Willebrand disease, entity of platelet increased count and aspirin use have been implicated in bleeding occurrence. Previous reports fail to demonstrate a correlation between *JAK2* mutation and bleeding risk. In contrast, in our cohort we found a significantly higher incidence of bleeding manifestations during follow-up in patients with higher allele burden. Interestingly no differences were seen in administration of anti-thrombotic drugs among quartiles, suggesting an independent role of *JAK2* allele burden in the different distribution of hemorrhagic events.

## PB2038

### *JAK2* ALLELE BURDEN IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

M. Napolitano<sup>1,\*</sup>, S. Siragusa<sup>1</sup>, S. Mancuso<sup>1</sup>, M. Santoro<sup>1</sup>, M.R. Lanza Caricchio<sup>1</sup>, M. Bono<sup>2</sup>, F. Di Piazza<sup>2</sup>, A. Russo<sup>3</sup>, V. Accurso<sup>1</sup>  
<sup>1</sup>UO Ematologia, <sup>2</sup>Laboratorio di genetica e oncologia molecolare, <sup>3</sup>UO Oncologia, University Of Palermo, Palermo, Italy

**Background:** The *JAK2*V617F allele burden (JAK-AB) plays a central role in chronic myeloproliferative neoplasms (cMPNs); its presence has also been advocated in the differential diagnosis of cMPNs and as independent risk factor for venous thromboembolic complications. New treatment with Ruxolitinib may decrease JAK-AB but at the present, it is not clear the clinical advantage of such reduction

**Aims:** Primary aim of the current study was to evaluate at diagnosis the JAK-AB in patients with Philadelphia negative cMPNs, in order to evaluate any association with standard demographic, clinical and laboratory parameters with particular reference to thrombotic risk.

**Methods:** Peripheral blood samples from patients with Ph-negative cMPNs were collected, DNA from leucocytes was analysed for *Jak-2* (V617F) gene mutation with amplification-refractory mutation system (ARMS) PCR, subsequently a real-time quantitative polymerase chain reaction (qRT-PCR) for *JAK2*V617F allele burden measurement was applied. A multivariate analysis was then performed to evaluate any association of AB with demographic and clinical data.

**Results:** One hundred and twelve patients with Philadelphia negative cMPNs were investigated: 52 females with a median age at diagnosis of 69 years (age range: 18-95 years), 60 males with a median age of 68 years (age range: 18-82 years). Thirty-four patients had Essential Thrombocythemia (ET), fifty-two had Polycythemia Vera (PV) and twenty-six had primary myelofibrosis (PMF). *JAK2*-AB of patients with an age of <69 years and ≥69 years, was respectively evaluated. Patients older than 69 years showed a significantly higher *JAK2*-AB. *JAK*-AB was significantly reduced in ET, when compared to PV and PMF. No correlation was found between median values of allele burden and IPSS and DIPSS scores. In patients with PV (n=52), a significant correlation was observed between allele burden and WHO2008 scoring system. No significant correlation was found between allele burden and thrombotic risk according to IPSET-t and IPSET-ET for PV and ET, respectively. Patients with a previous history of thrombosis had the highest *JAK2*-AB. In PMF, a positive correlation between *JAK*-AB and grading of fibrosis was found only for the highest grades (PMFIII and IV). *JAK*-AB had a positive correlation with splenomegaly in PMF.

**Summary/Conclusions:** Our report cannot confirm any correlation between allele burden and thrombotic risk, according to currently adopted scoring systems. A previous history of thrombosis is however associated with the highest AB in all cases.

## PB2039

### COMPARISON OF CLINICAL AND LABORATORY DATA, INCLUDING *JAK2* 46/1 HAPLOTYPE, BETWEEN PATIENTS WITH IDIOPATHIC ERYTHROCYTOSIS AND POLYCYTHEMIA VERA.

M. Napolitano<sup>1,\*</sup>, S. Siragusa<sup>1</sup>, M. Santoro<sup>1</sup>, F. Di Piazza<sup>2</sup>, M. Bono<sup>2</sup>, S. Mancuso<sup>1</sup>, A. Russo<sup>3</sup>, V. Accurso<sup>1</sup>  
<sup>1</sup>UO Ematologia, <sup>2</sup>Laboratorio di genetica e oncologia molecolare, <sup>3</sup>UO Oncologia, University Of Palermo, Palermo, Italy

**Background:** Idiopathic erythrocytosis (IE) is a relatively rare finding characterized by an increased red blood cell mass without an identifiable cause. Diagnosis of IE is based on the exclusion of primary and secondary erythrocytosis including *JAK2*-wild-type polycythemia Vera (PV).

**Aims:** In the current study, we report clinical features and laboratory data able to discriminate IE from PV, at diagnosis

**Methods:** We have here analyzed clinical and laboratory parameters, including *Jak-2* 46/1 haplotype, from patients with a confirmed diagnosis of IE and PV, followed from January 2010 to December 2016. Data were statistically analyzed, nominal variables were compared with  $\chi^2$  test and continuous variables with the Mann-Whitney test.

**Results:** Overall, 40 patients with IE and 93 patients with PV were included in the current analysis (Table 1). Splenomegaly and itch were reported only in one patient with IE. History of thrombosis and cardiovascular events was positive in one case with IE. *Jak-2* (V617F) and exon 12 mutations were negative in all patients with IE, while *Jak-2* 46/1 haplotype was found at heterozygous state in 18 patients and at homozygous state in 2 patients with IE.

Table 1.

	PV	IE	P
Patients N.	93	40	
MALE N. (%)	59 (63,44%)	38 (95%)	0.0001
FEMALE N. (%)	34 (36,56%)	2 (5%)	0.0001
MEDIAN AGE AT DIAGNOSIS, YEARS	66 (23 - 95)	58 (17 - 83)	0.007
SPLENOMEGALY N° (%)	38 (40,86%)	1 (2,5%)	0.000001
ITCH	36 (38,70%)	1 (2,5%)	0.000001
MEDIAN WBC COUNT X10 <sup>9</sup>	9,3 (4,535,2)	8,1 (4,2-14,3)	0.03
MEDIAN HB g/dl	17,5 (15,1-21,0)	17,4 (16,1-19,1)	0,9
MEDIAN HT %	53,3 (48,4 - 64,3)	52,4 (48,2 - 55,3)	0,1
MEDIAN PLTS COUNT X 10 <sup>9</sup>	435,0 (270-1013)	216 (178-339)	0.001
V617 F OF JAK2 POSITIVE N. (%)	86 (92,47)	0	
JAK2 EXON 12 MUTATION N. (%)	2 (2,15%)	0	
HAPLOTYPE 46/1 OF JAK2, ETHEROZIGOUS	42 (45,16%)	18 (45,0%)	0,98
HAPLOTYPE 46/1 OF JAK2, HOMOZIGOUS	25 (26,88%)	2 (5%)	0,008
PATIENTS WITH CARDIOVASCULAR EVENTS OR THROMBOSIS N %	32 (34,4%)	1 (2,5%)	0.000008

**Summary/Conclusions:** In the current study, we highlight peculiar clinical and laboratory findings of IE, in comparison with Polycythemia Vera. As shown by available studies, Hb and HCT level do not easily discriminate between the two categories of patients while gene panels may be useful to improve diagnostic accuracy of IE. We have here first observed the presence of Jak-2 46/1 haplotype in approximately half patients with IE, even in absence of JAK-2 mutations; the homozygous status was statistically different among PV and IE patients. The role of such association deserves further specific studies.

## PB2040

### LABORATORY RESPONSIVENESS OF LOW-DOSE ASPIRIN IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

E. Cacciola<sup>1,\*</sup>, E. Gentilini Cacciola<sup>2</sup>, R. Cacciola<sup>3</sup>

<sup>1</sup>Medical and Surgical Science and Advanced Technologies, <sup>2</sup>Haemostasis Unit, Catania, Italy, <sup>3</sup>Experimental and Clinical Medicine, Haemostasis Unit, Catania, Italy

**Background:** The essential thrombocythemia (ET) is a myeloid neoplasm characterized by platelet hyperreactivity and thrombosis. The daily low-dose aspirin (ASA) is a cornerstone in the prevention of the thrombotic events. In the ET an accelerated platelet turnover translates in a renewal of the drug target shortening the duration of cyclooxygenase (COX-1) inhibition and may dictate new dosing strategies particularly in ASA "low-responders" patients.

**Aims:** Therefore, we evaluated platelet count,  $\beta$ -thromboglobulin ( $\beta$ -TG) and platelet factor 4 (PF4), as markers of platelet activation, the platelet function activity (PFA), as indicator of ASA platelet sensitivity.

**Methods:** We studied 60 patients (20 men, 40 women; mean age 51 years, range 32-70) with ET according to WHO criteria. The mean duration of disease was 11 years. All patients were on ASA 100 mg once daily. Of the 60 patients, 45 were on anagrelide hydrochloride (daily dose 1.5 mg) (10 men, 35 women), 15 were on hydroxyurea (daily dose 2 mg) (10 men 5 women). None had inherited or acquired thrombotic risk factors. Sixty subjects served as controls. Platelets were measured by automated analyzer.  $\beta$ -TG and PF4 were determined by ELISA. ASA platelet sensitivity was measured by Platelet Function Analyzer (PFA-100).

**Results:** The mean platelet count was  $455 \pm 200 \times 10^9/L$ . All patients had normal  $\beta$ -TG and PF4 ( $12 \pm 5$  IU/ml and  $4 \pm 1$  IU/ml) and prolonged C/EPI closure time (T, unit: s, n.v. 84-160 s) ( $249 \pm 40$  s).

**Summary/Conclusions:** These findings suggest that in ET patients the daily low-dose ASA represents an optimal dosing strategy and that PFA test may be an useful tool to distinguish between the ASA "normal-responder" and "low-responder" ET patient.

## PB2041

### CLINICAL AND EXPERIMENTAL CHARACTERISTICS OF MYELOID/LYMPHOID NEOPLASMS DISPLAYING PDGFRA OR PDGFRB REARRANGEMENT

L. Kou<sup>1</sup>, J. Pan<sup>1</sup>, H. Qiu<sup>1,2,\*</sup>, S. Chen<sup>1</sup>, D. Wu<sup>1,2</sup>

<sup>1</sup>The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, <sup>2</sup>Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

**Background:** According to the 2016 revision to the WHO classification of myeloid neoplasms and acute leukemia, the cases with rearrangement of tyrosine kinase (TK) genes PDGFRA, PDGFRB are classified in Myeloid/lymphoid neoplasms with eosinophilia and rearrangement of PDGFRA, PDGFRB, or FGFR1, or with PCM1-JAK2. It is a rare event that patients presented rearrangements with these genes. And in the past decade, the dose of TKI to cases with PDGFRA and B abnormal was inconclusive.

**Aims:** The goal of the study was to assess the clinical and experimental characteristics and observe the response of Imatinib(IM) therapy of Myeloid/lymphoid neoplasms with PDGFRA or B abnormal.

**Methods:** Cytogenetic examination of bone marrow cells obtained from patients was performed by 24h culture method. R banding technical was used for karyotype analysis. PDGFRA and B gene rearrangement were detected by FISH using triple-color of 4q12 and dual color break-apart PDGFRB probes.

The fusion genes of rearrangements of PDGFRA and B genes were detected by RT-PCR. Immunophenotype analysis was carried out by flow cytometry. Most of all cases were treated with IM and followed up.

**Results:** The diagnoses included 27 cases of MPN, 1 case of AML-M2 and 1 case of non-hodgkin lymphoma. 21 cases were PDGFRA rearrangement, the other 8 were PDGFRB abnormal, 7 of 8 were EP fused gene, one of which concurrent with DEK-CAN fused gene, and the eighth had MYO18A-PDGFRB. 7 cases of the 8 PDGFRB rearrangement had a primary abnormality with t(5;12)(q33;p13) and the other one had a secondary abnormality of AML-M2. PDGFRA and B genes rearrangement detected by FISH and multiple-RT-PCR were positive. The immunophenotypical analysis showed myeloid or lymphoid. These cases achieve rapid and durable remissions on IM.

**Summary/Conclusions:** In summary, patients with significantly anemia and eosinophilia should be screened for the presence of PDGFRA and B rearrangements. The dual-colour FISH is a simple approach and should be added into the diagnostic work-up because these patients respond to imatinib therapy, and sustained responses have been observed. The OS of PDGFRA and B abnormal was similar with a previous report in a western population and another Chinese hematology center.

## PB2042

### PLATELET AGGREGATION STUDY OF ESSENTIAL THROMBOCYTHEMIA TREATED WITH ANAGRELIDE

Y. Hiramatsu<sup>1,\*</sup>, K. Furukawa<sup>2</sup>, K. Mizuhara<sup>1</sup>, T. Sakayori<sup>3</sup>, Y. Fujiwara<sup>1</sup>, N. Mochizuki<sup>1</sup>, S. Kubonishi<sup>1</sup>, Y. Komiyama<sup>3</sup>

<sup>1</sup>Department of Hematology and Oncology, <sup>2</sup>Department of Pathology and Clinical Laboratory, Japanese Red Cross Society Himeji Hospital, Himeji, <sup>3</sup>Hemostasis Product Engineering, Sysmex Corporation, Kobe, Japan

**Background:** Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by thrombocytosis and abnormal megakaryocyte proliferation. Patients with elevated platelet count are considered to be a high-risk group for thromboembolic and/or hemorrhagic complications. In Japan, anagrelide treatment was recently approved for the 1st line as a cell reduction therapy on ET. Even now, there are few study whether the risk of thrombosis has decreased after anagrelide treatment. Moreover, the platelet count problem uncertainty remains what is the best practice to follow when the platelet count in platelet-rich plasma (PRP) exceeds about  $600 \times 10^9/L$ , in the recent recommendations for the standardization of light transmission aggregometry by the platelet physiology subcommittee of Scientific and Standardization Committee /International Society of Thrombosis and Hemostasis.

**Aims:** The aim of this study was to characterize the platelet aggregation (PA) in patients with ET. We would also clarify whether there were any changes of hemostatic side effect and platelet aggregability before and after treatment with anagrelide.

**Methods:** This study has been conducted with blood sample obtained from six healthy subjects, compared to 18 consecutive patients with ET. None of the patients was taking anticoagulants or cytoreductive agents. We also studied six anagrelide-treated patients with ET. Whole blood aggregometry (WBA) and LTA using PRP were performed. ADP-induced PA or collagen-induced PA used natural count PRP and platelet count adjusted PRP with platelet-poor plasma. Data were compared in the groups using the Tukey-Kramer test. This study was approved by the Ethical committee of our hospital. All study procedures were performed in accordance with the Declaration of Helsinki.

**Results:** The result of WBA was not obtained, because the filter was obstructed by giant platelets. In the natural PRP, even over  $900 \times 10^9/L$ , the platelet aggregability was markedly increased compared with the control (ADP-induced PA:  $p=0.023$ , collagen-induced PA:  $p=0.001$ ), but, was not significantly different (ADP-induced PA:  $p=0.703$ , collagen-induced PA:  $p=0.986$ ) in the count adjusted PRP. These results were not confirmed in cases with platelet counts of less than  $600 \times 10^9/L$ . There was no decrease in platelet aggregation before and after treatment with anagrelide (ADP-induced PA:  $p=0.3403$ , collagen-induced PA:  $p=0.514$ ).

**Summary/Conclusions:** In the ET patients with platelet counts more than  $900 \times 10^9/L$ , the platelet aggregation by LTA with natural count PRP was remarkably accelerated and this data seemed to reflect the disease state. Although treatment with anagrelide showed cyto-reductive effect without any hemorrhagic complication in patients with ET, it did not fully reduce platelet aggregability.

## PB2043

### A SINGLE CENTRE EXPERIENCE OF MASTOCYTOSIS

G. Özkan<sup>1,\*</sup>, Ö. Tepe<sup>2</sup>, N. Demir<sup>1</sup>, Ö. Arslan<sup>1</sup>, S. Erdem<sup>1</sup>, Ö. Doğan<sup>2</sup>, N. Büyükbabani<sup>2</sup>, C. Baykal<sup>3</sup>, R. Tanakol<sup>4</sup>, M. Nalçacı<sup>1</sup>, A.S. Yavuz<sup>1</sup>

<sup>1</sup>Hematology, <sup>2</sup>Pathology, <sup>3</sup>Dermatology, <sup>4</sup>Endocrinology and Metabolism, Istanbul Medical Faculty, Istanbul, Turkey

**Background:** Mastocytosis considered as a subcategory of myeloid neoplasms based on World Health Organization (WHO) 2016 classification, is characterized by expansion and accumulation of abnormal clonal mast cells in

one or more organs. KITD816V mutation and other KIT mutations play as driver mutations in the pathogenesis of disease. KITD816V mutation is positive in %80 of systemic mastocytosis patients. Recent studies show that high allele burden of KITD816V and high serum tryptase levels correlate with aggressive disease. Recently the importance of CD30 expression on neoplastic mast cells has been confirmed. CD30 is expressed aberrantly on neoplastic mast cells in patients with advanced systemic mastocytosis.

**Aims:** In this study we aimed to present demographic data, clinical follow-up and treatment of patients with mastocytosis and identify the impact of KIT D816V allele burden and expression of CD30 by mast cells in systemic mastocytosis.

**Methods:** We performed a retrospective study on 54 adult patients with mastocytosis (24 female, 30 male; mean age:44±13) who fulfilled WHO criteria between 2006 and 2016. These patients comprise cutaneous mastocytosis (CM) (n=10), indolent systemic mastocytosis (ISM) (n=30), smoldering systemic mastocytosis (SSM) (n=2), aggressive systemic mastocytosis (ASM) (n=4), systemic mastocytosis associated hematologic neoplasm (SM-AHN) (n=3), mast cell leukemia (MCL) (n=4) and mast cell activation syndrome (MCAS)(n=1).

**Results:** At diagnosis, age of patients with advanced disease was higher than ISM and SSM group (p=0.001). Most frequent symptom of disease was skin lesion (urticaria pigmentosa) (%64). Skin lesions were significantly higher in patients with ISM and SSM than with advanced disease (p=0.009). But B symptoms were significantly higher in advanced disease variant (p=0.013). Anemia, thrombocytopenia, elevation of ALP and GGT, hypoalbuminemia were significantly higher in advanced disease than in ISM and in SSM. Osteopenia was higher in patients with ISM and SSM than with advanced disease.%56 and %18 respectively. KITD816V mutation was detectable in peripheral blood in 33 of 40 mastocytosis patients (%82) with a median Ct value 36±4. Median Ct value was significantly lower in advanced SM (Ct: 32±5) than in SM and SSM (Ct: 36±4) (p=0.028) showing a significantly higher allele burden. Expression of CD30 on mast cells in bone marrow biopsies with immunohistochemistry investigation was detectable in 20 of 32 systemic mastocytosis patients (%62). There was no significant difference expression of C30 on mast cell between patients with ISM (%65) (13/20) and advanced SM (%87) (7/8) (p=0.371). There was no significant correlation between elevated serum tryptase level and CD30 expression (p=0.114).

**Summary/Conclusions:** The definition of disease subcategories in systemic mastocytosis is important for choosing the treatment modality (cytoreduction or allogeneic stem cell transplantation vs treatment of the mediator symptoms) for the individual patient. CD30 is a diagnostic marker and also a possible therapeutic target.

**PB2044**

**JAK2 PSEUDO-KINASE AND KINASE MUTATIONS IN THE ETIOLOGY OF THROMBOCYTOSIS**

M. Coucelo<sup>1,\*</sup>, J. Azevedo<sup>1</sup>, A.L. Pinto<sup>1</sup>, A.T. Simões<sup>1</sup>, S. Marini<sup>1</sup>, T. Magalhães Maia<sup>1</sup>, J.C. Almeida<sup>1</sup>, A.I. Espadana<sup>1</sup>, L. Ribeiro<sup>1</sup>  
<sup>1</sup>Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Background:** Thrombocytosis is defined as an abnormally increased number of platelets (>450x10<sup>9</sup>/L) in the blood counts, whose cause can be primary or secondary, hereditary or acquired. Hereditary thrombocytosis is a rare congenital disease due to germ line mutations affecting thrombopoietin signaling genes such as THPO, MPL and, more recently, JAK2.

**Aims:** To describe five cases of persistent thrombocytosis in young patients with JAK2 mutations.

**Methods:** Four children (2F: 2M), median age of 8,8 years and 1 young adult (F) 21 years-old, with sustained elevation of platelet counts. None had previous history of thrombo-hemorrhagic events. Main causes of secondary thrombocytosis were excluded, and all patients tested negative for BCR-ABL1, JAK2V617F, CALR and MPL mutations. Sanger sequencing of exons 12 to 20 of JAK2 was performed in all patients. Family studies were possible in 3 families.

**Results:** Median CBC values: platelets- 630±90x10<sup>9</sup>/L; hemoglobin - 13,3±1,2 g/dl and leukocytes- 9,3±2,3x10<sup>9</sup>/L. Four different JAK2 mutations were identified in the 5 patients (Table 1): JAK2 S591L/R867Q/T875N/T875I. The patient with the JAK2 T875N mutations had a discrete splenomegaly Familial studies allowed the identification of JAK2 T875I mutation in 3 adults previously characterized as essential thrombocythemia (ET) triple negative

**Summary/Conclusions:** *In vitro* studies performed by other authors have demonstrated that JAK2 R867Q and JAK2 S591L, described in familial thrombocytosis, promote JAK-STAT activation. The germline nature of JAK2 T875N mutation, previously described in an acute megakaryoblastic leukemia primary cell line, was confirmed in DNA obtained from hair follicle. Two patients presented a non-described JAK2 T875I mutation. Familial studies clarified the etiology of thrombocytosis in 3 adults previously diagnosed as ET triple negative. The identification of different JAK2 germline pseudo-kinase and kinase domains mutations has settled the etiology of persistent thrombocytosis in 4 children and 1 young adult. Therefore, particularly in children, after excluding the main causes of secondary and acquired thrombocytosis, JAK2 gene sequencing should be incorporated in the differential diagnosis of this condition. The char-

acterization of these rare forms of thrombocytosis and the follow up of these patients across generations, will improve the understanding of this entity.

**Table 1.**

Patient characterization and familial studies										
Patient	JAK2 GENE		Sex	Age (y)	Hb (g/L)	WBC (x10 <sup>9</sup> /L)	PLT (x10 <sup>9</sup> /L)	CLINIC AND LABORATORIAL DATA

**COMPARISONS OF PATIENT MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK VS REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY**

C. Harrison<sup>1,\*</sup>, Z. Pemberton-Whiteley<sup>2</sup>, A. Mead<sup>3</sup>, S. Ali<sup>4</sup>, J. Mathias<sup>5</sup>, C. Thomas<sup>5</sup>, M. Campbell-Drew<sup>5</sup>, G. Taylor-Stokes<sup>6</sup>, J. Waller<sup>6</sup>, A. Ducres<sup>7</sup>, B. Taylor<sup>7</sup>

<sup>1</sup>Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, <sup>2</sup>Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, <sup>3</sup>Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, <sup>4</sup>Queens Centre, Castle Hill Hospital, Cottingham, <sup>5</sup>MPN Voice, London, <sup>6</sup>Adelphi Real World, Bollington, <sup>7</sup>Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

**Background:** Patient (Pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts across 6 countries and identified current treatment strategies in these pts.

**Aims:** To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

**Methods:** A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

**Results:** A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to start treatment rather than delay at diagnosis of PV or ET. A greater proportion of ROSW physicians reported they would observe >25% of patients at diagnosis (UK - 54% MF, 30% PV, 37% ET; ROSW - 51% MF, 48% PV, 50% ET). No difference was observed in the most commonly received treatments for each disease, but a greater proportion of UK patients reported receiving treatments than ROSW. This difference was greater in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 50%), aspirin (UK 53%, ROSW 37%), hydroxyurea (HU) (UK 31%, ROSW 28%) and transfusion (UK 27%, ROSW 23%), for PV they were aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 62%, 30% ROSW) and anagrelide (UK 14%, ROSW 18%). Physician reported data on treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians reported that their patients were more likely to 'often' disagree with their primary treatment recommendation than ROSW (16% vs 7%) but despite this UK patients were more likely to be 'completely' satisfied with their physicians understanding and support of their treatment goals (UK, 51%; ROSW 35%). Patients rated who they thought should be the main decision maker on a scale of 1 (the patient) to 10 (physician). UK patients were slightly more inclined to want to be involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physicians supported this as more 'agreed strongly' with the statement 'I involve my MPN patients in treatment decisions' (UK, 39%; ROSW 28%).

**Summary/Conclusions:** In comparison with ROSW: UK physicians were more likely to prescribe drug treatments for ET/PV. Interestingly, UK patients desired to be more involved in treatment decisions, and this was reflected in the physician's perspective to involve their patient in treatment decisions more. UK patients were also more likely to disagree with their physician on primary treat-

ment recommendations. However, this had no impact on satisfaction suggesting that UK patients welcome an open discussion on treatment options with their physician. These data highlight the importance of maximizing patient physician communication in order to improve patient satisfaction with treatment in the UK.

#### PB2046

##### ANALYSIS OF EMERGING MOLECULAR SIGNATURES AND ASSOCIATED CLINICAL FEATURES IN MPN

S. H Al Shemmari<sup>1,\*</sup>, R. Rajan<sup>2</sup>

<sup>1</sup>Department of Medicine, Kuwait University, <sup>2</sup>Bone Marrow and Stem Cell Transplant Lab, Kuwait Cancer Center, Kuwait, Kuwait

**Background:** Myeloproliferative neoplasms (MPNs) are a group of clonal hematological disorders that arise from transformation of a multipotent hematopoietic stem cell which includes polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Driver mutation's confer growth advantage on the cancer cell and most likely is selected in the tissue microenvironment within which the neoplastic cells arise. Three-quarters of these patients carry the unique JAK2V617F mutation, JAK2 exon 12 mutations are found in 5% of patients with PV, MPL exon 10 mutations are present in about 5% ET/PMF and CALR mutations are found in 50-70% patients with ET/PMF.

**Aims:** In this study we investigated the prevalence of these so called driver mutations in patients with MPN's from January 2007 – January 2017 reported in our center.

**Methods:** We analyzed 3000 samples with suspected MPN for JAK2V617F mutation by ARMS-PCR and their allele burdens were reported by RQ-PCR. We have screened a cohort of 500 patients for JAK2/MPL/CALR mutations by a sequential molecular analysis which includes PCR, RT-PCR and fragment analysis.

**Results:** JAK2V617F mutation is present in 50% of patients with MPN. Among 600 cases submitted for sequential molecular analysis identified 372 cases with JAK2V617F mutation, 70 cases with CALR mutation, and 6 cases with MPL mutations. Allele burden study on JAK2V617F positive patients revealed that patients with ET has the lowest allele burden, those with PV an intermediate one and those with PMF showed the highest burden. Measurement of JAK2V617F allele burden by RQ-PCR for a PMF case after allogeneic transplant (ASCT) reported that allele burden of 2.9% after 20 days of transplant and a negative result after 60 days of transplant vs 13% before ASCT. CALR mutation is found in ET and PMF cases that are mutually exclusive with JAK2V617F and MPL exon 10 mutations in ET whereas 2 cases with PMF found to be positive for JAK2V617F and CALR mutations. We found 40 cases with a 52-bp deletion, 4 cases with a 14bp deletion and 26 cases with a 5bp insertion. CALR variants reported in our cohort were 54% type 1 and 46% type 2 mutations. We found a tendency towards older age among type 2 carriers compared to type 1 carriers (median age at diagnosis: 57 years versus 52 years) or compared to non-type 2 carriers (median age at diagnosis: 57 years versus 53 years). Similarly, platelet count at diagnosis tended to be higher in the subgroup of type 2 mutation carriers than in patients with the type 1 mutation while hemoglobin levels and white blood cell count were lower compared to those with non-type 2 mutation. The mutual allele burden of JAK2V617F /CALR exon indel mutations of two PMF patients found as 10%/65% and 15%/55% respectively. In our cohort, 10% of the patients with CALR mutation had anemia, 21% had splenomegaly, and 43% had megakaryocytes at time of diagnosis. Compared with JAK2 V617F-positive ET and PMF, CALR-mutant ET and PMF are clinically correlated with lower WBC, leukocyte and hemoglobin counts, higher platelet counts, and a reduced risk of thrombosis.

**Summary/Conclusions:** Analysis of JAK2/MPL/CALR genes as molecular marker's for MPN's, allows the diagnosis of 95% of patients with MPN. As a novel mutation, CALR testing also has a prognostic significance and it was not mutually exclusive with JAK2V617F mutation. Measurement of JAK2 V617F allele burden early after transplantation is an important predictive parameter in monitoring patients following this treatment. The knowledge of driver mutations can provide valuable information for diagnosis and prognosis, which ultimately can be highly useful for clinical decision making for the management of patients with MPN.

#### PB2047

##### IMPACT OF THE TYPE OF CALR MUTATIONS ON THE CLINICAL AND LABORATORY FEATURES OF ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

E. Lisina<sup>1,\*</sup>, P. Butylin<sup>1</sup>, N. Siordia<sup>1</sup>, A. Silyutina<sup>1</sup>, E. Lomaia<sup>1</sup>, A. Zaritskey<sup>1</sup>

<sup>1</sup>Federal Almazov North-West Medical Research Centre, St. Petersburg, Russian Federation

**Background:** In 2013, in the majority of JAK2V617F negative patients with essential thrombocytosis (ET) and primary myelofibrosis (PMF) have been identified mutations in the 9 exon of CALR gene. Described more than 30 dif-

ferent mutations, subdivided into two subtypes: deletions (type I) and insertions (type II). There are data on the phenotypic effects, depending on the version of CALR mutations. However, the prognostic significance of mutations CALR is still insufficiently clear.

**Aims:** To assess the impact of the type I and type II mutations of CALR on the clinical and laboratory features of ET and PMF.

**Methods:** A multicenter retrospective study was carried out. Samples of peripheral venous blood was obtained from 149 patients with ET (n=76) and PMF (n=73). Patients that were negative for JAK2V617F and MPL515L/K mutations were studied for CALR mutations presence as described in original paper (T.Klampf, 2013). CALR Mutations were detected in 34 patients with ET (10 - men, 24 - women) and 25 patients with PMF (13 - men, 12 - women). Statistical data processing was carried out in the program STATISTICA for Windows 6.0.

**Results:** The frequency of mutations CALR was comparable in patients with ET and PMF (44.7% and 35.6%). Mutations of type II is 2 times more common in ET than with the TFM: 17.1% vs 9.6% (p=0.178). Mutations of type I detected in 21 cases in ET, in 18 cases - in PMF, type II in 13 cases - in ET and 7 - in PMF. The median of follow-up period of patients with ET with type I mutation was 36 months (3-87), with type II - 22 months (2-90). In PMF, the median of follow-up in the group with type I mutation was 46 months (3- 133), type II - 77 months (4-115). Hematological parameters in patients with ET showed higher levels of WBC in patients with type I mutation (p=0.043), the level of Hb in this variant was lower (p=0.009). In PMF levels of Hb were similar in the studied groups. Type of mutations had no significant effect on the number of WBC in patients with PMF. However, PLT was higher in PMF patients with type II mutations of CALR (p=0.014). Spleen size in ET patients on the time of the diagnosis date was slightly different: in type I - 106,5mm, type II - 119,6mm (p=0.076). The type of mutation in our study had no effect on the stratification according to the IPSET. Also there were no significant differences in assessing of the effect of therapy. Spleen size on the time of the diagnosis date in PMF patients with type I mutation were slightly larger (180,9mm vs 169,9mm). Revealed more pronounced fibrotic changes of the bone marrow (BM) in patients with type I CALR mutations (p <0,005). CALR mutation type had no influence on the distribution of patients with PMF, depending on the risk groups on the scale of IPSS and DIPSS.

**Summary/Conclusions:** The effect of the type of CALR mutation on the clinical and laboratory features of the ET and PMF has found. Type of CALR mutations in our study had no effect on the number of PLT in ET, but have a value for this index in PMF. Type I mutations in ET accompanied higher WBC level and a lower level of Hb. The published studies have not shown the influence of the type of mutation in the Hb level and the number of WBC in ET. An important observation was the detection of the effect of type I mutations on development fibrotic changes of BM in PMF. Our data are consistent with previously published studies that showed no effect on the stratification of patients according to the scale on the IPSS.

##### THE UNIQUE CASE OF GERMLINE CEBPA MUTATION IN PATIENT WITH FIP1L1/PDGFR A ASSOCIATED MYELOID/LYMPHOID NEOPLASM WITH EOSINOPHILIA

N. Gabeeva<sup>1,\*</sup>, E. Zvonkov<sup>1</sup>, E. Parovichnikova<sup>2</sup>, D. Koroleva<sup>1</sup>, O. Gavriliina<sup>2</sup>, S. Kusnetsova<sup>3</sup>, L. Grebenuk<sup>4</sup>, T. Obukhova<sup>4</sup>, A. Kovrigina<sup>5</sup>, L. Kuzmina<sup>6</sup>, V. Savchenko<sup>3</sup>

<sup>1</sup>Scientific and clinical department of chemotherapy for lymphomas, <sup>2</sup>Scientific and Clinical Department of Hemoblastosis Chemotherapy, Hematopoietic Depression and Bone Marrow Transplantation, <sup>3</sup>National Research Center for Hematology, Moscow, Russian Federation, <sup>4</sup>cytogenetics department, <sup>5</sup>Department of Pathological Anatomy, <sup>6</sup>Department of bone marrow transplantation, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Myeloid/lymphoid neoplasms with eosinophilia (MLNe) associated with PDGFRA rearrangement are rare disorders. The most frequent PDGFRA abnormalities is FIP1L1/PDGFR A (F/P) fusion gene results from a cryptic interstitial deletion at 4q12 with constitutive activation of tyrosine kinase (TK) activity. Although known since 2003, many questions remain in understanding the biology, disease course and response to therapy. The F/P fusion gene may clinically present as chronic eosinophilic leukemia (CEL), T-cell lymphoblastic lymphoma (T-LBL) or both concurrently. Acute myeloid leukaemia (AML) may also occur at presentation or during the course of the disease. While F/P is the driver mutation, to date there are few data about genetic variants of the disease that may contribute to clinical outcome. CCAAT/enhancer binding protein alpha (CEBPA) gene functions as key regulator of granulocytic differentiation. CEBPA mutations contribute to leukemogenesis by promoting proliferation and blocking differentiation of myeloid lineage in AML. Germline CEBPA mutations is a very rare and account about 1% in AML only.

**Aims:** We present the first case of detection of familial germline CEBPA muta-

tion in a patient with F/P MLNe who received related allogeneic transplantation from brother.

