: Gestational Thrombocytopenia (GT, 70% of the cases), Preeclampsia/Eclampsia/HELLP syndrome (PEHS, 21%) Immune Thrombocytopenia Purpura (ITP3%) and other causes (6%).
Aims: To compare the published causes of Thrombocytopenia with our data at the NMH. To investigate the effect of age and ethnicity on the differential diagnosis.
Methods: TP is defined as a platelet count below the 2.5th percentile (116,000/μL). For GT diagnosis, the following were taken into account: a low platelet number, presentation of thrombocytopenia in the third trimester, in the absence of a bleeding history, and a mild thrombocytopenia (>70,000/μ L) as no specific diagnostic test can distinguish GT from mild ITP. For Preeclampsia/Eclampsia/HELLP Syndrome we considered the detection of low platelets in the third trimester, duration (days, weeks), recovery of platelet numbers (in the immediate postpartum period), haemolysis phenomena (rise of Bilirubin and LDH), schistocytosis (blood smear), elevated liver enzymes (AST, ALT), Hypoalbuminaemia, and correlated symptoms (rise in diastolic blood pressure, proteinuria, seizures, stomach symptoms, etc). For ITP diagnosis: a past history of persistent thrombocytopenia (plt <100,000/μL), bleeding symptoms and no recovery of platelet numbers after delivery, although the final diagnosis was made based on the exclusion of other possibilities. For diagnosis of TTP and HUS, symptoms at CNS or Kidneys respectively, were taken into account.
Results: A total of 11,538 mothers delivered at the NMH in 2011. 97.6% of these mothers had normal counts and 2.4% (281) presented at booking or thereafter with a platelet count ≤ 116.000/μL; with the latter rising to 4.65% with a cutoff point of 140.000/μL. In 57 cases (20.3 %) was not possible to reach a diagnosis due to insufficient data. In 224 cases (79.7 %) the cause of thrombocytopenia was defined. PEHS was dignosed in 93 cases (46%), GT 83 cases (41%), ITP 19 cases (9,4%) and thrombocitopenia related with delivery 7 cases (3,5%). There were no registered cases of TTP or HUS. The mean duration of thrombocytopenia in PEHS was 6.5 days reaching statistical difference compared with other causes. There was not difference between the mean age of mothers with normal platelet counts (31.91±5.20 years) and mothers with counts <116000/μL (32.91±5.12 years), The differential diagnosis was independent to the patient's age and ethnic origin. However the age in the Irish mothers with TP was greater than in the non Irish population (33.7±5.03 vs 30.59±4.79 years, p 0.00).
Summary / Conclusion: 7.6% of women during pregnancy present with mild thrombocytopenia (100,000/μL - 150,000/μL) and 65% of them will not be associated with any pathology. There is a disparity between our results and the published results. A possible reason for this difference is the lack of clarity with defining the cut-off point in the published literature. The main cause of TP at the NMH was Preeclampsia/Eclampsia/HELLP syndrome (46% vs 21% published), Gestational thrombocytopenia (41.1% vs 70% published), ITP (9.4% vs 3% published) and other causes (3.5 % vs 6% published) and we had no cases of HUS or TTP in 2011. In summary we had less cases of thrombocytopenia when compared with data being published so far elsewhere, and a different proportion of diagnoses that neither the age nor the ethnicity could explain.

P478

MONITORING ANTIPLATELET THERAPY : ACTIVITY OF ADENOSINE DIPHOSPHATE RECEPTOR INHIBITORS IN PATIENTS AFTER PERCUTANEOUS CORONARY INTERVENTION

M Fedor[1,*] R Simonova[2], M Samos[3], J Fedorova[4], I Skornova[1], L Duraj[1], J Stasko[1], P Kubisz[1]

[1]National Centre of Haemostasis and Thrombosis, Clinic of Hematology and Transfusiology, [2]Clinic of Hematology and Transfusiology, [3]Clinic of Internal Medicine1, Comenius University, Jessenius Faculty of Medicine, University Hospital Martin, [4]Hemo Medika s.r.o, Centre of Haemostasis and Thrombosis, Martin, Slovakia

Background: Dual antiplatelet therapy with aspirin and adenosine diphosphate (ADP) receptor inhibitors (clopidogrel, prasugrel, ticagrelor etc.) represents standard prevention of thrombotic complications in patients undergoing percutaneous coronary intervention (PCI). However, resistant or low-responding patients are exposed to significantly increased risk of stent thrombosis, myocardial infarction and cardiac death. The most promising method for monitoring is vasodilator-stimulated phosphoprotein (VASP) assay. Based on flow cytometry, the assay is specifically aimed to determine activity of P2Y12 receptor (principle ADP receptor). On the other hand, results obtained by light transmission aggregometry (LTA) were proved to be valuable especially in association with clinical outcomes of the patients.
Aims: The main goal of our pivotal prospective study is to determine the diagnostic value of LTA and VASP assay.
Methods: Samples of venous blood from group of post-PCI patients were taken in three intervals: prior to PCI; 1day and 30 days after intervention. Further, samples undergo analysis by LTA (with induction by adenosin diphosphate and arachidonic acid) and VASP-P assay. Results will be correlated with treatment regimen, drug dose, clinical presentation and other selected attributes. Informed consent was obtained from all participants.
Results: Studied group (n=30) consisted of patients with acute coronary syndrome who underwent coronary intervention. Patients were in the age of 48 to 84 years. Benchmarks defining altered response to antiplatelet therapy were set at > 50% PRI for VASP-P assay, >50% for (ADP 10 µmol/l) and >20% (AA 0,5 µmol/L induction) for aggregometry assays. Seven patients experienced at least one of the severe complications : either intrastent thrombosis (n=3), myocardial infarction (n=4) or cardiac death (n=3). Five of these patients were detected as low-responders to ADP receptor inhibitor treatment.
Summary / Conclusion: Both LTA and VASP-P assays are clinically relevant diagnostic tests to identify patients not benefiting from antiplatelet therapy. However, challenge remains in standardising the benchmarks to distinguish poor responders.

P479

ANALYSIS OF RETICULATED PLATELETS IN THE ROUTINE CLINICAL PRACTICE USING THE CELL-DYN SAPPHIRE INSTRUMENT

S Jacobsson[1,*] H Orre-Ekdahl[1], J Hoffmann[2], H Wadenvik[3]

[1]Department of Clinical Chemistry and Transfusion Medicine, Sahlgrenska University Hospital, Göteborg, Sweden, [2]Abbott GmbH & Co. KG, Wiesbaden, Germany, [3]Department of Internal Medicine, Hematology, Sahlgrenska University Hospital, Göteborg, Sweden

Background: Major breakthrough in the treatment of thrombocytopenic conditions, especially chronic immune thrombocytopenia (ITP), has been seen in the last few years with introduction of thrombopoietin (TPO) receptor agonists. However, many important issues still need to be addressed in the management of thrombocytopenias and lack of diagnostic tests as well as clinical tools to guide treatment are important issues to be resolved. Indeed, even in ITP the thrombocytopenia is a result of both depressed platelet production and increased platelet destruction. The bone marrow produces around $2x10^{10}$/L platelets per day. The newly released platelets contain RNA and are named reticulated platelets (retPLT). They provide information about the thrombopoietic activity in analogy with reticulocytes for eryhtropoietic activity. The flow cytometric analysis of retPLT is a non-standardized test hampered by variable assay conditions, arbitrary separation between positive and negative cells and poorly defined reference ranges. The Abbot CELL-DYN Sapphire instrument measures reticulated platelets as part of the reticulocyte assay, which is automated and fast, and uses the fluorescent dye (*CD4K530)*. Also, it utilizes fully standardized assay conditions and two-dimensional gating for background fluorescence correction.
Aims: To evaluate the CELL-DYN Sapphire instrument for analysis of retPLT in the routine clinical practice.
Methods: During 4 consecutive weeks all blood samples from the Hematology Department at Sahlgrenska University Hospital were assayed for retPLT using the CELL-DYN Sapphire instrument, in duplicate. A total of 1382 samples were analyzed, coming from more than 600 patients. Reticulated platelets were measured in CELL-DYN Sapphire as a part of the reticulocyte assay in a blood sample diluted with the proprietary fluorescent dye CD4K530, which stains RNA in reticulocytes and retPLT. Then the blood cells pass through a laser beam, where 0°, 7° and 90° light scatter and green fluorescence (FL1) are recorded. Subsequently a variable gate is applied for separating RBC and PLT. Within the PLT cluster, mature and reticulated PLT are distinguished by their fluorescence intensity, using the FL1 vs. 7° scatter plot with dynamic compensation for the size-dependent background fluorescence of PLT. retPLT are expressed as a percentage of the total PLT count.
Results: The highest retPLT percentages were seen in patients with platelet counts below $50x10^9$/L (Figure 1). Platelet counts and retPLT percentages, for a representative patient following high dose chemotheraphy, are shown in Figur 2. Further clinical details of the patient population will be presented. The imprecision (coefficient of variation, CV%) for the retPLT analysis ranged between 11-32%, being highest for patients with the lowest platelet counts (Figure 3).
Summary / Conclusion: Reticulated platelet fraction is a potentially useful diagnostic test that might distinguish between decreased platelet production and increased destruction. It might also predict platelet regeneration after high dose chemotherapy. Measurement of reticulated platelet fraction with fully automated methods overcomes tedious flow cytometry with its lack of standardization. Further clinical studies are needed to assess the value of retPLT by the CELL-DYN Sapphire instrument in thrombocytopenic conditions.

