SUPPLEMENTAL METHODS

Cell separation, immunophenotyping and cell sorting

B lymphocytes were routinely separated from peripheral blood using Ficoll-Paque PLUS (GE Healthcare) gradient centrifugation coupled with a depletion of non-B cells by RosetteSep® Kits (Human B cell Enrichment Kit, CD3+ Depletion Kit; StemCell). Purity assessment and detailed immunophenotyping of separated cells were performed on CellLab Quanta™ SC or FC500 (Beckman Coulter Inc.). An aliquot of cells was stained with monoclonal antibodies against CD5, CD10, CD19, CD20, CD23, CD38, CD43, CD79b, FMC7, HLA-DR, sIgK and sIgL.

In specific cases (case 319, table 3), fluorescence activated cell sorting was performed using FACSaria III (BD Biosciences). B lymphocytes were stained against CD19 (anti-CD19-PE-Cy5, Beckman Coulter), sIgK (polyclonal anti-sIgK-FITC, ABserotech) and sIgL (polyclonal anti-sIgL-PE, ABserotech). Populations were sorted by the light chain isotype.

Equipment and software used for fragment analysis and sequencing

Either ABI PRISM 3130XL or 310 Genetic Analyzer (Applied Biosystems) were used for both methods. Results obtained from fragment analysis were processed by GeneMapper v4.1 or GeneScan v3.1.2. software. Sequences were inspected and processed in ABI PRISM® DNA Sequencing Analysis Software v5.3.1 and further handled in BioEdit v7.1.3.

Cloning strategy

Cloning of PCR amplicons was used if multiple IGHV-IGHD-IGHJ gene rearrangements were amplified from the same *IGHV* specific primer. PCR products were cloned into the pCR®2.1 vector which was used for transformation of competent E. coli (TA Cloning® Kit with One Shot® INVaF' Chemically Competent E. coli; Invitrogen), and multiple subcloned sequences were analyzed.

Allele-specific oligonucleotide assay experiments and calculation of IGH rearrangement proportions in MP-IGH CLL cases

Allele-specific oligonucleotide assays (ASO-qPCR) enabled assessment of clone proportion and long-term molecular monitoring of clonal dynamics. *IGHV* subgroup-specific TaqMan probes were used; the sense primer was targeted to the *IGHV* gene, while the antisense primer, which conferred specificity for individual rearrangements, was targeted to the CDR3 of each rearrangement. The set of assays for an individual patient was required to have efficiency difference <0.2. Albumin was used as a reference gene. ASO-qPCR assays were performed with FastStart TaqMan Probe Master (Roche) master mix using RotorGene 6000 (Corbett). Results and efficiency of the individual assays were evaluated by RotorGene 6000 Series Software 1.7.

The proportion R of individual *IGHV*-*IGHD*-*IGHJ* gene rearrangements was calculated as follows, based on the known value of an assay efficiency E and a C_t value when each of the rearrangements reached a certain number of copies c at certain level of detected signal intensity I . Hence, for each assay

$$I = c \cdot E^{C_t}$$

If assays for coexisting rearrangements reach equal level of intensity, then

$$c(1) \cdot E(1)^{C_t(1)} = c(2) \cdot E(2)^{C_t(2)}$$

For the proportion R of two IGH rearrangement

$$R = \frac{c(1)}{c(2)} = \frac{E(2)^{C_t(2)}}{E(1)^{C_t(1)}}$$

Considering that the relative number of copies gives $c_r(1) + c_r(2) = 1$, then

$$c_r(1) = \frac{R}{1+R} \quad \text{and} \quad c_r(2) = \frac{1}{1+R}.$$

Similarly, in a case of three co-existing IGH rearrangements, it can be derived that

$$c_r(1) = \frac{1}{1+R_A^{-1}+R_C^{-1}}, \quad c_r(2) = \frac{1}{1+R_A+R_B^{-1}}, \quad \text{and} \quad c_r(3) = \frac{1}{1+R_B+R_C^{-1}}$$

where

$$R_A = \frac{c(1)}{c(2)}, \quad R_B = \frac{c(2)}{c(3)}, \quad \text{and} \quad R_C = \frac{c(3)}{c(1)}.$$

Analysis of genomic defects

Deletions 11q, 13q and 17p, and trisomy 12 were assessed using interphase FISH in 77% of cases. For the respective regions, following probes were used: LSI p53/LSI ATM and LSI D13S319/LSI 13q34/CEP12 Multi-Color Probe Sets (Abott Molecular-Vysis), or XL ATM/p53 and XL DLEU/LAMP/12cen (MetaSystems) according to the manufacturers' recommendations. Identified chromosomal changes were classified according to the International System for Human Cytogenetic Nomenclature (ISCN) 2009.

Additionally, karyotype results from IL-2/CpG-stimulated metaphase cytogenetics were available in 52% of cases (Dicker F, Schnittger S, Haferlach T, et al. Immunostimulatory oligonucleotide-induced metaphase cytogenetics detect chromosomal aberrations in 80 % of CLL patients: a study of 132 CLL cases with correlation to FISH, IgVH status, and CD38 expression. Blood 2006;108(9):3152-60). Heparinized peripheral blood was cultured in RPMI-1640 (Sigma) supplemented with IL-2 (200 U/ml, Peprotech) and DSP30 (2 µmol/l, TIB MolBiol) for 72 hours at 37°C/5% CO₂. Colchicine was added 5-6 hours prior to analysis. Further sample processing (hypotonic treatment and fixation) and chromosome preparation and staining was conducted according to the standard protocols (Haferlach C et al. 2011). The cultivation was considered successful when minimum of 5 metaphase cells were found. Evaluation of metaphase cells was performed using Lucia Karyo (Laboratory Imaging). Karyotypes were classified according to the ISCN 2009.

In the case 319, chromosomal aberrations were assessed in sorted populations using multiplex ligation-dependent probe amplification (MLPA) using SALSA MLPA P040 CLL probemix (MRC-Holland) according to the manufacturer's recommendations.

Detection of TP53 gene mutations

TP53 mutations were identified by the yeast functional analysis (FASAY) described by Flaman and colleagues (Flaman JM, Frebourg T, Moreau V, et al. A simple p53 functional assay for screening cell lines, blood, and tumors. Proc Natl Acad Sci U S A. 1995;92:3963-7.). In this assay, the central part of the TP53 gene (amplified from cDNA between exons 4

and 10, ie. codons 42 to 374) is introduced into an *ADE2*⁻ yeast strain carrying a reporter with a p53-binding site upstream of the *ADE2* gene. On the plates containing a low level of adenine, the p53 wild-type (wt) samples form large white colonies, whereas the colonies with the *TP53* mutations (mut-p53) are small and red, which is attributable to limited growth and an accumulation of a reddish product of adenine metabolism. Samples containing a wt-p53 account for 90% or more of white colonies in the assay; the remaining 10% represent background, a consequence of PCR-induced mutations or a low-quality RNA. All *TP53* mutations were confirmed using sequencing from red colonies and a direct sequencing from corresponding patient genomic DNA (gDNA) (whole coding region, exons 2-11).