**Methods:** A 26 year-old male patient was presented with a 4-week history of fever, fatigue, difficulty in swallowing. Physical examination revealed generalized lymphadenopathy, splenomegaly, tonsils enlargement, leukocytosis ( $20 \times 10^9/L$ ), with marked eosinophilia ( $4,0 \times 10^9/L$ ). A bone marrow aspirate showed 2% blasts, 21% eosinophils. Histological examination of an cubital lymph node biopsy showed diffuse proliferation of medium-sized lymphoblasts. Immunohistochemistry and flow cytometry showed that the lymphoblastic population expressed CD2, CD5, CD7, CD4, CD99, TdT and CD1a. Polymerase chain reaction (PCR) analysis from samples of the lymph node and bone marrow failed to detect clonal T-cell receptor rearrangement. A diagnosis of T-cell lymphoblastic lymphoma (T-LBL) associated with reactive eosinophilia was rendered. The patient began standard multiagent chemotherapy in accordance with ALL-2009 protocol (ClinicalTrials.gov Identifier: NCT01193933) and achieved complete clinical remission. As he was planned to conduct autologous hematopoietic stem cell transplantation (HSCT), blood hematopoietic stem cells have been successfully harvested after stimulation of hematopoiesis. However, within 10 days after the discontinuation of G-CSF he developed leukocytosis ( $130 \times 10^9/L$ ) with 21% of eosinophils (absolute number  $27,3 \times 10^9/L$ ) and cubital lymphadenopathy. Histological examination of lymph node showed T-LBL relapse. Bone marrow biopsy revealed the expansion of predominantly eosinophilic cells. The study was carried out to exclude second myeloproliferative disease. Molecular and cytogenetic examinations of bone marrow failed to reveal BCR-ABL, FLT3 and NPM1, but showed CEBPA (TAD2) mutation. FISH probe revealed deletion 4q12 (F/P rearrangement), confirmed by RT-PCR. The same changes were also found in the lymph node cells. So, in accordance with 2008 WHO classification, he was diagnosed as «PDGFRA-associated MLNe». The patient was subsequently treated with imatinib mesylate at the dose 100mg daily and showed a good clinical response. After 4 months minimal residual disease still persisted in bone marrow (RT-PCR positive for F/P and PCR for CEBPA mutation) and he received an allogeneic HSCT from his brother. Routine testing of chimerism at 2 months after HSCT revealed the recipient DNA less than 5% and positive probe for F/P and CEBPA. We hypothesized the germinal origin of CEBPA mutation.

**Results:** The same N-terminal (TAD2) CEBPA mutation was found in the patient's skin, lymph node and bone marrow, and in the patient's brother bone marrow samples. Unfortunately, no materials from parents was available for analysis at that time.

**Summary/Conclusions:** Germline CEBPA mutations is very rare event and have been identified as causative gene mutations in familial AML. For the first time to our knowledge this mutation was detected in patient with PDGFRA-associated MLNe. This observation is of particular interest because it will provide novel insight about the genetic basis and the additional events responsible for the course of the disease.

## PB2050

### DEVELOPMENT AND DESIGN OF A RANDOMIZED CONTROLLED TRIAL USING ONLINE YOGA FOR SYMPTOM MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS

J. Huberty<sup>1,\*</sup>, R. Eckert<sup>1</sup>, K. Gowin<sup>2</sup>, B. Ginos<sup>2</sup>, H. Kosiorek<sup>2</sup>, A. Dueck<sup>2</sup>, L. Larkey<sup>3</sup>, R. Mesa<sup>2</sup>

<sup>1</sup>School of Nutrition and Health Promotion, Arizona State University, <sup>2</sup>Mayo Clinic, <sup>3</sup>College of Nursing and Health Innovation, Arizona State University, Phoenix, United States

**Background:** Patients with myeloproliferative neoplasms (MPNs) suffer from symptom burdens (*i.e.* fatigue, weight loss, night sweats, insomnia, sexual dysfunction, and pruritus) often not alleviated by JAK inhibition. We previously demonstrated feasibility of an online, home-based yoga 12 week intervention, in MPN patients on stable medical therapy. Specifically, online yoga was feasible in MPN patients (N=38) (*i.e.*, 68% satisfied with study, 75% felt it was helpful for symptom management and weekly yoga participation averaged ~51 min/week) and effective to alleviate residual MPN symptom burden (effect size [ES]=-0.36,  $p=0.004$ ), anxiety (ES=-0.67,  $p=0.002$ ), depression (ES=-0.41,  $p=0.049$ ), sleep (ES=-0.58,  $p<0.001$ ), and fatigue (ES=-0.33,  $p=0.04$ ).

**Aims:** To conduct a randomized controlled pilot study further investigating the preliminary effects of online streamed yoga to improve MPN patient symptom burden compared to a wait-list control and to determine the feasibility (*i.e.*, implementation, practicality) of collecting biomarkers that are potentially related to MPN symptoms and disease (*i.e.* inflammatory cytokines and cortisol) in a national study. The study is underway with early feasibility data reported herein; efficacy results to be reported at conference upon study completion.

**Methods:** MPN patients (on stable medications including JAK inhibition) were recruited (via online MPN organizations) and randomized to a yoga group (intervention - 12 weeks, 60min/week at Udaya.com) or wait-list control (usual care). The yoga "intervention" was developed with MPN-specific concerns in mind (*i.e.*, enlarged spleen/liver, older adult population) and based on feedback received from our feasibility study. Weeks 1-2 were introductory (5-6, 5-10 min videos), with weeks 3-12 progressing in video duration and intensity (2-3, 20-30 min videos). All participants completed weekly activity logs, symptom burden

questionnaires (MPN-SAF TSS and NIH PROMIS) at weeks 0,7,12, and 16 (follow-up), and wore a Fitbit Flex (objective activity and sleep monitor) through week 12. The yoga group only was also asked to receive a blood draw (*i.e.*, CBC, TNF- $\alpha$ , IL-6) and to provide saliva samples (*i.e.*, salivary cortisol) at baseline and will be expected to do so at post-intervention. Control group participants are asked to maintain usual levels of activity and will have access to the same videos as the yoga group after follow-up (week 16).

**Results:** A total of 260 MPN patients completed the eligibility questionnaire, of which 96 were eligible. Of those, the first 62 eligible were enrolled into the study (completed an informed consent). Thirty-four participants were randomized to the intervention group and 28 to the control group. Of those enrolled (n=62), 31% were diagnosed with PV (n=19), 37% with ET (n=23), and 32% with MF. The mean age of participants is 57.8 years ( $\pm 10.3$ ), 87% female (n=54), 95% Caucasian (n=59), and the mean BMI is 26.8 kg/m<sup>2</sup>. A total of 85% (n=29/34) of yoga group participants completed the baseline blood draw and 83% (n=15/18 eligible for saliva samples) completed the baseline saliva sample. Of those that completed their blood draw (distance travelled to receive blood draw ranged from 1.2 miles – 91.6 miles, avg. 16.3 miles). To date, seven participants have dropped out of the study due to: 1) study too time consuming/laborious (n=1), 2) Fitbit device being too difficult to use/wear (n=1), 3) non-study personal issue (n=2), or 4) never responding after completing the informed consent (n=2). Outcomes will be complete by May 8, 2017 with results to be presented at EHA.

**Summary/Conclusions:** Data presented here will inform next steps for a RCT investigating the effectiveness of online yoga for symptom management in MPN patients.

## PB2051

### COMPARISONS OF SYMPTOM BURDEN IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK VS REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

C. Harrison<sup>1,\*</sup>, Z. Pemberton-Whiteley<sup>2</sup>, S. Ali<sup>3</sup>, A. Mead<sup>4</sup>, J. Mathias<sup>5</sup>, C. Thomas<sup>5</sup>, M. Campbell-Drew<sup>5</sup>, G. Taylor-Stokes<sup>6</sup>, J. Waller<sup>6</sup>, A. Duces<sup>7</sup>, B. Taylor<sup>7</sup>

<sup>1</sup>Guy's and St Thomas' NHS Foundation Trust, Guy's Hospital, London, <sup>2</sup>Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, <sup>3</sup>Queens Centre, Castle Hill Hospital, Cottingham, <sup>4</sup>Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, <sup>5</sup>MPN Voice, London, <sup>6</sup>Adelphi Real World, Bollington, <sup>7</sup>Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

**Background:** Patients with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated patient-reported impact of MPNs across 6 countries.

**Aims:** To analyze differences in disease and symptom burden of MPN patients between the UK and the Rest of Surveyed World (ROSW).

**Methods:** A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of symptom burden.

**Results:** A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK patients reported more symptoms than those in ROSW (9.02 vs 5.95 respectively). A higher proportion of UK patients reported experiencing symptoms compared with ROSW (*e.g.* fatigue and tiredness UK - 87% MF and PV, 86% ET; ROSW – 64% MF, 39% PV, 45% ET). This pattern was observed for 28 of the 31 symptoms recorded. A similar difference was seen when physicians were asked about frequency of patient-reported symptoms (*e.g.* fatigue and tiredness UK – 90% MF, 67% PV, 70%; ROSW – 71% MF, 55% PV, 48% ET). Patients rated symptom severity from 1 (not severe at all) to 10 (worst possible). The UK was higher than ROSW for the three most common symptoms; fatigue and tiredness (mean: UK 6.73, ROSW 6.18), difficulty sleeping (mean: UK 6.09, ROSW 5.38) and loss of concentration (mean: UK 6.01, ROSW 5.67). This difference was not observed when physicians were asked to rate symptom severity. An overall symptom burden was calculated as a function of all patient-reported symptoms. UK patients were disproportionately represented in the high symptom burden group (UK 35% vs ROSW 16%) and had an average overall symptom burden score of 40.1 compared with 24.1 among ROSW patients. UK patients were also more likely to have been classified with a high risk score at diagnosis (UK 22% vs ROSW 9%). Despite the consistently greater symptom burden experienced by UK patients, little difference was observed in patient satisfaction with their physician's communication (UK 81% satisfied vs ROSW 90%) and disease management (UK 87%, ROSW 90%). However, UK patients were more likely to disagree with the statement 'My doctor understands how much my condition impacts my life' (UK 39% vs 22% ROSW). UK physicians had more MPN patients under their care than ROSW (mean patients under care in last 12 months; UK - 25 MF, 46 PV, 47 ET; ROSW - 15 MF, 31 PV, 20 ET) and were also more likely to agree with the statement 'There is not enough time during the appointment to discuss all of the symptoms a patient is experiencing' (UK 74% vs ROSW 54%).

**Summary/Conclusions:** UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn't perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROSW counterparts, they are also more likely to feel they don't have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

#### PB2052

##### MPN10 SCORE AND SURVIVAL OF MOLECULARLY ANNOTATED MYELOPROLIFERATIVE NEOPLASMS PATIENTS; A FIRST REPORT ON AN EGYPTIAN COHORT

Y. Elnahass<sup>1,\*</sup>, H. Mahmoud<sup>1</sup>, M. Mattar<sup>2</sup>, O. Fahmy<sup>2</sup>, M. Abdelmoaty<sup>1</sup>, R. Abdelfattah<sup>1</sup>, F. Elrefaey<sup>1</sup>, W. Elmetenawy<sup>2</sup>

<sup>1</sup>Haematology, National Cancer Institute- Cairo University, <sup>2</sup>Haematology, Faculty of Medicine- Cairo University, Cairo, Egypt

**Background:** The vast majority of myeloproliferative neoplasms (MPNs) patients are characterized by a molecular genetic background and by variable symptoms reflecting disease burden that may correlate with prognosis.

**Aims:** To study the impact of driver gene mutations: Janus kinase 2 (JAK2), calreticulin (CALR) and myeloproliferative leukemia virus oncogene (MPL) on disease burden and correlating mutational status with symptom severity calculated by MPN10 score, degree of bone marrow (BM) fibrosis, clinical characteristics and survival in MPNs patients.

**Methods:** MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) was assessed as mean/median of 10 items: fatigue, concentration, early satiety, inactivity, night sweats, itching, bone pains, abdominal discomfort, weight loss and fever. JAK2<sup>V617F</sup> and exon12 mutations were performed by allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) while CALR<sup>exon9</sup> insertion/deletion and MPL W515<sup>exon10</sup> mutations were assessed by high-resolution melting (HRM).

**Results:** 93 MPNs patients (48 males and 45 females): 18 polycythemia vera (PV), 41 essential thrombocythemia (ET), 24 primary myelofibrosis (PMF), 10 Post-ET/PV-myelofibrosis (post-ET/PV-MF) were included. Median age at diagnosis was 55 years (17-75) and was lower in ET than PV and PMF patients; 44 (19-75) years vs 56 (34-70) years and 56 (20-75) years, respectively ( $p < 0.001$ ). JAK2 mutation was positive 53/93 (57%); 16 (90%) PV patients, 14 (34%) ET patients, 15 (62%) PMF patients, 8(80%) post-ET/PV-MF patients ( $p < 0.001$ ). CALR mutation was positive in 14/93 (15%); 10 (24%) ET patients, 4 (17%) PMF patients, zero (0%) Post-ET/PV-MF patients ( $p = 0.050$ ). MPL mutation was positive in 3/93 (3%); 2 (5%) ET patients, 1(4%) PMF patients, zero (0%) Post ET/PV-MF patients. 23/93 (25%) patients were triple negative; 15 ET, 4 PMF and 2 post ET-MF. Median MPN10 score was 21 (4-45) in ET versus 37.5 (25-56) in PV, 54 (15-80) in PMF and 59 (45-75) in Post-ET/PV-MF ( $p < 0.001$ ). From 39 patients with BM fibrosis, 6 (15%) were triple negative vs 33 (85%) mutant patients ( $p = 0.007$ ). Among 52 patients with splenomegaly; 7 (13.5%) patients were triple negative vs 45 (87%) patients with a positive mutational status ( $p < 0.001$ ). Median MPN10 score was 48 (5-76) in JAK2 positive patients vs 25 (4-80) in JAK2 negative ( $p < 0.001$ ) and was 22.5 (4-65) in CALR mutants vs 35 (5-80) in CALR negative ( $p < 0.050$ ). Median MPN10 score was 21 (10-48) in triple negative patients vs 40 (4-80) in MPNs JAK2/CALR/MPL mutants ( $p < 0.001$ ). After a median follow-up period of 36 months (6.6-102), progression free survival (PFS) and overall survival (OS) of the whole cohort was 85% and 95%, respectively. PFS of JAK2 positive vs negative patients was 62% vs 100% ( $p < 0.001$ ). PFS of CALR positive vs negative patients was 100% vs 78% ( $p = 0.067$ ). PFS of triple negative vs mutant patients was 100% vs 75% ( $p = 0.004$ ). OS of JAK2 positive vs negative patients was 85% vs 100% ( $p = 0.011$ ). OS of CALR positive vs negative patients was 100% vs 92% ( $p = 0.197$ ). OS of triple negative vs mutant patients was 100% vs 90% ( $p = 0.015$ ) (Figure 1).

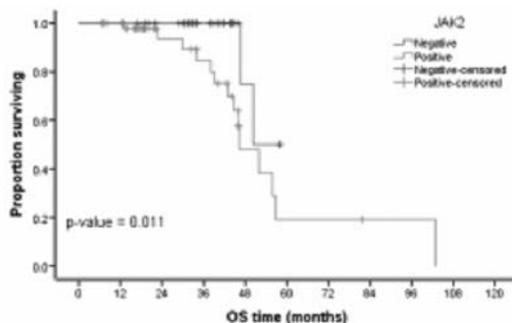

Figure 1.

**Summary/Conclusions:** MPN10 score is directly affected by JAK2 and CALR positivity and can be used as a major predictor of survival in MPNs patients. Triple negative ET patients in our cohort have significantly lower MPN10 score, show lower incidence of BM fibrosis and splenomegaly which may indicate a more indolent disease course.

#### PB2053

##### FINAL RESULTS FROM PEN-PV STUDY, A SINGLE-ARM PHASE 3 TRIAL ASSESSING THE EASE OF SELF-ADMINISTRATING ROPEGINTERFERON ALFA-2B USING A PRE-FILLED PEN IN POLYCYTHEMIA VERA PATIENTS

H. Gisslinger<sup>1,\*</sup>, B. Grohmann-Izay<sup>2</sup>, P. Georgiev<sup>3</sup>, A. Skotnicki<sup>4</sup>, L. Gercheva-Kyuchukova<sup>5</sup>, M. Egyed<sup>6</sup>, V. Rossiev<sup>7</sup>, P. <sup>1</sup>Hematology and Hemostaseology, Medical University Vienna, <sup>2</sup>AOP Orphan Pharmaceuticals AG, Vienna, Austria, <sup>3</sup>Clinic of Hematology, University Multiprofile Hospital for Active Treatment "Sveti Georgi", Plovdiv, Bulgaria, <sup>4</sup>Teaching Unit of the Hematology Department, University Hospital in Krakow, Krakow, Poland, <sup>5</sup>Clinical Hematology Clinic, Multiprofile Hospital for Active Treatment "Sveta Marina", Varna, Bulgaria, <sup>6</sup>Department of Internal Medicine II, Kaposi Mor County Teaching Hospital, Kaposvar, Hungary, <sup>7</sup>Samara Kalinin Regional Clinical Hospital, Samara, Russian Federation, <sup>8</sup>Department of Clinical Hematology, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic, <sup>9</sup>Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, <sup>10</sup>Department of Hematology, Cherkasy Regional Oncology Center, Regional Treatment and Diagnostics Hematology Center, Cherkasy, Ukraine, <sup>11</sup>First Department of Internal Medicine, Multiprofile Hospital for Active Treatment - Hristo Botev, Vratsa, Bulgaria, <sup>12</sup>Clinic of Internal Medicine - Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, <sup>13</sup>Department of Hematology, Roskilde Hospital, University of Copenhagen, Copenhagen, Denmark, <sup>14</sup>Centre d'Investigations Cliniques, Hôpital Saint-Louis and Université Paris Diderot, Paris, France

**Background:** Interferon-alpha (IFN $\alpha$ ) based therapies have been successfully used in myeloproliferative neoplasms for over thirty years. A known burden for long-term therapy applying IFN $\alpha$  in otherwise fit outpatients is the necessity of frequent hospital visits for product administration. Ropeginterferon alfa-2b (AOP2014) is a novel long-acting monopegylated IFN $\alpha$  allowing initially bi-weekly and, in long-term maintenance, monthly administration. To further improve on convenience and compliance, a pre-filled, dose-adjustable pen was developed for patient self-administration at home.

**Aims:** Open-label, single arm, multicenter phase III trial assessing the self-administration of AOP2014 using a pre-filled, dose-adjustable pen (NCT: 2014-001356-31).

**Methods:** The study was performed in 18 sites in 8 European countries. Patients were eligible who completed the AOP2014-arm in the PROUD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (two supervised self-administrations at site, followed by four self-administrations in the home-setting, and a final assessment visit at study site).

**Results:** A total of 36 patients were enrolled and received the AOP2014 pen for self-administration. The mean age was 58.5 years (range 37 to 77 years), 23/36 (63.9%) were male patients and a large proportion of patients (15/36 [41.7%]) entering the study received a baseline dose of 500  $\mu$ g AOP2014. 72.2% (26/36) used 2 pens (dose >250  $\mu$ g) and 27.8% of patients (10/36) used one pen (dose up to 250  $\mu$ g) to administer the appropriate dose. At the first supervised visit, 80.6% (29/36) of patients had achieved full success, defined as no technical problems with the pen experienced by the patient during the injection, and no early withdrawal of the pen (before injection was complete), both observed by the investigator. At the second supervised visit the full success rate was 91.7% (33/36). The majority of observations resolved after the second supervised visit. Only 5 patients (13.9%) needed one additional supervised visit prior using the pen correctly in a home-setting. All patients had achieved full success at Visit P7 (supervised assessment visit at study end).

The patients responded favourably to the use of the pre-filled pen for the administration of AOP2014 and the accompanying instructions. Based on the Investigator's assessment, no patients exhibited any visible pain or physical discomfort, appeared to be dissatisfied when using the pen or exhibited any frustration using the pen, nor did the patient report any pain arising from the use of the pen. The majority of patients (32/36 patients) rated the instructions for the AOP2014 pen (*i.e.* scope and structure of the leaflet, clarity and comprehensibility of the text, clarity of the images and design of the leaflet), and the AOP2014 pen itself (*i.e.* setting the dose, user-friendliness, injection procedure) as "very good" or "good". The haematological parameters and spleen size remained stable throughout the study, and the rate of responders (haematological response with and without spleen size) was maintained during the entire study, suggesting that the use of the pen device did not affect drug activity. Of the 47 adverse events (AE) reported during the study, 19 were related. Most AEs were mild to moderate in intensity. One serious AE (mild atrial fibrillation, unrelated), one pen-related AE (mild nervousness reported prior first administration in the home setting), and one Grade 3 TEAE (pain in extremity, related) were recorded, but none led to a dose reduction.

**Summary/Conclusions:** The AOP2014 pen was well accepted and no major difficulties were reported. The study drug performed as expected and there were no safety concerns arising from the administration of AOP2014 using the pen device. The AOP2014 pen allows for individual dosing and a patient-convenient mode of self-administration of ropeginterferon alfa-2b at home and is expected to support adherence and compliance in the long-term treatment of PV patients.

**PB2054**

**JAK2, CALR AND MPL MUTATIONS: CORRELATION WITH PHENOTYPE DISEASE AND HISTOPATHOLOGICAL FEATURES OF BONE BIOPSY**

H. J. Campo Palacio<sup>1,\*</sup>, M.J. Ramírez Sánchez<sup>1</sup>, A.M. Rodríguez Fernández<sup>2</sup>, L. Hermosín Ramos<sup>1</sup>, B. Bellosillo Paricio<sup>3</sup>, E. Carrillo Cruz<sup>4</sup>

<sup>1</sup>Haematology, <sup>2</sup>Pathology, Jerez De La Frontera Hospital, Jerez De La Frontera, <sup>3</sup>Pathology, Hospital del Mar, Barcelona, <sup>4</sup>Haematology, Hospital Virgen del Rocío, Sevilla, Spain

**Background:** Drivers mutations JAK2, CALR and MPL are mutually exclusive in Essentials thrombocytemia (ET) and these are included in the diagnostic criteria of myeloproliferative neoplasms (MPNs). Consistent with know literature, the molecular characterisation have implications in the phenotype disease and it might be interesting to study if these are associated with the histopathological characteristics of bone marrow biopsy

**Aims:** The purpose of this work is analyse the correlations between clinical-biological and histological characteristics of bone marrow biopsy and the mutational status (JAK2, CALR, MPL).

**Methods:** The study included 76 patients with ET diagnosed according to WHO criteria at the Haematology Department from Hospital de Jerez from January 2005 to December 2015. We examined the prevalence, and clinical and laboratory correlations of JAK2/CALR/MPL mutations. To evaluated the histology, one pathologist with expertise in haematopathology review the bone marrow biopsies corresponding to 44 patients with ET. We included only bone marrow biopsies of at least 10 mm in length and/or minimum 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

**Results:** There where 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and laboratory features of the patients are show in Table 1A. As can be seen, a 75% of patients belonged a high risk group, 18 (23%) patients presented thrombotic events before diagnosis and only 4 (5.3%) during the evolution. Clinical and molecular characteristics of patients as age, sex, hemoglobin level and stratification of risk were statistically significant. (Table 1A). Thromboembolics events seemed to be more frequent in patients with JAK2 mutation, although statistical significance was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B. We observed differences between the presence of laxes groups of megacaryocytes according with the mutational status and there were more frequently in patients with CALR mutation (p = 0.01). With a median of follow up of 4 years (ranger 0.3-11 años) a total of 6 patients had died. Two patients evolved to overt, one of them to acute leukaemia and the other one to myelofibrosis at 66 and 44 months from ET diagnosis respectively.

**Table 1.**

A										B

**Summary/Conclusions:** In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previous studies. The most consistent finding of this study was the presence of laxes groups of megacaryocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies, available to analysed, this might be the mayor causes for the lack of the data demostrating clinical and histological relevance. But our results should not be underestimated because, to our knowledge, this is the second study that has investigated this relation.

**CLINICAL IMPLICATION OF QUANTITATIVE JAK2 V617F ANALYSIS WITH DROPLET DIGITAL PCR IN MYELOPROLIFERATIVE NEOPLASMS**

E. Lee<sup>1,\*</sup>, K. J. Lee<sup>2</sup>, H. Park<sup>2</sup>, J. Y. Chung<sup>2</sup>, M.-N. Lee<sup>3</sup>, M.H. Chang<sup>4</sup>, J. Yoo<sup>5</sup>, H. Lee<sup>1</sup>, S.-Y. Kong<sup>6</sup>, H.-S. Eom<sup>1</sup>  
<sup>1</sup>Hematology, <sup>2</sup>National Cancer Center, Goyang, <sup>3</sup>Green Cross Laboratories, Yongin, <sup>4</sup>Oncology-Hematology, <sup>5</sup>Laboratory Medicine, National Health Insurance Service Ilsan Hospital, <sup>6</sup>Laboratory Medicine, National Cancer Center, Goyang, Korea, Republic Of

**Background:** JAK2 V617F is the most common genetic mutation in myeloproliferative neoplasms (MPN) and included in the major diagnostic criteria. Beyond the description of existence, quantification of mutational load is proposed as a useful information to classify subgroups of MPN and to predict prognosis. Droplet digital PCR (ddPCR) is a novel assay which has an advantage in accurate and reproducible quantitative analysis.

**Aims:** This study was planned to verify the correlation of ddPCR with pyrosequencing in diagnosis of MPN and to investigate clinical implication of the mutation burden in disease course.

**Methods:** Between 2012 and 2016, peripheral blood or bone marrow samples were obtained from 56 patients at diagnosis and every 3 months after enrollment. Inclusion criteria were 1) older than 20 years, 2) who were newly diagnosed with MPN and 3) diagnosed with MPN before, not met the indication of JAK2 inhibitor treatment yet. JAK2 V617F mutation was detected by pyrosequencing as diagnostic work-up. The ddPCR was performed using the same samples with pyrosequencing to prove correlations between assays and to establish a detection sensitivity cutoff. Clinical aspects and hematologic profiles of enrolled patients were reviewed.

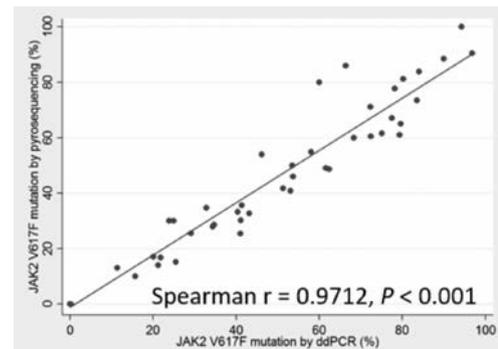

**Results:** The lowest value of measured JAK2 V617F allele by ddPCR except negative samples in our study was 0.01%, which was approximately 0.07 copies/uL of mutant allele. Some discrepancies were observed from 0.0001% to 0.01% concentration between the expected and measured values in ddPCR detection sensitivity assay, 0.1% was determined as the cutoff. Forty-two patients (75%) were positive for JAK2 V617F by pyrosequencing and 46 (82.1%) were positive by ddPCR. The mean mutated allele at diagnosis was 37.5%±30.08%. With ddPCR, the mean was 40.7%±31.2%. Pyrosequencing and ddPCR were highly correlated (r=0.9712, P<0.001). JAK2 V617F burden measured with ddPCR was significantly different by subgroups (P<0.001). In comparison of one disorder with another, polycythemia vera (PV) had more amount of mutant allele than essential thrombocytosis (ET) (P=0.001), however, differences between PV-myelofibrosis (MF) and ET-MF were not statistically significant. Follow-up samples were available in 12 patients and 8 were JAK2 V617F positive. Among them, reduction of mutant burden after treatment was observed in 6 patients (75%). JAK2 V617F burden showed initial reduction in a MF patient treated with JAK2 inhibitor, however, after dose reduction for toxicities, the JAK2 V617F mutation increment with hematologic aggravation was discovered. Mutation burden decrease showed a tendency consistent with hematologic improvement. Hematologic characteristics and JAK2 V617F load at the initial diagnosis and follow-up after treatment (Table 1, Figure 1).

**Table 1.**

Pt. No	Sex/Age	Subgroup	Initial JAK2 V617F allele (%)	Follow-up JAK2 V617F allele (%)	Difference	Initial CBC (WBC-Hb-Plt)	Follow-up CBC (WBC-Hb-Plt)	Treatment
1	F/56	PV	15.67	53.64	+37.97	15700-16.1-425K	4270-14.1-314K	Interferon alpha
2	F/63	PV	46.11	76.28	+30.17	10090-20.2-491K	6350-13.5-329K	Hydroxyurea, phlebotomy
3	M/72	PV	61.56	43.25	-18.31	15740-19.8-304K	7840-14.8-268K	Phlebotomy

7	M/75	MF	21.23	16.55*	-4.68	8700-8.5-124K	7370-10.1-176K	Ruxolitinib
8	F/51	ET	0.17	0.00	-0.17	6920-10.8-396K	5940-9.7-329K	Hydroxyurea

\* Data from the first follow-up sample.

† Data from the next follow-up sample in the same patient.

**Figure 1.**

**Summary/Conclusions:** Quantitative analysis of JAK2 mutation using ddPCR was highly correlated with pyrosequencing and might reflex clinical treatment response.

#### PB2056

##### CLINICAL IMPACT OF JAK2 AND CALRETICULIN GENE MUTATIONS ON PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

M. Napolitano<sup>1,\*</sup>, S. Siragusa<sup>1</sup>, S. Mancuso<sup>1</sup>, M. Santoro<sup>1</sup>, V. Leone<sup>2</sup>, C. Marino<sup>2</sup>, F. Di Piazza<sup>3</sup>, A. Russo<sup>4</sup>, V. Accurso<sup>1</sup>

<sup>1</sup>UO Ematologia, University Of Palermo, Palermo, <sup>2</sup>Oncoematologia, ASP Local Hospital, Trapani, <sup>3</sup>Laboratorio di genetica e oncologia molecolare., <sup>4</sup>UO Oncologia, University Of Palermo, Palermo, Italy

**Background:** JAK2 (V617F) gene mutation is found in approximately 60% of patients with Essential Thrombocythemia (ET), while 5-10% of JAK2 (V617F) negative ET patients carry MPL gene mutations involving codon 515. Recently, mutations at the exon 9 of calreticulin (CALR) gene have been identified in approximately 50% of patients with ET, unmutated for Jak2 and MPL.

**Aims:** Primary aim of the current study was to analyze the prevalence of JAK2, MPL and CALR gene mutations in patients with ET; secondary aim was to evaluate the impact of gene mutations on clinical features of ET at diagnosis.

**Methods:** A cohort of consecutive patients with a diagnosis of ET followed between January 2013 and June 2016 were considered. JAK2 (V617F) gene mutation was detected by PCR testing; MPL and CALR mutations were analyzed by direct sequencing methods. Thrombotic risk score was calculated according to European Leukemia Net recommendations. Data were statistically analyzed.

**Results:** Overall, 148 patients were included: 107 (72, 30%) had JAK2 (V617F) gene mutation (JAK2+), 12 (8, 10%) carried a mutation at exon 9 of CALR gene (CALR+), 3 (2, 02%) carried a mutation at codon 515 of MPL gene, 26 (17.58%) patients were not mutated for JAK2, CALR and MPL genes (triple negative). CALR+ subjects, compared to JAK2+ patients, had a younger age at diagnosis: median 48 year (25-92) in CALR+ patients vs 72 years (18-93, respectively). Patients with MPL mutation had a median age of 82 years while triple negative subjects had a median age of 59 years (23-89). The mean score for thrombotic risk was 0 in CALR+ patients and 1 in JAK2+, MPL+ and triple negative patients. The distribution of International Prognostic Score for Essential Thrombocythemia (IPSET) categories was also statistically significantly different ( $p=0.003$ ) for the three groups. The percentage of high-risk patients was 0 in CALR+ (0/12) group, 25, 60% (27/107) in JAK2+ group, and 18, 30% (5/26) in the triple negative group. The IPSET model also stratified patients with statistically significant difference ( $p=0.001$ ) among the three groups: the percentage of high-risk patients was 16, 66 (2/12) in the CALR+ group, 82, 35% (88/107) in the JAK2+ group, and 33, 33(9/29) in triple negative group. CALR+ patients belonged more frequently to the low /intermediate risk group than JAK2+ patients (80% versus 17, 5%,  $p=0.05$ ). The incidence of thrombotic events at diagnosis of ET was 0 in the CALR+ group, 28,03% (30/107) in the JAK2+ group and 23,07% (6/26) in the triple negative group. The median overall survival was not reached in any group.

**Summary/Conclusions:** CALR+ patients with ET are phenotypically distinct from JAK2+ and triple negative patients. We can speculate a potential protective role of CALR mutation given the absence of thrombosis in IPSS and IPSETt high-risk patients.

#### PB2057

##### RUXOLITINIB IN MYELOFIBROSIS: A MULTICENTRE EXPERIENCE FROM THE EAST OF ENGLAND

J. Russell<sup>1,\*</sup>, D. Sparksman<sup>2</sup>, A. Dicu<sup>3</sup>, K. Maw<sup>2</sup>, C. Gomez<sup>2</sup>, M. Mangi<sup>2</sup>, I. Whalley<sup>4</sup>, A. Collins<sup>3</sup>, S. Sadullah<sup>2</sup>

<sup>1</sup>Department of Haematology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, <sup>2</sup>James Paget University Hospital, Great Yarmouth, <sup>3</sup>Norfolk and Norwich University Hospital, Norwich, <sup>4</sup>Ipswich Hospital, Ipswich, United Kingdom

**Background:** Ruxolitinib, an oral Janus Kinase (JAK)1/JAK2 inhibitor, was approved in the EU in August 2012 for treating disease-related splenomegaly and constitutional symptoms in adults with primary myelofibrosis (PMF), post-polycythaemia vera myelofibrosis (PPV-MF), and post-essential thrombocythaemia myelofibrosis (PET-MF).

**Aims:** We present a retrospective multicentre analysis of MF patients treated with ruxolitinib from August 2012 to December 2016 at 3 centres in the East of England to assess its efficacy, safety, and tolerability in a 'real-world' clinical setting.

**Methods:** Retrospective data collection using electronic medical records and cancer registry data identified 49 MF patients treated with ruxolitinib at the James Paget, Norfolk and Norwich, and Ipswich hospitals (28, 14 and 7, respectively) over a 52-month period. Five had less than 3 months' follow-up and were excluded.

**Results:** The patient group was 61.4% male, with a median age of 71 years (41–91). There were 16 (36.4%) patients with PMF, 13 (29.5%) with PPV-MF,

9 (20.5%) with PET-MF, and 6 (13.6%) with post-myeloproliferative disorder (unclassified)-MF. The indication for treatment was painful splenomegaly in 20 (45.5%) patients, constitutional symptoms in 23 (52.3%), and portal hypertension in 1 (2.3%). Ruxolitinib was first-line therapy in 10 (22.7%) patients, second-line in 24 (54.5%), and third-line or greater in 10 (22.7%). Starting doses ranged from 5mg BD in 2 (4.6%), 10mg BD in 14 (31.8%), 15mg BD in 11 (25%) and 20mg BD in 17 (38.6%), with occasional dose reduction/interruption primarily due to thrombocytopenia. Fifteen (34.1%) patients were IPSS 3+, 22 (50%) IPSS 2, 6 (13.6%) IPSS 1, and 1 (2.3%) IPSS 0. Mutation analysis was available for 32 (72.7%) patients, of which 29 (90.6%) were JAK2 V617F-mutated, 2 (6.3%) were JAK2 V617F/exon 12-unmutated, and 1 (3.1%) was CALR-mutated. The median duration of treatment was 16.4 months (3–45) and median time to progression was 15.5 months (7–32). Progression-free survival (PFS) was 65.9% and overall survival (OS) 68.2%. Seven patients died from AML, 5 from progressive MF, and 2 from pneumonia. Multivariate analysis showed that 'advancing age' and 'excess peripheral blasts ( $\geq 1\%$ )' were predictive of poor outcomes (HR 1.08, 95% CI 1.01-1.16;  $p=0.024$  and HR 4.38, 95% CI 1.12-17.09;  $p=0.033$ , respectively). Clinical assessment of spleen size was available for 29 (65.9%) patients and showed a reduction in splenomegaly in 16 (55.2%), an increase in 8 (27.6%) and no change in 5 (17.2%). Weight gain occurred in 32 (72.7%) and demonstrated a strong survival advantage (HR 0.21, 95% CI 0.07-0.65;  $p=0.006$ ). The most common haematologic adverse events (AEs) were cytopenias. Forty patients (90.9%) had anaemia and 22 (50%) were transfusion-dependent, compared with 29 (65.9%) and 10 (22.7%) pre-treatment, respectively. Thirteen (29.5%) patients also received an erythropoiesis-stimulating agent. Thirty-one (70.5%) patients had thrombocytopenia (6.8% grade 4) compared with 13 (29.5%) pre-treatment. The most frequent non-haematologic AEs were minor infections, documented in 17 patients (38.6%), and included lower respiratory tract infections, candidiasis, and HSV/VZV reactivation. One patient died from Aspergillus pneumonia. Twenty-nine patients (65.9%) remain on treatment.