THE ROLE OF OXIDATIVE STRESS IN CHILDREN WITH ACUTE AND CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA

E Erduran[1,*] S Cakmak[2], Y Aliyazicioglu[3], I Turan[4]
[1]Pediatric Hematology and Oncology, [2]Karadeniz Technical University, Trabzon, Turkey, [3]Medical Biochemistry, Karadeniz Technical University, Trabzon, [4]bioengineering, Gumushane University, Gumushane, Turkey

Background: İdiopathic thrombocytopenic purpura (ITP) is an autoimmune disease but, every thrombocytopenia is not an autoimmune disease. Oxidative injury plays a pivotal role in pathogenesis of autoimmune diaseases resulting from DNA , protein and lipid oxidation.
Aims: To investigate whether oxidative damage is involved in acute and chronic idiopathic ITP in childhood.
Methods: Twenty-seven patients with a diagnosis of acute ITP and 27 with a diagnosis of chronic ITP were included in the study group. Thirty-one age and sex-matched healthy children constituted the control group. Cases were investigated in three groups; Group 1- chronic ITP cases, Group 2- acute ITP cases and Group 3- the control group. Total blood count, direct Coombs test, antinuclear antibodies, the oxidation products 8-OH deoxyguanosine (8-OHdG), protein carbonyl and malondialdehyde (MDA) and also total oxidative stress (TOS), total antioxidant capacity (TAC) and oxidant index (OI) for analysis of the oxidant/antioxidant balance were all investigated from specimens collected from peripheral blood in all three groups. OI value was obtained from the TAC/TOS ratio (OI=(TOS, µmol/L)/TAC, mmol trolox equivalent/lx100). Blood samples were collected following a one-month break in treatment from those patients in Group 1 receiving cyclosporine or other immunosuppressive drugs. Patients with a diagnosis of acute ITP were enrolled at time of diagnosis, before the administration of any drug. Data for the three groups were compared using SPSS 13.01.
Results: A statistically significant difference was determined in 8-OHdG, MDA, TAC and TOS levels between the three groups (P=0.000, P=0.000, P=0.004 and P=0.000, respectively). No significant difference was observed in protein carbonyl and OSI levels between the groups (P=0.208 and P=0.066, respectively). MDA, TAC and TOS levels in Group 1 were statistically higher compared to those in groups 2 and 3 (P=0.000, P=0.004 and P=0.000, respectively), and 8-OHdG levels in Group 2 were higher than those in groups 1 and 3 (P=0.000). 8-OHdG levels were higher in Group 2 compared to Group 1 (P=0.013), while 8-OHdG, MDA and TOS levels in Group 2 were higher than those in Group 3 (P=0.013, P=0.000 and P=0.000, respectively); MDA, TAC and TOS levels in Group 1 were again higher than those in Group 3 (P=0.000, P=0.004 and P=0.000, respectively).
Summary / Conclusion: Both oxidant stress and total antioxidant response as a response to this rise in acute and chronic ITP patients. 8-OHdG, MDA and TAC which shows the antioxidant defense system and TOS were higher in acute and chronic ITP patients compared to the control group. Protein carbonyl exhibited no statistically significant difference among the groups, suggesting that oxidative damage occurring in ITP affects the lipid in thrombocytes and DNA before the protein oxidation stage. In conclusion, we think that oxidative damage is involved in the pathogenesis of acute and chronic ITP.

P482

PILOT OBSERVATIONAL STUDY OF ROTATIONAL THROMBOELASTOMETRY (ROTEM) TO PREDICT BLEEDING RISK IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES (ATHENA STUDY)

L Estcourt[1,2,*] S Stanworth[1,2], A Mumford[3], P Harrison[4], G Powter[1], K Harding[5], C Dyer[1], S Howgate[4], M Murphy[1,2]
[1]NHS Blood and Transplant, [2]Radcliffe Department of Medicine, University of Oxford, Oxford, [3]University Hospitals Bristol NHS Foundation Trust, Bristol, [4]Oxford Haemophilia and Thrombosis Centre, Oxford University Hospitals NHS Trust, Oxford, [5]NHS Blood and Transplant, Bristol, United Kingdom

Background: Previous studies have shown that the platelet count is a poor predictor of bleeding in severely thrombocytopenic patients with hematological malignancies. Rotational thromboelastometry (ROTEM) detects thrombocytopenia but is also sensitive to functional alterations of platelets and soluble coagulation proteins which could contribute to bleeding in severe thrombocytopenia.
Aims: The aim of this study was to evaluate whether ROTEM parameters of extrinsically activated coagulation [EXTEM (clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), maximum lysis (ML))], intrinsically activated coagulation [INTEM (CT, CFT, MCF, ML] and the fibrinogen contribution to coagulation [FIBTEM (test based on EXTEM but contains cytochalasin D to inhibit platelets) (MCF, ML)] were better at predicting bleeding than the platelet count.
Methods: Prospective cohort study of adults with a hematological disorder undergoing intensive chemotherapy or stem cell transplant (ISRCTN81226121) at two UK centers (Bristol and Oxford) between September 2010 and September 2012. The study inclusion criterion was development of thrombocytopenia (platelet count ≤50x10^9/L). From the start of thrombocytopenia, the participants underwent daily formalized bleeding assessments until platelet count recovery, hospital discharge, death, or for up to 30 days. Bleeding was graded by the WHO score. Alongside routine tests, additional venous blood samples were collected into EDTA and citrate collection tubes three times a week for detailed analysis of platelet and ROTEM parameters. The data were analyzed using a generalized linear model with binomial family and logit link function clustered on patient identity to account for repeated measures.
Results: All 50 participants were followed up until study completion. The baseline characteristics were: mean age 51.0 years; male (33/50); diagnosis (leukemia 16/50; lymphoma 14/50; myeloma 9/50; other 11/50); treatment (chemotherapy 4/50; allograft 33/50; autograft 13/50). Bleeding symptom data were available for 99.7% of study days. The participants had a median 3 days of bleeding (any severity) (interquartile range (IQR) 0-6); and median 11 days (IQR 8-16) with platelet count ≤50x10^9/L. 30.6% of patients had at least one episode of WHO grade 2 or above bleeding during the study period. The unadjusted odds ratio (OR) for bleeding the following day when the platelet count was ≤50x10^9/L was 0.98 (95% confidence interval (CI) 0.97-1.00; P=0.03). The unadjusted OR for bleeding based on the ROTEM parameters (EXTEM MCF and INTEM MCF) were close to statistical significance. However, this effect was lost when the results were adjusted for the platelet count (Table 1). The unadjusted OR for WHO grade 2 or above bleeding the following day when the platelet count was ≤50x10^9/L was 0.98 (95% CI 0.96 to 1.00; P=0.055). The unadjusted OR for bleeding based on the ROTEM parameters (EXTEM MCF and INTEM MCF) were statistically significant but this effect was lost when the results were adjusted for the platelet count (Table 1).
The unadjusted OR for any bleeding or WHO grade 2 or above bleeding based on FIBTEM MCF were not significant.
Summary / Conclusion: This preliminary study does not suggest that ROTEM has any greater predictive value than the platelet count for any bleeding or WHO grade 2 or above bleeding. The statistically significant OR for some of the ROTEM parameters are likely to be explained by a direct effect of platelet count on the ROTEM assay endpoints.

Table 1.

	Unadjusted Odds Ratio	95% CI	P value	Odds Ratio adjusted for plt count	95% CI	P value
Any Bleeding						
Plt count	0.98	0.97 to 1.00	**0.03**			
ROTEM MCF						
EXTEM	0.97	0.95 to 1.00	0.058	0.98	0.94 to 1.03	0.405
INTEM	0.98	0.95 to 1.00	0.069	0.98	0.94 to 1.03	0.523
FIBTEM	1.01	0.97 to 1.05	0.50	1.02	0.98 to 1.06	0.346
WHO Grade 2 or above bleeding						
Plt count	0.98	0.96 to 1.00	0.055			
ROTEM MCF						
EXTEM	0.93	0.88 to 0.97	**0.001**	0.94	0.89 to 1.00	0.07
INTEM	0.93	0.89 to 0.98	**0.004**	0.95	0.89 to 1.01	0.214

P483

AUTOCRINE AMPLIFICATION OF INTEGRIN AIIBB3 ACTIVATION AND PLATELET ADHESIVE RESPONSES BY DEOXYRIBOSE-1-PHOSPHATE

D Vara[1,*] G Pula[1]
[1]Pharmacy and Pharmacology, University of Bath, Bath Spa, United Kingdom

Background: Platelet activation is a complex series of events originating from the stimulation of surface receptors by biochemical signals linked to vascular damage, such as the exposure of the subendothelial matrix and the generation of thrombin in the coagulation cascade. Besides responding to their microenvironment and to the biochemical messages released by other circulating or vascular cells, platelets also release their own rich array of extracellular signals. Amongst the small molecules released by platelets, thromboxane A_2 (TXA_2), adenosine diphosphate (ADP), epinephrine, and serotonin (5-HT) are key autocrine regulators of platelet responses. Recently, we utilised gas-chromatography mass spectrometry (GC-MS) to identify new molecules released by platelets. The pro-angiogenic metabolite deoxyribose-1-phosphate (dRP) was detected in micromolar concentrations in stimulated platelet supernatants.
Aims: In light of the ability of dRP to stimulate the generation of reactive oxygen species (ROS) in different cell types and the pro-aggregatory role of ROS in platelets, we investigated whether platelet-derived dRP plays any autocrine role in the regulation of the redox balance, the intracellular signalling, or the functional responses of platelets.
Methods: The experiments were performed on human platelets from healthy donors or mouse platelets, either wild type or transgenic characterised by genetic deletion of thymidine phosphorylase and uridine phosphorylase ($TP^{-/-}$ $UP^{-/-}$), which results in impaired dRP release upon platelet activation. The effects of deprivation of endogenous dRP (transgenic platelets) or addition of exogenous dRP were tested on washed platelet aggregation (by turbidimetry), integrin αIIbβ3 activation (by flow cytometry), washed platelet static adhesion (by phase contrast imaging), whole blood thrombus formation (by microfluidics and time-lapsed epifluorescence microscopy), ROS accumulation (by live platelet confocal imaging), and signal transduction pathway (by immunoblot).
Results: The addition of exogenous dRP to human platelets significantly increased platelet aggregation and integrin αIIbβ3 activation in response to thrombin. In parallel, genetically modified platelets with double genetic deletion of thymidine phosphorylase and uridine phosphorylase were characterised by reduced release of dRP, impaired aggregation and decreased integrin αIIbβ3 activation in response to thrombin. *In vitro* platelet adhesion onto fibrinogen and collagen under physiological flow conditions was potentiated by treatment of human platelets with exogenous dRP and impaired in transgenic platelets with reduced dRP release. Human and mouse platelets responded to dRP treatment with a sizeable increase in ROS generation and the pre-treament with the antioxidant apocynin abolished the effect of dRP on aggregation and integrin activation. Experiments directly assessing the activation of the small G protein Rap1b and protein kinase C suggested that dRP increases the basal levels of activity of these two pivotal platelet-activating pathways in a redox-dependent manner.
Summary / Conclusion: Taken together, we present evidence that dRP is a novel autocrine amplifier of platelet activation, which acts on platelet redox levels and modulates integrin αIIbβ3 inside-out signalling.

P484

INCREASED CIRCULATING MICROPARTICLES COEXPRESSING ENDOTHELIAL AND PLATELET MARKERS IN ISCHEMIC CEREBRAL STROKE

G Ezzat[1,*] S Rizk[2], S El Shafei[1], O Serafy[3], M Niazy[1], A Razik[1], M Ezzat[1]
[1]Clinical Pathology, Fayoum University, Fayoum, [2]Clinical Pathology, [3]Neurology, Cairo University, Cairo., Egypt

Background: Cellular microparticles (MPs) are submicron plasma membrane derived vesicles shed into the circulation by a variety of blood cells and vascular cells during cellular activation and apoptosis. Currently no practical, rapid and sensitive test is available for the diagnosis of acute ischemic stroke. Current knowledge from earlier studies on MPs suggests that they represent reliable biomarkers as they are cell specific and released early in the pathophysiological cascade of the disease.
Aims: To study the potential use of circulating microparticles assay as biomarkers in the prediction and early diagnosis of thrombotic stroke.
Methods: This study included 20 patients with acute cerebrovascular ischemic infarction confirmed by neuroimaging as well as 20 matched healthy controls. Full evaluation of clinical, radiological and laboratory data was done. Peripheral blood endothelial, platelet, erythrocyte and monocyte microparticles were measured by flowcytometry using their corresponding monoclonal antibodies (anti CD 62 E, anti CD 61 P, anti CD235 and anti CD 14) respectively. An informed written consent was obtained from all patients or their legally authorized relatives as well as the healthy controls prior to their enrolment. Approval of the Institutional Ethical Review Board was obtained.
Results: A significantly higher CD 235 and highly significantly elevated CD 61P and CD 14 were observed in stroke patients compared to controls where platelet derived microparticles PMPs were the most commonly occurring (28.8%). Co-expression of CD61P and CD62E was a common feature in stroke patients (39.5%) which was found to be highly significant when compared to controls. A cutoff value for the co-expression of CD 61P and CD 62 E as a marker of thrombotic stroke was suggested to be 13.5% using ROC curve statistical method. This co-expression was higher among stroke patients with diabetes mellitus and cardiac disease while CD61P expression was significantly higher in diabetic patients when compared to non-diabetics. A significant higher expression of CD 61P and CD 235 was found in patients not receiving anticoagulation at the time of sampling when compared to controls.The MPs of erythrocyte origin was present in 19.2% of patients while those of endothelial origin were the least occurring (2%).
Summary / Conclusion: The higher levels of CD 61P, CD 62 E, CD 14 and co-expression of CD 61P and 62E suggests that the systemic endothelial, platelet and inflammatory cell activation increases the risk for cerebrovascular morbidities especially in patients with diabetes mellitus and history of cardiac disease. MPs co-expressing CD62E and CD 61P can be used as a test for the early diagnosis of thrombotic stroke with high sensitivity and specificity. Establishing a cutoff value for co-expression of CD62E and CD61P in stroke patients can contribute to the clinical applications as using MP assay in diagnosis of thrombotic propensity, monitoring of anticoagulant therapy, and detection of risk of stroke and ischemic heart disease in high risk patients.

P485

LOW MOLECULAR WEIGHT HEPARIN (LMWH) FOR PRIMARY THROMBOPROPHYLAXIS OF AMBULATORY PATIENTS WITH SOLID CANCER –SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

A Gafter-Gvili[1,2,*] S Stemmer[1,3], O Shpilberg[1,2], A Sulkes[1,3], I Ben-Aharon[1,3]
[1]Sackler School of Medicine, Tel Aviv University, Tel Aviv, [2]Institute of Hematology, Davidoff Cancer Center, [3]Institute of Oncology, Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, Israel

Background: Patients receiving chemotherapy for cancer are at increased risk for venous thromboembolism (VTE). The role of low molecular weight heparin (LMWH) as antithrombotic prophylaxis has been appraised in several studies, yielding conflicting results in terms of efficacy and safety. Currently, prophylaxis is not routinely recommended for ambulatory patients receiving chemotherapy.
Aims: We performed a meta-analysis of all randomized controlled trials (RCTs) which evaluated the addition of LMWH as primary thromboprophylaxis in ambulatory patients with solid malignancies while receiving chemotherapy, in order to assess reduction of VTE.
Methods: A comprehensive search of The Cochrane Library, MEDLINE, conference proceedings and references was conducted until December2012. Two reviewers appraised the quality of trials and extracted data. We assessed both efficacy outcomes and safety outcomes. Outcomes assessed were: symptomatic VTE, pulmonary emboli (PE), any VTE, symptomatic DVT. In addition we assessed mortality and adverse events. For dichotomous data, relative risks (RR) with 95% confidence intervals (CIs) were estimated and pooled.
Results: Nine trials conducted between the years 2004 and 2012 met the inclusion criteria, and randomized a total of 6691 patients. The LMWH used in these trials included: nadroparin (3 trials), certoparin (2 trials), semuloparin (1 trial) and dalteparin (3 trials). Patients included in the trials had locally advanced or metastatic cancer. Cancer types included lung, breast, pancreas, stomach, bladder, colorectal and other. Primary prophylaxis with LMWH significantly reduced the rate of symptomatic VTEs (RR 0.47, 95% CI 0.32 to 0.69, 8 trials), the rate of PE (RR 0.51, 95% CI (0.30 to 0.86, 6 trials), the rate of symptomatic DVT (RR 0.35, 95% CI 0.21 to 0.60, 6 trials), and the rate of any VTE (RR 0.58, 95% CI 0.43-0.77, 8 trials). Meta-analysis of the sixtrials which reported mortaliy outcomes, revealed no statistically significant benefit for LMWH in 1 year mortality rates (RR 0.93, 95% CI(0.83 to1.04). There was no significant increase in major bleeding events in the LMWH arm (RR 1.36, 95% CI 0.91-2.04, 8 trials).
Summary / Conclusion: LMWH reduced the incidence of VTE in ambulatory patients receiving chemotherapy for cancer, with no apparent increase in major bleeding. Nevertheless, LMWH had no significant effect on survival outcomes. Future studies should delineate which specific cancer populations may benefit the most.

P486

PLATELET COUNTS DECREASE WITH INCREASING LUPUS-LIKE ANTICOAGULANT RATIOS, IRRESPECTIVE OF ANTIPHOSPHOLIPID SYNDROME CRITERIA

M Pereira[1,*] G Marques[2], N Silva[2], M Lourenço[2], G Ribeiro[2]
[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospitals, Coimbra, Portugal

Background: Thrombocytopenia has been described in association with clinically-expressed antiphospholipid syndrome (APS), in up to a quarter of patients, in whom it could be due to immune phenomena, consumptive thrombocytopenia or both. In contrast, the relationship between reduced platelet counts and the presence of lupus anticoagulant (LA) irrespective of APS criteria, has been less consensual, with some authors relating incidences of up to a third of patients, and others finding it a rare event.
Aims: To clarify the relationship between the behaviour of platelet counts and the quantification of LA, in a large cohort of LA-positive patients, irrespective of the presence of clinical criteria for APS.
Methods: We reviewed all requests received in the coagulation sector of our laboratory from 01-01-2000 to 12-31-2012, selecting the 7974 patients with LA determinations. Results were considered Negative when the Lupus Ratio was under 1.2; positive results were further divided into Low (1.20-1.99), Moderate (2.00-2.99) and High Positive (3.00 and over). Platelet counts were compared across these four groups. Results for activated partial thromboplastin time (aPTT) and prothrombin time (PT) were also compared over the four groups, as a control.
Results: LA ratios varied between 0.50 and 5.25, with a median of 1.06, being Positive in 13.7% (1095) of patients with LA determinations. Mean platelet counts were 235.3±102.3 G/L in Negative LA and decreased with increasing ratios of LA - 225.5±99.0 in Low, 195.4±81.3 in Moderate and 157.6±113.8 in High Positive results (P<0.001). Thrombocytopenia, defined as platelet counts under 150 G/L, was present in 13.6% of Negative patients and increased to 16.7% of Low, 28.0% of Moderate and 50.0% of High Positive patients (P<0.001). There were no statistical differences between Positive and Negative patients in mean platelet volume (9.2±1.4 and 9.1±1.3 fL, respectively) or platelet distribution width (16.5±3.0% and 16.5±3.1%, respectively).
As expected, and by definition, there was a significant correlation between increasing ratios of LA and increasing aPTT ratios (r^2 = 0.365). The mean aPTT increased with increasing positivity, being 29.8±8.0s in Negative LA, 41.5±18.7s in Low, 81.8±37.3s in Moderate and 94.6±34.0s in High (P<0.001), corresponding to aPTT ratios of 1.0±0.3, 1.5±0.6, 2.8±1.3 and 3.4±1.2, respectively (P<0.001). The mean PT was 15.4±4.7s in Negative LA (an increase of 1.9±4.7s over the control), and increased with increasing ratios of LA - 16.8±6.6s in Low, 20.4±9.0s in Moderate and 20.1±10.2s in High (P<0.001), corresponding to increases of 3.3±6.6s, 6.7±9.0s and 6.4±10.3s over the control, respectively (P<0.001).
Summary / Conclusion: In a large cohort of nearly 8000 patients with LA determinations, 14% of whom were positive for the presence of LA, we found that there was a consistent decrease in the mean platelet count, from Negative to High Positive lupus ratios, with a difference of nearly 80 G/L of platelets between the two extremes. The incidence of thrombocytopenia likewise increased significantly through the LA groups, rising from 14% of LA-Negative subjects to 50% of High Positive patients. We suggest that decreasing platelets are a feature of the presence of lupus-like anticoagulants, even in the absence of APS. We also show that overt thrombocytopenia is not the only manifestation of the impact of LA on platelet counts, with a consistent decrease being noted even before the threshold for thrombocytopenia is reached. Our results on aPTT were consistent with the published literature and with the known laboratory behaviour of lupus-like anticoagulants, pointing to the validity of our LA results. The described association between the intensity of platelet reduction and the severity of positivity for LA could help explain the opposing results reported by different authors, if distinct LA cut-off values are used, or APS-negative LA-positive patients are excluded.

P487

REDOX-DEPENDENT ANGIOGENESIS BY NUCLEOSIDE DERIVATIVES OF DEOXYRIBOSE-1-PHOSPHATE

D Vara[1,*] C Wheeler-Jones[2], H Mellor[3], G Pula[1]
[1]Pharmacy and Pharmacology, University of Bath, Bath Spa, [2]Comparative Biomedical Sciences , Royal Veterinary college, London, [3]School of Biochemistry, University of Bristol, Bristol, United Kingdom

Background: Reactive oxygen species (ROS) are associated with multiple cellular functions such as cell proliferation, differentiation and apoptosis. Signal transduction by ROS, 'redox signaling' in angiogenesis is an important and emerging topic in cardiovascular sciences. ROS mediate vascular endothelial cell (EC) proliferation and migration, but the molecular mechanism underlying this phenomenon remains largely unclear. Recently we investigated the pro-angiogenic effect of deoxyribose-1-phosphate (dRP) released by stimulated platelets, which was shown to induce an increase in EC motility *in vitro* and a strong angiogenic response *in vivo*.
Aims: In this study, we investigated the role of ROS generation in the angiogenic response mediated by dRP.
Methods: ROS generation was investigated in human umbilical vein endothelial cells (HUVECs) by live cell confocal imaging post stimulation with dRP or its derivatives, deoxyribose-5-phospate (dR5P), glyceraldehyde-3-phosphate (G3P), ribose-1-phosphate (R1P) and deoxyribose (dR). The protein expression of heme oxygenase-1 (HO-1) was investigated, which is known to be upregulated under oxidative stress conditions. We also analysed the protein expression of integrin β3 to investigate the link between dRP-dependent increase in endothelial ROS generation and cell motility. Endothelial cell motility *in vitro* was tested using monolayer repair scratch healing assay. The expression of critical pro-angiogenic molecules such as vascular endothelial growth factor (VEGF), interleukin 8 (IL-8), and stromal cell-derived factor 1α (SDF-1α) in HUVECs treated with dRP was tested by immunoblot.
Results: The addition of exogenous dRP decisively increased HUVEC ROS generation. Similarly, the dRP derivatives dR5P, G3P, and R1P also induced ROS accumulation in HUVECs, whereas dR did not. As expected, the redox stress marker HO-1 was shown to be upregulated by dRP and its derivatives. Interestingly, integrin β3 was shown to be upregulated by HUVEC treatment with dRP and its phorphorylated derivatives (i.e. except dR), as demonstrated by immunoblot experiments in the presence of the ROS scavenger N-acetylcysteine (NAC) and the antioxidant apocynin. In parallel, only the phosphorylated derivatives of dRP appeared to increase HUVEC cell motility in scratch-healing assay. The causative link between integrin β3 upregulation and increased HUVEC motility was proved using integrin-specific inhibitory antbodies.
Summary / Conclusion: In summary, this study demonstrates a link between dRP-dependent increase in endothelial ROS generation, the upregulation of integrin β3 and the increase in endothelial cell motility and angiogenic activity. The paracrine regulation of endothelial cell motility by platelet-derived dRP is likely to play an important role in the stimulation of postnatal angiogenesis and tissue repair.