**Summary/Conclusions:** Ruxolitinib was well-tolerated and effective in improving constitutional symptoms in our 'real-world' study population. Therapeutic response and safety profile was similar to trial data although we observed a higher incidence of minor haematologic AEs that were readily managed with supportive care. Weight gain was associated with a strong survival advantage and could prove a useful clinical marker of response. The majority of patients remain on active treatment.

#### PB2058

##### MONITORING OF TRANSIENT MYELOPROLIFERATIVE DISORDER AND LEUKEMIA IN DOWN'S SYNDROME : A SINGLE UNIVERSITY HOSPITAL STUDY

J.E. Park<sup>1,\*</sup>, I. Hwang<sup>1</sup>

<sup>1</sup>Pediatrics, AJOU University School of Medicine, Suwon, Korea, Republic Of

**Background:** Children with Down syndrome (DS) have a 10- to 20-fold increased risk of developing leukemia. But some patients don't suffer leukemia even they have significant numbers of blast cell in their peripheral blood. These condition called Transient myeloproliferative disorder (TMD), and it is a disease entity unique to DS newborns and is defined as the morphologic detection of blasts in DS less than three months of age.

**Aims:** This study gathered DS patients to find some difference between leukemia and TMD, to determine prognosis and risk factors.

**Methods:** We collect 317 patient's blood lab results in 433 DS patients. 102 patients has leukocytosis, and in 18 case found blast cells in their peripheral blood.

**Results:** 12 patients have found blast in three months of life, 11 of them finally diagnosed to TMD, and only 1 patient progress to Acute Myeloid Leukemia (AML) in 98 days of his life. Other 6 patients have blast in their blood after three months of life, and underwent chemotherapy due to hematologic malignancy. All patients with leukemia has anemia at diagnosis, which is not found in TMD patients ( $p=0.018$ ). In 7 Leukemia patients, 3 was acute Lymphoblastic Leukemia (ALL), 4 was AML. All AML patients has clonal change additional to trisomy 21 at their diagnostic point, which didn't found at TMD and ALL patients, even it didn't confirm former examination.

**Summary/Conclusions:** DS Patient who has blast in their peripheral blood before 3 months of life need closely follow up their Complete Blood Count and Chromosome analysis to find whether TMD progress to leukemia.

#### PB2059

##### INFECTIOUS EVENTS IN A COHORT OF PATIENTS WITH MYELOFIBROSIS UNDER TREATMENT COMPARING RUXOLITINIB WITH CONVENTIONAL THERAPY. A MONOCENTRIC EXPERIENCE OF 22 PATIENTS RETROSPECTIVELY ANALYSED

L. Torti<sup>1,\*</sup>, A. Morelli<sup>1</sup>, F. Bacci<sup>2</sup>, P. Di Bartolomeo<sup>1</sup>

<sup>1</sup>Department of Hematology and Bone Marrow Unit, Pescara, <sup>2</sup>Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

**Background:** Treatment with the Janus-activated kinase (JAK) 1 and 2 inhibitor ruxolitinib decreases constitutional symptoms and spleen size in myelofibrosis. However accumulating evidences suggest that the drug also exerts substantial immunosuppressive activity. The impressive clinical activity of ruxolitinib is predominantly mediated by its profound anti-inflammatory effects modulating dendritic cell (DC) function resulting in impaired CD4+ and CD8+ activity. Several studies have shown that Ruxolitinib affects different cytokines (IL1, IL6 and TNFalfa) and other immune processes and has been linked to increased incidence of opportunistic and no opportunistic infections. Herein we report our experience at our Centre.

**Aims:** In our retrospective study we analysed myelofibrosis patients treated with Ruxolitinib and cytoreductive treatment with Hydroxiurea and supportive therapy followed in our Department from 2012 to 2016 to evaluate rate of infections developed.

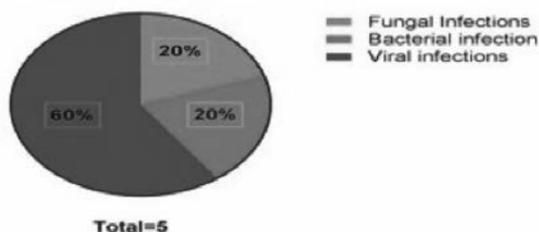

**Methods:** We reviewed 22 patients presenting myelofibrosis (median age 72, range 60-86)describing clinical and biological features (Table 1). Our aim was description of documented infections identified with conventional treatment and with Ruxolitinib. They were 11 treated with JAK inhibitors and 11 with Hydroxiurea taken orally, similar for age and clinical features.

**Results:** A total of 22 patients consecutively diagnosed were included in this analysis. There were 15 primary and 7 secondary myelofibrosis patients. According to the Dynamic International Prognostic Scoring System (DIPSS) 8 were low risk, 10 were intermediate risk and 4 were high. A total of 5 documented infections were identified throughout the evaluation period, 4 were grade 1 and one grade 2. They are various including oral herpes simplex reactivation, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. All of them were present in the subgroup of patients undergoing therapy with Ruxolitinib (45%) after a medium time of 8 months from beginning of therapy (range 3-10). No patients received any anti-infective prophylaxis. Median total daily dose of ruxolitinib was 10 mg (range 5-20). All of this infectious complications resolved after antimicrobial therapy and did not require hospitalization. None of patients were treated with concomitant immunosuppressive therapy. 3 of this patients presented renal impairment (median cratinine clearance of 46 ml/min).

Table 1.

CLINICAL AND BIOLOGICAL FEATURES OF PATIENTS REVIEWED		
Characteristics	Group treated with Ruxolitinib	Group treated with conventional therapy
Gender M/F	8/34	29/13
Median age in years (range)	72 (60-86)	69 (51-88)
Number	11	11
Kind of disease	Primary Myelofibrosis (7), secondary Myelofibrosis (4)	Primary myelofibrosis (8), Secondary myelofibrosis (3)
JAK2V617F mutation	Positive (8), Negative(3)	Positive (6), Negative(5)
MPL mutation	None	1 (W515P)
DIPSS score	intermediate -2 (7), High (4)	Low (8), Intermediate -1 (3)
Allelic JAK2V617F burden	45%, 65%, 99%, 38%, 88%, 79%, 82%, 65%	32%, 43%, 65%, 87%, 77%, 69%
Antiinfective prophylaxis	None	None
Cytogenetic evaluation	Deletion of chromosome 11 in one patient, rest are normal.	Deletion of chromosome 20 in one patient, rest are normal.
Renal impairment	5 patients	4 patients
Systemic symptoms	Present (11)	Present (7)
ECOG performance status 0-2	0-2 (8 patients), >2 (3)	0-2 (11 patients), >2 (0)

Infectious complications in patients treated with Ruxolitinib

**Summary/Conclusions:** These data in our small series of patients suggest a higher incidence of ruxolitinib associated infections observed in clinical practice compared to traditional treatment. Immunosuppressive effect of Ruxolitinib is reported and the use of this drug in the transplant setting with beneficial effects on alloreactivity and on graft versus host disease is becoming more common. These patients might benefit from receiving prophylactic therapy with antiviral

drugs or antibiotics or antifungal therapy or in alternative by careful monitoring. Finally nowadays physicians and patients should be aware of potential risks of using ruxolitinib including the risk of infections.

In summary, infections can occur in patients treated with ruxolitinib but are generally mild. Generally infections were non-life threatening and managed with appropriate supportive care.

Special care probably should be taken for patients older (more than 75 years old), treated with corticosteroid therapy and with renal impairment. However larger studies are needed to confirm these observations.

**PB2060**

**THE JAK2V617F MUTATION AND LEUKOCYTOSIS AS RISK FACTORS FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA**

E. Simonovic<sup>1,\*</sup>, V. Colic<sup>1</sup>

<sup>1</sup>Internal Medicine, General Hospital Leskovac, Leskovac, Serbia

**Background:** Polycythemia vera (PV) is a clonal, chronic, progressive myeloproliferative disease, caused by transformation of pluripotent hematopoietic stem cell. It is a malignant hematological disease that leads to excessive proliferation of erythroid, myeloid and megakaryocytic elements in the bone marrow. Essential thrombocythemia (ET) is a clonal disorder of unknown etiology that affects multipotent hematopoietic stem cell, and it is characterized by enhanced formation of megakaryocytes in the bone marrow and for no apparent cause, by markedly increased platelet counts in peripheral blood. PV and ET belong to a group of Philadelphia chromosome negative myeloproliferative neoplasms. Thrombotic and hemorrhagic complications are the most common cause of morbidity and mortality in patients with PV and ET. It is thought that the mechanisms that lead to thrombosis in MPN are the following: increased blood cell mass, abnormal platelet function and the phenomenon of spontaneous aggregation. The contribution to the incidence of thrombosis: increased level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.

**Aims:** The aim of this study is to monitor JAK2V617F mutations and leukocytoses as potential risk factors for the development of thrombotic complications in patients with polycythemia vera and essential thrombocythemia.

**Methods:** During the five-year period we monitored the occurrence of thrombotic complications in 56 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 22 patients (of both sexes, aged between 38 and 79 years) being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. With regard to the risk factors we followed the presence of JAK2V617F mutations and leukocytoses.

**Results:** Leucocyte count ranged from 5,2-27,1 x 10<sup>9</sup>/L. The highest leucocyte count was recorded in the group of patients with PV (p<0,01). JAK2V617F mutation was also statistically more significantly present in patients with PV. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications in those groups were more frequent in percentage with patients diagnosed with leukocytosis, but statistical significance was present only in the group with PV. Thrombotic complications were in both groups more frequent in percentage with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients.

**Summary/Conclusions:** Leukocytosis and JAK2V617F may be considered as potential risk factors for the incidence of thrombosis in patients with PV and ET. Further follow-up of those patients, as well as a larger number of subjects are needed.

**PB2061**

**RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS**

E. Simonovic<sup>1,\*</sup>, L. Macukanovic-Golubovic<sup>2</sup>

<sup>1</sup>Internal Medicine, General Hospital Leskovac, Leskovac, <sup>2</sup>Internal Medicine, Clinic of Hematology, Niš, Serbia

**Background:** Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullary hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Bleeding may complicate the clinical course of the IMF. It is manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrolled esophageal bleeding. Bleeding occurs due to ineffective megakaryocytopoiesis, retention of platelets in the large spleen, qualitative

platelet disorders, acquired deficiency of factors V and vWF, disseminated intravascular coagulation.

**Aims:** The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values as potential risk factors for the incidence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.

**Methods:** During the three-year period we monitored the occurrence of hemorrhagic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (61); 2. Group with essential thrombocythemia (ET) (28); 3. Group with idiopathic myelofibrosis (IMF) (25); 4. Group with unclassified myeloproliferative neoplasm (MPNs) (25). The following possible risk factors were monitored: counts of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values. We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.

**Results:** The highest percentage of hemorrhagic complications were in the group of patients with ET and IMF ( $p < 0.01$ ), followed by the group with MPNs ( $p < 0.05$ ). In all three groups, the incidence of hemorrhagic complications in patients older than 65 years of age was higher ( $p < 0.001$ ). The erythrocyte count ranged from  $6.45\text{--}8.89 \times 10^{12}/\text{L}$ , leukocyte count  $1.2\text{--}27.1 \times 10^9/\text{L}$  and the platelet count ranged from  $10.2\text{--}1986.5 \times 10^9/\text{L}$ . Hemoglobin values ranged from  $176\text{--}210 \text{ g/L}$ , and hematocrit from  $0.58$  to  $0.83 \text{ L/L}$ . The highest erythrocyte count, the highest hemoglobin and hematocrit values, as well as the highest leukocyte count was recorded in the group of patients with PV and MPNs ( $p < 0.001$ ) and the lowest in the group of patients with IMF ( $p < 0.01$ ). Among the group of patients with ET and MPNs there was no statistically significant difference in those parameters. In the group of patients with PV and MPNs hemorrhagic complications were more frequent in percentage in patients with leukocytosis and erythrocytosis, but without statistical significance. The highest platelet count was found in the group of patients with ET and MPNs ( $p < 0.001$ ), and the lowest in the group of patients with IMF ( $p < 0.01$ ). Among the group of patients with PV and MPNs there was no statistically significant difference with regard to platelet count. Hemorrhagic complications were more frequent both in patients with platelet count below  $10 \times 10^9/\text{L}$  ( $p < 0.05$ ) and in patients with platelet count over  $1000 \times 10^9/\text{L}$  ( $p < 0.01$ ). The increase in platelet count influences the adsorption of larger von Willebrand multimers on the platelet membrane, thus having an effect on their elimination from circulation and degradation.

**Summary/Conclusions:** The platelet count can be considered a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Deviation from the count of leukocytes, erythrocytes, hemoglobin and hematocrit values may be considered as a potential risk factor for bleeding in patients with myeloproliferative neoplasms, but further follow-up and a larger number of subjects are needed. The age of the patient can also be considered as a risk factor for the incidence of hemorrhagic syndrome in those patients. The follow-up of patients with unclassified myeloproliferative neoplasms has been particularly important, which showed a high prevalence of hemorrhagic complications, and with the purpose of their further differentiation.

## PB2062

### CLINICAL RELEVANCE OF JAK2V617F MUTATIONAL LOAD IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS FROM REPUBLIC OF MACEDONIA (SINGLE-CENTER EXPERIENCE)

M. Popova-Labachevska<sup>1</sup>, L. Cevreska<sup>1</sup>, A. Dimovski<sup>1</sup>, M. Ivanovski<sup>1</sup>, D. Dukovski<sup>1</sup>, B. Kocoski<sup>1</sup>, A. Eftimov<sup>1</sup>, S. Trajkova<sup>1</sup>, I. Panovska-Stavridis<sup>1</sup>  
<sup>1</sup>Hematology, University Clinic of Hematology, Skopje, Macedonia, The Former Yugoslav Republic Of

**Background:** Polycythemia vera (PV), essential thrombocytosis (ET), and primary myelofibrosis (PMF) are Philadelphia chromosome negative myeloproliferative neoplasms (MPN) characterized by the expression of an acquired activated JAK2V617F mutation. Up to date, it remains controversial how one mutation can lead to expression of three different clinical MPN phenotypes. However, several studies have shown that the JAK2V617F allele burden may correlate with specific MPN entity.

**Aims:** In order to further clarify these observations, we evaluated the JAK2 mutational status and its clinical implications in 233 JAK2 V617F+patients with different MPNs from the Republic of Macedonia.

**Methods:** We conducted a single center retrospective study which included 233 patients with JAK2V617F+MPN diagnosed according to WHO criteria, with median follow up period of 4 years. Quantification of the JAK2V617F mutation was analyzed with the Real Time PCR method using the Larsen protocol. Based on the mutational load patients were divided in three groups: first with  $<10\%$  mutational load, second with  $10\text{--}50\%$  load and third with  $>50\%$  mutational load. The correlation of the allele burden with various clinical parameters was done by Mann-Whitney and student's tests using Statgraphics 4.3 software.

**Results:** Our study shows that median allele burden was lowest in patients with ET (22.8%), followed by PV patients (37.1%) and PMF pts (49.6%) ( $p < 0.01$ ). A higher mutation burden ( $>50\%$  vs  $<10\%$ ) was associated with advanced age

(67.5 vs 58.5 years and 65 vs 58 years in ET and PMF pts respectively), with higher leucocyte count ( $10^3/\mu\text{L}$ ) (9.87 vs 8.87, 13.8 vs 12.4, and 18.99 vs 14.8 in ET, PV and PMF pts respectively), with elevated erythrocyte count (5.76 vs 4.85 and 5.59 vs 4.52 in ET and PMF pts respectively), and with higher hemoglobin level (g/dL) and platelet count  $10^3/\mu\text{L}$  (15.45 vs 14.35 and 1071.5 vs 860.5 in ET patients respectively) ( $p < 0.05$  for all comparisons)

**Summary/Conclusions:** Our study confirmed that higher allele burden is associated with advanced age, polycythemic features, and increased leukocytes and platelets counts regardless of the diagnosed MPN entity and suggests that implementation of JAK2V617F allele burden in the diagnostic workup of MPN pts could help for choosing the optimal treatment option in this group of patients.

## PB2053

### CSF3R T618-MUTATED CHRONIC NEUTROPHILIC LEUKEMIA: A RARE CASE SUCCESSFULLY TREATED WITH RUXOLITINIB

V. Calafiore<sup>1</sup>, M. Parisi<sup>1</sup>, V. Zammit<sup>1</sup>, E. Martino<sup>1</sup>, M. C. Piroso<sup>1</sup>, A. Spitaleri<sup>1</sup>, F. Stagno<sup>1</sup>, C. Conticello<sup>1</sup>, F. Di Raimondo<sup>1</sup>

<sup>1</sup>Division of Hematology, A.O. "Policlinico-Vittorio Emanuele", University of Catania, Via Citelli 6, 95124 Catania, Italy, Catania, Italy

**Background:** Chronic neutrophilic leukemia (CNL) is a rare BCR-ABL1-negative myeloproliferative neoplasm (MPN) with only 200 patients reported to date according to the WHO criteria. These cases are characterized by a high number of mature neutrophils in peripheral blood (PB), a hypercellular bone marrow due to neutrophilic granulocyte proliferation and hepatosplenomegaly. None standard of care exist for CNL; most patients are palliated with hydroxyurea, interferons, splenic radiation or splenectomy.

In the past years CNL has been often confused with chronic myeloid leukemia (CML), atypical CML (aCML) or chronic myelomonocytic leukemia (CMML), however, this diagnosis has been more defined since the oncogenic mutations in the granulocyte colony-stimulating 3 factor receptor (CSF3R) gene were identified in approximately 83% of WHO-defined CNL patients.

CSF3R T618I mutation is now considered as a highly specific molecular marker for CNL that is sensitive to *in vitro* and *in vivo* inhibition by currently approved protein kinase inhibitors.

**Aims:** here we report a case of a 76-years old man with diagnosis of chronic neutrophilic leukemia, according to WHO criteria, successfully treated with ruxolitinib.

**Methods:** On May 2015 a 76 aged male patient presented at our Institution with fatigue, night sweats, neutrophilic leukocytosis (neutrophils  $42.080/\text{mmc}$ , immature granulocytes  $<5\%$ ), and symptomatic splenomegaly ( $277 \times 127 \times 200 \text{ mm}$ ). Marrow biopsy was hypercellular (100%) with myeloid hyperplasia, mild myeloid dysplasia and profound erythropoietic hypoplasia; reticulin fibrosis was minimally present. Molecular profiling demonstrated no mutations of JAK2 or CALR and polymerase chain reaction (PCR) studies for t(9; 22) and BCR-ABL fusion, was negative.

The patient was initially treated with hydroxyurea with a provisional diagnosis of pre-fibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb  $9.9 \text{ gr/dl}$ ) and thrombocytopenia ( $82.000/\text{mmc}$ ); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in overt PMF, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

**Results:** on a follow-up of 6 months after initiation of ruxolitinib therapy, symptoms resolved, hemoglobin and platelet levels improved (PLT  $186.000/\text{mmc}$ ), leukocytosis persisted (WBC  $24.600/\text{mmc}$ ), and the patient achieved a dramatic reduction in spleen size ( $209 \times 119 \times 74 \text{ mm}$ ).

**Summary/Conclusions:** Current data suggest that constitutively active JAK-STAT signaling plays a central role in the pathogenesis of BCR-ABL1-negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib use in CNL patients can induce partial responses by improving marrow function (normalization of hemoglobin and platelets count), splenomegaly and symptoms.

## Non-Hodgkin & Hodgkin lymphoma - Biology

### PB2064

#### PERIPHERAL BLOOD CELL STUDY FROM PATIENTS WITH FOLLICULAR LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA: WHAT SHOULD WE EXPECT?

D. Subirá<sup>1,\*</sup>, H. Guillén<sup>1</sup>, C. Fernández Maqueda<sup>2</sup>, Á. Gil<sup>1</sup>, D. de Miguél<sup>1</sup>, N. Golbano<sup>1</sup>, F. Barriopedro<sup>1</sup>, M. Morales<sup>1</sup>, M. Díaz Morfa<sup>1</sup>, J. Arbeteta<sup>1</sup>, A. Vázquez<sup>1</sup>, S. Herrero<sup>1</sup>

<sup>1</sup>Haematology, Hospital Universitario de Guadalajara, Guadalajara, <sup>2</sup>Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

**Background:** Follicular lymphoma (FL) may evolve to diffuse large B-cell lymphoma (DLBCL) and interactions between neoplastic cells and immune tumour microenvironment have been involved in this process. However, the potential value of the peripheral blood study to identify FL patients at high risk of progression is less known.

**Aims:** To describe the peripheral blood findings of patients with FL and DLBCL at diagnosis, and to investigate whether a particular lymphoid distribution could be associated with aggressive disease.

**Methods:** The study (performed between September 2012 and January 2017) included 52 patients (50% female) with a median age of 70.5 years (71% >60 years). Patients were newly diagnosed with *in situ* FL (n=1), Grade 1,2 FL (n=12), Grade 3 FL (n=11), and DLBCL not otherwise specified (n=28). *In situ* FL and Grade 1,2 FL were grouped as low-grade FL. Most patients with FL (11/13 low-grade FL and 8/11 Grade 3 FL) had clinical stages III/IV. Patients with primary or secondary immunodeficiency and those who had already received corticosteroids or chemotherapy were excluded from this study. A whole blood sample was studied at diagnosis of lymphoma and prior to the start of therapy, using multicolour flow cytometry immunophenotyping and a standard stain-lyse-wash protocol. A single monoclonal antibody panel including reagents against CD19, CD20, CD22, kappa, lambda, CD3, CD4, CD8, CD56 and CD45 was used, and a minimum of 300,000 events were acquired on the flow cytometer. Results were expressed as the absolute number/ml of monocytes, lymphocytes, T cells, CD4, CD8 and NK cells. Polyclonal and monoclonal B lymphocytes were also identified.

**Results:** No difference in the distribution by sex or age was found between patients with FL and DLBCL. A low cell count in at least, one lymphocyte population was detected in 35/52 patients (67.3%); 100% of cases had a low number of polyclonal B cells (<100/ml). Comparison of low-grade FL, grade 3 FL and DLBCL did not show any statistically significant difference regarding monocytes, CD4, CD8 and total T cells. Low-grade FL and DLBCL showed the highest number of differences, involving lymphocytes (2571±2439 *versus* 1495±671, p=0.001), NK cells (381±312 *versus* 204±167, p=0.03), the CD4:CD8 ratio (1.54±0.49 *versus* 2.06±1.44, p=0.002), and circulating monoclonal B cells, for both percentage (15.2±23.23 *versus* 1.94±5.23, p<0.001) and absolute number (869±1758 *versus* 18.75±46.47, p<0.001). Grade 3 FL and DLBCL also showed a different CD4:CD8 ratio (1.16±0.45 *versus* 2.06±1.44, p=0.001), with a trend toward significance regarding CD4 T cells (413±184 *versus* 685±457, p=0.077). Grade 3 FL had a lower number of polyclonal B cells as compared to DLBCL (66±41 *versus* 105±102, p=0.048). The peripheral expression of monoclonal B cells was higher in low-grade FL than in grade 3 FL, in both percentage (15.2±23.23 *versus* 4.58±8.48, p=0.008) and number (869±1758 *versus* 43.36±69.91, p=0.002) of monoclonal B cells. The number of lymphocyte subpopulations (≤1 *versus* ≥2) with low-cell counts was higher in grade 3 FL than in low-grade FL (p=0.03).

**Summary/Conclusions:** The peripheral lymphocyte profile in patients with FL and DLBCL is heterogeneous, but B-lymphopenia and CD4:CD8 ratio deviations are frequent findings. Regardless of clinical stage, low-grade FL had more circulating lymphoma cells and preserved lymphocyte populations than grade 3 FL. Further studies are warranted to confirm these exploratory findings and determine their clinical implications.

### PB2065

#### POTENTIALITY OF PDPK1 AS A THERAPEUTIC TARGET MOLECULE IN MANTLE CELL LYMPHOMA

S. Maegawa<sup>1,\*</sup>, S. Tatekawa<sup>1</sup>, Y. Chinen<sup>1</sup>, T. Tsukamoto<sup>1</sup>, K. Tanba<sup>1</sup>, Y. Kimoto-Matsumura<sup>1</sup>, T. Takimoto<sup>1</sup>, Y. Mizuno<sup>1</sup>, Y. Shimura<sup>1</sup>, T. Kobayashi<sup>1</sup>, S. Horiike<sup>1</sup>, M. Taniwaki<sup>1</sup>, J. Kuroda<sup>1</sup>

<sup>1</sup>Hematology, Kyoto prefectural university of medicine, Kyoto, Japan

**Background:** The deregulated activation of a Ser/Thr kinase 3-phosphoinositide-dependent protein kinase 1 (PDPK1) has been shown to promote the disease progression in various solid cancers. In hematologic malignancies, we have recently identified that the constitutive activation of PDPK1 and its downstream kinase RSK2 (PDPK1/RSK2 signaling axis) plays pivotal roles in multiple myeloma (MM) pathophysiology by promoting myeloma cell survival and proliferation (Chinen Y, Cancer Res 2014; Shimura Y, Mol Cancer Ther 2012). Mantle cell lymphoma (MCL) is cytogenetically and molecularly characterized

by chromosomal translocation t(11;14)(q13;q32) for deregulated cyclin D1 (CCND1) overexpression, and has remained as one of hard-to-treat subtypes of non-Hodgkin lymphomas (NHLs).

**Aims:** The development of novel therapeutics for MCL has been urgently needed, therefore, this study investigated the potency of PDPK1 as a therapeutic target molecule in MCL cells.

**Methods:** Four MCL-derived cell lines (MINO, Jeko-1, JVM-2 and Z138 cells), three diffuse large B-cell lymphoma (DLBCL)-derived cell lines (KPUM-MS3, KPUM-UH1 and A3/KAW cells) and a Burkitt lymphoma (BL)-derived cell line (Namalwa) were utilized in this study. Patient-derived biopsied specimens were obtained with informed consent and subjected to the immunohistochemical (IHC) staining of phospho (p-) PDPK1<sup>Ser241</sup>. Cell proliferation was assessed by a modified MTT assay. Antibodies utilized for Western blotting was performed for evaluating protein expression levels of PDPK1, p-PDPK1<sup>Ser241</sup>, p-RSK2<sup>Ser227</sup>, and RSK2. BX-912, a specific inhibitor for PDPK1, was purchased from Selleckchem (USA). RNA interference of PDPK1 was performed by transfecting short hairpin RNA plasmids into MCL cell lines by means of nucleofection (Lonza, Switzerland). This study was approved by the institutional review board of our institute.

**Results:** By means of IHC examination, our study revealed that PDPK1 was activated through phosphorylation in tumor cells of all 7 MCL patient-derived specimens examined, and this was also the case in all 5 DLBCLs examined and in all 5 follicular lymphomas examined. These indicated that PDPK1 is generally active in various types of B-cell lymphoid neoplasms. The *in vitro* treatment with BX-912 for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC<sub>50</sub> 0.9–2.5 mM), and this inhibitory effect of BX-912 was more profound in MCL cell lines compared with three DLBCL cell lines (IC<sub>50</sub> 3.7–17.0 mM) and a BL cell line (IC<sub>50</sub> 2.9 mM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by PDPK1 blockade with BX-912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, PDPK1 blockade by BX-912 resulted in dephosphorylation of RSK2-NTKD, while AKT activity or CCND1 expression was unaltered by BX-912 treatment in MCL cells. By gene knock-down of PDPK1 by RNA interference using three different short hairpin RNAs, we further validated that the reduction of PDPK1 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with various agents those are utilized for the treatment of MCL, such as doxorubicin, etoposide, fludarabine, bortezomib, or ABT263, BX-912 showed additive/synergistic growth inhibitory effects in MCL cell lines.

**Summary/Conclusions:** Collectively, our study suggested that PDPK1/RSK2 signaling axis is the potential therapeutic target in MCL.

### PB2066

#### THE ACQUISITION OF RESISTANCE TO BENDAMUSTINE HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KPUM-YY1

T. Takimoto<sup>1,\*</sup>, H. Nagoshi<sup>1</sup>, S. Maegawa<sup>1</sup>, S. Tatekawa<sup>1</sup>, T. Tsukamoto<sup>1</sup>, Y. Chinen<sup>1</sup>, Y. Shimura<sup>1</sup>, M. Yamamoto-Sugitani<sup>1</sup>, T. Kobayashi<sup>1</sup>, T. Taki<sup>1</sup>, S. Horiike<sup>1</sup>, M. Taniwaki<sup>1</sup>, J. Kuroda<sup>1</sup>

<sup>1</sup>Kyoto prefectural university of medicine, kyoto, Japan

**Background:** Bendamustine hydrochloride (BH) has been one of the most promising genotoxic moieties for mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.

**Aims:** We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.

**Methods:** This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient's sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KPUM-YY1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KPUM-YY1 (KPUM-YY1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cytogenetic analysis was performed by double color-fluorescence *in situ* hybridization and spectral karyotyping (SKY). The comparative gene expression profile (GEP) and the ingenuity canonical signal pathway analyses between of KPUM-YY1 and KPUM-YY1R were performed to identify the differential gene expression pattern along with the acquisition of BH resistance. Cell viability was evaluated by a modified MTT assay.

**Results:** SKY analysis revealed that both primary tumor cells and KPUM-YY1 had complex karyotype including three-way translocation t(8;14;11)(q24;q32;q13), involving the rearrangement of *cyclin D1*. The growth inhibitory IC<sub>50</sub> to BH was 20 μM in KPUM-YY1 cells, while the cell proliferation was not inhibited by up to 60 μM of BH in KPUM-YY1R cells. When compared with the parental KPUM-YY1 cells, KPUM-YY1R cells showed the partial cross-resistance against doxorubicin, mafosfamide, melphalan, and vincristine. By GEP analyses, total of 472 genes were differentially expressed in KPUM-YY1R compared with KPUM-YY1 cells, including 312 upregulated more than 1.5-folds and 160 downregulated less than 0.67-folds in KPUM-YY1R cells. The ingenuity canonical signal pathway analysis based on the GEP results sug-

gested that KPUM-YY1R cells harbored the distinct gene expression patterns in *MDR1*, a gene for p-glycoprotein (P-gp) of drug transporter molecule, *MGST1*, a member of glutathione S-transferase (GST) families, and argininosuccinate synthetase 1 (*ASS1*), a rate-limiting enzyme for arginine biosynthesis. The upregulation of *MDR1* (P-gp) and *MGST1* were confirmed by Western blot or RT-PCR analysis in KPUM-YY1R compared with KPUM-YY1. Importantly, the addition of P-gp inhibitors, such as cyclosporine A, or GST inhibitors, such as ethacrynic acid, at least partly restored the sensitivity to BH in KPUM-YY1R cells, indicating the functional significance of the upregulation of *MDR1* and *MGST1* in the development of BH resistance in MCL. In addition, BH-resistance cells were also found to express decreased mRNA level of *ASS1* which has been reported to play tumor suppressor roles and its loss has been associated with clinical aggressiveness in various cancers.

**Summary/Conclusions:** This study revealed that the multiple molecular mechanisms overlappingly underlie the development of BH resistance, therefore, the acquisition of BH resistance potentially leads multidrug resistance in MCL cells. The newly developed KPUM-YY1 cells and KPUM-YY1R cells deserve the identification of multiplex mechanisms underlying BH activity/resistance and the future development of strategy which overcomes the treatment refractoriness in MCL.

#### PB2067

##### COMPARISON OF OVERALL SURVIVAL ACCORDING TO BONE MARROW ASPIRATION RESULTS IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

J.Y. Choi<sup>1,\*</sup>, K.-W. Kang<sup>1</sup>, J.H. Kim<sup>1</sup>, D.S. Kim<sup>1</sup>, E.S. Yu<sup>1</sup>, S.R. Lee<sup>1</sup>, H.J. Sung<sup>2</sup>, S.J. Kim<sup>2</sup>, C.W. Choi<sup>1</sup>, B.S. Kim<sup>1</sup>, Y. Park<sup>1</sup>

<sup>1</sup>Division of Hematology and Oncology, Korea University School of Medicine, <sup>2</sup>Division of Hematology and Oncology, Samsung Medical Center, Seoul, Korea, Republic Of

**Background:** Bone marrow (BM) biopsy with or without aspiration is usually included in the staging workup for patients with non-Hodgkin's lymphoma (NHL). According to the National Comprehensive Cancer Network guidelines, BM biopsy is mandatory for lymphoma, but aspiration is optional. Moreover, the role of BM aspiration is controversial. Other studies have shown that BM aspiration morphologically or flow cytometry is often inconsistent with biopsy and is less likely to detect lymphoma than biopsy. There are no clear guidelines regarding results that are positive in BM aspiration and negative in biopsy.

**Aims:** The aim of this study was to establish guidelines through a comparison of the overall survival (OS) of patients with NHL using morphological method.

**Methods:** We performed a retrospective analysis of BM involvement in patients with newly diagnosed NHL in the Korea University Hospital from January 1991 to December 2016. OS was compared according to the BM groups, which were divided into three groups: the group without BM involvement in both BM aspiration and biopsy, the group with atypical lymphocytes only in BM aspiration, and the group with BM involvement in biopsy regardless of BM aspiration results. Atypical lymphocytes were identified as positive in BM aspiration if they displayed cleaved nuclei, vacuolation, and granulation including lymphoid aggregates, leukemic presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using a Cox proportional hazards model.

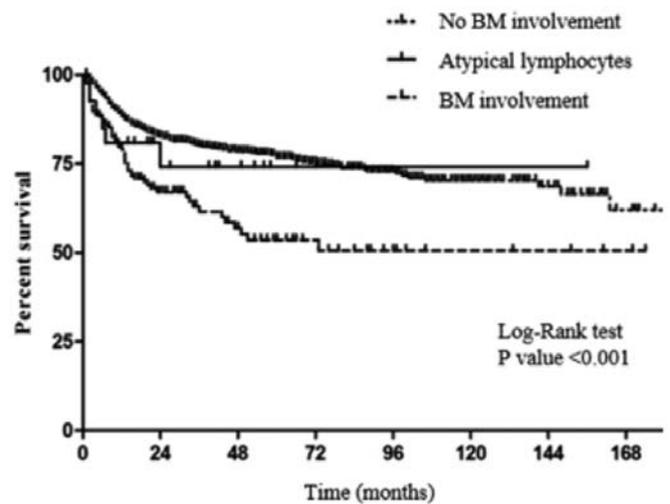

**Results:** In total, the data of 1,773 patients, of which 391 patients had indolent NHL and 1,382 patients had aggressive NHL, were reviewed. Of the 1,773 patients, 1,148 (64.7%) yielded negative results on both BM aspiration and biopsy, 30 (1.7%) yielded positive results with atypical lymphocytes only in BM aspiration, and 190 (10.7%) yielded positive results on biopsy. Remaining 405 patients were excluded owing to inadequate results in BM aspiration and/or biopsy. Median follow-up duration was 37.62 months (range, 0-288).

At the time of Kaplan-Meier survival analysis, OS was significantly worse for patients with BM involvement in biopsy compared with those with no BM involvement in both BM aspiration and biopsy (2-year OS, 39.0% v 60.6%; log-rank  $P < 0.001$ ). However, there was no significant difference in OS between patients with atypical lymphocytes only in BM aspiration and those with no BM involvement in both BM aspiration and biopsy (2-year OS, 42.8% v 60.6%; log-rank  $P = 0.184$ ). Patients with atypical lymphocytes only in BM aspiration also had no significant difference compared with those with BM involvement in biopsy (log-rank  $P = 0.291$ ; Figure 1).