P488

THE JAK2 V617F MUTATION IN PATIENTS WITH CEREBRAL VENOUS THROMBOSIS IS ASSOCIATED WITH AN INCREASED RISK OF RECURRENCE

V De Stefano[1,*] T Za[1], A Ciminello[1], S Betti[1], F Pilato[2], G Marca[2], R Morosetti[2], P Chiusolo[1], V Di Lazzaro[3], E Rossi[1]
[1]Institute of Hematology, [2]Institute of Neurology, Catholic University, [3]Institute of Neurology, Campus Bio-Medico University, Roma, Italy

Background: Cerebral venous thrombosis (CVT) is a rare and severe event. Recently a part of patients has been reported to carry the molecular marker of myeloproliferative neoplasm (MPN) JAK2V617F. Little is known about the follow-up of CVT patients.
Aims: To investigate in a cohort of patients with CVT the rate of recurrent venous thromboembolism and the risk for recurrence associated with either thrombophilia and the JAK2V617F mutation
Methods: We investigated an ambispective cohort of 114 CVT patients; 25 (M/F 18/7) were aged <18 years (median5, range 0-13). The 89 adults (M/F 16/73) had a median age of 35 (range 18-82). Patients with cancer were excluded. Inherited thrombophilia, antiphospholipids, and JAK2V617F were searched in all patients. A follow-up >6 months after CVT was recorded in 72 patients (60 adults), being prospective in 50 of them (31 adults). The probability of recurrence was estimated by the Kaplan–Meier method.
Results: In pediatric patients the leading causes of CVT were loco-regional infections (n=13, 52%). Thrombophilia was diagnosed in 5 (20%); no child had JAK2V617F. In adults CVT was associated with oral contraceptives or pregnancy in 35 (48% of females) and 16 (22% of females), respectively, with other risk circumstances in 13 (14% of cases), and was unprovoked in 24 (27%). Thrombophilia was diagnosed in 27 (30%). Eight patients had JAK2V617F (9%); only one CVT was unprovoked. Four of them had diagnosis of MPN at the CVT event. In the 60 adult patients with an evaluable follow-up (median 2.3 years, range 0.5-32.6, total 336) the incidence of recurrent venous thrombosis was 3.1% pt-years (11 events in 10 patients: three CVT, six DVT- two in the same patient -, two splanchnic thromboses). Recurrences occurred in one of 31 reference patients without either thrombophilia and JAK2V617F (3.2%), three of 21 patients with thrombophilia (14.3%), and six of seven patients with JAK2V617 (86%). No increase in risk was associated with thrombophilia (hazard ratio, HR, 1.11, 95%CI 0.18-6.76); in contrast, the overall HR ratio for recurrence associated with JAK2V617F was 4.75 (95%CI 1.81-35.77). The incidence of recurrence was 9.1% pt-years in the JAK2V617F-positive patients and 1.8% pt-years in those JAK2V617F-negative.
Summary / Conclusion: In CVT patients the overall risk of recurrence is low and is not associated with thrombophilia. However, JAK2V617F is associated with an exceedingly high risk of recurrence, suggesting need for long-term anticoagulation.

P489

RETROSPECTIVE THREE YEAR AUDIT COMPARING HOSPITAL ACQUIRED THROMBOSIS RATES FOR UNPLANNED AND ELECTIVE ADMISSIONS

H Rowswell[1,*] T Nokes[1]
[1]Department of Haematology, Plymouth Hospitals Nhs Trust, Plymouth, United Kingdom

Background: Since 2010, data has been collected on both total venous thromboembolism (VTE) and hospital acquired thrombosis (HAT) events within Derriford Hospital, using the radiological reporting system (CRIS). Root cause analysis is then undertaken reviewing a number of standards, including appropriate VTE prevention. Feedback in real-time on HAT events is then shared with the speciality involved, including whether adequate prevention was used. HAT data has been scrutinised by speciality against the number of admissions to produce information about the incidence of HAT within disciplines and to observe trends.
Aims: Having identified HAT outcome data and incidence by speciality, type of admission (elective or unplanned), was reviewed to see if it had any impact on HAT metrics. Four main surgical specialities; orthopaedic, neurosurgery, cardiac surgery and general surgery, were selected over three years, to determine whether the type of admission influenced the number of HAT events.
Methods: HAT data from 2010-2012 was used to identify events from the four specialty areas investigated. These events were cross-checked with the hospital patient information system to determine whether the admission was elective or unplanned presentation. Information was then produced on the annual number of admissions by speciality, with separate totals for both elective and unplanned. Data was then analysed using a statistical package 'R' reviewing HAT by percentage of admissions for each speciality, by year and for both elective and emergency, to provide outcome data.
Results: Table 1 identifies data for the four specialties showing an increase in HAT for unplanned compared to elective admissions for three of the four specialties. In general surgery, no difference is seen between elective and unplanned HAT probably because 50% of surgical unplanned admissions are discharged without surgery, therefore no analysis for this group was possible. In the three remaining specialities where almost all elective and unplanned patients have an operation, chi squared test was used to assess the total incidence of HAT for all admissions, showing these were statistically similar for every year (x^2=0.1575, p value 0.9243). Comparing elective and unplanned admissions using The Cochran-Mantel-Haenszel test for conditional independence, this showed a statistically significant difference in the incidence of HAT over the three years (P-value 1.533e-11, 95% CI 0.238 – 0.459 for the null hypothesis). Furthermore, HAT rates are significantly different between elective and unplanned admissions according to a chi-squared test of proportions (X^2= 50.6538, p-value 1.102e-12, 95% CI -0.008717488 - -0.004133094 for the null hypothesis). A Fishers exact test gives the same result. [odds ratio (0.3307654)]. These analyses all demonstrate that VTE is significantly higher in the unplanned over elective surgical admission groups.
Summary / Conclusion: Outcome data demonstrates statistically significant increase in HAT for unplanned admissions (2-3 fold), compared to elective admissions in orthopaedic, neurosurgery and cardiac surgery. Elective patients are usually more fit and often attend preoperative clinics where VTE information is given. The importance of VTE risk assessment, prophylaxis and education is important for all surgical patients but particularly emergency patients as the risk of HAT is higher than elective admissions and been shown to remain elevated for several months post discharge.

Table 1. HAT by speciality 2010-2012.

		ELECTIVE		UNPLANNED	
Surgical Speciality	Year	Total HAT/ Total Admissions	HAT %	Total HAT/ Total Admissions	HAT %
Cardiac	2010	2/821	0.24	2/248	0.81
Cardiac	2011	4/921	0.43	2/234	0.85
Cardiac	2012	3/983	0.31	2/236	0.85
Neuro	2010	8/1725	0.46	10/596	1.68
Neuro	2011	8/1502	0.53	10/596	1.68
Neuro	2012	4/1604	0.25	6/646	0.93

ADVANTAGES AND DISADVANTAGES OF INCORPORATING C-REACTIVE PROTEIN LEVELS, AGE AND D-DIMER LEVELS IN DIAGNOSING PULMONARY EMBOLISM

M Crop[1,*] C Siemes[2], P Berendes[3], F van der Straaten[4], M Levin[1]
[1]Internal Medicine, Albert Schweitzer Hospital Dordrecht, Dordrecht, [2]Internal Medicine, Erasmus MC, Rotterdam, [3]Clinical Chemistry, [4]Radiology, Albert Schweitzer Hospital Dordrecht, Dordrecht, Netherlands

Background: Over the past several years the number of performed radiological scans to diagnose pulmonary embolism (PE) increased dramatically, while the incidence of PE hardly increased. This resulted in an increased number of patients exposed to radiation and higher costs. Recently, the use of an age-adjusted D-dimer cut-off value was suggested to increase specificity of D-dimer testing.
Aims: This study investigated the impact of incorporating age and levels of C-reactive protein (CRP) and D-dimer on the sensitivity and specificity to diagnose PE.
Methods: This observational study (2004-2007) included all consecutive patients suspected for PE presenting on the Emergency Department and with simultaneously measured levels of CRP and D-dimer. Only patients who received pulmonary CT angiography were further analyzed. We investigated the correlation between age, CRP, D-dimer and the effect of using an age-adjusted cut-off values for D-dimer [age in years/100 mg/L] for patients ≥50 years. Moreover, the predictive value of these parameters for PE was studied.
Results: Of 4609 patients suspected for PE, 1164 patients got radiological imaging. PE was demonstrated in 309 patients (26.5%). Correlation between D-dimer and CRP levels was 18% (P<0.001) i.e. 18% of variation in D-dimer can be explained by variation in CRP. Interestingly, D-dimer levels were positively correlated with age (8%, P<0.01), but only in patients >50 years and independent of presence of PE. Multivariate regression analysis showed significant contribution of age, D-dimer levels and age*D-dimer (i.e. age-adjusted D-dimer) in the prediction of PE, while CRP did not. Compared to the conventional cut-off level, using an age-adjusted D-dimer cut-off value in patients ≥50 years the negative predictive value decreased from 96% to 93%, while specificity increased from 37% to 50%. In patients ≥70 years this effect was even stronger.
Summary / Conclusion: In the prediction of PE, age and dimer levels are relevant, while CRP levels are not. Using an age-adjusted D-dimer cut-off in older patients modestly reduces the negative predictive value, but dramatically increases the specificity of D-dimer testing, thus reducing the need of performing CT scans.