Multivariate analysis was performed by adjusting survival related variables such as sex, age, lactate dehydrogenase, Ann Arbor stage, Eastern Cooperative Oncology Group performance status, number of extranodal sites, lymphoma characteristics (indolent vs aggressive), and transplantations. The classification according to BM involvement remained a significant prognostic factor for OS ( $P < 0.001$ ). However, in the subgroup analysis, the group with atypical lymphocytes only in BM aspiration showed no significant difference compared to the group without the BM involvement in both BM aspiration and biopsy (Odds ratio, 1.915; 95% confidence interval, 0.940-3.903;  $P = 0.074$ ). Therefore, the detection of atypical lymphocytes only in BM aspiration had no significant difference in the OS even when the relevant factors were corrected.

**Summary/Conclusions:** This study suggests that the detection of morpho-

logically atypical lymphocytes only in BM aspiration, but not in biopsy, is not significant in predicting the OS of patients with NHL. Therefore, even if atypical lymphocytes are detected during BM aspiration in patients with NHL, it may not be sufficient to judge the BM involvement and predict the OS of these patients.

**Kaplan-Meier curves of overall survival according to the BM groups.**

**Figure 1.**

#### PB2068

##### IN VIVO IMAGING OF LUMINESCENT DIFFUSE LARGE B-CELL LYMPHOMA XENOGRAFTS COMBINED WITH MASS SPECTROMETRY IMAGING IDENTIFY SPECIFIC MOLECULAR ALTERATION DURING R-CHOP RELAPSE.

C. Côme<sup>1,\*</sup>, F. Barré<sup>2</sup>, F. Dewez<sup>2</sup>, R. Heeren<sup>2</sup>, B. Cillero Pastor<sup>2</sup>, A. Lund<sup>3</sup>, K. Grønbæk<sup>1</sup>

<sup>1</sup>Epigenomlaboratoriet, Rigshospitalet Dept. 3733, Bartholin Institut, Copenhagen N, Denmark, <sup>2</sup>Division of imaging mass spectrometry, M4I institute, Maastricht, Netherlands, <sup>3</sup>Lund Group, Biotech Research and Innovation Centre, Copenhagen N, Denmark

**Background:** Diffuse large B-cell lymphoma (DLBCL) is the most common B-cell non-Hodgkin's lymphoma (NHL) throughout the world, comprising 30-35% of all NHLs, with approximately 71 000 new cases and 19 000 deaths estimated for 2014. Currently, R-CHOP, a combination of immunotherapy (Rituximab, targeting the cell surface protein CD20 expressed by B cell lymphoma) and chemotherapy (Cyclophosphamide, doxorubicin, vincristine and prednisone), remains the most commonly used regimens for newly diagnosed advanced DLBCLs. However, as it is a biologically aggressive disease, up to one-third of patients will ultimately become refractory to initial therapy or relapse after treatment and display poor survival outcome, underlying the urgent need for novel therapeutic approaches based upon selective molecular targets. We are combining *in vivo* luminescent/fluorescent DLBCL xenograft models with mass spectrometry imaging (MSI) analysis to study the tumors characteristics during R-CHOP treatment and relapse. The *in vivo* imaging approach allows us to precisely quantify tumoral development and response to therapy, as well as to differentiate tumoral cells from the tumoral micro-environment. On the other hand, MSI technique provides information regarding analyte composition at an almost cellular level. Therefore, we can identify, localize the molecules, proteins, drugs or metabolites. 2 types of analysis are performed: i) comparison between primary untreated tumors and tumors relapsing from R-CHOP therapy. ii) study of the therapy resistant and sensitive areas of each tumor.

**Aims:** Our aim is to investigate and analyze the various chemical composition of DLBCL xenografts during tumoral development and R-CHOP treatment relapse, in order to identify yet uncharacterized targets that could become alternative targets for therapy.

**Methods:** 10 millions cells of a U2932 lymphoma cell line were xenografted into 60 athymic nude immuno-deficient mice. Tumoral growth was repeatedly quantified in a non-invasive manner based on tumors' luminescent signal using the *in vivo* imaging system (IVIS) Lumina II. R-CHOP treatment was applied to mice after primary tumoral growth. 2 types of samples are generated: i) untreated tumors, ii) tumors relapsing from R-CHOP

Mass spectrometry imaging is then used to analyze and compare the chemical and biological profiles of DLBCL xenografts at these stages of tumoral growth. **Results:** *In vivo* imaging allows us not only to precisely assess primary tumor

development but more importantly, to monitor accurately response to R-CHOP and relapse from this therapy. The tumors at different stages of response to R-CHOP therapy are being analyzed and compared from lipidomics, metabolomics and proteomics point of view. Primary analysis indicate very distinctive metabolomics and lipidomic profiles between relapsed and non treated tumors. **Summary/Conclusions:** Combining IVIS and MSI allow us for a better understanding of the disease and the treatment effects and the possible mechanisms allowing tumor cells to escape therapy. We are currently investigating in more details these different lipidomics, metabolomics or proteomics signatures between the different stages of DLBCL response to R-CHOP treatment in order to identify new candidates for alternative therapies.

#### PB2069

##### THE PROGNOSTIC ROLE OF INDOLEAMINE 2,3-DIOXYGENASE EXPRESSION IN HODGKIN'S LYMPHOMA.

T. Skrypets<sup>1,\*</sup>, O. Novosad<sup>1</sup>, N. Svergun<sup>2</sup>, O. Skachkova<sup>2</sup>, O. Gorbach<sup>2</sup>, V. Sokolov<sup>3</sup>, N. Khranovska<sup>2</sup>, I. Kryachok<sup>1</sup>

<sup>1</sup>Oncohematology, <sup>2</sup>Experimental Oncology, National Cancer Institute, <sup>3</sup>Thoracic surgery, Clinical Hospital №18, Kiev, Ukraine

**Background:** Indoleamine 2,3-dioxygenase (IDO) is an inducible enzyme that catalyzes the initial and rate-limiting step in tryptophan along the kynurenine pathway. IDO is a key factor maintaining immune tolerance and expression and it correlates with poor clinical outcome in different types of cancer and hematological malignancies. It also plays a role in a lot of pathophysiological processes, such as antitumor and antimicrobial defense. IDO causes immunosuppression in the tumor microenvironment by tryptophan breakdown. Although, only several reviews have been made to evaluate IDO prognostic value and its expression value in hematological malignancies.

**Aims:** The aim of the study was to assess the impact of the IDO expression on clinical outcome in patients with Hodgkin's lymphoma (HL).

**Methods:** A total number of 35 patients with HL were included in the group (10 males and 25 females; median age: 17-60 years, range: 38.5 years). Early stages (I-II) and advanced stages (III-IV) were diagnosed in 48.5% (17/35) and 51.4% (18/35) of patients, respectively. B-symptoms had 37.1% (13/35) of patients at the time of diagnosis. Patients were treated with ABVD or BEACOPP (14/esc) and radiation therapy. The mRNA expression level of IDO was measured in pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.

**Results:** For 35 patients with HL, the overall response rate after the first-line therapy was 88.6% (31/35). Progression of the disease during the therapy was observed in 11.4% of patients (4/35). Among the patients, who achieved a remission, 9 had relapses. In our study, only 20% (7/35) of HL patients were IDO-positive (IDO<sup>+</sup>), while the majority of cases in the group (80%, 28/35) were IDO-negative (IDO<sup>-</sup>). There were no significant differences in IDO expression between histological subtypes of HL. We also did not find any association between stage of disease and IDO expression in our study. Patients with the absence of IDO expression tended to have a better response to the 1<sup>st</sup> line chemotherapy comparing to patients with positive IDO expression. The overall response rate was achieved in 71.4% (5/7) of IDO<sup>+</sup> cases and in 92.9% (26/28) of IDO<sup>-</sup> cases. The relapsed/refractory disease was more frequently found in HL cases with IDO<sup>+</sup> compared IDO<sup>-</sup> expression (28.5% (2/7) versus 7.1% (2/28), respectively,  $p < 0.05$ ). We did not register any death of patients in IDO<sup>-</sup> group, while one patient in IDO<sup>+</sup> group died during the follow-up period (median duration – 37 months; range 10–65 months). ROC analysis revealed that the expression of IDO in the tumor is an important marker which is associated with clinical outcome of HL patients ( $Se=46.2\%$ ;  $Sp=95\%$ ;  $AUC=0.71$ ,  $p=0.004$ ). The presence of IDO expression in pre-treated HL biopsies was associated with the reduced event-free survival (EFS) in HL patients. A 4-year EFS rate for IDO<sup>+</sup> HL patients was 50% compared with 73% for IDO-negative HL patients ( $p=0.002$ ). The prognostic significance of IDO<sup>+</sup> expression in clinical outcome of HL (EFS) was also confirmed by multivariate analysis ( $HR=2.9$ ;  $95\%CI$  0.8-10.1,  $p=0.006$ ).

**Summary/Conclusions:** On the base of the study, our findings suggest that IDO might be a promising marker for HL prognosis as well as represents an attractive target for HL immunotherapy in patients with poor outcome.

#### PB2070

##### SECONDARY CHROMOSOMAL ABNORMALITIES AND THEIR IMPACT ON TREATMENT OUTCOME IN PEDIATRIC BURKITT LEUKEMIA.

S.I. Salem<sup>1,\*</sup>, H. Abdelrahman<sup>2</sup>, M. Tantawy<sup>3</sup>, S. Talaat<sup>2</sup>, R. Hamdy<sup>4</sup>

<sup>1</sup>Clinical Pathology, <sup>2</sup>Pediatric Oncology, NCI, Cairo University and Children Cancer Hospital Egypt-CCHE, <sup>3</sup>Clinical Pathology, <sup>4</sup>Research Department, Children Cancer Hospital Egypt, 57357, Cairo, Egypt

**Background:** Burkitt leukemia (BL) constitutes around 13.5% of pediatric mature B-cell non Hodgkin's lymphoma. It is characterized by translocation involving the *MYC* gene to one of the immunoglobulin genes. The clinical significance of secondary chromosomal abnormalities associated with this characteristic translocation remains unknown.

**Aims:** We aim to analyze the impact of secondary chromosomal abnormalities on treatment outcome in pediatric Burkitt leukemia.

**Methods:** Patients with BL presenting to Children Cancer Hospital in Egypt-57357 (CCHE) from July 2007 till end of December 2015, were reviewed for karyotyping, *cMYC* status by FISH using break apart probes, and secondary chromosomal abnormalities. These results were correlated with survival analysis.

**Results:** Eighty-seven BL patients were diagnosed and treated during the study period according to the FAB/LMB 96 protocol. Majority were males (77.3%) and above 10 years of age at presentation (42%). Associated central nervous system involvement was diagnosed in 32.9% of the patients. LDH more than 2 times the upper limit was seen in 79.5%, and 52.3% of the patients suffered from tumor lysis syndrome at presentation. Informative karyotype for 66 patients demonstrated translocation of the *MYC* and *IGH* genes in 54 patients (86%) while translocation of the *IGK* and *IGL* were found in 2 (3%) and 7 (11%), respectively. Secondary chromosomal abnormalities were detected in 40 (60%) patients, with 5 or more abnormalities in 4 patients, 3 chromosomal abnormalities in 12 patients, and 2 chromosomal abnormalities in 20 patients. The most common secondary chromosomal abnormality was duplication of chromosome 1q which was found in 16 patients. Other secondary chromosomal abnormalities included structural abnormality of chromosome 14q other than *MYC* translocation (6 patients), chromosome 6q deletion (4 patients), chromosome 13q deletion (3 patients), marker chromosome (3 patients), loss of chromosome 17p (2 patients), isochromosome 9q (2 patients), translocation of chromosome 13, trisomy 13 and trisomy 9 in one patients each. Relapse or tumor progression on chemotherapy was seen in 16% of the whole group of patients. The 5 year OS was 57.7%, while 5 year EFS was 51.6%. When comparing incidence of relapse in relation to complex karyotype, we found that nine out of 16 (56.2%) patients having complex karyotype experienced relapse whereas relapse occurred in only 6 (12.5%) patients having non-complex karyotype ( $p$ -value= 0.005)

**Summary/Conclusions:** The frequency of secondary chromosomal abnormalities in our series is in concordance with other publications with duplication 1q being the most common, followed by deletion 6q, 13q, and 17p. Complex karyotype was significantly associated with higher incidence of relapse and poor outcome.

#### PB2071

##### IGVH SOMATIC MUTATION PROFILE AS PATHOGENETIC SIGNATURE IN SPLENIC MARGINAL ZONE LYMPHOMA AND SPLENIC DIFFUSE RED PULP LYMPHOMA

H.L. Julhakaran<sup>1,\*</sup>, B. Biderman<sup>1</sup>, L. Al-Radi<sup>1</sup>, I. Yakutik<sup>1</sup>, S. Korzhova<sup>1</sup>, A. Kovrigina<sup>1</sup>, A. Sudarikov<sup>1</sup>, V. Savchenko<sup>1</sup>

<sup>1</sup>National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

##### Background:

Splenic lymphomas (SLs) are rare chronic lymphoproliferative neoplasms with a very indolent clinical course and a non-characteristic phenotype and karyotype. Splenic marginal zone lymphoma (SMZL), a specific type of small B-cell lymphoma and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation. Splenic diffuse red pulp lymphoma been introduced as a provisional entity but differential diagnosis with other SLs is needed to be clarified since the therapeutic approaches are distinct.

**Aims:** The aim of our study to determine the immunoglobulin variable heavy chain (IgVH) gene usage and somatic mutation patterns in a series of SMZL and SDRP patients.

**Methods:** We studied 24 patients with SMZL, 40 patients with HCL and 10 patients with SDRPL. Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. Rearranged IgVH genes were amplified essentially in reactions that contained only one of the 5' leader region primers for the indicated 6 VH families and a 3' J primer. All PCR reactions were performed using appropriate positive and negative controls. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippling mutations were identified.

**Results:** A comparison of the VH genes to reported germline sequences in SMZL revealed that 6 cases used the VH3 family VH gene segments, 2 the VH4 family, 16 the VH1 family segments. The VH1 family genes V1-2 were used in 16 cases. In 4 out of 24 cases (16.67%), IgVH genes were in germline or near germline configuration, whereas in 20 cases (83.33%), IgVH genes were somatically mutated. We have shown no differences in clinical and laboratory characteristics, immunophenotype, outcome or overall survival were found between the mutated and unmutated cases of SMZL. A comparison of the VH genes to reported germline sequences in SDRPL revealed that five cases used the VH3 family VH gene segments and five the VH4 family, one of case with unmutated IgVH genes.

**Summary/Conclusions:** Our analysis also showed the selective use of VH1 family genes in a high proportion of SMZL cases (66.67%), while VH4 and VH3 family genes were represented at a lower frequency (8.33% and 25%, respectively). The present study may revealed that SMZL and SDRPL derive from different cellular origin and may use in differential diagnosis.

## PB2072

**CELL OF ORIGIN ASSIGNMENT USING IMMUNOHISTOCHEMISTRY IS INFLUENCED BY BCL-2 EXPRESSION IN DLBCL PATIENTS TREATED WITH CHEMO-IMMUNOTHERAPY**R. Yassin<sup>1</sup>, S. Shieban<sup>2</sup>, T. Pasha<sup>1</sup>, G. Gmati<sup>1</sup>, H. Salama<sup>3</sup>, K. Abuelgasim<sup>3</sup>, M. Al-Zahrani<sup>1</sup>, A. Hejaz<sup>3</sup>, A. Ahmed<sup>3,4</sup>, M. Damla<sup>1,4,\*</sup><sup>1</sup>Oncology, <sup>2</sup>Pathology & Laboratory Medicine, <sup>3</sup>King Abdulaziz Medical City, <sup>4</sup>King Abdullah International Medical Research Center (KAIMRC), Riyadh, Saudi Arabia

**Background:** Diffuse Large B-cell Lymphoma (DLBCL) is a heterogeneous disease with variable clinical and pathologic presentations. Using gene expression profiling or Lymph2Cx assay, DLBCL can be assigned as germinal center (GCB) or non-germinal center (Non-GCB) subtype. However such assays remain cumbersome or unavailable for routine clinical care. Immunohistochemical (IHC) algorithms, such as the one proposed by Hans *et al.*, are easy to use tools but demonstrated variable concordance to gene expression profiling. Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, antiapoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.

**Aims:** To examine the prognostic impact of cell of origin (COO) assignment in conjunction with BCL-2 expression in a cohort of DLBCL patients.

**Methods:** After due IRB approval, adult patients diagnosed with DLBCL and treated at our institution between 2010 – 2015 were identified. Clinical and pathologic variables were retrospectively abstracted. IHC expression was deemed positive if >30% of staining was observed. Cell of origin analysis was determined by the Hans criteria. All patients were treated with combinational chemotherapy containing rituximab. Patients who died prior to receiving therapy were excluded. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log ranks. Relapse, progression or death was considered an event for PFS estimation. Analysis was computed using JMP software, version 11.

**Results:** A total of 122 patients were identified and analyzed. Median follow up of the cohort was 21.8 (1.47 – 107) months, during which OS was 73.5% and PFS was 59.9%. Stratified by IPI, 2-year OS was 85%, 76.3%, 72% and 49.5% for low, low-intermediate, high-intermediate and high risk patients, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, baseline characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different.

At 2-years, PFS was significantly higher for GCB vs Non-GCB at 72.5% vs 48.6%, respectively (p=0.008) but OS was similar at 77.6% vs 69.9% (p=0.2) (Figure 1). Interestingly, BCL-2 expression predicted OS irrespective of COO assignment. Patients with BCL-2 expression had a 2-year OS of 55.6% vs 56.2% for GCB and non-GCB, respectively. Whereas, patients without BCL-2 expression has a superior 2-year OS at 79.9% vs 78.3% for GCB and non-GCB, respectively (p=0.02).

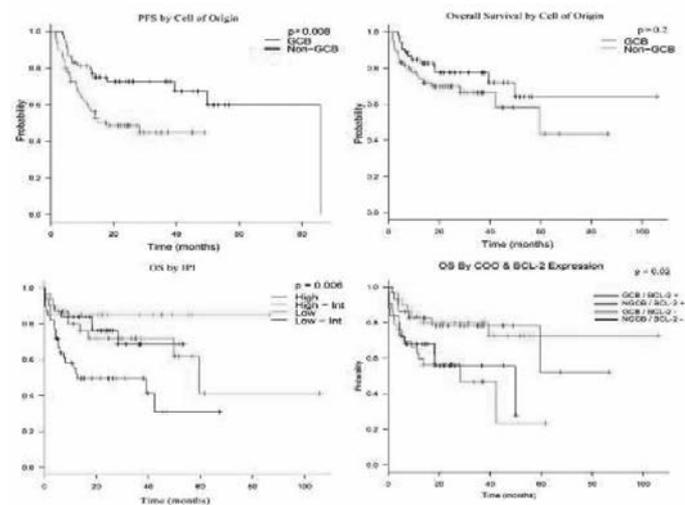

Figure 1.

**Summary/Conclusions:** COO assignment using IHC demonstrated superior PFS for GCB over non-GCB however this was mitigated by BCL-2 expression. This raises questions regarding the currently presumed pathogenesis of the different subtypes and how to utilize the currently available targeted therapies including BCL-2 inhibitors. These observations warrant further study.

## PB2073

**ARE DIFFERENCES BETWEEN PEDIATRIC EBV-ASSOCIATED LYMPHOMAS AND CARRIERS REGARDING LATENCY PROFILE AND MICROENVIRONMENT COMPOSITION INVOLVED IN LYMPHOMAGENESIS?**A. Vistarop<sup>1</sup>, M. Cohen<sup>1</sup>, O. Jimenez<sup>1</sup>, F. Huaman<sup>2</sup>, E. De Matteo<sup>3</sup>, M.V. Preciado<sup>1</sup>, P. Chabay<sup>1,\*</sup><sup>1</sup>Molecular Biology Laboratory, Pathology Division, Ricardo Gutierrez Children Hospital, <sup>2</sup>Histopathological Laboratory, National Academy of Sciences, <sup>3</sup>Pathology Division, Ricardo Gutierrez Children Hospital, Buenos Aires, Argentina

**Background:** Epstein-Barr virus (EBV) infects more than 90% of the population worldwide. The virus has evolved to persist life-long in B-lymphocytes of infected individuals, but disruption of this tightly regulated B-cell infection could result in EBV-associated B cell lymphomas. In Argentina, primary infection is mostly subclinical and 90% of patients are seropositive by 3 years old. However, EBV presence is statistically associated with Hodgkin lymphoma (HL) and Diffuse Large B cell lymphoma (DLBCL) in patients younger than 10 years, suggesting a relationship between low age of EBV infection and B-cell lymphoma development in children from Argentina.

**Aims:** Given that viral latent proteins and microenvironment composition play a key role in tumor pathogenesis or control of viral infection, our aim was to compare this scenario in pediatric EBV-associated lymphomas derived from the germinal center (GC) and post-GC with the same areas in tonsils from pediatric EBV carriers, to investigate whether an alteration of microenvironment could be related to lymphomagenesis

**Methods:** Formalin fixed paraffin embedded (FFPE) pediatric biopsy samples from 26 DLBCL, 55 HL and 41 tonsils from EBV carriers were analyzed. Immunohistochemistry for LMP1, EBNA2, CD4, CD8, Foxp3 and GrB was performed, together with EBERs *in situ* hybridization, and positive cells were counted in the EBV+ milieu.

**Results:** Latency II pattern (LMP1+ EBNA2-) was predominant in HL (100%), DLBCL (55%), as well as in EBV+ GC in pediatric carriers (90%). CD4+ cell count displayed no differences between EBV+ and EBV- HL or DLBCL (p>0.05, Mann Whitney test), whereas statistically higher CD4+ cells were counted at the EBV+ GC in pediatric carriers (p=0.014, Mann Whitney test). On the other hand, CD8+ cells did not exhibit statistical differences neither in EBV-associated lymphomas nor in benign conditions at the GC, and the same was observed for Foxp3 regulatory cells (p>0.05, Mann Whitney test). In contrast, CD8+ cell count were statistically higher exclusively at EBV+ subepithelial region in tonsils, compared to EBV- counterpart (p=0.0039, Mann Whitney test). Finally, cytotoxic activity evaluated by GrB expression displayed a trend to higher mean in EBV+ DLBCL (p=0.057, Mann Whitney test) but no in HL. Concerning EBV, pediatric carriers did not shown differences in cytotoxic activity according to EBV presence at the GC (p>0.05, Mann Whitney test). In fact, GrB cytotoxic activity was prevalent only at the EBV+ subepithelial region (p= 0.0420, Mann Whitney test).

**Summary/Conclusions:** Latency II pattern prevails in both pediatric EBV-associated lymphomas and in EBV+ GC from carriers, indicating that LMP1 expression may collaborate in the lymphomagenesis process at the GC in pediatric patients from our country. Cytotoxic activity against EBV infection may be only relevant in pediatric DLBCL, and in EBV+ subepithelial regions in pediatric carriers, whereas in EBV+ HL is not increased, in contrast to previously described. CD4+T helper cell response plays a key role at the GC region in EBV carriers, by participating directly as effectors cells, by helping to the overall immune response in the control of viral infection and restrict latency expression to type II pattern, and, ultimately, by limiting the cell outgrowth. Failure in this process may trigger malignant transformation in EBV-associated lymphomas.

## PB2074

**MICROARRAY EXPRESSION PROFILE OF LONG NONCODING RNAs IN GERMINAL CENTER-LIKE DIFFUSE LARGE B-CELL LYMPHOMA**H. Gao<sup>1,\*</sup>, Z. Gong<sup>1,2</sup>, W. Yang<sup>1</sup><sup>1</sup>Hematology, Shengjing hospital of China Medical University, Shenyang, China, <sup>2</sup>Hematopathology, The University of Texas, MD Anderson Cancer Center, Houston, United States

**Background:** Long noncoding RNAs (lncRNAs) are constantly transcribed and involved in a variety of biological activities. The contributions of lncRNAs to the development of germinal center (GCB)-like diffuse large B-cell lymphoma (DLBCL) remain largely unknown.

**Aims:** The aim of this study was to investigate the expression profile of lncRNAs in human GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) and normal B lymphocytes by microarray.

**Methods:** We used Arraystar Human LncRNA Microarray V3.0 for profiling of lncRNAs in our specimens. Sample labeling and array hybridization were performed according to the Agilent One-Color Microarray-Based Gene Expression Analysis protocol (Agilent Technology) with minor modifications. Quantitative

real-time polymerase chain reaction (qRT-PCR) was used to confirm the results of six upregulated and two downregulated lncRNAs. Bioinformatic analysis (gene ontology analysis, pathway analysis and network analysis) was performed to predict the biological functions and potential mechanisms of the differentially expressed lncRNAs in GCB DLBCL.

**Results:** We demonstrated that 21,539 lncRNAs were expressed in all samples analyzed, of which 1,648 lncRNAs were upregulated and 2,671 lncRNAs were downregulated in GCB DLBCL cell lines (OCI-ly1 and OCI-ly19) ( $\geq 2.0$ -fold,  $P < 0.05$ ). Pathway analysis indicated that 64 pathways corresponded to upregulated transcripts, and 62 pathways corresponded to downregulated transcripts ( $P < 0.05$ ). In addition, a lncRNA-mRNA co-expression network was constructed to identify potential target genes related to the 3 upregulated and 2 downregulated lncRNAs.

**Summary/Conclusions:** Our data suggested that lncRNAs may play an important role in the pathogenesis of GCB DLBCL, and profile of lncRNAs may be used as a potential biomarker in the diagnosis of DLBCL and predicting its clinical outcome.

## PB2075

### FLOW CYTOMETRY IN EVALUATION OF EXTRANODAL LYMPHOMA PRESENTING AT UNUSUAL LOCATIONS COMPARED TO NODAL LYMPHOMAS

P. Prakhar<sup>1,\*</sup>, M. Choudhury<sup>2</sup>, S. Sharma<sup>2</sup>

<sup>1</sup>Pathology, Lady Hardinge Medical College, New Delhi, India, <sup>2</sup>Pathology, Lady Hardinge Medical College, New Delhi, India

**Background:** Immunophenotyping is a fundamental step in the diagnosis of hematolymphoid neoplasms. Lymphomas arising at extranodal sites can present significant diagnostic challenges due to their morphological diversity. In recent years flow cytometry (FCM) has proven useful in the evaluation of nodal and extranodal lymphoproliferative disorders on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). For years FNAC has been used for initial evaluation of suspected hematolymphoid neoplasms. Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and any aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.

**Aims:** The aim of our study was to evaluate the efficacy of flow cytometer for the evaluation of extranodal and nodal lymphomas on 40 patients.

**Methods:** The current study was prospectively conducted on 40 patients with a clinical suspicion of hematolymphoid neoplasms. Samples for flowcytometric immunophenotyping (FCI) were obtained by fine needle aspiration (FNA) or by tissue scraping along with samples for cytomorphological, histological and immunohistochemical (IHC) evaluation. Samples collected in Isotone were submitted for FCI on 5-color Beckman Coulter FC-500, using a set of mature and immature antigens markers for lymphoid cells. Results of FCI on cytological specimens along with cytological findings were compared with histological and IHC diagnosis.

**Results:** Flowcytometric immunophenotyping conducted on extranodal sites included total 10/40 (25%) cases out of which most common site was GIT (4 cases) followed by CNS (3 cases), Kidney (1 case), Thyroid (1 case), Breast (1 case), and Tonsil (1 case). Definite diagnosis using only FCI could be obtained in 25/40 (62.5%) cases in which 6/10 (60%) cases was conducted on extranodal and 19/30 (63%) cases on nodal tissue samples. The remaining 15 cases which could not be categorized by FCI included Hodgkin lymphoma (6 cases), inadequate cellularity (5 cases), Tuberculosis (2 cases), ALCL (1 case), Mantle cell lymphoma (1 case) and Ewing's/PNET (1 case). Combining FCI with cytological findings definite diagnosis could be found in 33/40 (82%) cases, compared to 38/40 (95%) cases by histological and IHC examination. As per World Health Organization (WHO) classification of tumors of the hematopoietic and lymphoid tissues 2008 most common lymphoma at extranodal site was DLBCL followed by acute lymphoblastic leukemia/lymphoma. Whereas at nodal site most common lymphoma was DLBCL followed by Hodgkin's lymphoma. The estimated diagnostic sensitivity of FCI alone was 60.5% with 50% specificity, similar for both extranodal and nodal tissue samples. Whereas after combining FCI with cytological findings sensitivity and specificity was found to be 78.4% and 100% respectively. Immunophenotyping of lymphoblastic leukemia/lymphoma by FCM on cytological specimens was found to be in 100% concordance with FCI on peripheral blood/bone marrow aspirates.

**Summary/Conclusions:** Flowcytometric immunophenotyping along with fine needle aspiration cytology offer a rapid, simple and minimally invasive procedure for the detection of hematolymphoid neoplastic cells in solid tissue especially at extranodal sites. Flow cytometry alone may not consistently provides a definite diagnosis of lymphoma subtypes but can be very helpful in diagnosing extranodal lymphoma and nodal lymphoblastic leukemia/lymphoma.

**KEYWORDS:** Flow cytometry, extranodal lymphoma

### POSSIBLE ROLE OF FLOW CYTOMETRY TO CHARACTERIZE INFILTRATING CD4 CELLS IN THE MICRO ENVIRONMENT OF LYMPHOMA TISSUE SAMPLES

R. Di Gaetano<sup>1,\*</sup>, D. Belvini<sup>1</sup>, B. Callegari<sup>1</sup>, M.A. De Benedetto<sup>1</sup>, E. Pilotto<sup>1</sup>, R. Sartori<sup>1</sup>, L. Vassallo<sup>2</sup>, A. Scapinello<sup>2</sup>, T. Giuseppe<sup>1</sup>

<sup>1</sup>Haematology Castelfranco Veneto, <sup>2</sup>Pathology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

**Background:** In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analyzed by flow cytometry (FC) the rich infiltrated characterizing the microenvironment of Hodgkin lymphoma (HL), mainly comprised of CD4 T lymphocytes. We confirmed that the majority of these CD4 T expressing the activation markers (CD38) but lose the CD26 and we suggested to identify the subset CD4+CD26-CD38+ to identify the non-neoplastic cellular pattern in HL. A subset connectable to regulatory T (Treg) cells, because the low expression of CD26 (DPP4) added to the presence of CD39 (NTPDase) may be responsible for the generation of adenosine, which plays a major role in Treg-mediated immunosuppression.

**Aims:** We wanted to test if this subset may also characterize T infiltrating lymphocytes the lymph nodes of Non-Hodgkin's lymphomas (NHL) and to verify the expressions of the two enzymatic markers (CD26 and CD39) in microenvironments of HL and NHL analyzed by FC.

**Methods:** In 2016 we analyze by FC in lymph nodes of 6 HL and in 32 NHL (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL) the CD4 T subset testing the expression of CD26, CD38, CD39.

**Results:** In CD4 T HL, CD39 is expressed in 44% of the subset and the increased presence (50%) of CD4+CD26-CD38+ cells is confirmed. Compared with HL, the cells of DLBCL are not statistically (t Student test) different: CD38 (64 vs 55;  $p=0.39$ ), CD26-CD38+ (50 vs 46;  $p=0.66$ ), CD39 (44 vs 59;  $p=0.15$ ). While HL and FL cells are significantly different: CD38 (64 vs 23;  $p < 0.05$ ), CD26-CD38+ (50 vs 18;  $p < 0.05$ ), CD39 (44 vs 23;  $p < 0.05$ ). The other three types of NHL, few in number, show a tendency to a significant difference compared with DLBCL.

**Summary/Conclusions:** Our data show the phenotypic variations in the microenvironments of different types of lymphoma emphasizing of DLBCL the similarity with HL and the difference with FL and other NHL. They also suggest a link between an activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC of CD4 T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target.

## PB2077

### TREG CD4 PHENOTYPE IN THE PERIPHERAL BLOOD OF LYMPHOMAS

R. Di Gaetano<sup>1,\*</sup>, D. Belvini<sup>1</sup>, E. Pilotto<sup>1</sup>, B. Callegari<sup>1</sup>, M.A. De Benedetto<sup>1</sup>, R. Sartori<sup>1</sup>, G. Tagariello<sup>1</sup>

<sup>1</sup>Haematology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

**Background:** The T regulatory (Treg) cells down-regulate antitumor responses by several distinct mechanisms. One is the adenosinergic pathway which, through ectonucleotidases, sequentially converts ATP to AMP and generates immunosuppressive adenosine. Several studies have demonstrated in humans the overexpression of CD39 (NTPDase) and low adenosine deaminase (ADA) levels, the enzyme responsible for adenosine breakdown, and of CD26, a surface-bound ADA associated glycoprotein. In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analysed by flow cytometry (FC) the T CD4 lymphocytes of solid biopsies, the surrounding neoplastic cells in Hodgkin lymphoma (HL) lymph nodes (LN) and we demonstrated the presence of an activated profile (CD38+) with a reduction of CD26 (CD4+CD26-CD38+). We also confirmed a link of this subset with an overexpression of CD39.

**Aims:** By using the same FC technique we wanted to explore if, as in the lymph nodes, CD4+CD26-CD38+ subset and high levels of CD39 might characterize the peripheral blood (PB) of HL at diagnosis and possibly to distinguish them from those of B Non-Hodgkin lymphomas (B-NHL).

**Methods:** We have analysed by FC the PB of 16 healthy controls (HC), 10 HL and 22 NHL testing within T CD4 cells the expression of CD26, CD38 and CD39.

**Results:** In HC CD26-CD38+ cells were 2.6% of all T CD4 and 5.5% expressed CD39. Compared with HC, the subset CD4+CD26-CD38+ of HL was statistically different (2.6 vs 17;  $p < 0.05$ ) as well as in B-NHL (2.6 vs 12.9;  $p < 0.05$ ). The expression of CD39 between HC and HL was not different (5 vs 9.8;  $p=0.1$ ), while it was statistically significant between HC and NHL (5 vs 19.5;  $p < 0.05$ ).

**Summary/Conclusions:** Our results may suggest that T CD4 profile in the PB can characterize the patients with HL and B-NHL and this could be probably variable according to the type of neoplasm. The significant presence of CD4+CD26-CD38+ subset in PB of HL and B-NHL would seem to suggest that the low expression/reduction of CD26 of ADA activity may indicate the Treg-mediated immunosuppression. Interesting is the diversity of NHL showing increased CD39 expression on T CD4 lymphocytes probably connected with

the clone of B lymphocytes involved in cancer. This may support that leukemic cells may contribute to create and to characterize an immune-subversive environment and to facilitate immune escape mechanisms. FC analysis of CD26 and CD39, markers likely connected with the adenosinergic pathway, in PB can represent effective parameters to determine and characterize the Treg CD4 in different types of lymphoma and could serve as targets in the follow-up of HL and B-NHL.