P491

EVALUATING ACQUIRED DISORDERS OF PROTEIN C SYSTEM IN PATIENTS ON VITAMIN K ANTAGONISTS TREATMENT BY THE CALIBRATED AUTOMATED THROMBOGRAM

V Shmeleva[1,*] O Golovina[1], Y Namestnikov[1], O Matvienko[1], V Soldatenkov[1], N Saltikova[1], L Papayan[1]
[1]Russian Research Institute of Hematology and Transfusion, Saint-Petersburg, Russian Federation

Background: There is a theoretical concern that abrupt vitamin K antagonists (VKA) discontinuation may result in a temporary hypercoagulable state due to imbalance in the rates of normalization of activity of the vitamin K dependant coagulation factors on the one hand and the natural anticoagulants protein C (PC) and protein S on the other hand. Results of the studies concerning this problem are inconsistent. The Calibrated Automated Thrombogram (CAT) is now considered to better correlate with patients phenotype compared to traditional coagulation tests. When thrombomodulin (TM) is used thrombin generation (TG) becomes sensitive to all disorders of the PC system.
Aims: Aim of our study was to determine how PC system is affected by VKA treatment at different dose regimens (INR range 0,9-3,4).
Methods: TG was measured according to Hemker *et al.* with fluorogenic assay, at 5 pM TF and 4 μM phospholipids in platelet poor plasma (PPP) with PPP plasma+/-TM reagent (Thrombinoscope BV, Maastricht, The Netherlands). The procedure was carried out on an automated fluorometer (Fluoroscan Ascent, Thermolab system, Finland). Thrombin generation curves were calculated using the Thrombinoscope software (Thrombinoscope BV, The Netherlands). The study involved 43 patients with venous thrombosis on VKA in the extended-treatment phase (M/F 23/20, mean age 54,6±15,8 yrs, duration of VKA 1,5-4 yrs), among them 19 patients with therapeutic INR range of2,0 to3,0 and 24 patients at low intensity treatment before the discontinuation of VKA's therapy with INR range of 0,9 to1,8. Control group (n=28) was age matched. STATISTICA 6.1 was used.
Results: From four parameters derived from the thrombin generation curves: Lag time (min), endogenous thrombin potential ETP (nMmin), peak height for thrombin (nM), time to peak (min) only ETP and peak height for thrombin (PHT) seemed important to evaluate disorders of PC system. When the PC pathway was challenged by adding TM to plasma both ETP and PHT were markedly reduced. Normal ranges of reduce defined as 5-95th percentile of ↓ETP calcu-

lated as (ETP in PPP_{-TM} minus ETP in PPP_{+TM})/ETP in PPP_{-TM}×100% and ↓PHT calculated as (PHT in PPP_{-TM} minus PHT in PPP_{+TM})/PHT in PPP_{-TM}×100% in controls were 21-62% and 14-51% respectively. Interquartile range of ↓ETP and ↓PHT in controls was 35-54% and 24-43% respectively. Significant inverse correlation with INR was found both for ↓ETP and ↓PHT (R =-0,72 and R =-0,52, respectively, P<0,05). Values below 21% for ↓ETP and 14% for ↓PHT (i.e. abnormal) were found in 79% of patients with INR 1,9-3,4 (15 persons from 19) and 8% (2 patients from 24) for ↓ETP and 4% (1 patient from 24) for ↓PHT in those with INR 0,9-1,8. Importantly in 26% of cases (5 patients from those 19 with INR range 1,9-3,4) PC system was markedly affected - ↓ETP below 10% and ↓PHT below 5%.

Summary / Conclusion: When TG is measured both with and without TM it is possible to evaluate the function of PC system in the presence of antithrombotic therapy. The results of our study suggest that patients with therapeutic INR range of2,0 to3,0 are at greater risk of rebound phenomenon (i.e. temporary hypercoagulable state) associated with abrupt discontinuation of VKA than low intensity VKA patients and patients on gradual tapering of the dose to discontinuation. Our data support the positions that certain patients could benefit from dose adaptation under CAT controlling and that in thrombophilia patients gradual tapering of the dose to discontinuation could be preferable.

P492

CONTROL OF VITAMIN-K ANTAGONIST TREATMENT BY MEASURING THROMBIN GENERATION IN WHOLE BLOOD – EFFECT OF THROMBOMODULIN

S Bloemen[1,*] M de Laat[1], A ten Cate-Hoek[2], H ten Cate[2], B de Laat[1], C Hemker[1], R Al Dieri[1]
[1]Synapse BV, [2]Department of Internal Medicine, CARIM, Maastricht, Netherlands

Background: Whole blood thrombin generation (TG) testing has been recently introduced. If it can be used for evaluating the effect of antithrombotic treatment this would be a starting point for the development of point of care and home control of vitamin K antagonist (VKA) treatment. The antithrombotic action of VKA treatment results from the fact that its effect on factors II, VII, IX and X overrules the concomitant decreases of the natural anticoagulants protein C and S. In clotting tests the effect on anticoagulant factors goes unobserved, but not in TG experiments. We therefore also investigated the effect of addition of soluble thrombomodulin (TM).

Aims: To compare, in samples from patients taking VKA, TG in whole blood to TG in plasma and to investigate the effect of activation of the APC system with TM in both types of test and to relate the results to the degree of anticoagulation as assessed by the International Normalized Ratio (INR).

Methods: In blood samples from 105 consenting patients on VKA treatment (mainly because of atrial fibrillation) TG was measured with calibrated automated thrombinography (CAT) in the absence and presence of exogenous TM. This was performed in whole blood, platelet rich and platelet poor plasma (PRP, PPP). The INR was determined in PPP of the same patients.

Results: Endogenous thrombin potential (ETP), peak height, lag time and time to peak (ttpeak) measured in whole blood were all significantly correlated with the ones determined in plasma (P<0.01). The concentration dependent parameters of TG (ETP and peak) from whole blood, PRP and PPP of the patients correlated significantly to the inverse of the INR (P<0.01). The time dependent TG parameters (lag time and ttpeak) correlated linearly with the INR (P<0.01). In the majority of the patients, addition of TM (20 nM) to a level that reduced the ETP to around 50% in normal plasma, caused less inhibition in plasma from the patients: 29.8±12.8% in whole blood, 28.5±19.8% in PRP and 39.6 ±12.0% in PPP. This effect was virtually independent of the INR (1.1-5.9).

Summary / Conclusion: This study demonstrates that whole blood thrombin generation can be considered as a reliable tool for determining the anticoagulant activity of vitamin K antagonists. VKA therapy induces TM –resistance when assessed by TG in whole blood as well as in plasma. This effect appears to be independent of the level of anticoagulation.

P493

THE ROLE OF ANTICOAGULANT THERAPIES ON COAGULOPATHY (DISSEMINATED INTRAVASCULAR COAGULATION) IN PATIENTS WITH HEMOLYTIC–UREMIC SYNDROME AFTER INFECTION WITH ENTEROHEMORRHAGIC ESCHERICHIA COLI O111.

J Murakami[1,*] M Kigawa[2], K Arita[1], A Wada[1], T Miyazono[1], A Ueda[1], S Yasumura[3], T Sugiyama[1]
[1]Internal Medicine 3 , Toyama Univercity Faculty of medicine, [2]Biostatistics and ClinicalEpidemiology, Univercity of Toyama Graduate School of Medicine and Pharmaceutical Sciences, [3]Division of Transfusion Medicine and Cell Therpy , Toyama University Hospital, Toyama City , Japan

Background: Enterohemorrhagic Escherichia coli (EHEC) is a major cause of hemolytic uremic syndrome (HUS) and its outbreaks sometimes occur. In 2011, EHEC O111 outbreaks occurred in Japan. A multicenter survey revealed that EHEC-HUS developed in 32 out of 71 patients, resulted in poor prognosis in spite of intensive care. The pathogenesis of HUS is thought to be microangiopathies, but the optimal management using anticoagulant agents and transfusions remains to be established.

Aims: To assess the effectiveness of anticoagulants in hospitalized EHEC-HUS patients.

Methods: We retrospectively reviewed medical records of all hospitalized HUS patients over the outbreak period. Patients' characteristics, therapies and outcome were analyzed. Anticoagulants were as follows: antithrombin (AT), low molecular weight heparin (LMWH), protease inhibitors (PI) and recombinant human thrombomodulin alpha (TM). To clarify which factors were responsible for the outcome, we compared clinical data of survival patients with that of dead patients. Statistical analyses were performed using JMP 10.0.0 (SAS Institute Inc.).

Results: Confirmed and probable EHEC infections were found in 71 out of 181 suspected patients. 32 out of 71 patients diagnosed as clinical HUS [11 males, 21 females; median age at diagnosis 19.9 years (range, 1-70 years)]. Seventeen out of 25 evaluable cases met the overt DIC criteria of International Society on Thrombosis Haemostasis. 26 out of 32 patients (81.2%) received anticoagulants therapies solely or in combination; 5 patients were treated with AT, 5 with LMWH, 20 with PI, and 12 with TM. 23 patients (71.9%) also underwent plasmapheresis at least once. Blood transfusions were performed as necessary. HUS-related encephalopathy was developed in 20 patients (62.5%). 5 patients (15.6%) died with disease; all of them were suffered from encephalopathy. Early/concomitant onset of encephalopathy was associated with poor prognosis. We then assessed the relationships between clinical interventions and outcomes. Univariate analyses showed that platelet counts and several biomarkers for coagulopathy seemed to be improved after administration of anticoagulants and blood transfusions. Decrease of plasma FDP level was associated with treatment of TM (paired t-test; P=0.039). Decrease of serum creatinine level was associated with treatment of TM (P=0.0013). However, in terms of prognosis, no interventions including anticoagulants were associated with survival and duration of inpatient care. Hemorrhagic and thrombotic events were not increased in usage of anticoagulants.

Summary / Conclusion: Although management for EHEC-HUS using anticoagulants was likely to improve laboratory abnormalities, no prognostic advantage was found in our retrospective cohort. TM is a candidate drug to relieve HUS, but it is clear that further investigations are needed.

P494

UNEXPECTED FATAL PULMONARY EMBOLISM FOUND AT FORENSIC AUTOPSIES

M Scivetti[1,*] L Ström[2], F Hajbolouri-Björk[2], E Eriksson[1], H Eriksson[1]
[1]Depatment of Medicine, Sahlgrenska University Hospital/ Östra, [2]Department of Forensic Medicine, Gothenburg., The National Board of Forensic Medicine, Göteborg, Sweden

Background: The most threatening complications of venous thromboembolism are non-fatal and fatal pulmonary embolism (PE). During treatment of a verified deep vein thrombosis or PE the rate of fatal PE is infrequent ranging from about 0.5% to 1.5%, respectively. If a PE is left untreated the mortality is high reaching above 30%. In some cases the first and only objective finding of pulmonary embolism is through an autopsy. The data on unexpected fatal PE mostly found at autopsies are sparse.

Aims: To investigate patients with fatal unsuspected PE diagnosed at forensic autopsies. We wanted to study extension of PE, possible source of emboli as well as co-morbidity and possible risk factors.

Methods: We studied all fatal PE found as the primary cause of death at forensic autopsies during a seventeen year period between 1992 and 2008 at the Department of Forensic Medicine in Gothenburg, Sweden. We searched data from forensic reports, police reports and medical records at local hospitals.

Results: During this 17 yrs. period 150 (94 men and 56 female) out of 15028 autopsies (1 per 100) had a fatal PE as primary cause of death corresponding to less than 1 fatal PE per 100000 persons per year in the underlying population of about 1.5 million people from the region of Västra Götaland, Sweden. The mean age of fatal PE was 63±16 yrs (range 19-93 years) and no difference between male and female. Place of death was in 78% (n:116) at home, 17% (n:26) during hospitalizations, 4% outdoors and 1% at elderly residences. Of those 26 who died of fatal PE during hospitalization the causes of hospitalization were multi-trauma (9), postoperative (3), psychiatric diseases (4), acute dyspnea (2), chest pain (1), suspected PE (1), post-abortion (1) and unknown causes (5). Of all fatal emboli, 147 (98%) had massive extension or a saddle emboli. In 62% (n:93) thrombotic residuals could be found in the legs as a possible source of PE. Of possible thromboembolic risk factors, 25% (n:37) were obese with BMI>30. About 10% had cancer. Psychiatric diseases could be found in 29% (n:44) and alcohol abuse was found in 32% (n:48) being significantly more common in males (47% vs 13%, P<0.0001). In 5% (n:8) abuse of drugs and in 1% (n:2) narcotics were used. Of cardiovascular diseases 15% (n:23) had severe coronary atherosclerosis. In 25% (n:37) the patient had before death complained of syncope (n:10), dyspnea (n:15), chest pain (n:7) or pain in a leg (n:5), but only 9 of these patients had asked for medical attention.

Summary / Conclusion: Among 150 fatal PE found at forensic autopsies, besides hospitalizations of various causes, alcohol abuse (especially among men) and psychiatric diseases might be important risk factors for sudden unexpected death as well as overweight in the form of obesity. Even though one out of four fatal PE had shown symptoms that might recall PE it remains unclear why only a few of them asked for medical advice and how physicians consider the probability of thromboembolism.

P495

INCIDENCE OF VENOUS THROMBOEMBOLISM FOLLOWING ABDOMINAL CANCER SURGERY IN KOREA

S Bae[1,*] S Bang[2], M Jang[3], K Kim[4], Y Kim[5], H Yhim[6], S Nam[7], S Kim[8], Y Mun[9], I Kim[10], C Jung[11], D Oh[3]
[1]Catholic University of Daegu School of Medicine, Daegu, [2]Seoul National University Bundang Hospital, [3]CHA University School of Medicine, Seongnam, [4]Soonchunhyang University College of Medicine, Seoul, [5]Chonnam National University Hospital, Hwasun, [6]Chonbuk National University Hospital, Jeonju, [7]VHS Medical Center, Seoul, [8]Dong-A University College of Medicine, Busan, [9]Ewha University College of Medicine, [10]Seoul National University Hospital, [11]Sungkyunkwan University College of Medicine, Seoul, Korea, Republic Of

Background: Cancer and major surgery are well known risk factors of venous thromboembolism (VTE) in Western populations. They have developed several guidelines of thromboprophylaxis for cancer patients who undergoing major surgery. However, there are few epidemiologic studies regarding post operative VTE in Asian cancer patients.
Aims: We performed this study to evaluate the incidence of VTE after general abdominal surgeries for the frequent cancers in Korea.
Methods: The VTE patients after major abdominal cancer surgeries from 2007 to 2011 were retrospectively identified by both diagnostic codes and prescription codes of heparin or low-molecular-weight heparin, using nationwide data from Health Insurance Review and Assessment Service.
Results: Of the 87403 patients who underwent stomach cancer surgery in Korea between 2007 and 2011, 409 patients (0.47%) developed VTE. Of those 409 patients, 306 (0.35%) had deep vein thrombosis (DVT) and 103 (0.12%) had pulmonary embolism (PE) with or without DVT. Multivariate analysis showed advanced age was a risk factor for developing VTE after stomach cancer surgery. Of the 73961 colorectal cancer surgeries, VTE, DVT, and PE cases represented 1235 (1.67%), 1111 (1.50%), and 125 (0.17%), respectively. Laparoscopic surgery significantly increased the risk of VTE after colorectal cancer surgery. The incidence of VTE, DVT and PE after 24026 hepatobiliary cancer surgeries were 0.48%, 0.31% and 0.17%, respectively. Age and female sex were risk factors of VTE after hepatobiliary cancer surgery. The incidence of VTE, DVT and PE after pancreatic cancer surgery were 1.42%, 1.11% and 0.31%, respectively.
Summary / Conclusion: This epidemiologic study demonstrates the lower incidence of VTE after abdominal cancer surgery in Korean populations compared with Western populations. Our study warrants further prospective investigations on the incidence of VTE in abdominal cancer patients with operable disease of different ethnic groups to propose optimal thromboprophylaxis in Asian cancer patients.

P496

ANTITHROMBOTIC PROPHYLAXIS IN PREGNANT WOMEN WITH ANTITHROMBIN CONGENITAL DEFICIENCY IS EFFECTIVE IN PREVENTING ADVERSE OUTCOMES

V De Stefano[1,*] A Ciminello[1], T Za[1], S Betti[1], S Marietti[1], P Chiusolo[1], G Leone[1], E Rossi[1]
[1]Institute of Hematology, Catholic University, Roma, Italy

Background: Type I (quantitative) or II (qualitative) antithrombin (AT) deficiency is caused by more than 200 mutations of AT gene. Type II deficiency is subclassified according to dysfunction of the reactive site (RS) or heparin binding site (HBS) or pleiotropic effects (PE). Type II HBS is associated with a low thrombotic risk.
Aims: To investigate the rate of thrombotic and obstetric complications in pregnant women with AT congenital deficiency and the effect of antithrombotic prophylaxis on the outcome of pregnancy.
Methods: We investigated in 32 women with congenital AT deficiency the outcome of their pregnancies with or without antithrombotic prophylaxis. Twenty-two women had type I deficiency and 10 type II (6 HBS, 2 RS, 2 PE); 24 were probands, and eight were relatives of eight probands.Nine women (none with HBS deficiency) had VTE prior to the first pregnancy. The outcomes were venous thromboembolism (VTE) or obstetric complications (OC) (early/late fetal loss, intrauterine growth restriction (IUGR), preeclampsia). Heparin prophylaxis was administered as therapeutic unfractionated or low molecular weight heparin (UFH or LMWH) in 21 women with type I or II (RS or PE) deficiency, as a sequence therapeutic UFH-warfarin-UFH in five women with type I deficiency and as prophylactic LMWH in all women with HBS deficiency.
Results: We analyzed ambispectively 69 pregnancies. Forty-seven non-HBS pregnancies (19 women) were not prophylaxed, and 53% were complicated: seven by VTE (four antepartum), 18 by OC, one was interrupted. Fifteen non-HBS pregnancies (11 women) received intensive antithrombotic prophylaxis, and IUGR occurred in one (relative risk 0.12, 95%CI 0.01-0.84, vs. no prophylaxis). Thus, intensive prophylaxis reduced by 88% the risk of pregnancy complications. Four HBS pregnancies in four women were conventionally prophylaxed and uneventful; finally, two HBS women had three pregnancies not prophylaxed, with OC in one pregnancy.
Summary / Conclusion: Use of therapeutic dosages of heparin in pregnant women with AT deficiency is effective in preventing adverse outcomes; prophylactic dosages of LMWH seem enough in the low-risk HBS deficiency.

P497

HIGH PREVALENCE OF PROTEIN S DEFICIENCY IN THAI POPULATION

P Rojnuckarin[1,*] B Akkawat[1], N Uaprasert[1], R Settapiboon[1], S Teocharoen[1], T Intragumtornchai[1]
[1]Department of Medicine, CHULALONGKORN UNIVERSITY, Bangkok, Thailand

Background: Factor V Leiden and prothrombin mutations were the most prevalent hereditary thrombophilia in Western patients, while protein S and protein C deficiencies are more common among Asian venous thromboembolism (VTE). In Caucasian population, the prevalence of protein S or protein C deficiencies was approximately 0.2%. Preliminary data suggested that the frequency in Asian population was higher. However, all previous reports in Asians did not repeat the tests to confirm the persistently deficient states.
Aims: The study aimed to investigate the prevalence of protein S deficiency in general Thai population.
Methods: Free protein S antigen and protein C activity were assayed in healthy Thai volunteers in Bangkok and nearby provinces. Subjects with low protein S or protein C were called to repeat the tests and investigate to exclude the acquired causes of deficiencies, i.e. hormonal uses, vitamin K deficiency or antagonist, liver dysfunction, autoimmune diseases or HIV infection.
Results: There were 5244 subjects participating in the study. The mean age was 44.4±13.8 years and 40.9% were male. The numbers of low protein S and protein C on the first tests were 254/5243 (4.84%) and 56/5234 (1.07%), respectively. For protein S, a volunteer with hormonal use and the other with HIV infection were excluded. Fifty-one had persistently low free protein S levels. The lowest estimated prevalence of protein S deficiency was 0.97% (51/5243, 95% CI 0.71-1.23%). The uses of sex-adjusted normal values gave similar results. The mean age was 42 years and 36 (71.6%) were type III protein S deficiency. All cases had no thrombosis, but 5 had history of miscarriages and 2 had family history of thrombosis. For protein C, 2 volunteers with abnormal liver function tests were excluded. Sixteen had repeatedly low protein C activity. Therefore, the lowest estimated prevalence of protein C deficiency was 0.31% (16/5234, 95% CI 0.17- 0.45%).
Summary / Conclusion: Protein S deficiency is more common in Thai population compared with Caucasians. This may explain the different risks for VTE among races. The heritability and clinical significance remain to be determined.

P498

MANAGEMENT OF EXCESSIVE ANTICOAGULATION IN PATIENTS TREATED WITH ACENOCOUMAROL, A VITAMIN K ANTAGONIST.