#### PB2078

##### **BCL-2 AND KI-67 AS INDEPENDENT PREDICTORS OF POOR-RISK IPI GROUP OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA**

E. Suljovic Hadzimesic<sup>1,\*</sup>, S. Radovic<sup>2</sup>, A. Sofo-Hafizovic<sup>1</sup>, N. Obralic<sup>3</sup>, N. Bilalovic<sup>4</sup>, A. Kozaric<sup>4</sup>, A. Dizdarevic<sup>1</sup>, S. Kurtovic<sup>1</sup>, V. Bijedic<sup>3</sup>, M. Skuric-Tomic<sup>3</sup>

<sup>1</sup>High Dose Therapy Department, Clinical Center University of Sarajevo, Hematology Clinic, <sup>2</sup>Institute of Pathology, Medical Faculty University of Sarajevo, <sup>3</sup>Clinical Center University of Sarajevo, Hematology Clinic, <sup>4</sup>Clinical Center University of Sarajevo, Pathology, Cytology and Human Genetics Department, Sarajevo, Bosnia and Herzegovina

**Background:** Diffuse large B cell lymphoma (DLBCL) is heterogeneous disease in terms of clinical behaviour, morphology, phenotype and genetics. Gene expression profiling has made a distinction between two entities germinal center B-phenotype (GCB), activated B-center phenotype (ABC). Use of immunohistochemical algorithms for identification of these phenotypes has been translated into clinically feasible approach defining groups as GCB, non-GCB. These algorithms do not provide completely accurate prognostic information so the International Prognostic Index (IPI) which identifies poor- and good-risk patients with diffuse large B cell lymphoma (DLBCL) is still part of all current diagnostic guidelines; however, the majority of patients have an intermediate IPI, with an uncertain prognosis.

**Aims:** In this study, we investigated the impact of bcl-2, bcl-6, CD10, MUM1 and Ki-67 on IPI as well as impact of GCB and non-GCB subclassification according to Hans and Muris algorithm on IPI risk stratification.

**Methods:** We have analyzed 50 patients with DLBCL for the expression of bcl-2, bcl-6, CD10, MUM1 and Ki-67. Patients were divided into two groups, the non-GCB, GCB group or favorable group 1 and unfavorable group 2, according to Hans's algorithm and Muris's algorithm. Clinical-pathological, biochemical parameters of disease have been correlated with subgroups of DLBCL and biomarkers individually. The impact of the expression of bcl-2, bcl-6, CD10, MUM1 and Ki67 on IPI-highest score in multiple regression analysis, afterwards in regression equation and variance analysis.

**Results:** Group with GCB phenotype (defined by expression of bcl-2, bcl-6, CD10 and MUM1) according to Hans's and Muris's algorithm showed positive correlation with good-risk patients identified by IPI. Multiple regression analysis proved impact of biomarkers on IPI. Following this analysis, bcl2 i Ki67 are independent predictors of poor-risk IPI group of patients, (bcl-2: p 0,0107, Ki67: p 0,0377). The value of F-ratio 2,9845 proves that there is a linear connection between models including all variables bcl-2, bcl-6, CD10, MUM1 and variable depended on the value (IPI)(p 0,0210). The mutual impact of bcl-2, bcl-6, MUM1, Ki67 is significantly related to poor-risk IPI patients.

**Summary/Conclusions:** Multiple regression analysis proved impact of biomarkers on IPI. Ki67 and bcl-2 are independent predictors of poor-risk IPI group of patients. Sequential addition of bcl-2 expression, Ki67 and GCB phenotype into the IPI significantly improves risk stratification in DLBCL. These finding can be part of treatment strategies that should be considered in future trials.

#### PB2079

##### **COMPARATIVE PATHOLOGIC ANALYSIS OF MEDIASTINAL B-CELL LYMPHOMAS: EXPRESSION OF P63 BEST DIFFERENTIATES PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA FROM CLASSICAL HODGKIN LYMPHOMA**

H.-J. Kim<sup>1</sup>, G. Park<sup>2</sup>, S.K. Min<sup>3</sup>, H.K. Kim<sup>4</sup>, J.H. Han<sup>5</sup>, H.J. Cha<sup>6</sup>, H. Lee<sup>7</sup>, S. J. Choi<sup>8</sup>, J.E. Kim<sup>9,\*</sup>

<sup>1</sup>Pathology, Sanggye Paik Hospital, Inje University college of medicine, <sup>2</sup>Pathology, Seoul St. Mary's Hospital, The Catholic University, Seoul, <sup>3</sup>Pathology, Hallym University Sacred Heart Hospital, Anyang, <sup>4</sup>Pathology, Soonchunhyang University Hospital, Pucheon, <sup>5</sup>Pathology, Ajou University School of Medicine, Suwon, <sup>6</sup>Pathology, Ulsan University Hospital, Ulsan, <sup>7</sup>Pathology, Eulji University Hospital, Seoul, <sup>8</sup>Pathology, Inha University Hospital, Incheon, <sup>9</sup>pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

**Background:** Mature B-cell lymphomas of the mediastinum include primary mediastinal large B-cell Lymphoma (PMLBCL), classic Hodgkin Lymphoma (CHL), B-cell lymphoma unclassifiable, with features intermediate between diffuse large B-cell lymphoma and CHL (gray zone Lymphoma) and others. PMLBCL and mediastinal CHL, mostly nodular sclerosis (NS) share many clinico-pathologic characteristics, however, therapeutic options and responses are quite different.

**Aims:** We aimed to find distinctive histologic or immunohistochemical findings to better differentiate PMLBCL and CHL of the mediastinum.

**Methods:** A total of 32 cases of mediastinal B-cell lymphomas consisting of PMLBCL (N=16), CHL (N=13), and gray zone lymphoma (N=3) were collected from 6 university hospitals from Korea. Immunohistochemistry (IHC) for various cell lineage markers and EBV *in situ* hybridization were performed to confirm the diagnosis, and additionally, expression of P63, GATA3 and cyclinE was investigated.

**Results:** Most clinical features were overlapped between PMLBCL and CHL except more frequent disease progression and mortality in PMLBCL (p<0.05). In pathologic review, presence of epithelioid granuloma favored CHL (p=0.078), whereas fine reticulated fibrosis was unique for PMLBCL (p<0.001). By IHC, P63 was predominantly positive in PMLBCL (15/16) than CHL (2/11) with the highest diagnostic power (p<0.001). GATA3 was expressed in the majority of CHL (9/12) compared with PMLBCL (0/16) (p<0.001). Expression of cyclinE was rarely found in a minor population of PMLBCL.

**Summary/Conclusions:** Expression of P63 in the tumor cells, even focal, is the most helpful feature to distinguish PMLBCL from mediastinal CHL. Additional diagnostic markers include GATA3 in CHL and reticular fibrosis in PMLBCL.

#### PB2080

##### **CASTLEMAN'S DISEASE: HISTOLOGICAL SUBTYPES AND MICROVESSEL DENSITY**

A. Mikhailov<sup>1,\*</sup>, V. Baykov<sup>2</sup>, S.S. Bessmeltsev<sup>3</sup>, G. Raskin<sup>4</sup>, V. Rugal<sup>5</sup>, N.Y. Semenova<sup>3</sup>

<sup>1</sup>Department of hospital therapy and cardiology, North-Western state medical university n.a. I.I.Mechnikov, <sup>2</sup>Department of pathology, First St.-Petersburg state medical university n.a. I.P.Pavlov, <sup>3</sup>Russian research institute hematology and transfusiology, <sup>4</sup>Department of pathology, Russian National scientific centre of Radiology and surgical technologies, <sup>5</sup>Department of pathology, Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

**Background:** Castleman's disease (CD) is a rare non-clonal lymphoproliferative disorder. Most of the cases are characterized by increased vascularity in the affected tissue. The disease falls into two major histological variants: plasma cell type and hyaline vascular type. However, the correlation between microvessel density and the subtype of the disease has not been established yet.

**Aims:** To investigate the association between microvessel density and histological type of CD.

**Methods:** Twenty-eight lymph nodes from patients diagnosed with CD were used for the study. The age of the patients ranged from 24 to 65 years, 14 were male and 14 were female. Three nodes without evidence of metastasis removed for breast cancer were used as controls. The diagnosis of hyaline vascular CD was based on overall preserved immunohistochemistry with typical angio-follicular hyperplasia, circular arrangement of mantle cells around hyalinized germinal centers ("onion skin" pattern). The plasma cell type of CD was confirmed by presence of perifollicular sheets of CD138+ plasma cells. Vessels were labeled with CD34 immunostain. Slides were scanned by the whole slide digital Panoramic scanner. Percentage of blood vessel area (vessel density index) was calculated using Panoramic Viewer software, statistical analysis was conducted with Student's t-test.

**Results:** The plasma cell variant of CD was diagnosed in 8 patients, the hyaline vascular variant – in 20 patients. In control group vessels occupied 10±1,0% of the area. In patients with plasma cell variant percentage of blood vessel area was increased to 15.1±1.4% (p<0,05). Patients with hyaline vascular CD were divided into 2 groups depending on the vessel density index. In 15 patients (75%) percentage of vessel area was 6.8±2.3%, which was somewhat lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12,3±1,5% (p<0.05) and did not differ from levels in patients with plasma cell variant.

**Summary/Conclusions:** The highest index of vessel density in the lymph nodes with CD was observed in plasma cell variant. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

#### PB2081

##### **PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL MARKERS IN R-CHOP TREATED DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS**

A.-M. Picleanu<sup>1,\*</sup>, S. Patrascu<sup>2</sup>, L. Mogoanta<sup>3</sup>

<sup>1</sup>Hematology, Filantropia Hospital Craiova, <sup>2</sup>Surgery, Emergency Hospital Craiova, <sup>3</sup>Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

**Background:** Despite its clinical, morphological and molecular heterogeneity, diffuse large B-cell lymphoma (DLBCL) is the most frequent lymphoid malignancy

nancy in adults. The role of immunophenotype variability for the therapeutic outcome has long been the cornerstone for DLBCL management strategy.

**Aims:** To evaluate the immunophenotypic characteristics of DLBCL and the prognostic significance of specific biomarkers such as bcl2, bcl6, CD 10 and MUM1, in a population-based cohort of patients treated with R-CHOP.

**Methods:** We performed a retrospective assessment of all cases of DLBCL diagnosed at our institution between 2005-2013. The immunohistochemical expression patterns of all DLBCL patients were analyzed and correlated with the therapeutic response to R-CHOP regimen.

**Results:** The study included 101 patients diagnosed with DLBCL, with a median age at diagnosis of 57.1 years (19-90 years) and male/female ratio of 1.3/1. Ninety-one patients were eligible for R-CHOP treatment. The median follow-up was 41 months. Out of the 90 cases analyzed by immunohistochemistry CD 10, BCL2, BCL6 and MUM1 expression was found in 17.6%, 50.5%, 72.7% and 81.8% of cases, respectively. Negative expression for CD10, as well as positive expression of BCL2 were adverse prognostic factors for 3-years overall survival (OS) and disease free survival (DFS) (OS for bcl2: 72.3 vs 89.7, p<0.05, OS for CD10: 84.1 vs 75.1, p<0.05). BCL6 and MUM1 expressions, however, did influence neither OS nor DFS.

**Summary/Conclusions:** This study confirms the prognostic value of a multi-marker assessment which includes bcl2, bcl6, CD 10 and MUM1 expression for patients R-CHOP therapy.

## Other Non-malignant hematopoietic disorders

PB2082

### LYMPHOID NEOPLASMS: A REALLY IMPORTANT TRIGGER IN HEMOPHAGOCYTTIC LYMPHOHISTIOCYTOSIS

V. Martínez Robles<sup>1,\*</sup>, S. Calleja<sup>2</sup>, B. Ballina<sup>1</sup>, S. Cerdá<sup>1</sup>, S. Fernández-Ferrero<sup>1</sup>, F. Escalante<sup>1</sup>, F. Ramos<sup>1</sup>, J.A. Rodríguez-García<sup>1</sup>  
<sup>1</sup>Hematology and Hemotherapy, <sup>2</sup>Immunology, Complejo Asistencial Universitario de León (CAULE), León, Spain

**Background:** Triggered by several conditions Hemophagocytic lymphohistiocytosis (HLH) is an unusual, aggressive and life-threatening dysfunction caused by an excessive immune activation. It has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith, next case was reported in 1952 by Farquhar and Claireaux describing two infant siblings with progressive and lethal cytopenias, hepatosplenomegaly, and fevers with autopsy showing hemophagocytosis. A lengthy and unstoppable activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells is characteristic. This condition leads to an important hyperinflammatory situation and organ damage including splenomegaly, fever, cytopenia, hypertriglyceridemia and/or coagulopathy. Histiocyte Society (HS) criteria have been applied for diagnosing HLH, however not all of them are usually showed at the presentation. This disease can be described in two different scenarios: primary (usually in children, genetic, and known as familial form) and secondary (acquired). It can be triggered by a large variety of events that disrupt immune homeostasis. When we talk about triggers, we can divide them in two broad categories, those that cause immune activation and those that lead to immune deficiency. Lymphoid neoplasms can be both.

**Aims:** Due to the lack of publications about HLH secondary to Lymphoid Neoplasms (LN), we would like to analyze the casuistry of our hospital and making a comparison with the current literature.

**Methods:** We conducted a retrospective analysis through medical files of all patients with suspected diagnosis of HLH between 1994 and 2017 in our inpatient ward. Clinical features, age, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study 18 out of 50 patients met the requested criteria for HLH diagnosis.

**Results:** We report 10 LN secondary cases (4 males, 6 females). The median age at diagnosis was 60,5 years, ranged between 46 and 80 years. In all of them, but in one, who presented long-term pancytopenia, symptoms were developed very fast. The most frequent causes of consultation were cytopenia and general syndrome. In two of them HLH was diagnosed with LN relapse, in one patient during a transformation from a low-grade B-cell lymphoma to DLBCL (Diffuse large B-cell lymphoma), in 6 of them we diagnosed LN and HLH concomitantly, and in the last one coinciding with a Richter Syndrome. Four of 10 were secondary to T-cell neoplasm. All patients met 5 or more HS diagnostic criteria. In only 3 of them HLH was healed. One patient is still in remission. Nine died, 7 of them due to HLH complications. Treatment was chemotherapy (depending on their LN) in almost all of them. Fluctuations were detected among activity HLH parameters due to LN response. Detailed characteristics of patients are shown in Table 1.

Table 1.

Case	Age (y)	Sex	BCC (p184/nb/p184/x330/w/p184/p184)	LDH (U/L)	Tig (mg/dL)	Fibr (mg/dL)	Ferritin (ng/dL)	PS	Adheno-pat	Spleno-megaly	Trigger	Treatment	Evolution	Cause of death	Diagnos-ic Criteria

9	78	F	1,7/9/54	750	600	ND	16400	2	Yes	No	Yes	DLBCL relapse	HLH 2004	Initial HLH recovery, aggravation because febrile	Yes	6
10	67	F	4,2/8/98	643	251	235	3015	3	Yes	Yes	Yes	Non aggressive Lymphoproliferative active Sy to DLBCL Transformation	R-CHOP x 3	HLH complete remission, death due to infection after chemo.	No	5

**Summary/Conclusions:** HLH triggered by LN is diagnosed in older patients than other causes secondary HLH (46-80 vs 4-84 y/o in our center), we think this is because in our experience there are not children or Young adult in HLH due to LN group. We would like to highlight that although LN is a very common HLH trigger there are a few works describing them in the literature, that is why we would like to spread our experience. We would like to emphasize in the importance of an early diagnosis. Despite being a serious disease, it is still underdiagnosed, reaching the diagnosis most of the times after seeing hemophagocytic phenomena in bone marrow biopsy. Agreeing with literature, main consulting reasons are similar to our series. Correlation between neoplastic activity and immune activation, as well as test and facts which could predict evolution should be more studied. Finally we would like to address the necessity of considering this possibility in the face of a patient with fever which does not respond to antibiotics and has not clarified cytopenia, as well as the importance of conducting cheap and very profitable test such as ferritin or tryglycerides level when symptoms or clinical features of lymphoid neoplasm are not concordant with the expected evolution.

**Background:** Health networks focused on rare diseases were created following a call for proposals from the French Ministry of Health in the summer of 2013. The main objective of these networks is to facilitate and to coordinate the actions being implemented by all actors involved in treating rare diseases. Of the 23 national networks identified in 2014 in France, the network for rare immunohematological rare diseases "MaRIH" brings together national reference centres and recognized centres of expertise as well as patients' associations involved in treating those pathologies, on behalf of scientific medical societies.

**Aims:** Improving care, communication and training, pushing forward research development and epidemiological surveillance.

**Methods:** MaRIH brings together people involved in those medical pathologies: 8 national reference centres, 5 centres of expertise, more than 50 diagnosis and/or research laboratories, 9 patients' associations on behalf of 7 scientific societies.

**Results:** The main missions of this network are to improve the care, the research and to educate professionals, patients as well to disseminate more information to the general public on these rare diseases. *Improving care:* Thanks to its visibility (events, leaflets, website), MaRIH should help primary care doctors to more quickly diagnose and therefore provide faster and appropriate treatment based on best practice recommendations at the national level (PNDS) as well as international guidelines. The network will also be setting up new multidisciplinary meetings for specific immunological and hematological rare disorders through MaRIH centres so physicians in France or in other countries can have easily an expert opinion for their patients. At the same time, improving the child-adult transition was identified by the steering committee as a top priority. *Communication and training:* MaRIH is involved in organizing many multidisciplinary events in France to improve the visibility of the centres and to provide education on these rare diseases. The 1st annual conference of the network took place on June 25<sup>th</sup> 2015 and the third one is planned on June 1<sup>st</sup> 2017 in Paris. Moreover, a patient's day meeting was organised on

January 30<sup>th</sup> 2016 in Paris to inform on the update status of research on their disease as well as to help patients in daily common problems (sport, psychology, transfusion...). *Pushing forward research development and epidemiological surveillance:* the network has appointed a research project manager for its scientific and strategic committee to support, provide stability for and add value to research centre activities. The research project manager watch out for calls for tender, set-up of new registers and continually monitor the regulations for retrospective and prospective studies, both in France and at the international level. Furthermore, MaRIH supported successfully the application of several of its members for European reference networks (Figure 1).

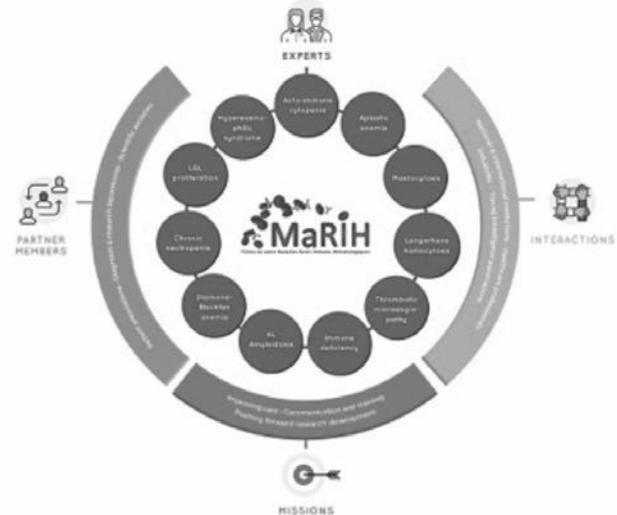

Figure 1.

**Summary/Conclusions:** The creation of these new networks allows strengthening the links between the various actors involved in the field to improve care and answer transversal questions. In this way, MaRIH pilot concerted actions to all its members around immunohematological rare diseases by: 1- increasing the visibility of the actors on the web or during events. The MaRIH website includes all the informations of the members as well as recommendations and events ([www.marih.fr](http://www.marih.fr)). 2- communication and training. MaRIH organizes two annual events, one for patients and another one for professionals. Moreover, MaRIH sends clinical cases by email to professionals and produce an annual webcast. 3- pushing forward research development and epidemiological surveillance. Thanks to his research project manager, MaRIH facilitates the submission and the set-up of new registries or clinical studies. In the future, MaRIH will continue and further develop all these actions, in close collaboration with the French Ministry of health.

#### PB2084

#### CLINICAL FEATURES AND ETIOLOGY OF PATIENTS WITH THROMBOTIC MICROANGIOPATHIES

Ü. Ergene<sup>1,\*</sup>, C. Özlü<sup>1</sup>

<sup>1</sup>hematology, saglik bilimleri university, izmir, Turkey

**Background:** Thrombotic microangiopathy (TMA) is a heterogeneous group of disease that has a fatal pattern of endothelial damage. TMA can be found in association with diverse clinical conditions such as carcinoma metastasis, malignant hypertension, infections, and TTP (thrombotic thrombocytopenic purpura). TTP is a rare, life-threatening multisystem disease, characterized by microangiopathic hemolytic anemia, thrombocytopenia, fever, renal dysfunction, and neurological disorders.

**Aims:** The purpose of this study is to evaluate the etiology associated with TMA. **Methods:** All of the six TMA patients who were newly admitted to our clinic in two months period were enrolled in this study. Effectiveness, response, adverse effects and safety of plasmapheresis were evaluated using laboratory and clinical findings. (See Table 1).

**Results:** First patient presented with cachexia, thrombocytopenia, and TMA. He did not respond to plasmapheresis and corticosteroid treatment. We diagnosed carcinoma metastasis and liver metastasis, respectively, through bone marrow biopsy and PET (positron emission tomography). We thusly ascertained that TMA was due to carcinoma unknown primary. The second patient presented with general neurological findings like Guillain-Barre Syndrome and paraplegia with renal failure, thrombocytopenia, and TMA. After PLEX and corticosteroid treatment, laboratory and neurological clinical recovery were observed after one month. The third patient had chronic obstructive pulmonary disease and pneumonia in anamnesis. who presented with anemia, thrombocytopenia, fever and pneumonia findings. We conducted PLEX therapy. On the 8<sup>th</sup> day of PLEX, the patient had anaphylaxis, we performed cardio pulmonary resuscitation. The fourth patient

presented with acute renal failure with malign hypertension. We performed hemodialysis together with PLEX treatment. Because his diagnosis was acute renal failure, malign hypertension, and TMA. The fifth patient presented with epistaxis and sepsis. He had chronic TTP diagnosis from two years ago. We diagnosed the patient as relapse TTP. Early treatment against infection and PLEX increased his platelet counts as early as the second day of treatment. The sixth patient presented with a fever that had been going on for five days. We treated the patient with PLEX together with the corticosteroid. Because his ADAMTS13 level was very low and he had 35% schistocytes.

Table 1.

Features and Findings of Patients										
Patient number	Etiology	Age	Gender	Hemo globin (g/dl)	Platelets	LDH (U/L)	Total Bilirubin (mg/dL)	ADAMTS13 Activity	Steglia ToxicShig & toxin-producing Escherichia Coli	Schistocyte Count (%)
1/141 Y	Carcinoma Metastasis	60	Male	5.6	17000	1062	2.65	39.92	+	5
5/141 C	Idiopathic Vira Infection	62	Male	7.8	12000	389	1.21	28.38	-	20
3/141 G	Malign Hypertension	60	Male	7.9	16000	1208	2.66	55.79	+	10
6/141 E	Sepsis	24	Male	7.6	82000	455	0.81	96.24	+	6
5/141 K	Bacterial Infection	54	Male	10.6	47000	382	0.83	0.2	-	24
6/141 Y	Bacterial Infection	52	Male	9.2	20000	765	1.2	0.69	+	35

**Summary/Conclusions:** We diagnosed our first patient with carcinoma unknown primary, who did not respond to PLEX and corticosteroid treatment. The results we received for that patient indicate that PLEX with corticosteroid treatment alone, remain ineffective in cancer-related TMA patients. Etiology of our second patients TMA was idiopathic. His clinical and laboratory findings improved rapidly in response to PLEX and pulse corticosteroid treatment. One viral infection induced TMA patient had anaphylactic reaction receiving his 8<sup>th</sup> PLEX. Allergic reactions should always be kept in mind when administering PLEX. One patient with TMA and malign hypertension-induced renal failure was successfully treated with PLEX, hemodialysis and antihypertensive treatment. We successfully treated our bacterial infection and sepsis-induced TTP patients with PLEX and antibiotic administration. In second TMA patient, we coupled PLEX with high dosage corticosteroid treatment even though he had an infection. For he had high schistocyte count and atypical neurological findings. ADAMTS 13 activity may only be a guide for diagnosis of TTP, but it is unreliable for a definitive one. In conclusion, diagnosis of TTP and other TMAs is difficult. Etiology, clinical features, laboratory findings should all be taken into account when diagnosing TMA. While it is established that ADAM TS13 deficiency is the major cause in acquired TTP, finding the etiology of other TMAs is determinant for a successful treatment of the latter.

**PB2085**

**HAEMOLYSIS AS SCREENING TEST IN LYSOSOMAL STORAGE DISEASES**

L. López De Frutos<sup>1,2,\*</sup>, J.J. Cebolla<sup>1,3,4</sup>, P. Irún<sup>1,3</sup>, P. Giraldo<sup>1,2,3</sup>  
<sup>1</sup>Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragón (IIS Aragón), <sup>2</sup>Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), <sup>3</sup>Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), <sup>4</sup>Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, Zaragoza, Spain

**Background:** Lysosomal storage disorders (LSDs) are a group of rare inherited metabolic diseases, whose clinical hallmark is organomegaly among others, due to progressive accumulation of several non-catalyzed products inside the lysosomes. This storage leads to intracellular oxidative stress status triggering oxidized metabolites production as oxysterols, which are related to apoptosis and cellular eriptosis, as well as haemolysis dysregulation.  
**Aims:** To evaluate the link between LSDs and haemolysis and if it could be used as a screening test in LSDs.  
**Methods:** The osmotic resistance test (ORT) was evaluated in 150 samples including controls, LSDs carriers (LSDs-C) and LSDs patients (LSDs-P). Briefly, the blood was mixed with different concentrations of sodium chloride solution (NaCl) and the haemoglobin released was quantified by spectrophotometry. The raw data was normalized using isotonic solution (0.9% NaCl). The statistical analysis (non-parametric tests and ROC curves) was computed by IBM SPSS statistics v22 software and all statistical tests will be considered and taken as bilateral significance level  $\alpha=0.05$ .  
**Results:** The analysis shown that haemolysis at 0.48% of NaCl allow us to sort out controls vs LSDs-C/LSDs-P (AUC=0.726) whereas no significant differences were observed between LSDs-C and LSDs-P (p-value>0.05).  
**Summary/Conclusions:** According to our results the ORT test is an useful screening test in LSDs.

**PB2086**

**CLINICAL SIGNIFICANCE OF ELEVATED SERUM COBALAMIN (VITAMIN B12) LEVELS**

I. Yaman Bajin<sup>1,\*</sup>, E. Sabanci<sup>2</sup>, S. Akyan<sup>2</sup>, S. Aytac<sup>1</sup>, M. Çetin<sup>1</sup>, F. Gümrük<sup>1</sup>  
<sup>1</sup>Pediatric Hematology, <sup>2</sup>Pediatrics, Hacettepe University, Ankara, Turkey

**Background:** Hypercobalaminemia is a frequent but underestimated abnormality. Elevated serum cobalamin levels may be a sign of a wide range of diseases like solid neoplasms, haematological disorders like myeloproliferative disorders, chronic myelogenous leukemia, promyelocytic leukemia, polycythemia vera, hypereosinophilic syndrome as well as liver and kidney diseases.  
**Aims:** We aimed to evaluate the underlying disorders of the patients with high cobalamin levels (>1000 pmol/l) between 01.02.2016- 01.02.2017 in Hacettepe University Pediatric Hematology Department.  
**Methods:** We investigated the patient records of the patients examined between 01.02.2016- 01.02.2017 in our department and included the patients with serum cobalamin levels higher than 1000 pmol/l. We excluded the patients who are taking Vitamin B12 supplement.  
**Results:** There were 46 patients with serum cobalamin levels higher than 1000 pmol/l out of 14367 patients seen between 01.02.2016- 01.02.2017 in our department. The reason to check the cobalamin levels were anemia, neutropenia and thrombocytopenia in most of the patients. Only 2 patients were referred to our department because of hypercobalaminemia. The underlying disorders were found to be leukemia in 3 patient ( Acute lymphoblastic leukemia (ALL) n:1, acute myeloblastic leukemia (AML) n:1 , large granular lymphocytic leukemia (LGLL) n:1), myelodisplastic syndrome (MDS) in 2 patients, isolated thrombocytopenia in 4 patients, isolated neutropenia in 7 patients, bicytopenia in 4 patients and aplastic anemia in 2 patients, cobalamin metabolism defects in 10 patients, hypereosinophilia in 2 patients, pellsitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMF (familial mediterranean fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor 7 deficiency in 1 patient, thrombosis in 1 patient and epistaxis in 1 patient.  
**Summary/Conclusions:** An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflammation and infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.

**PB2087**

**THE HEMATOLOGIC FINDINGS OF INHERITED METABOLIC DISEASE; THEY ARE MORE THAN EXPECTED**

I. Yenicesu<sup>1,\*</sup>, A.E. Sal<sup>2</sup>, I. Okur<sup>2</sup>, Z. Kaya<sup>1</sup>, F.S. Ezgu<sup>2</sup>, U. Kocak<sup>1</sup>, L. Tumer<sup>2</sup>  
<sup>1</sup>Pediatric Hematology, <sup>2</sup>Gazi University, Faculty of Medicine, Ankara, Turkey

**Background:** Inherited metabolic diseases are pathological conditions that generally develop as a result of impairment of the production or breakdown of protein, carbohydrate and fatty acids. Hematological problems are some of the most frequently observed findings of inherited metabolic diseases. These may be seen together with other systemic findings or sometimes as the first and only diagnostic finding of disease. Early determination of hematological findings has a positive effect on the prognosis of metabolic diseases.  
**Aims:** The aim of this study is to evaluate the incidence of hematological findings in inherited metabolic diseases since there are a few studies about the true incidence in literature.  
**Methods:** Three hundred eighteen patients who were being followed-up within the previous 6 months at Gazi University Department of Pediatric Nutrition and Metabolism, Turkey, were included in the study. Patients' hematological findings were taken from Department of Pediatric Nutrition and Metabolism and hospital data-processing records. Since patients were in different age groups, hematological findings were compared with normal values for each patient's age group. The hematological findings were classified under seven main groups; anemia of chronic disease, iron deficiency anemia, vitamin B12 deficiency anemia, hemophagocytosis, leukocytosis and thrombocytosis. Metabolic diseases were classified according to the textbook of Inborn Metabolic Diseases: Diagnosis and Treatment.  
**Results:** Nine hundred twenty-two hematological examinations of the 318 patients were included to the study, and 282 hematological findings were determined, 127 anemia of chronic disease, 80 iron deficiency anemia, 56 cytopenia and four vitamin B12 deficiency anemia. Leukocytosis (n=1), thrombocytosis (n=5) and hemophagocytosis (n=9) were also observed.  
**Summary/Conclusions:** It was determined that although anemia of chronic disease and nutritional anemia are the most common hematological findings, these may be diagnosed late, while neutropenia, thrombocytopenia, pancytopenia and hemostasis disorders may be diagnosed earlier. Metabolic diseases must be considered in the evaluation of cytopenias, particularly in cases with an atypical cause that are resistant to treatment and have additional accompanying findings. Our study is the most comprehensive one in the liter-

ature, and we think it would positively contribute to the monitoring and prognosis of congenital metabolic diseases.

#### PB2088

##### HEMATOTOXIC EFFECTS OF GENERIC TRIAZOLE FUNGICIDES TEBUCONAZOLE ON WISTAR HANNOVER RATS

T. Usenko<sup>1,\*</sup>, V. Shulyak<sup>1</sup>, N. Nedopytanska<sup>1</sup>, M. Prodanchuk<sup>1</sup>

<sup>1</sup>L.I. Medved's Research Center of Preventive Toxicology, Food and Chemical Safety, Ministry of Health, Kiev, Ukraine

**Background:** Pesticides are extensively used in agriculture today. Fungicides based on derivatives of triazole are the most widespread all over the world. Tebuconazole (TB) is one of the most frequently used substance of this group. Literature review confirms that triazole fungicides have the ability to cause different hematotoxic effects.

**Aims:** Since 2007-2016 years we have investigated 10 test-substances of generic tebuconazoles (purity up to 97%) from different manufacturers with purpose to assess their hematotoxic action on males Wistar Han rats peripheral blood in the subchronic 90-days oral toxicity study (according to SOP and OECD 408 recommendations in compliance with GLP).

**Methods:** The Wistar Han males were randomly allotted to four groups. The input controls of peripheral blood parameters were conducted after a period of animals acclimatization. The goal was to evaluate the physiological state of the Wistar Han rats and the blood picture before treatment. Doses 0; 10; 50; 200 mg/kg/bw/day were defined and were the same in all studies. Blood samples for hematological measurements were examined at 4, 9, 13 weeks after TB exposure in the same groups of animals throughout the experiment. Hemoglobin (HGB) concentration, hematocrit (HCT), total amount of erythrocytes (RBC), leukocytes (WBC) and platelets (PLT), mean corpuscular hemoglobin (MCH) were evaluated.

**Results:** As a result, all generic TBs on high toxic doses level (200 mg/kg/bw/day) had shown the tendencies for quantitative hematological changes. TBs mainly provoked the significant decrease of HGB concentration and RBC count on 4th and 9th weeks of exposure. Morphological changes of RBC (anisocytosis) were seen too. It means that generic TBs had anemic effect. In general, changes of hematological parameters were not principally significant and did not differ from control values at 13th weeks of experiments, except two TB's, which had shown significant decrease of HGB. Also some of generic TBs lead to decrease (leukopenia) or increase (leukocytosis) of leukocytes count in peripheral blood. In case of generic pesticides, the presence of impurities can demonstrate various hematotoxic action. Also the adverse effects on peripheral blood of males Wistar Han rats were observed at a dose of 50 mg/kg/bw/day and demonstrated the lesions of red blood. But abovementioned changes were not so clearly expressed. Any adverse hematotoxic effects at 10 mg/kg/bw/day dose were not observed in all studies.

**Summary/Conclusions:** As a conclusion, due to our results the triazole fungicides generic tebuconazoles have hematotoxic action. They induce anemia in Wistar Han rats and quantitative white blood cells changes. Today it is very important to investigate the hazardous effects of pesticides on the blood system.

#### PB2089

##### WHAT WE CAN DO TO MAKE A STANDARDIZATION AND HARMONIZATION OF APTT?

M. Pamukcuoglu<sup>1,\*</sup>, M. Falay<sup>2</sup>, S.M. Urlu<sup>1</sup>, M.A. Ucar<sup>1</sup>, F. Ceren<sup>1</sup>, S. Dagdas<sup>1</sup>, G. Özet<sup>1</sup>

<sup>1</sup>Hematology, <sup>2</sup>Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey

**Background:** Transfusion enhanced many kind of complication in patients therefore peri-operative coagulation monitoring was suggested before the surgical procedure to protect the patients against bleeding. Also there are some diseases which had bleeding events in surgical procedure or spontaneously. We should detect these kind of diseases and we should examine the correct measure of active partial thromboplastin time (APTT) before surgical procedure by detecting the mild or moderate deficiencies of plasma factor levels and by eliminating the lupus anticoagulant from plasma. This was caused to make the importance of APTT reagents.

**Aims:** We tried to show the importance of APTT reagents and how to reach the correct measure of APTT in this study.

**Methods:** We are planning to examine 300 patients, 109 of 300 patients were included as yet. Patient's APTT levels were calculated ACL-TOP analyzer by using three different reagents. First reagent was Hemosil APTT-SP which was sensitive against both plasma factors and lupus anticoagulant. It contains mix colloidal silica and normal range of APTT-SP was 25.4-36.9 s. Second reagent was Hemosil SynthAsil-SS which was sensitive against only plasma factors. It contains silica and normal range of APTT-SS was 25.1-36.5 s. The third reagent was Hemosil SynthA Fox-SF which was sensitive against only lupus anticoagulant. It contains ellagic acid and normal range of APTT-SF was 21.5-30.4 s.

**Results:** Forty-five of 109 patients had normal level of APTT by measuring

three types of reagents. Seventeen of 109 patients had long level of APTT by measuring three types of reagents. Twenty of 109 patients had long level of APTT by measuring Hemosil synthAsil-SS reagent and had normal level with Hemosil SynthA Fox-SF and Hemosil APTT-SP. Seven of 109 patients had long level of APTT by measuring Hemosil synthAsil-SS reagent and Hemosil APTT-SP reagent and had normal level of APTT with Hemosil SynthA Fox-SF. Twenty of 109 patients had long level of APTT by measuring Hemosil synthAsil-SS reagent and Hemosil SynthA Fox-SF reagent and had normal level of APTT with Hemosil APTT-SP.