J Cesar[1,*] A Garcia-Avello[1], P Herrera[1], M Calbacho[1], N Revilla[1]
[1]Hematología, Hospital Ramón y Cajal, MADRID, Spain

Background: Excessive anticoagulation is frequently seen in patients treated with vitamin K antagonists (VKA) drugs. The management of this situation is controversial concerning the administration and amount of the natural antidote, vitamin K (VK).
Aims: Evaluate the efficacy of VK therapy in terms of both, correction of INR and percentage of subjects reaching a therapeutic range in in-patients with an excessive anticoagulation by acenocoumarol.
Methods: We performed a retrospective study in 801 patients treated with acenocoumarol who had 852 episodes of excessive anticoagulation in absence of bleeding. INR ranging 4-5 have been managed with withholding a dose or, reducing acenocoumarol amount. The choice in patients with an INR ranging from 5-6, 6-7 or 7-8 was to withhold one dose of acenocoumarol, or to administer, in addition a small dose (1 mg) of vitamin K. Those patients with an INR between 8 to10 were managed by withholding one dose of acenocoumarol and some of them also received 1 or 2 mg or vitamin K. If the INR was above 10, the VKA was discontinued for one or two days, and some of these patients were treated with 2 mg of VK.
Results: In patients with INR ranging 4 to5, the withholding of a dose (n=77) achieved a higher decrease in the INR at 24 hr (3.1±0.9) compared with the reduction of one dose of acenocumarol (3.5±0.9, n=92, P<0.001), but with this approach, more patients had INR below therapeutic range (P=0.008). There were no differences between both choices at 72 hr. The reduction of INR, measured at 24 or 72 hr, in those patients treated with 1 mg of VK was not influenced by the route, either oral or subcutaneous. Forty five out of 196 patients with an

INR ranging from 5 to 6 were treated with 1 mg VK and their INR at 24 hr (2.8±1.2) was lower (P<0.05) compared with those patients that did not receive VK (3.2±1.1). However, more patients (24.4% vs 7.3%) were below therapeutic range at this time (P=0.003). No differences were observed at 72 hr. In addition to withhold one dose of VKA, 1 mg of VK was given to 90 out of 230 patients with INR ranging between 6 to 7. This practice achieved a lower INR at 24hr (3.1±1.4 vs 3.9±1.5, P<0.0001) and 72 hr (2.2±0.9 vs 2.8±1.2, P<0.001). Nevertheless, VK administration was associated to more patients with an INR below the recommended range at 24 hr (20.0% vs. 3.6%, P=0.001) and 72 hr (47.8% vs. 21.7%, P=0.001). In patients with an INR from 7 to 8, the withdrawal of one dose of AVK plus the administration of 1 mg of VK (53 out 105) resulted in a lower INR at 24 hr (3.5±1.6 vs 4.0±1.4, P<0.0001), and also at 72 hr (2.2±0.9 vs 3.4±1.5, P<0.001), compared to those patients managed with the withdrawal of one dose of acenocoumarol. In addition, VK administration was associated with fewer patients with INR above 4 at 72 hr (P=0.01). Patients with INR ranging 8-10 treated with, either 1 or 2 mg of VK in addition to withdraw one dose of AVK, reached similar reductions of their INR at 24hr (3.6±1.7 vs 3.8±2.0) and 72 hr (2.5±1.1 vs 2.2±0.8), but improved the reduction obtained at 24 hr with respect those subjects who did not receive VK (5.3±2.4, P<0.001). The number of patients reaching an INR within the therapeutic range at 24 hr was also similar with either dose of VK and improved the group that was not treated with VK (P=0.003). In addition to withhold one dose of acenocoumarol, 26 out of 52 patients with an INR above 10, were given 2 mg of VK. This therapy resulted in a higher reduction of the INR at 24 hr (5.6±2.7 vs 7.3±3.0, P<0.05) and also, fewer patients maintained an INR above 4 (P=0.003). However, the INR was similar in both groups after 72 hr, probably due to the fact that, in 14 patients who were not treated with VK, the acenocumarol had to be withdrawn for two days.

Summary / Conclusion: The current work suggests that the management of overanticoagulation by acenocoumarol requires different strategies including the extent of INR prolongation but also the individual risk of bleeding and thrombosis.

P499

GENETIC POLYMORPHISMS RELATED TO HEMOSTASIS AND THEIR ASSOCIATION WITH PRIMARY RECURRENT PREGNANCY LOSS

E Guerra-Shinohara[1,*] J Bertinato[1], G Gomes[1], M do Rosario Boacnin[1], A Amorim-Filho[2], M Burlacchini de Carvalho[2], Marcelo Zugaib[2]
[1]Analises Clinicas e Toxicologicas, Faculdade de Ciëncias Farmacëuticas da Universidade de Sao Paulo, Brasil, [2]Departamento de Obstetrícia e Ginecologia, Faculdade de Medicina da Universidade de São Paulo, Sao Paulo, Brazil

Background: Pregnancy is characterized by a hypercoagulable state in which levels of some coagulation factors and fibrinolytic inhibitors are increased, whereas levels of the natural anticoagulant free protein S are decreased. Single nucleotide polymorphisms (SNPs) can be associated with alterations in the concentrations of factors, and may be related to the gain of function and formation of thrombus in the placenta.

Aims: The aim of this study was to investigate the association between SNPs in genes of proteins related to coagulation (FI, FII and FV), fibrinolysis (PAI1 and TAFI) and generation of thrombin (PC, AT, TM and TFPI) and risk of RPL.

Methods: This is a case-control study that included 117 unrelated non-pregnant women with three or more consecutive losses prior to 20 weeks of pregnancy without a previous history of carrying a fetus to viability (primary RPL), who were evaluated in the Prenatal Care Unit at the Hospital of the University of Sao Paulo. The control group was comprised of 264 unrelated healthy fertile women recruited among users of Public Health Service or employees of the University of Sao Paulo, who had at least two term deliveries and without known pregnancy losses as well as known medical history of thrombosis, diabetes, hypertension, cancer and autoimmune disorders. Real Time PCR, from Applied Biosystems, was performed using validated TaqMan SNP genotyping assays to determine polymorphisms in fibrinogen beta chain (*FGB* 455G>A, rs1800790 and *FGB* 148C>T, rs1800787), protein C (*PROC* 2418A>G,rs1799809 and *PROC* 2405C>T, rs1799808), antithrombin (*SERPINC1* 786G>A, rs2227589), thrombomodulin (*THBD* 1418C>T, rs1042579), TFPI (*TFPI* T-287C, rs10931292, *TFPI* T-33C, rs8176592 and *TFPI* C-399T, rs10153820) and TAFI (*CBP2* 505G>A, rs3742264) genes. SNPs in factor V (Factor V Leiden, *F5* 1691G>A, rs6025), prothrombin (*F2* 20210 G>A, rs179963) and PAI1 (*PAI1* 4G/5G rs1799889) genes were determined by polymerase chain reaction followed by enzymatic restriction (PCR-RFLP). A model of multivariate forward conditional logistic regression for dependent variable to have RPL was carried out including as independent variables the genotypes for 13 SNPs. The reference for each SNP was: GG + GA genotypes for *FGB* 455G>A, CC genotype for *FGB* 148C>T, AA genotype for *PROC* 2418A>G, CC genotype for *PROC* 2405C>T, GG genotype for *SERPINC1* 786G>A, CC genotype for *THBD* 1418C>T, TT genotype for *TFPI* T-287C, TT for genotype *TFPI* T-33C, CC for *TFPI* C-399T and GG genotype for CBP2 505G>A.

Results: In a forward conditional logistic regression, 2 SNPs related to thrombin generation were selected in model (Table 1). The SNPs in genes related to coagulation and fibrinolysis were not associated with RPL.

Summary / Conclusion: Our data indicate that the variant of *FGB* 148C>T, *THBD* 1418C>T and *CBP2* 505G>A SNPs are associated with higher risk of having RPL, while the variant of TFPI T-287C SNP has a protection effect.

Financing: Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP 2007/57605-0)

Table 1. Forward conditional logistic regression for dependent variable to have RPL.

Independent variables	OR	95% CI	P value
FGB 148C>T	2.06	1.20 – 3.55	0.009
THBD 1418C>T	1.75	1.01 – 3.06	0.048
TFPI T-287C	0.41	0.20 – 0.83	0.014
CBP2 505G>A	2.43	1.37 – 4.32	0.002

The independent variables included in the model were the genotypes for *FGB* 455G>A (reference: GG + GA genotypes), *FGB* 148C>T (reference: CC genotype), *PROC* 2418A>G (reference: AA genotype), *PROC* 2405C>T (reference: CC genotype), *SERPINC1* 786G>A (reference: GG genotype), *THBD* 1418C>T (reference: CC genotype), *TFPI* T-287C (reference: TT genotype), *TFPI* T-33C (reference: TT genotype), *TFPI* C-399T (reference: CC genotype) and *CBP2* 505G>A (reference: GG genotype).

P500

HIGH ON-TREATMENT PLATELET REACTIVITY: NOT AN ISOLATED PROBLEM

M Jakl[1,2,*] J Maly[3], I Fatorova[3], J Horacek[1,3], R Pudil[2]
[1]Department of Field Internal Medicine, University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic, [2]1st Department of Internal Medicine - Cardioangiology , University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Czech Republic , [3]4th Department of Internal Medicine - Hematology , University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Czech Republic, Hradec Kralove, Czech Republic

Background: High on-treatment platelet reactivity is associated with increased risk of repeated acute coronary syndrome and mortality. Unfortunately, there is a lack of evidence about association with other hemostasis system abnormities. Such knowledge is necessary for effective management of patients with poor response to antiplatelet drugs.

Aims: The aim of the study was to assess the relationship between high on-treatment platelet reactivity and other hemostasis abnormities in patients with acute coronary syndromes.

Methods: A total of 72 patients (57 men, 15 women, average age 64.1±10.4 years) with acute myocardial infarction treated by percutaneous coronary intervention were enrolled in the study. In these patients the response to aspirin and clopidogrel was assessed by impedance aggregometry. Simultaneously NT-proBNP, TNF-α, of markers of primary hemostasis (platelet count, mean platelet volume, von Willebrand factor, P-selectin), coagulation (prothrombin time, activated partial tromboplastin time, fibrinogen, D-dimers, factor VIII, tissue microparticles), fibrinolysis (plasminogen, tissue plasmin activator, plasminogen inhibitor activator1, thrombin activated fibrinolysis inhibitor) were assessed.

Results: In patients with poor response to aspirin, we documented increased level of von Willebrand factor (380.6±35.3 % vs. 201.8±76.6% P<0.001), factor VIII (408.1±201.2% vs. 227.6±92.0 %P<0.01), fibrinogen (6.4±1.6 g/L vs. 4.8±0.8 g/L P<0.001) plasminogen inhibitor activator 1 (26.7±4.3 µg/L vs. 15.9±9.7 µg/L P<0.05), NT-proBNP (631.9±732.4 vs. 262.2±423.7, P<0.05) and TNFα (10.5±5,2 vs. 6.0±5.4 P<0.05).

Summary / Conclusion: Poor response to aspirin is associated with severe disturbances in the whole hemostasis system. It might be related to heart failur and immune system activation as well. Detailed description of these changes is essential for improvement of acute coronary syndrome treatment.On the other side, we did not find any factor associated with poor response to clopidogrel.

The work was supported by a long-term organisation development plan 1011 (FMHS).

P501

EVALUATION OF PIVKA-II AS A PREDICTOR MARKER FOR PORTAL VEIN THROMBOSIS IN HEPATOCELLULAR CARCINOMA PATIENTS

M Ayoub[1,*] K Hemida[2], W Kamal[2], G Riad[2], N Adel[2], D Ayoub[3]
[1]Hematology, [2]Gastroentrology, [3]clinical pathology, Ain shams university, Cairo, Egypt

Background: Hepatocellular carcinoma (HCC) is the sixth most common malignancy and the third most common cause of cancer-related death worldwide. While the survival of patients with most malignancies has improved over the last decade, 5-year survival of patients with HCC has remained less than 10% . Presence of portal vein thrombosis hinders prognosis and limits therapeutic options of management in HCC. Des-gamma carboxyprothrombin (DCP), also known as protein induced by vitamin K absence/antagonist-II (PIVKA-II), is an abnormal form of the coagulation protein, prothrombin .
Aims: The aim of our study was to evaluate the value of PIVKA-II measurement as a predictor of portal vein thrombosis among other factors when HCC on liver cirrhosis is diagnosed with trans-abdominal ultrasound.
Methods: The present study included fifty newly diagnosed patients (37 males and 13females) with proved histopathological diagnosis of HCC who were diagnosed at Hepatology Unit at Ain Shams University hospital. Patients were subjected to history taking, physical examination and radiological assessment with abdominal ultrasonography and computerized tomography. The following laboratory investigations were done, -Complete blood picture (CBC),Prothrombin time (PT) and international normalized ratio (INR).,Liver function tests (ALT, AST, ALP, serum albumin and serum bilirubin) :,Kidney function tests (serum creatinine).,Alpha feto protein (AFP) determination (using AFP Mab ELISA Kit by EQUIPAK).and Serum PIVKA-II level determination using micro cup type enzyme immunoassay test kit (Eitest PIVKA-II kit by sanko junyako – Tokyo Japan)
Results: In the present study, a statistically higher PIVKA-II (z=2.575; P=0.010) has been found in patients with PVT on comparison with patients without PVT. PIVKA-II levels were 97.0mAu/ml±81.3 (median=88.4), with a range from 0.8 to 266.3 for patients with PVT and 40.2mAu/ml±40.6 (median=39.2), with a range from 0.2 to 146.3 for patients without PVT. For determination of the best PIVKA-II cut-off value that best predicts PVT, a receiver operating characteristics curve (ROC curve) has been plotted. The best cut-off value of PIVKA-II that best predicts the PVT was 100 mAU/mL. AT this cut-off point the diagnostic performance of PIVKA-II was 74.0% with 47.6% sensitivity and 93.1% specificity with a highly significant association between the studied marker and PVT.
Summary / Conclusion: serum PIVKA II levels >100mAu/ml is a predictor for development of PVT in patients with HCC and which influences the therapeutic options available for the patients

P502

HIGH INCIDENCE OF VENOUS THROMBOEMBOLISM AND ITS PROGNOSTIC IMPLICATION IN PATIENTS WITH SMALL CELL LUNG CANCER

Y Lee[1,*] E Lee[1], I Kim[1], K Lee[1], T Kim[1], S Lee[1], D Kim[1], D Heo[1]
[1]Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: Recent studies reported that cisplatin is associated with an increased risk of venous thromboembolism (VTE) in patients with advanced solid tumors compared to non-cisplatin-based chemotherapy. Small-cell lung cancer (SCLC) is highly responsive to platinum-based combination chemotherapy; cisplatin in combination with etoposide or irinotecan is the most commonly used regimen. Therefore, we can assume that the risk of VTE in SCLC is quite high.
Aims: This study aims to determine the incidence, risk factors and prognostic implication of VTE in patients with SCLC. We also evaluated the association between cisplatin-based chemotherapy for the treatment of SCLC and the risk of VTE.
Methods: Between January 2006 and June 2010 we consecutively enrolled 221 patients diagnosed with SCLC at Seoul National University Hospital. We retrieved all reports of radiologic or nuclear medicine studies performed on each patient from the electronic medical record. All reports were converted to Microsoft Office Excel files and identified for VTE cases by search function. Two independent investigators double-checked the diagnoses of VTE by reviewing respective records. In order to minimize the observed confounding bias, we used propensity score-matching to compare overall survival between patients with and without VTE.
Results: The 6-month and 2-year cumulative incidence of VTE were 8.2% and 11.8%, respectively. The 2-year cumulative incidences of VTE were 5.1% in limited-stage and 17.6% in extensive-stage. The only independent predictor of VTE was the extensive-stage (vs. limited-stage) (HR 3.9; 95% CI 1.12–13.59; P=0.033). Among a total of 18 cases of VTE, 15 (83.3%) were developed in the first 6 months after cancer diagnosis. About 80% of patients had received cisplatin-based chemotherapy and all 13 cases of VTE developed during chemotherapy had occurred after the exposure to cisplatin. Cisplatin-based chemotherapy increased the risk of VTE approximately 2-times higher than non-cisplatin based chemotherapy (HR 2.11; 95% CI 0.27–16.17; P=0.47), which were not statistically significant. The development of VTE was not associated with an increased risk of death in overall (HR 1.48; 95% CI 0.91–2.41; P=0.18) and propensity-matched (HR 1.43; 95% CI 0.71–2.89; P=0.32) cohort.
Summary / Conclusion: Our study shows that the risk of VTE in patients with SCLC is quite high. The exposure to cisplatin could not influence meaningful differences in the incidence of VTE according to the exposure status. Instead, cisplatin-based chemotherapy may increase the overall incidence of VTE in SCLC. A significant association between VTE development and decreased survival was not found in patients with SCLC.

Health economics

P503

PERIPHERALLY INSERTED CENTRAL CATHETERS (PICCS) CAN BE SUCCESSFULLY UTILIZED IN HAEMATOLOGICAL PATIENTS RECEIVING INTENSIVE CHEMOTHERAPY OR ALLOGENEIC/AUTOLOGOUS STEM CELL TRANSPLANTATION

A Malato[1],* A Luppino[1], R Pipitone[1], M Grazia Dona'[1], F Acquaviva[1], R Di Bella[1], R Scimè[1], F Fabbiano[1]
[1]UOC Ematologia con UTMO, Ospedali Riuniti Villa Sofia-Cervello, Palermo, Palermo, Italy

Background: Patients with haematological disorders frequently require the insertion of medium or long-term central venous catheters (CVCs) for stem-cell transplantation, the administration of chemotherapy, or transfusions. Although peripherally inserted central catheters (PICCs) have been in use for many years, little data exist on their use in patients receiving intensive chemotherapy and blood progenitor cell transplantation.
Aims: Here, we carried out a clinical prospective investigation to determine the efficacy of these interventions in reducing the rate of PICC-related complications (thrombotic events, exit site infection and other complications requiring early removal of PICCs); the studied population included hematology patients receiving intensive chemotherapy compared to allogeneic/autologous stem cell transplant recipients.
Methods: Evidence-based interventions were implemented in our department from November 2009 to July 2012, and include: 1.An high level nurse education program for correct practices and prevention of catheter-associated complications. was developed for PICC nursing team; 2) The use of ultrasound guide for the insertion of the tip of PICCs, thanks to a special operator training; 3) Bedside placement and confirmed PICC tip placement by chest radiography after removal of the guidewire and before the securing of the catheter; 4) Maintenance of maximum sterile barrier precautions during PICC insertion and aftercare; 5) chlorhexidine preparation, replace 10% povidone iodine for skin antisepsis; 6) adoption of PICC patient nurse archive, including the information of weekly PICC line review at our department for each patient.

Table 1. Outcomes according to underlying disease and relative adhibition.

	Chemotherapy		ASCT		Statistics					Odds Ratio	
Diagnosis	% Definite CRBSI	% Thrombosis	% Definite CRBSI	% Thrombosis	Definite CRBSI (%)	Definite CRBSI per 1000 PICC days	Thrombosis (%)	Thrombosis per 1000 PICC days	Range (days)	Means (days)	OR CRBSI	OR Thrombosis
Lymphoma (n. 182))	0,69	4,16	2,63	2,63	1,10	0.10	3,85	0,34	4-336	146,3	3,86	0,62
Acute Leukemia (n 120))	0.95	4.76	0	13.33	0,83	0.07	5,83	0,46	99-432	213.8	0	3.07
Others (n. 62)	0	2.32	0	0	0,00	0	1,61	0,19	6-287	79.2	0	0
Overall	0.68	4,11	1.39	4,17	0,82	0.07	4,12	0,36	0-482	112,94	2,042	1,014

Results: Three hundred sixty-four (364) PICCs were in place in 299 patients for a total of 41.111 PICC days (range, 1-482 days; mean 112,94 days); 292 were inserted in patients receiving conventional chemotherapies, and 72 in patients undergoing allogeneic or autologous hematopoietic stem cell transplantation (SCT). Sixty-six (60) PICCs were inserted during severe thrombocytopenia (platelets <50x10^9/L), seventy (70) during severe neutropenia (neutrophils <0.5x10^9/L) and thirty-eight (38) during antithrombotic prophylaxis. Predominantly, patients had Lymphoma (50%). The rate of major complication was very low: 15 thrombotic complications PICC-related (4%; 0.36 per 1,000 CVC days), and 3 CRBSI (0,8%; 0.07 per 1,000 CVC days) during neutropenia. Mechanical complications occurred in 52 catheters, and were accidental dislodgement (30), catheter break (3), catheter inadequate (19); other reasons for catheter removal were completion of therapy (137), lumen occlusion (19) and death (58). Interesting, taking in account the underlying disease, lymphoma and leukemia patients have, respectively, an increased risk of developing a CRBSI and a thrombotic PICCs-complication when submitted to hematopoietic stem cell transplantation (SCT) (Table 1). However, compared with allogeneic/autologous stem cell transplant group, the intensive chemotherapy group was associated with a marginally lower incidence of CRBSI complication rate (0.6 % vs 1.0 %, 0.10 vs 0.60 per 1,000 CVC days) [odds ratio (OR)2,042]; no relevant differences in terms of thrombotic complications between the two cohorts (4.11 % vs 4.17%), 0.29 vs 0.39 per 1,000 CVC days) [odds ratio (OR) 1.014].
Summary / Conclusion: Our findings suggest, therefore, PICC devices are a viable and safe option for management of the haematology patients receiving intensive chemotherapy and even in patients particularly prone to infective and thrombotic complications such as patients receiving blood stem cell transplantation.

P504

PICC INSERTION AND MANAGEMENT IN HEMATOLOGY PATIENTS: 5 YEARS PROSPECTIVE STUDY THE CAGLIARI'S DEPARTMENT OF HAEMATOLOGY

D Derudas[1],* G Longhitano[1], D Ibba[1], M Poddigue[1]
[1]UOC Ematologia e CTMO- Ospedale Oncologico di Riferimento Regionale "A. Businco", Cagliari, Italy

Background: Central Venous Catheter (CVC) is crucial for a haematology patients appropriate clinical management (chemotherapy, supportive treatment, aphaeresis procedure, hematopoietic stem cell transplantation). However these devices can cause clinical complications either related to disease itself or to catheter features.
Aims: The purpose of our study was to evaluate if introduction of Peripheral Insertion Central Venous Catheter (PICC) in clinical practice is feasible and could simplify patients management.