**Summary/Conclusions:** Haemostasis is a complex physiological cascade which was began at the endothelium injury. Many kinds of complex procedures occurred after this injury. Because of this complex cascade pathway, bleeding is not occurred every kind of APTT level. Bleeding events usually occurred at <30% level of plasma factors but mild or moderate plasma factor levels can cause bleeding. Therefore sensitivity of APTT reagents are very important. Every kind of APTT reagent do not have equal sensitivity against plasma factor levels, phospholipid composition and concentration in thromboplastin reagent. Several studies suggested that range of APTT should be determined according to the devices and reagents and also several studies compared APTT reagents which was included silica, ellagic acid and phospholipids by composed of synthetic or animal originated and several studies determined a target level of APTT for looking at the plasma factors levels. If we want to get a correct result of APTT, ranges of APTT must be determined according to reagents which was used in APTT devices and APTT reagents must be sensitive against borderline cases who had a mild or moderate low levels of factors and the presence of lupus anticoagulant. We need further studies to make a standardization and harmonization of APTT.

#### PB2090

##### ACQUIRED PURE RED CELL APLASIA IN AN ADOLESCENT: COULD IT BE ANYTHING ELSE?

S. Yılmaz Bengoal<sup>1,\*</sup>, Ö. Tüfekçi<sup>1</sup>, M. Erdem<sup>1</sup>, D. Kızmaoğlu<sup>1</sup>, H. Ören<sup>1</sup>

<sup>1</sup>Pediatric Hematology, Dokuz Eylül University, İzmir, Turkey

**Background:** Pure red cell aplasia (PRCA) is a syndrome characterised by normocytic (sometimes macrocytic), normochromic anemia with severe reticulocytopenia and marked reduction or absence of erythroid precursors from the bone marrow. PRCA may be congenital, in the form of Diamond-Blackfan Anemia, or acquired which is rather rare in childhood. An immune mechanism interrupting erythroid differentiation is responsible in primary autoimmune PRCA, on the other hand secondary acquired PRCA may be associated with autoimmune/collagen vascular disorders, infections, lymphoproliferative disorders, hematological malignancies, solid tumors and drugs.

**Aims:** Here we report a 16-year-old male with acquired pure red cell aplasia who was treated successfully with steroids and cyclosporine after elimination of the secondary causes.

**Methods:** Case: An 16-year-old boy presented with a history of pallor and fatigue noticed three months prior to admission. He had been diagnosed with immune thrombocytopenia when he was 5 years old and had been in remission since that time. There was no history of blood transfusion, chronic illness or any other medication. His physical examination revealed pallor and a 2/6 systolic murmur with no other abnormalities. Complete blood count revealed severe macrocytic anemia and reticulocytopenia with hemoglobin: 2.2 g/dL, hematocrit: 6.2%, mean corpuscular volume: 108.7 fL, red blood cell:  $0.57 \times 10^{12}/L$ , reticulocyte: 0.2% and mild leukopenia and lymphopenia. Peripheral blood smear showed macrocytic red cells with occasional tear drop cells. Stool for occult blood was negative. The direct and indirect antiglobulin tests were negative Serum bilirubin, LDH, haptoglobin, liver function tests and renal function tests were in normal limits. Hemoglobin F was 2.9%. Bone marrow aspiration showed red cell hypoplasia, without dysplasia or giant pronormoblasts and normal myeloid and megakaryocytic series. A high resolution computed tomography of chest ruled out thymoma. Serum immunoglobulins revealed low IgA with normal IgG and IgM levels. Anti-nuclear antibody was negative but anti-dsDNA was positive. Parvovirus B19 DNA and other serologic markers including antibodies to HIV and hepatitis A, B and C were all negative. He was transfused with erythrocytes and discharged with a hemoglobin value of 7.2 g/dL. On his follow-up, hemoglobin levels were observed to decrease again. A diagnosis of primary acquired PRCA was considered and prednisone with a dose of 1 mg/kg/day and cyclosporine with a dose of 6 mg/kg/day were started to maintain through levels of 150-250 ng/mL. His hemoglobin level gradually increased and reached to 12 g/dL and leukopenia and reticulocytopenia resolved completely. Prednisone was tapered after 4 weeks and stopped. He is still on cyclosporine treatment and has been transfusion free with stable hemoglobin levels in the second month of his treatment.

**Results:** Primary acquired PRCA is very rare in childhood, secondary causes must be eliminated for definitive diagnosis. Our patient was found to have lymphopenia, low immunoglobulin A level and positive anti-dsDNA in further investigations, yet these results are not sufficient for a specific diagnosis like common variable immune deficiency or systemic lupus erythematosus. Therefore we considered primary acquired PRCA as the most possible diagnosis and started immunosuppressive therapy; his clinical follow-up will probably give us further details about the underlying disease.

**Summary/Conclusions:** Immunosuppressive therapy including cyclosporine with or without steroid has been reported as the most effective treatment in primary acquired PRCA. Consistently, we had a dramatic response to immunosuppressive therapy in our patient.

**PB2091**

**APLASTIC ANEMIA IN CHILDHOOD: A TEN YEARS' SINGLE CENTER EXPERIENCE**

A. Apsemidou<sup>1,\*</sup>, T.-S. Tziola<sup>1</sup>, A. Tragiannidis<sup>1</sup>, E. Chatzipantelis<sup>1</sup>, M. Papageorgiou<sup>1</sup>, L. Damianidou<sup>1</sup>, T. Papageorgiou<sup>1</sup>, T. Koletsa<sup>2</sup>, A. Giannopoulos<sup>3</sup>

<sup>1</sup>Pediatrics-Pediatric Hematology/Oncology, <sup>2</sup>Pathology, <sup>3</sup>Pediatrics-Pediatric Cardiology, AHEPA University Hospital, Thessaloniki, Greece

**Background:** Aplastic anemia in childhood is a rare, life-threatening disorder, characterized by peripheral blood pancytopenia and a hypocellular bone marrow without signs of dysplasia or fibrosis. Acquired aplastic anemia needs to be distinguished from inherited bone marrow failure syndromes or myelodysplastic syndromes.

**Aims:** The aim of this study is to assess the clinical and laboratory findings at the time of diagnosis, the treatment approach and the outcome of children with aplastic anemia treated in our department during the past decade.

**Methods:** This retrospective study evaluated 9 children with aplastic anemia, who were treated and followed up in the Pediatric Department of AHEPA, during the period 2006-2016.

**Results:** We identified 9 children with aplastic anemia. The patients' population included 6 (66.7%) males and the mean age at admission was 9.7 years. At the time of diagnosis, the average neutrophil count was 750/mm<sup>3</sup>, the Hb count was 8.4mg/dl and platelets count was 8770/mm<sup>3</sup>. In all of our cases aplastic anemia was acquired, except one case of Fanconi anemia. Predisposing risk factors (including drugs exposure, viral infections, chemicals) were identified in 4 patients. Among the 9 studied patients, 3 (33.3%) had moderate-non severe, 2 (22.2%) had severe and 4 (44.5%) had very severe aplastic anemia. All of the patients received immunosuppressive therapy (consisting of antithymocyte globulin, cyclosporine A and steroids), 2 remained transfusion independent, 4 underwent bone marrow transplantation- 2 from a matched related donor and 2 from a matched unrelated donor. One patient with refractory disease received, as an alternative first line therapy, eltrombopag. Complete response was achieved in 22.2%, partial response was achieved in 22.2%, relapse occurred in 11.1% and 44.5% of the patients had refractory disease. The overall survival was 77.8%.

**Summary/Conclusions:** A remarkable progress has been made during the past decades in the understanding of pathogenesis and management of children with aplastic anemia. Bone marrow transplantation from a matched related donor is the recommended first line therapy resulting in an excellent survival rate that exceeds 90%. In the future the development of targeted strategies for patients and the enhancement of supportive care will further improve outcome and diminish the disease's late complications.

**PB2092**

**CAUSES OF IRON DEFICIENCY ANEMIA IN THE HEMATOLOGY CLINIC – SINGLE CENTER EXPERIENCE**

M. Ionita<sup>1,\*</sup>, I. Ionita<sup>1</sup>, D. Calamar<sup>1</sup>, D. Oros<sup>1</sup>, V. Todorescu<sup>1</sup>, C. Ionita<sup>1</sup>, C. Sorica<sup>1</sup>, H. Ionita<sup>1</sup>

<sup>1</sup>Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

**Background:** Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.

**Aims:** Of the study is to evaluate retrospectively adult men with IDA that were hospitalized in our Hematology Clinic.

**Methods:** Two hundred fifteen male with IDA were enlisted at this study from January 2005 to december 2015. Anemia was defined as Hg <13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15 ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination, the history of the disease and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Most patients underwent esophagogastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive. The abdominal CT scan were performed according to clinician's recommendation together with other tests related with blood lost.

**Results:** The median age was 62 ( range 32 to 86 ) years old. 168 of 215 ( 78.13% ) men with IDA had symptoms such as fatigue, dizziness, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 32 (14,88%), 43 (20,0%), patients, respectively. FOBT was positive in only 65 (30.23%) subjects. 170 (79.06%) patients under-

went EGD. The most common findings from EGD were gastritis (48 patients) and peptic ulcer (39 patients). Seventy eight (36.27%) patients were found to have upper gastrointestinal disorders ( 20 patients with erosive gastritis, 19 gastric ulcer, 16 duodenal ulcer, 23 gastric cancer. Eighty-nine (41.39%) patients underwent colonoscopy. That showed 44 clinically important lesions that probably caused IDA ; colon cancer in 17 (7.90%) patients, colon polyp in 10 (4.65%) patients and hemorrhoid in 17 (7,90%) patients. Concerning malignant lesions which are responsible for IDA, the malignant lesions were found more frequent in patients older than 50 years accounting for 20.45% (27/132 patients) and patients younger than 50 years 17.80% (13/73 patients).

**Summary/Conclusions:** This study demonstrated that gastrointestinal blood loss is the main cause of IDA in adult men, and that there is a high rate of malignancy in men older than 50 years.

**PB2093**

**IMPACTS OF CLINICAL AND BIOCHEMICAL PARAMETERS ON KEY HEMATOLOGICAL INDICES IN ADULTS: A COHORT STUDY**

C.-C. Chen<sup>1,\*</sup>, M.-H. Lin<sup>2</sup>, Y.-H. Yang<sup>3</sup>, C.-E. Huang<sup>1</sup>, H.-Y. Tsou<sup>1</sup>, C.-C. Hsu<sup>1</sup>, Y.-Y. Wu<sup>1</sup>

<sup>1</sup>Department of Medicine, <sup>2</sup>Center of Excellence for Chang Gung Research Datalink, <sup>3</sup>Department of Traditional Chinese Medicine, Chang-Gung Memorial Hospital, Chiayi, Chiayi, Taiwan, Republic of China

**Background:** Studies in Caucasians have shown that values of hematological parameters could be affected by a wide variety of factors, most notably age and gender. However, parallel work in different ethnical populations, especially from Asia-Pacific region, is lacking. Importantly, it remains largely unknown whether some fundamental variables such as nutritional status, lipid profile, and hepatitis infection (either HBV or HCV) also affect the variation of values in hemogram.

**Aims:** Therefore, we conceptualize this study to explore through several key parameters regarding their potential impacts on the changes of hemogram.

**Methods:** Adult individuals aged 18 or older from several adjacent villages in Yun-Lin County, located in the central part of western Taiwan, who came to our hospital for annual health exams were screened for the current study. The work, retrospective in nature, was approved by institutional IRB. Information on age, gender, hemogram, levels of total cholesterol (TC), triglyceride (TG), apolipoprotein B (Apo B) as well as albumin, and results of serological testing for hepatitis B and C infection, was obtained from a centralized digital data base. All the clinical data, after given a coding number for each case, were encrypted and provided to the investigators without identifiable personal information. We analyzed the impacts of various parameters on several key hematological indices.

**Results:** Overall, 26,497 individuals were included in the current analysis after excluding those with hemogram data fell outside of normal range. Carriers of either hepatitis B (HBV) or C (HCV) who had abnormal liver function (defined by elevated levels of aspartate transaminase or alanine transaminase) were excluded as well. Age, gender, and serum levels of TC, Apo B, and albumin all significantly impacted most key hematological profiles. As the levels of TC and Apo B correlated well with each other (correlation coefficient  $r=0.82211$ ,  $p < 0.0001$ , Pearson's correlation), we did not incorporate TC in our multi-variate analysis. Several key variables were found to influence some hematological indices in the multi-variable regression model. Increasing age and male gender negatively affected the platelet count, whereas higher Apo B level was associated with elevated platelet count. Surprisingly, hepatitis C carriers with normal hepatic function had slightly higher platelet number than non-HCV carriers. Gender and serum albumin level were the major determinants of variation in hemoglobin level. Total white cell count increased with male gender and elevating Apo B level but was inversely correlated with change in age and serum albumin level (Table 1).

**Table 1.**

Variables	Beta coefficients of the least square

HCV	0.0001	0.0001	0.0001	0.0001	0.0001	0.0001	0.0001	0.0001

**Summary/Conclusions:** The hematological indices are influenced by a wide variety of factors, especially age, gender, and serum level of Apo B. As age,

Apo B, white cell count, and platelet count all impose risk of thromboembolism, further work exploring the interactions and impacts of these parameters on the development of cardiovascular diseases should be mandatory.

#### PB2094

##### UNUSUAL DISTRIBUTION OF INTERLEUKIN-10 C-592A GENE POLYMORPHISM IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FROM NORTH-WESTERN RUSSIA

S. Kapustin<sup>1,\*</sup>, I. Zotova<sup>2</sup>, S. Gritsaev<sup>2</sup>, J. Sidorova<sup>1</sup>, I. Pavlova<sup>3</sup>, A. Pavlova<sup>3</sup>, S. Bessmeltsev<sup>2</sup>

<sup>1</sup>Laboratory of Biochemistry, <sup>2</sup>Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation, <sup>3</sup>Laboratory of Immunohematology, Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

**Background:** Primary immune thrombocytopenia (ITP) is a rare hematological disease with unknown etiology. It is characterized by heterogeneity of the laboratory parameters as well as the features of clinical manifestation. DNA polymorphism of several cytokine genes has been suggested to modulate the risk of ITP development or/and treatment response in distinct population groups. There is no data on the prevalence of cytokine gene polymorphisms in ITP patients from the North-Western region of Russia (NWR).

**Aims:** To establish the features of genotypes distribution for several cytokine promoter gene polymorphisms in ITP patients from NWR.

**Methods:** A total of 68 patients (59 women and 9 men) with chronic primary ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). In 19 (32.2%) women, ITP was diagnosed before 30 years old; 26 (38.2%) patients (5 men and 21 women) were diagnosed at age 30-50 years; 23 (33.8%) patients (4 men and 19 women) developed ITP after 50 years old. The control group consisted of 240 healthy persons originated from NWR. Nucleotide variations in the genes coding for interleukin (IL)-1b (-31T/C), IL-6 (-174G/C), IL-10 (-592C/A) and tumor-necrosis factor alpha (TNFA -308 G/A) were discriminated by PCR and subsequent restriction analysis (PCR-RFLP). Intergroup differences in genotype frequencies were assessed by Fisher's exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using the GraphPad Prism 5.0 software.

**Results:** The frequency of the IL-10 -592CC genotype was slightly increased in the ITP group when compared to controls (65.7% vs 54.0% respectively; OR=1.6, 95% CI: 0.9-3.1, p=0.15). Interestingly, this variant of the IL-10 gene was more prevalent among women than men with ITP (71.2% vs 25.0% respectively; OR=7.4, 95% CI: 1.4-40.5, p=0.016). When compared to controls, the IL-10 -592CC genotype was significantly overrepresented in the group of women with ITP (71.2% vs 54.0%; OR=2.1, 95% CI: 1.1-4.2, p=0.044). On the contrary, in the group of affected men we observed the increase of persons who had IL-10 -592A allele (75.0% vs 46.0% in control group; OR=3.5, 95% CI: 0.7-18.3, p=0.15). Genotype frequencies for other studied genes were similar between the patients and control group as well as between women and men with ITP. We have also found almost 2-fold increase of the IL-1b -31CC frequency in women diagnosed before 30 years old compared to other patients (15.8% vs 8.2% respectively; OR=2.1, 95% CI: 0.4-10.5, p=0.39). The presence of the TNFA -308A allele was more often seen in patients diagnosed before 50 years old (26.7% vs 8.7% in other ITP patients; OR=3.8, 95% CI: 0.8-18.8, p=0.12).

**Summary/Conclusions:** We suggest that the IL-10 -592CC genotype is associated with increased risk of ITP in women from NWR. On the other hand, the IL-10 -592A allele could be involved in pathogenesis of ITP in men. Further studies are needed to clarify the significance of TNFA and IL-1b gene polymorphism in ITP development.

## Platelets disorders

#### PB2095

##### COMBINED TREATMENT OF AZATHIOPRINE AND ROMIPILOSTIM IN PATIENTS ITP REFRACTORY TO STEROIDS OR THROMBOPOIETIN ANALOGS

M. E. Mingot-Castellano<sup>1,\*</sup>, I. Sánchez-Bazán<sup>1</sup>, J. Díez-Pastor<sup>1</sup>

<sup>1</sup>Hematology, Regional University Hospital of Málaga, Málaga, Spain

**Background:** More than 70% of patients with Immune Primary Thrombocytopenia (ITP) respond to steroids, but 40 to 70% relapse in the first year follow-up. The use of romiplostim in this group is effective, although 9% failure has been described. In recent literature, there are clinical cases and small series describing the potentiating effect of combined treatment with thrombopoietin analogues and immunosuppressive drugs such as steroids, cyclophosphamide and rituximab. We have not found references to the combined use of azathioprine (AZA) and romiplostim (ROM).

**Aims:** To describe our experience in the combined use of azathioprine and romiplostim as a rescue treatment in patients with acute or newly diagnosed ITP refractory to corticosteroids or corticosteroid-dependence and refractory to maximal doses of romiplostim monotherapy.

**Methods:** We analyzed patients with newly diagnosed or persistent ITP, with corticosteroid-dependence or refractory to steroids and refractory to romiplostim, both in monotherapy. We have considered refractoriness to steroids not reaching platelets higher than  $30 \times 10^9/L$ . Corticosteroid-dependence as the need for ongoing or repeated doses administration of corticosteroids for at least 2 months to maintain a platelet count at or above  $30 \times 10^9/L$  and/or to avoid bleeding. We considered refractoriness to romiplostim not get platelets greater than  $30 \times 10^9/L$  with 10mcg/kg/week for at least 3 consecutive weeks. All patients have been diagnosed in a single center with the same physician responsible for the treatment and follow-up. The initial doses of AZA was 100mg/days (2mg/kg/day) and ROM 10mcg/kg/week. Patients have been evaluated every week until platelets were higher than  $30 \times 10^9/L$  for consecutive weeks, after this they were reviewed monthly.

**Results:** We treated 4 patients (75% female) with a median age at diagnosis of ITP of 53 years old (RIQ, 20-61 years). Treatments received prior to the use of the combination of AZA and ROM were polyspecific immunoglobulins (Ig), steroids (dexamethasone, prednisone) and romiplostim. Responses to steroids and romiplostim in monotherapy were: • Median dexamethasone cycles (40mg/days x 4 days) was 2.5 (2-4 cycles, IQR). The initial dose of prednisone was 1-2mg/kg/days with a median treatment day of 31.5 days (28-60 days, IQR). The type of response to steroids was PR with corticosteroid-dependence in one patient, 3 patients NR. • Median time from ITP diagnosis and romiplostim indication was 9.5 weeks (7-48 weeks, IQR). Median platelets count at the start of romiplostim was  $6 \times 10^9/L$  ( $2-13 \times 10^9/L$ , IQR). The median platelet count achieved at maximal doses of romiplostim for at least 2 consecutive weeks was  $10 \times 10^9/L$  ( $3-19 \times 10^9/L$ , IQR). Once established the refractoriness to romiplostim, we maintained ROM 10mcg/kg/week and AZA was initiated at 100mg/day. The median time from romiplostim indication to the association with azathioprine was 9.8 weeks (5.5 to 15 weeks, IQR). The median time to response after initiation of combination of AZA and ROM was 21 days (15-35 days, IQR). The types of response were: • One patient did not respond after 60 days of combined treatment. • 1 patient with RC maintains for 7 months in the absence of active treatment. The combined was necessary during 8 months. • 2 CRs still undergoing combined dose reduction (current dose romiplostim 2mcg/kg/week and azathioprine 50mg/d). Median platelets from onset of dose reduction  $169 \times 10^9/L$  ( $128-176 \times 10^9/L$ , IQR). Duration of RC, 7 and 14 months. Non adverse events have been described in combination treatment.

**Summary/Conclusions:** The use of azathioprine and romiplostim in combination could be a safe and effective alternative in subjects refractory to steroids or corticosteroid-dependence and thrombopoietin analogs alone. More studies are needed to clarify the mechanism of complementation between the two drugs.

#### PB2096

##### AGONIST-INDUCED PLATELET REACTIVITY CORRELATES WITH BLEEDING IN HEMATO-ONCOLOGICAL PATIENTS

B. Batman<sup>1,\*</sup>, E.R. van Bladel<sup>1</sup>, M. van Hamersveld<sup>2</sup>, P.C. Pasker - de Jong<sup>1</sup>, S.J. Korporaal<sup>3</sup>, R.T. Urbanus<sup>3</sup>, M. Roest<sup>3</sup>, L.A. Boven<sup>2</sup>, R. Fijnheer<sup>1,3</sup>

<sup>1</sup>Internal Medicine, <sup>2</sup>Department of Clinical Chemistry, Meander Medical Center, Amersfoort, <sup>3</sup>Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Prophylactic platelet transfusions are administered to prevent bleeding in hemato-oncological patients. However, bleeding still occurs, despite these transfusions. This practice is costly and not without risk. Better predictors of bleeding are needed and flow cytometric evaluation of platelet function might aid the clinician in identifying patients at risk of bleeding. This evaluation can be performed within the hour and is not hampered by low platelet count.

**Aims:** Our objective was to assess a possible correlation between bleeding and platelet function in thrombocytopenic hemato-oncological patients.

**Methods:** Inclusion was possible for admitted hemato-oncology patients aged 18 years and above after written informed consent. Furthermore, an expected need for platelet transfusions was necessary. Bleeding was graded according to the WHO bleeding scale. Platelet reactivity to stimulation by either adenosine diphosphate (ADP), crosslinked collagen-related peptide (CRP-xL), PAR1- or PAR4-activating peptide (AP) was measured using flow cytometry.

**Results:** A total of 114 evaluations were available from 21 consecutive patients. Platelet reactivity in response to stimulation by all four studied agonists was inversely correlated with significant bleeding. Odds Ratio's (OR) for bleeding were 0.28 for every unit increase in median fluorescence intensity (MFI) [95% Confidence interval (CI) 0.11-0.73] for ADP; 0.59 [0.40-0.87] for CRP-xL; 0.59 [0.37-0.94] for PAR1-AP and 0.43 [0.23-0.79] for PAR4-AP. The platelet count was not correlated with bleeding (OR 0.99 [0.96-1.02]).

**Summary/Conclusions:** Agonist-induced platelet reactivity was significantly correlated to bleeding. Platelet function testing could provide a basis for a personalized transfusion regimen, in which platelet transfusions are limited to those at risk of bleeding.

**PB2097**

**TUMOR NECROSIS FACTOR-A AND TUMOR NECROSIS FACTOR-B SINGLE NUCLEOTIDE POLYMORPHISM AND CHRONICITY IN EGYPTIAN PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA**

N. El-Gharbawi<sup>1</sup>, G. Shahin<sup>1</sup>, A. Eid<sup>1</sup>, N. Diaa<sup>1</sup>, M. El-Ghamrawy<sup>2,\*</sup>  
<sup>1</sup>Clinical and Chemical Pathology, <sup>2</sup>Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

**Background:** Although the etiology of immune thrombocytopenic purpura (ITP) remains unclear, both genetic and environmental factors may contribute to the development of disease. Tumor necrosis factor alpha & beta (TNF-α and TNF-β) are important pro-inflammatory cytokines that play a role in regulation of cell differentiation, proliferation and death, as well as in inflammation, innate and adaptive immune responses, and have been implicated in a wide variety of human diseases. We hypothesized that inflammatory cytokine genes polymorphisms (TNF-α and TNF-β) in ITP pediatric patients may play a fundamental role in pathogenesis of the chronic course of the disease and this might be the base for future specific immunomodulatory therapies for chronic ITP (cITP) in children.

**Aims:** The current case-control study aimed at detecting TNF-α (-308 G/A) and TNF-β (+252 A/G) genes polymorphism in Egyptian children with cITP and studying their possible association with chronic evolution of the disease.

**Methods:** The current study included 80 Egyptian cITP patients at Pediatric Hematology Unit, Cairo University (mean age 7.08±3.64 years) and 100 matched unrelated healthy controls. Genotyping was performed using polymerase chain reaction restriction fragment length polymorphism technique (PCR-RFLP).

**Results:** TNF-α genotyping revealed that wild G/G, heterozygous G/A and homozygous A/A genotypes among cITP patients were 81.2%, 15% and 3.8% respectively *versus* 79%, 20% and 1% in control group, while TNF-β wild A/A, heterozygous A/G and homozygous G/G genotypes among cITP patients were 55%, 40% and 5% respectively *versus* 60%, 28% and 12% in control group, with no statistically significant difference between both groups. Patients having homozygous TNF-α genotype showed statistically significant higher mean age, longer disease duration & lower mean platelet count (p=0.005, 0.024 and 0.008 respectively). TNF-α polymorphism was more frequent among unresponsive patients compared to responsive patients with statistically significant difference. Calculated risk estimation revealed that combined genes polymorphism conferred three fold increased risk of development of cITP (OR=3.491, 95% CI: 1.235-9.869, p=0.015).

**Summary/Conclusions:** We hereby report a strong association between combined polymorphisms of both TNF-α & TNF-β genes and susceptibility to chronicity of ITP in Egyptian children. Further studies for gene polymorphisms which could affect the pathogenesis of ITP and facilitate the development of new therapeutic modalities are recommended.

**PB2098**

**PROGNOSTIC FACTORS IN PRIMARY IMMUNE THROMBOCYTOPENIA OF CHILDHOOD**

A. Gkoutisias<sup>1</sup>, T. Palianopoulos<sup>1</sup>, E. Pappa<sup>2</sup>, E. Papapetrou<sup>3</sup>, C. Tsaousis<sup>3</sup>, N. Chaliasos<sup>1</sup>, A. Makis<sup>1,\*</sup>  
<sup>1</sup>Department of Pediatrics, <sup>2</sup>Department of Internal Medicine, <sup>3</sup>Hematology Laboratory, University Hospital of Ioannina, Greece, Ioannina, Greece

**Background:** Primary immune thrombocytopenia (ITP) is an immune disorder with varied course. According the duration of the disease, it is distinguished in newly diagnosed (<3 months), persistent (3-12 months) and chronic (>12 months). International studies have highlighted prognostic factors for each form of ITP in children, but similar studies have yet to be performed in Greece.

**Aims:** The evaluation of clinical and laboratory parameters and the identification of prognostic markers for the three forms of the disease in children with ITP from an academic reference center in Greece.

**Methods:** This retrospective study included 57 children with ITP in the past 13 years, aged 1-16 years (median age 5.2). The following data were recorded: age, gender, preceding infection, bleeding type, duration of symptoms and platelet count at the diagnosis, treatment, disease course and immunological markers and comparison was made among the three types of ITP.

**Results:** 39 children had newly diagnosed, 4 had persistent and 14 had chronic disease. Due to the small number of children with persistent form they were incorporated in the group of children with newly diagnosed ITP. In chronic ITP children are more likely to be above 10 years of age (p=0.015) and to have gradual initiation of the disease (p=0.001) compared with newly diagnosed/persistent group (57% vs 21% and 79% vs 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (79% vs 21%, p=0.013). Platelet count below 10 x 10<sup>9</sup>/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% vs 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% vs 50%, p=0.81). Children with newly diagnosed/persistent disease had less frequently impaired immunological markers (12% vs 65%, p <0.003) and received more frequent intravenous gamma globulin and/or corticosteroids (p>0.05). None of the children exhibited severe spontaneous bleeding.

**Summary/Conclusions:** Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/persistent and the chronic form of the disease are characterized by different predictive parameters that can be used in clinical practice.

**PB2099**

**CANCER-ASSOCIATED IMMUNE THROMBOCYTOPENIA**

G. Pinto<sup>1,\*</sup>, P. Herrera<sup>1</sup>  
<sup>1</sup>Hematology, Hospital Ramon y Cajal, Madrid, Spain

**Background:** Cases of cancer-associated immune thrombocytopenia (IT) have been reported recently, but there are few reports and case series that describe clinical features and response to treatment.

**Aims:** We report our experience of 10 years at a single hospital in Spain, in patients with IT concurrent with neoplasia.

**Methods:** We identified the patients by data search of hospital records from 2006 to 2016, with diagnosis of IT with previous diagnosis of cancer, not related with chemotherapy or radiotherapy, not suggestive of bone marrow infiltration, drug-induced, infection of disseminated intravascular coagulation. For the diagnosis, the examination of bone marrow was not mandatory.

**Results:** The two most common cancers associated with IT were bladder and lung neoplasms, but the occurrence of prior cancer (third part of patients) was not uncommon. The IT can appear at any stages of cancer, and it is mainly detected at the first two years after the diagnosis when the patient have been in acceptable antitumoral response. They usually manifest with very low platelet count <20.000, but not always with evident clinical bleeding. The response to therapy was fast and complete with corticoids (usually in the first week) in the majority of patients, but some cases require the combination second line with immunoglobulins or thrombopoietin receptor agonists, and in the follow-up, the response was persistent without recurrence in the first year post-treatment (Table 1).

**Table 1.**

Patients with immune thrombocytopenia diagnosed concurrently with cancer											
PATIENT	GENDER	AGE	TYPE OF CANCER	STAGE	PREVIOUS CANCER	TIME OF STARTING	BLEEDING PHENOTYPE	PLATELETS /mm <sup>3</sup>	TREATMENT	OUTCOME OF IT	TIME OF RESPONSE
1	female	47	BREAST	4	no	SECOND YEAR	without bleeding	10.000	CT	CR	2 days
2	male	60	LUNG	4	no	FIRST YEAR	gastrointestinal	2.200	CT+IVIG	CR	20days
3	female	52	LUNG	3	breast	FIRST YEAR	without bleeding	50.000	CT+TRA	CR	20days
4	male	77	BLADDER	2	no	SECOND YEAR	epistaxis	2.600	CT	CR	5 days
5	male	80	LUNG	3	no	CONCURRENT	gastrointestinal	30.000	CT	CR	4 days
6	male	88	BLADDER	2	prostate	FIRST YEAR	without bleeding	17.000	CT	CR	20days
7	male	55	COLON	4	no	SECOND YEAR	gastrointestinal	1.000	CT	CR	2 days
8	female	86	IDOMETRIA	1	no	FIRST YEAR	without bleeding	16.000	CT	CR	4 days
9	female	78	BLADDER	1	breast	FIRST YEAR	gastrointestinal	2.100	CT+TRA	CR	30days

Abbreviations: PC: previous cancer; CT: corticosteroids; IVIG: intravenous immunoglobulin; TRA: thrombopoietin receptor agonists; IT: immune thrombocytopenia CR: Complete response [continuous platelets count >30,000 by treatment]

**Summary/Conclusions:** The CAIT is a rare hematological paraneoplastic syndrome that occur in solid tumors, usually associated to low platelet count but without life-threatening bleeding, requiring therapy with corticosteroids as first line, and generally related with a benign clinical course with a rapid and persistent response.

**PB2100**

**THE ROLE OF MEAN PLATELET VOLUME IN NEONATAL SEPSIS: A RETROSPECTIVE CASE CONTROL STUDY IN A LEVEL III NEONATAL INTENSIVE CARE UNIT**

A. Srinivasan<sup>1,\*</sup>, X. Ameer<sup>1</sup>, M. Marron-Corwin<sup>1</sup>  
<sup>1</sup>Pediatrics, Harlem Hospital Center, New York, United States

**Background:** Sepsis is a relatively common diagnosis in the neonatal period. Apart from blood cultures which are the gold standard, C-reactive protein (CRP), total white blood cell count (WBC) and the ratio of immature to mature neutrophils (I:T) are considered to be useful markers of sepsis in the neonatal period. There are a few studies that show that mean platelet volume (MPV) is elevated in infectious disease processes.

**Aims:** The aim of this study was to investigate whether mean platelet volume is increased in neonates with sepsis.

**Methods:** Only term neonates were included in the study. Exclusion criteria included: (a) Any neonate born with a genetic defect, (b) Any neonate with suspected immunodeficiency, (c) Any neonate requiring surgery in the post-natal period, (d) Neonates admitted to NICU for hyperbilirubinemia, (e) Neonates requiring extensive resuscitation at birth resulting in documented Hypoxic Ischemic Encephalopathy or requiring transfer to a Regional Perinatal Center. Medical records were reviewed from March 2015 to June 2016 and a total of 114 eligible neonates were included in the study and they were divided into 2 groups: 39 neonates with clinical sepsis (as defined by either culture positivity and/or clinical features plus treatment with antibiotics exceeding 48 hours) and 75 healthy controls (as defined by neonates in whom antibiotics were never started or discontinued when cultures were negative for 48 hours and the absence of clinical features of sepsis). Total white blood cell count, C-reactive protein, immature to total neutrophil count and mean platelet volume drawn on two occasions (first within 24 hours and the second between 24 to 48 hours after delivery) were compared between the two groups.

**Results:** There was no statistically significant difference in the mean platelet volume between the study group and the control group (p value 0.9 in the first 24 hours and p value of 1 in the 24-48 hour sample). There was however, a statistically significant difference between immature to total neutrophil count and C-reactive protein on both samples (p value <0.0001) (Table 1).

**Table 1.**

Two-sample t-test for characteristics in the two groups

Measurements	Mean (se)		p-value
	Study	Control	
Age	39.2 (0.18)	39.1 (0.13)	0.4085
Weight (gm)	3409.0 (93.36)	3398.4 (529.70)	0.9156

Chi-Square Test for Gender Frequencies in the two groups

Gender	n (%)		p-value
	Study	Control	
female	31 (41.33%)	13 (33.33%)	0.4052
Male	44 (58.67%)	26 (66.67%)	

Comparison of markers between control and study group

	Study	Control	p-value
WBC1	14.3 (0.89)	14.5 (0.46)	0.2817
WBC2	20.4 (1.27)	17.9 (0.57)	0.1249
IT1	0.2 (0.03)	0.1 (0.01)	<0.0001*
IT2	0.1 (0.02)	0 (0.01)	<0.0001*
MPV1	8.7 (0.16)	8.7 (0.09)	0.9074
MPV2	8.9 (0.14)	8.8 (0.08)	1.0
CRP1	6.6 (1.98)	0.5 (0.21)	<0.0001*
CRP2	26.4 (4.17)	2.6 (0.44)	<0.0001*

\*Used a two-sample t-test. The others used a Mann-Whitney t-test.

**Summary/Conclusions:** In our study there was no statistically significant difference in the mean platelet volume values between neonates with sepsis and healthy controls. C-reactive protein and immature to total neutrophil count continue to be reliable markers of neonatal sepsis.

## PB2101

### IS PLATELET TRANSFUSION WARRANTED IN PATIENTS WITH ACUTE TTP REQUIRING CENTRAL VENOUS CATHETER INSERTION?

R. Low<sup>1,\*</sup>, T. Dutt<sup>2</sup>

<sup>1</sup>Postgraduate Department, Central Manchester Foundation Trust, Manchester, <sup>2</sup>The Roald Dahl Haemostasis and Thrombosis Centre, Royal Liverpool University Hospital, Liverpool, United Kingdom

**Background:** Thrombotic thrombocytopenic purpura (TTP) has a high mortality rate. The cornerstone of management is plasma exchange (PE) which usually requires urgent insertion of a central venous catheter. Patients often have a platelet count of <50x10<sup>9</sup>/L at presentation however, National BCBSH Guidance advises against platelet transfusion in TTP due to the perceived high aggregability state and reports of associated fatal thrombosis. The risk of thrombocytopenia related haemorrhage however creates anxiety and dilemma for the team responsible for line insertion and may lead to delays or unnecessary platelet transfusion.

**Aims:** The aim of the study is determine the average platelet count at time of line insertion and to see if any bleeding complications are observed.

**Methods:** We retrospectively reviewed all central venous catheter lines inserted in patients presenting to a regional TTP Centre over a 4-year period from 2012-2016.

**Results:** A total of 48 patients confirmed to have TTP with an ADAMTS13 <5% underwent line insertion: 94 central venous catheter lines were inserted: 40% femoral, 60%–internal jugular vein. The median number of lines inserted per patient episode was 3, with a range of 1-5. Median presenting platelet count for first line insertion was 25x10<sup>9</sup>/L (IQR 9-26 x10<sup>9</sup>/L). 70% of lines were inserted by critical care and the remaining 30% by interventional radiology. Platelet transfusion was not administered pre line insertion in any case. No significant bleeding complications were documented during or after line insertion. 5 patients had 'excessive oozing at the insertion site' documented, within the first 24 hours of insertion, for which no intervention was required. There were no deaths related to line insertion.

**Summary/Conclusions:** In conclusion, this study shows no significant bleeding risk associated with central venous catheter insertion in thrombocytopenic patients presenting with TTP. The results support guidance against prophylactic platelet transfusion in this setting and provide reassurance for teams tasked with central line insertion in this critically unwell patient group.

## PB2102

### LONG-TERM EFFICACY AND SAFETY OF THROMBOPOIETIN AGONISTS IN ADULT REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIA

M. Kalliou<sup>1</sup>, E. Gavrilaki<sup>1,\*</sup>, G. Papaioannou<sup>1</sup>, Z. Bousiou<sup>1</sup>, M. Iskas<sup>1</sup>, C. Vadioliou<sup>1</sup>, C. Lalayanni<sup>1</sup>, A. Athanasiadou<sup>1</sup>, R. Saloum<sup>1</sup>, A. Anagnostopoulos<sup>1</sup>

<sup>1</sup>Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

**Background:** Management of chronic immune thrombocytopenia (cITP) aims not only to increase and maintain platelet counts in safe levels, but also to improve quality of life. Thrombopoietin agonists eltrombopag and romiplostim have been approved in refractory ITP. The lack of randomized studies allows only for real-world data comparison on the two agents.

**Aims:** In the present study we evaluate and compare long-term efficacy and safety of eltrombopag and romiplostim in clinical practice and assess the switching feasibility between the two agonists.

**Methods:** Treatment with thrombopoietin agonists was initiated in 20 adult patients (pts) with refractory cITP between June 2011-2016. Patients resistant or intolerant to the first agonist switched to the second one. Complete response (CR) was defined as a platelet count of ≥100x10<sup>9</sup>/L.

**Results:** Eltrombopag was administered in 15 pts, 6 male:9 female with a median age of 46 years (19-76 yrs) for 13 months (1.4-54 mo). Patients had received a median of 1 previous treatment (range 1-7): corticosteroids (15/15), intravenous immunoglobulin (5/15), rituximab (2/15), vincristine (1/15), cyclosporine (2/15), romiplostim (2/15), danazol (1/15) and splenectomy (1/15). Before eltrombopag treatment, the majority (8/15) showed grade 4 (WHO) thrombocytopenia. Initial dose was 50 mg and increased to 75 mg daily in 3/15 pts and in combination with corticosteroids that were gradually tapered by the 5<sup>th</sup> week in 12/15. Median platelets value by the 2<sup>nd</sup> week of administration was 140x10<sup>9</sup>/L (5-450 x10<sup>9</sup>/L); whereas, by the 4<sup>th</sup> week increased to 185x10<sup>9</sup>/L (16-500x10<sup>9</sup>/L). At the end of follow-up, all patients but one achieved CR with median platelets of 145x10<sup>9</sup>/L (60-400 x10<sup>9</sup>/L). Regarding adverse events, 1/15 pt presented hemolytic anemia, 1/15 pt hepatotoxicity grade 2 with episodes of thrombocytopenia grade 4 and 1/15 pt pulmonary embolism during the second month of treatment. The latter 2 pts switched to romiplostim. Romiplostim was administered in 9 pts, 4 male:5 female aged 44 years (33-63 yrs) for 40.7 months (22.4-60.1). They had received a median of 3 previous treatments (range 1-8): corticosteroids (9/9), intravenous immunoglobulin (6/9), rituximab (6/9), vincristine (2/9), cyclosporine (2/9), eltrombopag (2/9), danazol (1/9) and splenectomy (2/9). The majority (5/9) presented thrombocytopenia grade 4 before romiplostim. Median platelets number by the 2<sup>nd</sup> week of administration was 50x10<sup>9</sup>/L (8-140 x10<sup>9</sup>/L); whereas, by the 4<sup>th</sup> week increased to 115x10<sup>9</sup>/L (20-400x10<sup>9</sup>/L). At the end of follow-up, 6/9 patients achieved CR with median platelets at 145x10<sup>9</sup>/L (110-400x10<sup>9</sup>/L). All patients received concomitant steroid treatment that was gradually tapered and stopped in 6/9 pts. 2/9 pts switched to eltrombopag due to thrombocytopenia grade 3 and 1/9 pt to danazol and low-dose steroids achieving CR. No adverse events associated with romiplostim treatment were reported.

No significant differences were found between the 2 treatment groups. All 4 patients that switched to the other agonist achieved CR without adverse events.

**Summary/Conclusions:** Our real-world data suggest that both eltrombopag and romiplostim are safe, well tolerated and highly effective in refractory cITP and furthermore, switching to another agonist is safe and effective. Future studies will determine predisposing factors for adverse events and more accurate classification of patients that will allow for better treatment guidance.

## PB2103

### VITAMIN D RECEPTOR GENE POLYMORPHISMS IN ADULT PRIMARY IMMUNE THROMBOCYTOPENIA

M. Sakr<sup>1,\*</sup>

<sup>1</sup>Internal Medicine- Hematology, Menoufia University, Cairo, Egypt

**Background:** Recently, several studies have demonstrated the role of vitamin

D receptor (VDR) polymorphisms in the development of autoimmune diseases. Vitamin D affect both innate and adaptive immune responses that have been blamed in immune thrombocytopenia (ITP) pathogenesis.

**Aims:** The aim of this study is to assess the association of vitamin D receptor gene polymorphism *BsmI* in cases of adult primary immune thrombocytopenia.

**Methods:** Vitamin D receptor polymorphism *BsmI* (rs1544410) was detected by Polymerase Chain Reaction followed by Restriction Fragment Length Polymorphism (PCR-RFLP). Deoxyribonucleic acid (DNA) samples were extracted from peripheral blood of 40 ITP patients and 60 geographically and ethnically matched healthy controls.

**Results:** Statistically significant difference was found in the *BsmI* polymorphism between ITP patients and controls ( $\chi^2=8.77$ , P value=0.01). The *BsmI* polymorphism B allele was higher in ITP group than that in controls but in statistically insignificant difference ( $\chi^2=2.125$ , P=0.145). *bb* genotype played a protective role in ITP incidence.

**Summary/Conclusions:** This is the first published report on VDR gene polymorphisms in adult primary ITP patients. The *BsmI* genotype was associated with increased risk for ITP incidence with no obvious effect on bleeding severity, platelet count nor site of bleeding.

## PB2104

### A SURVEY OF THE TREATMENT OF THE PREVENTION OF NAIT IN THE UK AND IRELAND

D. O'Keeffe<sup>1</sup>, V. Broderick<sup>1,\*</sup>

<sup>1</sup>UHL, Dept of haematology, Limerick, Ireland

**Background:** Neonatal alloimmune thrombocytopenia, (NAIT) is caused by maternal antibodies generated against alloantigens carried on fetal platelets, which cross the placenta and induce destruction of platelets in the fetus. In most cases the maternal immunisation is triggered by exposure to fetal blood at delivery. As a result, the clinical presentation tends to be more severe in subsequent pregnancies. Recent studies and guidelines have suggested that intravenous immunoglobulin (IVIg) with or without steroids can significantly reduce the severity of thrombocytopenia in subsequent pregnancies.

**Aims:** We set out to establish if there is consistency in the management of the prevention of NAIT across Ireland and the United Kingdom (UK).

**Methods:** A survey was set up on Survey Monkey and all members of the UK-Ireland Haematology group were contacted by email with a link to the survey in January 2015. In total 90 individual Specialists were contacted across 70 centres.

**Results:** 30 responses were received to the following questions. Who manages the prevention of NAIT in your centre? 34% of respondents stated that it was managed jointly by haematologist/feto-maternal specialists, with 26% responding it was overseen solely by haematologists and 40% solely by feto-maternal specialists. Secondly what risk stratification each respondent used to decide risk of NAIT in the current pregnancy? 82% stated that they took into account multiple risk factors but 18% stratified risk based only on the outcome of previous pregnancy. Thirdly how many groups do you define after risk stratification? 60% identified 3 strata of risk (standard, high and very high) with 40% classifying two risk groups (standard versus high risk). Fourthly respondents outlined their management of a standard risk group defined as confirmed thrombocytopenia with antibody. 43% give IVIg 1g/kg weekly from 20 weeks, 28% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 6% starting 1g/Kg IVIg from 24 weeks. 23% referred to feto-maternal specialist to decide IVIg. Just 20% give 0.5mg/kg of steroids from 20 or 32 weeks. For high risk pregnancies defined as confirmed antibody positive with previous intracranial haemorrhage (ICH) after 28 weeks: 36% of centres give IVIg 1g/kg from 20 weeks, 36% give 1g/kg from 20 weeks increasing to 2g/kg at 32 weeks with 14% giving 2g/kg from 20 weeks and 14% initiating at 12 weeks. 40% gave 0.5mg/kg of steroids varying from 12-32 weeks starting. 60% of centres use a very high risk protocol (ICH before 28 weeks) with more intensive IVIg starting at 12 or 20 weeks with steroids of variable intensity and duration. Finally respondents were questioned whether there was a planned delivery time and method for the pregnancy? 58% plan a delivery at 38 weeks with no specific delivery mode. 18% plan delivery at 38 weeks by caesarean section, 8% plan a caesarean section but with no set time and 16% have no specific protocol plan for delivery.

**Summary/Conclusions:** The results of this survey reveal that the optimal medical management for the prevention of NAIT, namely the medication, dosage and schedule vary widely reflecting the lack of good evidence to guide centres in this very challenging area. Based on this survey we plan with our colleagues in UKOS a prospective study of treatment and outcomes.

## PB2105

### THE EVALUATION OF REACTIVE OXYGEN SPECIES IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA AND HELICOBACTER PYLORI INFECTION VERSUS CHRONIC ITP WITHOUT HELICOBACTER PYLORI INFECTION

M.-A. Gaman<sup>1,\*</sup>, A. M. Gaman<sup>2,3</sup>

<sup>1</sup>"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, <sup>2</sup>Hematology, Filantropia City Hospital, <sup>3</sup>Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

**Background:** Chronic idiopathic thrombocytopenic purpura (ITP) is an acquired disease characterized by a low platelet count caused by an immunological peripheral platelet destruction or a decreased platelet production. Several studies have shown increased reactive oxygen species (ROS) levels in chronic ITP and also a possible association between *Helicobacter pylori* (*H. pylori*) infection and immunological peripheral platelet destruction.

**Aims:** To evaluate whether patients with chronic ITP and *H. pylori* infection exhibit higher ROS levels compared to patients with chronic ITP and no *H. pylori* infection and whether there are statistically significant differences between the two groups.

**Methods:** We studied 29 patients with chronic ITP (median age 39 years) hospitalized in the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, between 2014 and 2016 (informed consent obtained). All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. The patients were divided in two groups: patients with ITP and *H. pylori* infection (group A) and patients with chronic ITP without *H. pylori* infection (group B). Serological tests (ELISA) were used to indicate the presence of a *H. pylori* infection and reactive oxygen species were evaluated by FORT (Free Oxygen Radicals testing) test from a single drop of capillary blood, at the time of diagnosis, before the administration of any drug (the normal value of FORT is considered less than 2.3 mmol/L H<sub>2</sub>O<sub>2</sub>), using a CR3000 analyzer (Callegari SpA, Parma, Italy). The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

**Results:** Group A consisted of 11 patients positive for *H. pylori*, whereas group B included 18 patients with no *H. pylori* infection. ROS levels, measured by the FORT test, were elevated in both groups (between 2.8 – 3.6 mmol/L H<sub>2</sub>O<sub>2</sub>). However, statistically significant differences were found in favour of group A, with higher ROS values than group B. The A group also associated lower platelet counts and more patients pertaining to this group relapsed in comparison to group B.

**Summary/Conclusions:** In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via highly a immunogenic activity. On the other hand, association of *H. pylori* infection, via chronic inflammation, led to a supplementary increase in ROS levels and increased platelet destruction.

## PB2106

### IMMUNE THROMBOCYTOPENIA AND PREGNANCY: A SPANISH CASE SERIES OF 270 PREGNANCIES IN PRIMARY ITP.

T.J. González-López<sup>1,\*</sup>, J. Bastida<sup>2</sup>, P. Olivera<sup>3</sup>, I. Jarque<sup>4</sup>, S. Bernat<sup>5</sup>, B. Sánchez-González<sup>6</sup>, E. Bolaños<sup>7</sup>, G. Conesa<sup>13</sup>, N. Bermejo<sup>14</sup>, M. T. Alvarez<sup>15</sup>, C. Fernández-Miñano<sup>16</sup>, L. Guerrero<sup>17</sup>, S. Marcellini<sup>18</sup>, M. Sierra Pachó<sup>19</sup>, E. Parda<sup>20</sup>, C. Muñoz<sup>21</sup>, G. Hermida<sup>1</sup>, J.R. Gonzalez Porras<sup>2</sup>

<sup>1</sup>Department of Hematology, Hospital Universitario de Burgos, Burgos, <sup>2</sup>Department of Hematology, Hospital Universitario de Salamanca, Salamanca, <sup>3</sup>Department of Hematology, Hospital Valle de Hebron, Barcelona, <sup>4</sup>Department of Hematology, Hospital La Fe, Valencia, <sup>5</sup>Department of Hematology, Hospital la Plana, Castellon, <sup>6</sup>Department of Hematology, Hospital del Mar, Barcelona, <sup>7</sup>Department of Hematology, Hospital Clínico San Carlos, <sup>8</sup>Department of Hematology, Hospital Gregorio Marañón, Madrid, <sup>9</sup>Department of Hematology, Hospital de León, León, <sup>10</sup>Department of Hematology, Hospital de Avila, Avila, <sup>11</sup>Department of Hematology, Hospital Universitario de Valdecilla, Santander, <sup>12</sup>Department of Hematology, Hospital Clínico de Valladolid, Valladolid, <sup>13</sup>Department of Hematology, Hospital de Elche, Elche, <sup>14</sup>Department of Hematology, Hospital de Cáceres, Cáceres, <sup>15</sup>Department of Hematology, Hospital Universitario La Paz, Madrid, <sup>16</sup>Department of Hematology, Hospital Vega Baja, Orihuela, <sup>17</sup>Department of Hematology, Hospital Rio Carrión, Palencia, <sup>18</sup>Department of Hematology, Hospital de Segovia, Segovia, <sup>19</sup>Department of Hematology, Hospital de Zamora, Zamora, <sup>20</sup>Department of Hematology, Hospital Virgen del Puerto, Plasencia, <sup>21</sup>Department of Hematology, Hospital Infanta Leonor, Madrid, Spain

**Background:** Effect of pregnancy on the course of primary immune thrombocytopenia (ITP) is not well known. Besides, due to the lack of clinical assays, evidence about outcome predictors of pregnant and neonates born to mothers with ITP is scarce.

**Aims:** To evaluate management and results of pregnancy and delivery on pregnant ITP women and on their offspring.

**Methods:** All women diagnosed of primary ITP (according to international consensus criteria) from 2011 to 2016 in 23 Spanish Hematology Departments who had at least one pregnancy after ITP onset were included in this registry. **Results:** We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median platelet count was  $18 \times 10^9/l$  (IQR, 6-35). Median time from ITP diagnosis to pregnancy was 167 months (IQR, 0-366). Median number of pregnancies prior to ITP diagnosis were 1 (IQR, 0-2) with 1 pregnancy (IQR, 1-2) after ITP diagnosis as a median.

50.8% of women received corticosteroids, immunoglobulins (IVIg) (16.9%), rituximab (6.8%) and/or splenectomy (8.4%) as ITP treatments between or before new pregnancies. On the other hand, 26.4% of women needed treatment for ITP during pregnancy, mainly steroids (13.5%) and IVIg (10.2%). The median platelet-count nadir during pregnancy was  $74 \times 10^9/l$  (IQR, 36-172). 127 (47%) pregnancies suffered from non-haemostatic platelet levels (less than  $50 \times 10^9/l$ ) with 73 (27.0%) women who achieved less than  $30 \times 10^9/l$ . 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.

Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was  $110 \times 10^9/l$  (IQR, 76-181). 43 patients (23.4%) experienced 57 bleeding episodes.

We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.

**Summary/Conclusions:** Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy and/or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

**Background:** Immune thrombocytopenia (ITP) consists of various acquired disorders caused by autoantibodies against platelets resulting in increased platelet destruction and impaired thrombopoiesis. ITP is characterized as primary when an underlying etiology cannot be identified and secondary when a certain etiology exists. Data concerning ITP characteristics at a national level are limited.

**Aims:** The purpose of the study was to access systematically the demographic, clinical, laboratory and treatment-related data of ITP in Greece based on the national database (ITP registry) operated and supported by the Hellenic Society of Haematology.

**Methods:** Patient data were collected over 2013-2016. The data source is a unique database initiated and managed by the Haematology Department of the University of Crete (UoC) and supported by the Center of Information and Communications Technologies of the UoC. The registry has been configured for national and regional base usage considering hospitals as the core unit. A certified researcher/administrator has access to a platform where he/she can record and study patients' data. The entire project has been developed using the robust open source tools of operating systems and Relational Data Base Management System (RDBMS) packages.

**Results:** We analyzed data from 696 adult ITP patients registered from 14 different hospitals from all parts of Greece. The median age at diagnosis was 53 years (range 15-97 years). Two peaks were observed at the age of 19-30 and 71-80 years. There was a female (60.89%) versus male (39.1%) predominance with higher frequency of females in younger (19-30 years) and of males in older (71-80 years) ages. Females appeared with more severe thrombocytopenia. The median platelet count at diagnosis was  $15 \times 10^3/ml$ . The majority of patients presented with hemorrhagic symptoms (70.9%). The main manifestations were cutaneous bleeding (64%), oral cavity bleeding (20.9%), epistaxis (8.9%), menorrhagia (7.8%) and gastrointestinal bleeding (5.5%). 430 patients (61.78%) had

primary ITP and 266 (38.22%) secondary ITP. Among these secondary ITP cases, 44.22% were related to infectious agents, 25.74% to drugs, 17.17% to collagen vascular diseases and 12.87% to cancer. Patients with positive ANA antibodies with no evidence of any underlying diseases were included in the primary ITP group. The main patient comorbidities were hypertension (22.64%), thyroid disease (12.32%) and cardiovascular disease (10.17%). Treatment was given in 620 patients at diagnosis. Specifically, 577 (93%) patients were treated with corticosteroids, 322 (51.9%) with intravenous IgG, 265 (42.7%) with both, and 112 (18%) received other treatments including rituximab (4.8%), anti-D immunoglobulin (4%) and thrombopoietin receptor agonists (4%). The majority of the patients (85%) responded to the initial treatment. Follow-up data for more than one year are currently available in 259 patients (133 with persistent ITP and 126 with chronic ITP). Splenectomy has been performed in 59/696 patients (8.47%).

**Summary/Conclusions:** Primary ITP is more frequent than secondary ITP in Greece, the disease displays two peaks at the ages of 19-30 and 71-80 years, presents a female predominance and high frequency of hemorrhagic symptoms. Treatment is mainly based on corticosteroids and/or intravenous IgG. Registration and follow-up of larger number of patients and evaluation of response to various treatments are anticipated to extend our knowledge on the pathophysiology and natural history of ITP and may also reveal peculiarities at local level.

## PB2108

### PRESENTING SYMPTOMS AFFECT OUTCOME IN IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

J. Khwaja<sup>1,\*</sup>, F. Alwan<sup>1</sup>, C. Vendramin<sup>2</sup>, K. Langley<sup>2</sup>, M. Thomas<sup>1</sup>, J.P. Westwood<sup>1</sup>, M. Scully<sup>1</sup>

<sup>1</sup>Haematology Department, University College London Hospital, <sup>2</sup>Haemostasis Research Unit, University College London, London, United Kingdom

**Background:** Whilst immune mediated Thrombotic Thrombocytopenic Purpura (TTP) has classically been suspected by the presence of a pentad of symptoms (microangiopathic haemolytic anaemia, fever, disturbed neurological function, renal failure, thrombocytopenia), the limitations of this have long been recognized and a wide variety of symptoms are seen on initial presentation.

**Aims:** A retrospective review of the significance of specific symptoms and their duration on mortality.

**Methods:** A retrospective review of all consecutive admissions to a single tertiary center between 2009 and 2015. Only patients who required plasma exchange were included. Patients' symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

**Results:** 106 patients (68% female) were included with a median age of 48. 58% were Caucasian and 19.8% Afro-Caribbean. The mortality rate was 7.4% (n=8). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/petechial rashes (19.8%), speech disturbances (encompassing expressive/receptive dysphasia, aphasia, dysarthria and slurred speech, 19.8%) and TIA or stroke like symptoms encompassing hemiplegia or facial weakness/droop (16%). The highest rates of mortality were seen in patients who experienced loss of consciousness (mortality 33.3%), abdominal pain (mortality 22.2%) and heavy bleeding (mortality 16.7%). The anti-ADAMTS13 IgG level was not however significantly higher in these symptoms when compared to others (Table 1) suggesting microangiopathic thrombosis location plays an important role in TTP prognosis. The median duration of symptoms prior to presentation was 7 days (range 1-60 days). 8.5% of patients were asymptomatic, all relapsed TTP. Patients in the highest quartile for symptom duration (>10 days) had significantly higher anti-ADAMTS13 IgG antibody level than those in the lowest quartile for symptom duration (<2 days) (65% vs 26%, p=0.002) and may have increased mortality (symptoms <2 days mortality 7.4%, symptoms >10 days 14.3%, p=0.19).

**Table 1.**

Symptom (n)	Mortality	Antibody (NR: <6%)	Antigen (NR: 74-134%)
LOC (6)	33.3%	44%	2.9%
Abdominal pain (9)	22.2%	50%	3.3%
Heavy bleeding (18)	16.7%	28%	2.9%
Headache (29)	3%	44%	4.5%
Speech Disturbance (21)	4.8%	48%	4.2%
Tia/stroke symptoms (17)	5.9%	42%	4.8%
Pyrexia (16)	12.5%	32%	5.7%
Lethargy (15)	13.3%	58%	7%
Spontaneous Bruising (15)	6.7%	56%	6.4%
Confusion (10)	0%	48%	4.2%
SOB (10)	10%	45%	4.1%

**Summary/Conclusions:** Whilst there is little difference in the anti-ADAMTS13 IgG antibody and ADAMTS13 levels seen with different symptoms, there is a wide disparity in terms of mortality suggesting the effect of microangiopathic thrombosis differs by location. Abdominal pain, not previously recognized as a significant symptom in TTP, seems to be a poor prognostic indicator although this should be interpreted with caution given the sample size. Anti-ADAMTS13 IgG antibody level increases with symptom duration and this may lead to increased mortality.

**PB2109**

**NOVEL TECHNIQUES FOR MONITORING GALNZMANN THROMBASTHENIA PATIENT UNDERGOING SURGICAL INTERVENTIONS**

A. Barg<sup>1,2,\*</sup>, H. Hauschner<sup>1,2</sup>, M. Misgav<sup>1,2</sup>, E. Avishai<sup>1</sup>, N. Rosenberg<sup>1,2</sup>, G. Kenet<sup>1,2</sup>

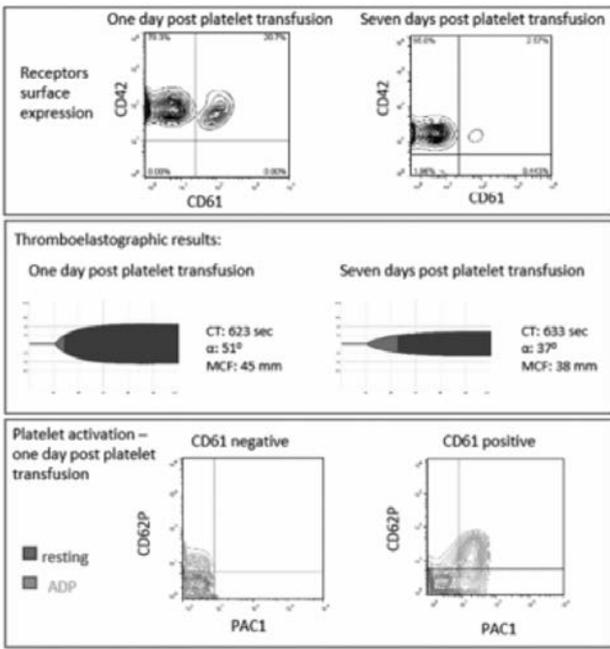

<sup>1</sup>Institute of thrombosis and hemostasis, Sheba medical center, <sup>2</sup>Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

**Background:** Glanzmann thrombasthenia (GT) patients undergoing surgical procedures are often treated by platelet transfusion. However many GT patients who have been previously exposed to platelets may form antibodies either against the missing  $\alpha$ IIb $\beta$ 3 antigen or directed against MHC-class molecules thus hampering the efficacy of care. Due to the rarity of disease there is paucity of data regarding platelet transfusion protocols during the perioperative period. We herein describe our experience with monitoring the proportion of donor platelets following transfusion, and their contribution to whole blood clot formation.

**Aims:** To describe the use of flow cytometry (FC) analysis in order to detect donor transfused platelets in A GT patient undergoing a minor surgical procedure and to assess the correlation between FC analysis and the results of Rotational thromboelastography(ROTEM).

**Methods:** A nine year old female patient with GT underwent teeth extraction. The Patient received platelet transfusion around the procedure. Complete blood counts, ROTEM, FC to detect the number of donor platelets and their ADP dependent activation, were sampled and followed till 7 days post teeth extraction.

**Results:** Prior to teeth extraction upon injection of local anesthetics patient developed a buccal hematoma probably owing to local blood vessel penetration. The patient did not experience any post extraction bleeding. Hematoma was absorbed within several days. Post transfusion platelets FC demonstrated 20.6%% donor platelets equivalent to 55,620 donor platelets. Platelets activation was determined following ADP addition by examination CD62 antigen expression. Seven days post platelet transfusion FC demonstrated 2.6% equivalent to 8,658 donor platelets. The decline in the number of active platelets was associated with a reduced clot firmness (MCF) and lower  $\alpha$ -angle as assessed by ROTEM (Figure 1).

**Figure 1.**

**Summary/Conclusions:** Clinical decision making in patients with GT may be aided by application of novel techniques, evaluating the number of active donor platelets and actual clot formation. This data may help making more knowledgeable decisions as for the need for further platelet transfusion or for the need for rFVIIa. Thus leading to improved monitoring and better patients' care.

**PB2110**

**CAN HISTOCHEMICAL C-MPL POSITIVITY IN BONE MARROW BE A PREDICTOR FOR SPLENECTOMY IN IMMUNE THROMBOCYTOPENIA?**

I. Yavasoglu<sup>1</sup>, N. Gencer<sup>1</sup>, F. Cantas<sup>2</sup>, F. Doger<sup>3</sup>, Z. Bolaman<sup>1,\*</sup>

<sup>1</sup>Adult Hematology, <sup>2</sup>Biostatistics, <sup>3</sup>Pathology, Adnan Menderes University Medical Faculty, Aydin, Turkey

**Background:** Splenectomy is used as the second line therapy in patients with immune thrombocytopenia (ITP). However, there is no parameter predicting splenectomy decision.

**Aims:** Aim of the present study was to evaluate immune histochemical Cloned Myeloid Leukemia Virus (c-mpl) positivity in bone marrow specimens of ITP patients with or without splenectomy indications.

**Methods:** Bone marrow specimens were taken from 24 patients who were diagnosed with ITP and who had splenectomy (15 female, 9 male, mean age 50±16) before splenectomy and 30 patients who were diagnosed with ITP but did not have splenectomy (15 female, 15 male, mean age 52±19). c-mpl staining was carried out retrospectively. Immunohistochemical (IHC) staining using Avidin-Biotin complex system (ABC) was conducted. For IHC, dissections prepared from blocks were taken onto poly-L-lysine coated slides (MicroSlides Snowcoat X-tra, Surgipath, Richmond, IL, USA) and kept in an incubator at 37 °C overnight. Dissections were treated with IHC c-mpl (Santa Cruz/sc-13187) stain. Cytoplasmic and nuclear staining was observed in megakaryocytes using IHC c-MPL and vitamin D. Evaluation was made based on the intensity of the staining; i.e. negative (0), weak (1+), moderate (2+) and strong (3+) (1). All patients who had splenectomy were in chronic phase of the disease. The present study was supported as a Scientific Research Project by Adnan Menderes University (TPF-15027).

**Results:** c-mpl positivity was statistically significant in patient group who did not have splenectomy (Table 1). In patient group who had splenectomy, c-mpl was not associated with refractory status.

**Table 1. c-mpl positivity in patients group who had and did not have splenectomy.**

	with splenectomy(n)	without splenectomy (n)	p value
c-mpl positivity(n)	1	12	<0.001
c-mpl negativity(n)	23	18	<0.001
Total (n)	24	30	<0.001

**Summary/Conclusions:** Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might be useful for splenectomy indication.

**PB2111**

**CLINICAL SIGNIFICANCE OF IMMATURE PLATELET FRACTION MEASUREMENT IN THROMBOCYTOPENIC DISORDERS DURING PREGNANCY**

R. Coll<sup>1,\*</sup>, A. Marull<sup>1</sup>, M. Sagüés<sup>1</sup>, N. Kelleher<sup>1</sup>, O. Jimenez<sup>1</sup>,

C. Morales-Indiano<sup>1</sup>, M. Serrando<sup>1</sup>

<sup>1</sup>Hematology Department, Institut Català de la Salut, Girona, Spain

**Background:** Thrombocytopenia is the second most common hematologic abnormality during pregnancy and is usually a benign condition. The challenge to the clinician is to weigh the risks of maternal and fetal bleeding complications against the benefits of diagnostic tests and interventions. This condition can also be associated with several diseases, either pregnancy specific or not, such as preeclampsia, HELLP syndrome, or idiopathic thrombocytopenic purpura (ITP). The differential diagnosis between ITP and gestational thrombocytopenia is clinically important with regard to the fetus, due to the risk of neonatal thrombocytopenia. The immature platelet fraction (IPF) is young cells that have recently been released into the circulation, and are considered indicators of bone marrow recovery. They contain a higher concentration of RNA than mature platelets. Measure of immature platelet fraction (IPF) has been suggested as a less invasive and early diagnostic test in the study of thrombocytopenic disorders. Immature platelet fraction can be currently measured by fully automated hematology analyzers providing clinical utility for diagnosing and monitoring thrombocytopenia.

**Aims:** The aim of this is to know whether IPF can be a useful parameter in pregnant women with thrombocytopenia to predict the potential risk of bleeding.

**Methods:** Pregnant women with thrombocytopenia were selected (2015-2016); a total of 25 patients (mean age: 33 yrs, range 19-43 yrs) were examined with platelet count <100.000 platelets/ $\mu$ L. Venous whole-blood samples were collected into Vacutainer EDTA-K2E tubes (Becton Dickinson and Company, Plymouth, UK). Complete blood counts and immature platelet fraction (%IPF) were immediately analyzed within 2 h of blood withdrawal by Sysmex XN20 system (Sysmex Corporation, Kobe, Japan). Novel PLT-F channel uses fluorescent light and stains platelets specifically with Oxazine Dye (Fluorescent Fluorocell). Bleeding complication has been collected in order to know if there is related to %IPF.

**Results:** Mean platelet count was 73.000 platelets/ $\mu$ L (range of 69-91) and IPF mean was 11% (2,5-23,4). Lab test Hemoglobin shows a mean of 95,17 g/L [range of 45-132] ( in no-bleeding group was 105,8 g/L whereas in bleeding-group was 86,14 g/L p=0,0768) p=0,07. IPF% was <10% in 11, which means a 44% of the patients. 14 patients bled during or after labor, 56% among all the patients in this study. Related to this group, 11 patients had IPF <10%; 3 of bleeding patients showed an IPF >10%. All pregnant women with an IPF <10% (11/11) bled as a complication. Pregnant women with thrombocytopenia and a IPF <10% has a higher risk of bleeding during and/or after labor compared with pregnant women with a IPF>10% (Fisher 12,41, P<0,001). 5 (20,83%) patients among all of them were under treatment (earlier or during labor): 3 (12,5%) with steroids and 2 (8,33%) with other methods.

**Summary/Conclusions:** Thrombocytopenia is a potential risk of bleeding during the labor. A high IPF indicates either consumptive or recovering thrombocytopenic disorders, such as immune thrombocytopenic purpura, while low IPF is characteristic of bone marrow suppression states. Although not directly used in clinical decision making, the reference range is critical to the introduction of new parameters and the interpretation of laboratory results. Our results suggest that IPF is an easy laboratory parameter to be measured and a level <10% might be an independent bleeding factor which can be useful for detecting high risk pregnant patients. It should be corroborated in further studies.

##### DOES EARLY RESPONSE TO FIRST LINE CORTICOSTEROID THERAPY PREDICT REQUIREMENT FOR SECOND LINE THERAPY IN IMMUNE THROMBOCYTOPENIA?

S. Kucukyurt Kaya<sup>1,\*</sup>, S. M. Bakanay<sup>1</sup>, T. Hacıbekiroğlu<sup>2</sup>, S. Akinci<sup>2</sup>, M. Gündüz<sup>2</sup>, S. Maral<sup>2</sup>, A. Senturk Yikilmaz<sup>1</sup>, I. Dilek<sup>1</sup>

<sup>1</sup>Department of Hematology, Ankara Yıldırım Beyazıt University, <sup>2</sup>Department of Hematology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

**Background:** Immune thrombocytopenia (ITP) is an acquired, immune-mediated disease that is characterized by increased destruction of platelets by autoantibodies. ITP is characterized by mucocutaneous bleeding. Rarely, life-threatening bleeding such as central nervous system bleeding can occur. Typically, patients have isolated thrombocytopenia. The diagnosis of ITP is one of exclusion. Corticosteroids are chosen as a first-line therapy for adult patients who require treatment. Responses to first line therapy with corticosteroids is about 80% with approximately 20% to 30% long term complete remission. Most patients finally relapse, requiring second-line therapy.

**Aims:** Our aim was to investigate potential effects of early platelet response to corticosteroid therapy on achieving long term complete remission.

**Methods:** We retrospectively evaluated 43 ITP patients who were followed-up at our institution. All patients' thrombocyte counts were below  $30 \times 10^9/L$  at diagnosis. All patients received initially methylprednisolone (MP) 1 mg/kg/day. For patients who responded with platelet count  $\geq 150 \times 10^9/L$  methylprednisolone was tapered over 3 months. Those who were unresponsive to MP or relapsed after a complete response, were treated with second line therapies that splenectomy or medical treatment agents. The platelet counts of the patients on day 0, 3 and 7 were evaluated by complete blood counts and were confirmed with peripheral smears examination. Effect of the platelet counts on day 3 and 7 were compared in terms of second line therapy requirement or not. A platelet count of  $>30 \times 10^9/L$  on day 3 and  $>100 \times 10^9/L$  on day 7 was considered as a complete response. Vaccination against encapsulated organisms was given and imaging was done to detect accessory spleen before splenectomy.

**Results:** Baseline characteristics of the cohort of 43 patients with an initial diagnosis of ITP are shown in Table 1. The mean age at diagnosis was 51 years (18-84) with female/male : 25/18. All patients presented with severe thrombocytopenia (platelet counts below  $30.0 \times 10^9/L$ ). Most patients presented with mucocutaneous bleeding (n=39), only three patients had genitourinary or gastrointestinal tract bleeding and one patient was asymptomatic. Bone marrow aspiration and biopsy was done in 14 (32.6) patients due to various reasons mainly, failure to respond to ITP treatment (7 patients) and advanced age (7 patients). On third and seventh day of MP therapy, median platelet counts were  $30 \times 10^9/L$  ( $2.0 \times 10^9/L$  -  $150 \times 10^9/L$ ) and  $100 \times 10^9/L$  ( $1.0 \times 10^9/L$  -  $347 \times 10^9/L$ ), respectively. When platelet counts on the 3rd and 7th day in each patient were compared, a significant association was found in correlation analysis ( $p < 0.05$ ). 21 patients (48.8) required second line therapy which were splenectomy (76.2%) or medical treatment (23.8%). Medical therapy consisted of rituximab, eltrombopag, danazol. There was a statistically significant difference between the patients with platelet count below and over  $30 \times 10^9/L$  on 3rd day of the MP therapy in terms of requirement for a second line therapy. ( $p = 0.04$ ). On the other hand, when 7th day was taken into consideration, there was not a statistically significant difference when cut off was taken as  $100 \times 10^9/L$  ( $p = 0.09$ ) or  $50 \times 10^9/L$  ( $p = 0.06$ ).

**Summary/Conclusions:** In the era of novel therapies used as second line, predicting the prognosis of an ITP patient at diagnosis has been a challenge. If disease related factors at diagnosis can be identified, then patients can be rescued from long term corticosteroid exposure and its adverse effects. Early response of platelet counts after starting corticosteroids seems to predict long-term complete remission. Expanding the study population may contribute more to our findings.

#### PB2113

##### THE IMPACT OF FC GAMMA RECEPTOR IIA AND IIIA GENE POLYMORPHISMS ON THE THERAPEUTIC RESPONSE OF RITUXIMAB IN EGYPTIAN ADULT IMMUNE THROMBOCYTOPENIC PURPURA

H. Ellithy<sup>1,\*</sup>, S. Hassan<sup>2</sup>, G. Shaheen<sup>3</sup>, M. Mattar<sup>4</sup>

<sup>1</sup>Internal medicine- Hematology subdivision, <sup>2</sup>Internal medicine, <sup>3</sup>Clinical Pathology, <sup>4</sup>Internal medicine- Hematology subdivision, Kasr Al-Ainy school of medicine- Cairo university, Cairo, Egypt

**Background:** Chronic primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by enhanced clearance of platelets and impaired platelet production. Corticosteroid is the ministry line of treatment of ITP, patients who fail to respond to steroid (steroid resistant) or who relapse (steroid dependant) face the options of treatment with second line including anti CD-20 monoclonal antibody rituximab. Rituximab is a chimeric IgG1 monoclonal antibody (mAbs). The major mechanism of action of rituximab is the antibody-dependent cellular cytotoxicity (ADCC), ADCC effectiveness is influenced by process of activation of effector cells via their immunoglobulin G fragment C receptors (FcγRs). Fcγ receptors show distinct affinity to bind to IgG subtype specificities. Differential response to rituximab has been reported to correlate with specific polymorphisms in two of FcγR genes: FcγRIIa (H131R) and FcγRIIIa (V158F) in some diseases.

**Aims:** To clarify the effect of FcγRIIa-131 R/H and FcγRIIIa-158 V/F genes polymorphism on the response to rituximab in ITP patients.

**Methods:** We studied the frequency of the FcγRIIa (H131R) and FcγRIIIa (V158F) gene polymorphisms, in 100 chronic ITP patients; divided into 2 equal groups, first group received rituximab ( $375 \text{ mg/m}^2$  per dose weekly for four weeks) and the other group received non-mabthera second line therapy. A polymerase chain reaction-restriction fragment length polymorphism assay [PCR-RFLP] was used to detect FcγRIIa-131 R/H and FcγRIIIa-158 V/F genes polymorphism. Evaluation of platelets counts was assessed initially before starting second line therapy then weekly for 3 months. At the end of third month the response to second line therapy was considered according to the following criteria; complete response (CR)  $PLT > 100 \times 10^9/L$ , partial Response (R),  $PLT = 30 - 100 \times 10^9/L$ , no response (NR),  $PLT < 30 \times 10^9/L$ .

**Results:** Regarding FcγRIIa gene (H131R) polymorphism distribution in the 100 patients; 28 patients (28%) had wild HH genotype, 41 patients (41%) have heterozygous genotype (HR) and 31 patients (31%) have homozygous mutant genotype (RR). In our study, the 100 ITP patients included showed wild type of FcγRIIIa (V158F) gene polymorphism. By the end of month 3 of the second line therapy, 43/100 patients (43%) achieved CR, 37/100 patients (37%) achieved PR and 20/100 patients (20%) achieved NR. Among the 50 patients who treated with Rituximab; 18 patients (36%) achieved CR, 19 patients (38%) achieved PR and 13 patients (26%) achieved NR. Out of the 18 patients who achieved CR, 8/18 patients (44.4%) carried FcγRIIa RR genotype and 7/18 patients (38.9%) carried FcγRIIa HR, compared to 3/18 patients (16.7%) carried FcγRIIa HH genotype. However it was not statistically significant. Among the 13 patients who achieved NR, lowest rate was patients carried FcγRIIa RR genotype 3/13 patients (23.1%) compared to HR (38.5%) and HH (38.5%) genotypes. However it is not statistically significant. The mean value of platelet count at end of week 1, Week 2 and Week 3 of rituximab therapy show statistically significant differences (P value 0.001) being higher in patients achieved CR than who achieved PR or NR.

**Summary/Conclusions:** The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRIIa RR genotype is predictive for better response to rituximab in ITP patients.

#### PB2114

##### IMMUNE THROMBOCYTOPENIA. EGYPTIAN EXPERIENCE WITH STUDY OF IL-17, TGFB, IL-35 AND IL-12 CYTOKINES IN CHRONIC AND PERSISTENT IMMUNE THROMBOCYTOPENIA PATIENTS

N. El Husseiny<sup>1,\*</sup>

<sup>1</sup>kasr al aini hospital, cairo, Egypt

**Background:** The role of T cells in the pathophysiology of immune thrombocytopenia (ITP) is heterogeneous and complex. It has been studied in active and reactive ITP but not to same extent in chronic and persistent type.

**Aims:** In this study we review the demographic features of 150 immune thrombocytopenic Egyptian patients and for cases who were chronic and persistent with negative both autoimmune screen and virology for hepatitis B and C

**Methods:** We measured IL-12, IL-35, IL-17 and TGF-β by ELISA to assess role of subtypes of T cells in the pathophysiology of ITP.

**Results:** Our results revealed Chronic and persistent cases who fulfilled the criteria for cytokine assay were 45 cases with a mean ( $\pm$  SD) age of  $31.60 \pm 8.78$  years. Thirty two patients were presented by skin manifestations (71.1%). Eight patients presented with mucous bleeding (17.8%) and five patients presented by combined skin and mucous membrane bleeding (11.1%). Comparison between the cases studied and control groups revealed statistically significant lower platelet count in cases rather than the control. While the four measured cytokines were statistically significant higher in cases rather than the control. Correlation between platelet count and the level of cytokines was statistically insignificant. All cases were under treatment by low dose corticosteroid in addition to another immunosuppression medication. No correlation between measured cytokines and platelet count.

**Summary/Conclusions:** The higher expression of IL-12 and IL-35 is due to persistently higher TH1 activity which explain continuity of the disease. While the higher expression of Treg cytokines (IL-17 and TGF-β) may be explained by effect of immune suppression use or up regulation of their receptors on Treg cells which have resistance to their activity. In chronic ITP, the level of T cell cytokines can't predict the course of disease.

**PB2115**

**SWITCH OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FLORENCE MONOCENTRIC EXPERIENCE**

C. Biagiotti<sup>1,\*</sup>, V. Carrai<sup>1</sup>, F. Bacchiari<sup>1</sup>, A. Bosi<sup>1</sup>  
<sup>1</sup>Hematology, Careggi Hospital, Florence, Italy

**Background:** Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet count of <100.000/µl in the absence of an identifiable underlying cause of thrombocytopenia. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction.

**Aims:** We evaluated patients treated with both TPO-mimetics.

**Methods:** From November 2008 and February 2017, 65 patients were treated with TPO-mimetics with a median follow up of 29 months (1-96): 39 patients underwent therapy with Romiplostim and 26 to Eltrombopag. In our study we evaluated 18 patients who received both therapies: among patients treated at first with Romiplostim, 10 patients (9F; 1 M) switched to Eltrombopag and 8 patients (3 M; 5 F) switched from Eltrombopag to Romiplostim. In the group of 10 patients treated at first with Romiplostim, 5 patients started Eltrombopag because were no responders, 3 for loss of response and 2 patients because of adverse events. In the group of 8 patients at first treated with Eltrombopag, 4 patients didn't obtain any response with Eltrombopag and switched to Romiplostim, 1 patient underwent to Romiplostim for loss of response and 3 patients because of adverse events.

**Results:** Among patients switched from Romiplostim to Eltrombopag, 2 achieved complete response, 4 response and 4 were no responders; among patients switched from Eltrombopag to Romiplostim, 4 obtained complete response, 3 response, 1 was no responder.

**Summary/Conclusions:** Romiplostim and Eltrombopag stimulate the TPO-R but have different mechanisms of action, therefore, in our limited experience switching from one thrombopoietic receptor agonist to the other could be beneficial in clinical practice for patients with severe chronic immune thrombocytopenia who failed to respond or experienced adverse events to the first treatment.

**PB2116**

**COEXISTENCE OF GLANZMANN'S THROMBASTHENIA AND MAPLE SYRUP URINE DISEASE: IMPLICATIONS FOR HEMOSTATIC MANAGEMENT**

M. Elshinawy<sup>1,\*</sup>, A. Alrawas<sup>2</sup>, Y. Wali<sup>2</sup>

<sup>1</sup>Pediatric Hematology, SQUH, Alexandria University, Muscat, Oman, Egypt,  
<sup>2</sup>Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman

**Background:** In Oman, autosomal recessive disorders are relatively commoner than western communities due to the high prevalence of inter-tribal marriage. Unfortunately, some patients have got more than one autosomal recessive genetic disorder, owing to complex consanguinity which might further complicate proper management plans.

**Aims:** To report an interesting case of combined Glanzmann's thrombasthenia and MSUD, and to review the existing data of platelet function disorders in Oman.

**Methods:** Case report and retrospective data analysis of all cases with confirmed or suspected platelet function disorders in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2006 till December 2016.

**Results:** We report a 4 year-old girl who is a known case of MSUD. Her parents are double first cousins (from both maternal and paternal sides). At the age of 3 months, she required Gastrostomy tube (G-tube) insertion. Preoperatively, full blood count and coagulation screen were perfectly normal. Unfortunately, she developed profuse bleeding at the site of G-tube insertion, followed by massive hematemesis. The patient received multiple blood products, but bleeding didn't stop. As an emergency measure, recombinant activated factor VII (rFVIIa) was given and resulted in cessation of bleeding. Platelet aggregation studies revealed defective aggregation with ADP, arachidonic acid, collagen and epinephrine which is consistent with Glanzmann's thrombasthenia. The diagnosis was further confirmed by platelet flow cytometry which showed no activity with CD41 and CD61, indicating absent GPIIb/IIIa complex. The patient experienced a severe bleeding phenotype, which is further complicated by multiple coexisting factors, including the recurrent episodes of metabolic crises which provoked worsening of platelet function, the development of platelet refractoriness at the age of 1 year, and the need for recurrent invasive procedures such as G-tube and central line insertion. Currently, the bleeding episodes are managed by rFVIIa at a dose of 120-180 µg /kg/dose. Excluding von Willebrand disease, we have 38 cases of confirmed or suspected platelet function disorders in our center, including 15 cases with Glanzmann's thrombasthenia, 7 cases with Bernard-Soulier syndrome, 5 cases with May-Hegglin anomaly and 11 cases of suspected, yet unconfirmed platelet storage pool deficiency.

**Summary/Conclusions:** In conclusion, children with platelet function disorders still have plenty of unmet needs, ranging from deficient accurate diagnostic facilities to the lack of agreed upon consensus management guidelines. The coexistence of another hereditary disorder may result in mutual management difficulties of both diseases. In developing countries, proper registry is needed to establish optimum care of such rare disorders.

**PB2117**

**ASSESSMENT OF PLATELET REACTIVITY TO ASPIRIN AND CLOPIDOGREL WITH POINT-OF-CARE VERIFYNOW® ASSAY AND TWO ALTERNATIVE METHODS IN PATIENTS WITH CEREBRAL ANEURYSMS TREATED WITH ENDOVASCULAR PROCEDURES**

D. Velasco-Rodríguez<sup>1,\*</sup>, R. Vidal<sup>1</sup>, S. Martín Herrero<sup>1</sup>, T. Castaño Bonilla<sup>1</sup>, A. García Raso<sup>2</sup>, M. Martínez-Galdámez<sup>3</sup>, P. Llamas<sup>1</sup>

<sup>1</sup>Hematology, <sup>2</sup>Health Care Institute, <sup>3</sup>Neuroradiology, Fundación Jiménez Díaz, Madrid, Spain

**Background:** Stent thrombosis and hemorrhage are the main complications after endovascular procedures for cerebral aneurysm treatment. Identifying an optimal pre-procedure response to antiplatelet therapy is essential to guarantee a successful result. A high variability in the individual responses to the antiagregant effect of aspirin and, specially, with clopidogrel has been reported. The VerifyNow® System (Accumetrics, San Diego, CA, USA) performs a turbidimetric-based optical detection of induced platelet aggregation in response to major antiplatelet agents (P2Y12 inhibitors, aspirin, GP IIb/IIIa inhibitors).

**Aims:** 1) To measure the antiplatelet effect of aspirin and clopidogrel with the point-of-care VerifyNow® assay in patients with brain aneurysms before undergoing endovascular treatment. 2) To compare the results with two alternative methods: impedance aggregometry, and PFA-100.

**Methods:** 38 patients with cerebral aneurysms, scheduled for elective endovascular procedure, were included in the study. All of them had started taking aspirin at a dose of 100 mg daily and clopidogrel at a dose of 75 mg daily 7 to 10 days before testing aspirin and clopidogrel sensitivity. The following functional tests were performed in all of them before the procedure: 1) VerifyNow® assay: Aspirin Reaction Units (ARU) <550 and P2Y12 Unit Reaction Units (PRU) <208 were considered to be good response to aspirin and clopidogrel respectively. PRU <85 was considered hyper-response to clopidogrel. 2) Impedance aggregometry from whole blood (Multiplate® analyzer, Roche Diagnostics, Mannheim, Germany): arachidonic acid (AA), adenosine diphosphate (ADP) and thrombin receptor activating peptide (TRAP) were used as agonists. TRAP was used to determine baseline platelet function. Aggregation with AA <40 U and aggregation with ADP <47 U were considered good responses to aspirin and clopidogrel respectively. 3) PFA-100: an overall assessment of platelet function was performed using epinephrine-collagen (COL/EPI) and ADP-collagen (COL/ADP) cartridges. Although COL/ADP is not an appropriate method to evaluate the effect of tienopyridines, we performed it to analyze whether hyper-responders to clopidogrel detected by VerifyNow® were also identified with PFA-100.

**Results:** The results of platelet function testing with three different methods are summarized in Table 1. None of the patients showed thrombocytopenia. Good response to aspirin was observed in 84.21%, 97.36% and 93.75% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. Good response to clopidogrel was detected in 86.84%, 38.88% and 62.5% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. VerifyNow® identified 6 (15.78%) aspirin-resistant patients. However, PFA-100 and Multiplate® assays showed a significant aspirin-mediated platelet dysfunction in 5 of them. Low response to clopidogrel was detected by VerifyNow® in 5 (13.15%) patients consistent with Multiplate® results. VerifyNow® identified 10 patients with excessive response, but only 2 of these results were reproduced by Multiplate® or COL/ADP. Multiplate® detected 19 patients (50%) with suboptimal response to clopidogrel, although these results did not correlate with those obtained by VerifyNow®.

37	344000	448	149					
38	240000	527	109	150	300	15	33	98

**Summary/Conclusions:** The effect of aspirin can be accurately measured by platelet aggregation and PFA-100 (with COL/EPI); however, VerifyNow® seems to identify a higher number of poor responders. Multiplate® assay using only

ADP is not good enough to detect clopidogrel-mediated platelet dysfunction since it is not specific for the P2Y<sub>12</sub> receptor. The addition of PGE<sub>1</sub> to the ADP test may increase its sensitivity. VerifyNow® assay seems to overestimate the effect of clopidogrel, since hyper-response data are not reproduced by other techniques. According to our results, a high interindividual variability in response to clopidogrel is observed.

#### PB2118

##### THROMBOPOIETIN-RECEPTOR AGONISTS IN ITP - EXPERIENCE OF A CENTER

M. J. Teles<sup>1,\*</sup>, M. Gomes<sup>2</sup>, F. Ferreira<sup>2</sup>, J. E. Guimaraes<sup>2</sup>

<sup>1</sup>Clinical Pathology, <sup>2</sup>Clinical Hematology, Sao Joao Hospital Centre, Porto, Portugal

**Background:** Thrombopoietin-receptor agonists (TRA), romiplostim and eltrombopag, are part of the treatment of chronic immune thrombocytopenia (ITP), resistant to first line therapy (corticosteroids and/or immunoglobulins) and with a significant bleeding risk. Both are approved for adult patients, but only eltrombopag was approved for pediatric use. When used before splenectomy, these treatments may serve as a bridge for surgery or even postpone/avoid the procedure.

**Aims:** In this report, we aim to evaluate the response to TRA treatment in patients with ITP and associated side effects in our center.

**Methods:** Inclusion criteria: patients with ITP resistant to first line treatment. Patients characteristics, response to TRA, clinical evolution and adverse effects were evaluated by retrospective analysis.

**Results:** Thirty-eight patients with ITP were included: 31.4% (12) were male and the median age at diagnosis was 38 years. 44.7% (17) had relapsed/resistant disease after splenectomy and 13.2% (5) were treated with a TRA as a bridge for this procedure. Sixteen (42.1%) of ITP patients were treated with romiplostim: 12 patients (75%) had a response to treatment, and 4 (25%) were resistant. In 11 of these patients, romiplostim was replaced by eltrombopag, either because of resistant disease, or more convenient administration (oral therapy). Thirty-three (86.8%) patients were treated with eltrombopag (5 pediatric cases): 27 patients (81.8%) responded while 6 patients had resistant disease (3 of these were HIV positive). The response rate was higher in patients with previous splenectomy (91.7% with romiplostim and 92.9% with eltrombopag) compared to those with no previous splenectomy (25% with romiplostim and 73.7% with eltrombopag). Six patients maintained response after treatment suspension (5 treated with eltrombopag and 1 treated with romiplostim). Generally, both treatments were well tolerated, with only one case of eltrombopag suspension because of a thromboembolic event.

**Summary/Conclusions:** In the current study, both TRA were effective in the treatment of ITP resistant to several lines of treatment, with similar response rates. As described in the literature, the response rate was higher in patients with previous splenectomy, and some cases maintained response after treatment suspension. The toxicity profile was acceptable. However, there are some concerns about their safety in long term therapy, namely the development of myelofibrosis, cytogenetic abnormalities and malignant evolution. Consequently, there is an urgent need for prospective studies to define the optimal period of treatment and surveillance, especially in pediatric patients. In our center, the median time of treatment with eltrombopag for all patients was 5.5 months (range between 1 to 34 months) and with romiplostim was 12 months (range between 1.5 to 85 months). The duration of treatment with eltrombopag in children and adolescents was around 6 months.

#### PB2119

##### THE EVALUATION OF REACTIVE OXYGEN SPECIES IN ESSENTIAL THROMBOCYTEMIA AND CORRELATION WITH JAK2V617F MUTATION

M.-A. Gaman<sup>1,\*</sup>, C. Moisa<sup>2</sup>, A. M. Gaman<sup>3,4</sup>

<sup>1</sup>"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, <sup>2</sup>Emergency County Hospital Slatina, Slatina, <sup>3</sup>Hematology, Filantropia City Hospital, <sup>4</sup>Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

**Background:** Essential thrombocytemia (ET) is a clonal disorder of the hematopoietic stem cells characterized by excessive myeloid proliferation, with predominant megakaryocytic expansion and a potential of transformation to acute myeloid leukemia. 50 to 60% of ET cases present a JAK2V617F mutation. 5% to 10% of JAK2V16F negative ET patients have MPL mutations at codon 515 and 50% to 70% of ET patients with non-mutated JAK2 and MPL (double-negative) carry mutations at exon 9 of CALR. Genomic instability in ET may be associated with an increased level of reactive oxygen species (ROS) which also leads to DNA damage. Hematopoietic stem cells of JAK2V617F positive murine models have higher ROS levels than found in normal mice (Marty et al, 2013).

**Aims:** To evaluate ROS levels in patients with ET and to observe if JAK2V617F positive cases associate higher ROS levels compared to patients without JAK2V617F mutation.

**Methods:** We studied 23 patients with ET admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, diagnosed with ET according to the

2008 revised WHO criteria (informed consent obtained). All analysis were performed after diagnosis and before the start of therapy. The JAK2V617F mutation was detected by allele specific polymerase chain reaction (PCR) testing. ROS levels were detected by flow-cytometry using a Cy Flow Space Sysmex flow-cytometer and a DCFDA Cellular ROS Detection Assay Kit. Studied parameters were compared both to healthy controls and to each other. Exclusion criteria were presence of any condition associated with an increased oxidative status (alcohol consumption, smoking, diabetes mellitus, hyperlipidemia, chronic renal failure, human immunodeficiency, cirrhosis, and active infection), use of antioxidants or iron supplementation. Data analysis was performed using Flow Max software. The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

**Results:** The study group involved 12 females and 11 males, with a median age of 48 years. All patients had increased ROS levels at diagnosis compared to healthy controls. Eleven patients had JAK2V617F mutation and twelve were JAK2V617F mutation negative. Significantly higher ROS levels were found in JAK2-positive patients compared to JAK2-negative patients.

**Summary/Conclusions:** In our study, patients with ET had increased ROS levels. Cases with JAK2V617F mutation associated higher ROS levels compared to those without JAK2V617F mutation. In our future research, we will focus on the follow-up of these patients for a period of four years and we will try to observe if increased ROS levels enhanced genomic instability and transformation to acute myeloid leukemia.

#### PB2120

##### VARIATIONS IN PARAMETRES OF PLATELET COUNT AND PLATELET VOLUME ACCORDING TO GESTATIONAL AGE

S. Akarsu<sup>1,\*</sup>, M. Aydin<sup>1</sup>, E. Taşkın<sup>1</sup>

<sup>1</sup>Firat Üniversitesi Tıp Fakültesi, Elazığ, Firat Üniversitesi Tıp Fakültesi, Elazığ, Turkey

**Background:** Reference ranges of haematological parameters in preterm infants are limited.

In hematological evaluation not only platelet (PLT) counts but also 3 important platelet volume parameters (mean platelet volume [MPV], platelet distribution width [PDW], plateletcrit [PCT]) are also taken into consideration.

**Aims:** We wanted to investigate the impact of gestational age by determining variations in platelet volume parameters according to gestational weeks.

**Methods:** Medical records were prospectively reviewed in preterm infants admitted to Firat University Hospital from January 2001 to December 2007. Study group consisted of only one-hour-old newborns delivered in the clinics of Department of Gynecology, and Obstetrics of our hospital. The exclusion criteria included those with maternal history of antepartum haemorrhage, chorioamnionitis, fever, sepsis, preeclampsia and hypertension; and perinatal history of twin-to-twin transfusion syndrome, fetomaternal transfusion, injury and infection. A hundred and ninety-three newborns with apparent health problems were excluded from our study. Study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. Blood samples from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance. We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

**Results:** Platelet counts increased beginning from the 26<sup>th</sup> up to 28<sup>th</sup> weeks. They did not change between 29<sup>th</sup> and 33<sup>rd</sup> weeks, while their levels rose again conspicuously between 34<sup>th</sup> and 37<sup>th</sup> weeks. At 38<sup>th</sup> week a dramatic increase occurred at 38<sup>th</sup> week. MPV, and PDW values slightly decreased, while PCT values increased dependent on the gestational age. When we classified newborns in groups of 24<sup>th</sup>-31<sup>th</sup>, 32<sup>th</sup>-36<sup>th</sup>, and 37<sup>th</sup>, and 38<sup>th</sup> weeks, prominent, and statistically significant variations were observed between groups.

**Summary/Conclusions:** We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

##### RISK OF LUPUS AFTER PRIMARY IMMUNE THROMBOCYTOPENIC PURPURA: A 14 YEAR SINGLE CENTER EXPERIENCE

M. Ayesh (Haj Yousef)<sup>1,\*</sup>, K. Alawneh<sup>1</sup>, Y. Khader<sup>2</sup>, F. Malkawi<sup>3</sup>

<sup>1</sup>Medicine, <sup>2</sup>Public Health, Jordan University of Science and Technology, <sup>3</sup>Department of Laboratory, King Abdullah University Hospital, Irbid, Jordan

**Background:** Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. ITP may occur concurrently or precede the occurrence of SLE, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Few studies have addressed the risk of systemic lupus erythematosus (SLE) after ITP.

**Aims:** To estimate the risk of SLE after ITP in adult Jordanian patients

**Methods:** All patients diagnosed with ITP and with a platelet count  $<100 \times 10^9/L$ , between September 2002 and January 2017 were included in the study. Patients were retrospectively reviewed for diagnosis of SLE, and inclusion criteria included only those patients who had initial ANA screen at the time of the first presentation of ITP. All patients with the diagnosis of SLE at the time and before the presentation of primary ITP were excluded from the study.

**Results:** This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.2 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference ( $p$ -value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus ( $P < 0.005$ ).

**Summary/Conclusions:** SLE developed in patients with primary ITP in with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant

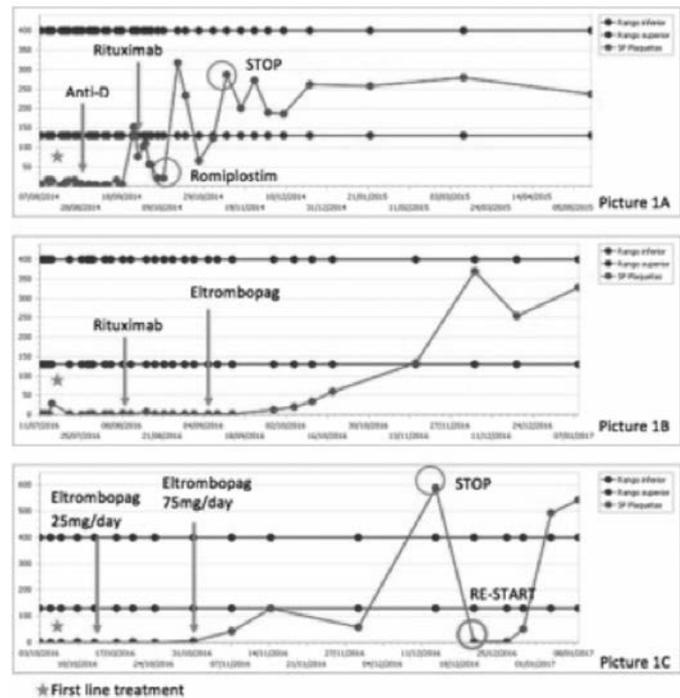

**PB2122**

**TREATMENT OF REFRACTORY IMMUNE THROMBOCYTOPENIA WITH THROMBOPOIETIN RECEPTOR AGONISTS: OUR EXPERIENCE IN CHILDHOOD**

J. Zanabali Al-Sibai<sup>1,\*</sup>, T. Arias Fernández<sup>1</sup>, M.P. Palomo Moraleda<sup>1</sup>, L.R. Morais Bras<sup>1</sup>, C. Castañón Fernández<sup>1</sup>, L.F. Ávila Idrovo<sup>1</sup>, A. Solé Magdalena<sup>1</sup>, S. González Muñoz<sup>1</sup>, M.Á. Fernandez Rodríguez<sup>1</sup>  
<sup>1</sup>Hematology, HUCA, Oviedo, Spain

**Background:** Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most affected children, ITP is a self-limiting disease. Approximately, 10% of all ITP patients eventually develop refractory ITP (RITP). Thrombopoietin receptor agonists (TPO-RA) stimulate thrombopoiesis and are an alternative to Rituximab (Rtx) and splenectomy.

**Aims:** We present 3 different children with RITP treated with TPO-RA.

**Figure 1.**

**Methods:** CASE 1. A 5-year-old girl admitted to the hospital due to ITP with mucocutaneous bleeding. She was refractory to corticoids, immune globulin (Ig) and anti-D Ig. Rtx was started. After the 3rd dose, she responded tem-

porarily along with fever, renal insufficiency and arterial hypertension, probably related to Ig A deficiency, not previously diagnosed. Romiplostim was indicated, reaching complete remission after 2 doses and it was stopped after the 4th dose, without any adverse reaction. Nowadays, plt count remains within normal limits (Figure 1A). CASE 2. A 5-year-old boy was diagnosed of ITP with cutaneous bleeding. He received treatment with prednisone and Ig with short response. Rtx was indicated; after 4th dose, severe thrombocytopenia and cutaneous bleeding persisted. Eltrombopag was started with response after 6 weeks of treatment (Figure 1B) and bleeding symptoms recovery. CASE 3. A 4-years-old boy with RITP was referred to our hospital. We decided to initiate treatment with Eltrombopag. He developed response after 4 weeks of treatment with a dose of 75mg/24h. Six weeks later, he presented 600,000plts/ $\mu L$ , so the drug was stopped. We observed a quick descent in plts levels and Eltrombopag was restarted with progressive response (Figure 1C).

**Results:** In all cases, splenectomy was avoided due to long-term risk of sepsis, as well as immunosuppressive agents like RTX in 3rd case. In 1st case, TPO-RA was able to stop with sustained response as described in some publications.

**Summary/Conclusions:** In our experience, TPO-RA appear to be efficacy and well tolerated in children.

**PB2123**

**INVESTIGATION OF PLATELET FUNCTIONS IN PSEUDOTHROMBOCYTOPENIA**

B. Onec<sup>1,\*</sup>, S. Cesur<sup>2</sup>, K. Onec<sup>2</sup>, E. Caliskan<sup>3</sup>, S. Cangur<sup>4</sup>  
<sup>1</sup>Hematology, <sup>2</sup>Internal Medicine, <sup>3</sup>Medical Microbiology, <sup>4</sup>BioStatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

**Background:** Pseudothrombocytopenia (pseudoTCP), is incorrectly detection of low platelet counts in automatic blood counter devices and is most frequently caused by ethylene diamine tetra-aseticacid (EDTA) induced platelet clumping and *in vitro* agglutination. Therefore, pseudoTCP which accounts 15-30 of thrombocytopenic admissions, actually is not associated with a bleeding tendency. This situation may be detected with a careful investigation of peripheral blood smears (PBS) by experienced clinicians but in centers which does not have these facilities; misleading of worried patients through advanced centers or even unnecessary treatments with steroids and platelet transfusions often occurs.

**Aims:** In theory, formation of platelet clusters in the presence of EDTA requires functional adhesion molecules, so platelet adhesion and aggregation tests are expected to be in normal range. We aimed to investigate the capacity of simple platelet function analyzers for making the distinction between pseudo TCP and real thrombocytopenia.

**Methods:** Platelet functions were measured as collagen-ADP and collagen-epinephrine closure times (ColADP and ColEPI) by Platelet Function Analyzer (PFA-200™) for all patients who are referred to our clinic as thrombocytopenia (TCP,  $plt < 150 \times 10^3/\mu L$ ) and value of this new method for determining pseudoTCP is compared with PBS which is accepted as the gold standard by using Receiver Operating Characteristic (ROC) curve analysis. PFA-200 system closure time is expected to be longer in true thrombocytopenia and normal in pseudoTCP, but there is no study investigated this system for this purpose. Descriptive analyses were presented using means  $\pm$  standard deviations for normally distributed variables or median and interquartile range (IQR) for nonparametric continuous variables. An overall  $p$ -value of less than 0.05 was considered to show a statistically significant result. This study is supported by Duzce University with project number of 2015.04.03.370 and these are preliminary results.

**Results:** We included 59 patients who were referred to our clinic with thrombocytopenia (TCP,  $Plt < 150 \times 10^3/\mu L$ ) and 11 healthy controls ( $Plt > 150 \times 10^3/\mu L$ ). Median age was 54 (IQR:37-68) for thrombocytopenic subjects and 37 (%63) of them were female. Median Plt count was  $61 \times 10^3/\mu L$  (IQR:30-90) in TCP group but WBC and Hb were not different from control subjects. Subjects referred with TCP were grouped with PBS as pseudo-TCP and real-TCP. There was no difference in terms of Plt, MPV, PCT, WBC or Hb between these groups but age was younger (median age 46 vs 62,  $p < 0.05$ ) and PDW was higher in pseudoTCP group (med 17.6 vs 16.8,  $p < 0.01$ ). ColEPI and ColADP measures were significantly lower (med 125 vs 287 for ColEPI, med 84 vs 224 for ColADP,  $p < 0.001$  for both) at pseudoTCP group. The capacity of ColEPI and ColADP values in predicting pseudoTCP were analyzed using ROC curve analysis. We found that, when the manufacturer's recommended cut-off value (150 s) was used, the sensitivity and specificity were 74.4% and 95%, with overall accuracy of 81.4% for ColEPI (AUC 0.813, SD:0.061,  $p < 0.001$ , %95CI: 0.694-0.933). Similarly sensitivity and specificity were 79.5%, and 95%, with overall accuracy of 84.7% for ColADP using manufacturer's cut-off value of 100 s (AUC 0.878, SD:0.055,  $p < 0.001$ , %95CI: 0.770-0.986).

**Summary/Conclusions:** We concluded that, running PFA tests for everybody with thrombocytopenic counts, could be used for differentiate pseudoTCP and realTCP in centers which does not have conditions for proper BS. Especially long closure times excludes pseudoTCP with a high specificity and could make clinicians quick decisions for further investigations.

## PB2124

**MANAGEMENT OF ADULT CHRONIC IMMUNE THROMBOCYTOPENIA. SINGLE CENTER EXPERIENCE**

C. Ionita<sup>1</sup>, I. Ionita<sup>1</sup>, D. Calamar-Popovici<sup>1</sup>, D. N. Oros<sup>1</sup>, M. Iordache<sup>1</sup>, M. Ionita<sup>1</sup>, I. Pascu<sup>1</sup>, M. Ibrose<sup>1</sup>, H. Ionita<sup>1,\*</sup>  
<sup>1</sup>UMF "Victor Babes" Timisoara, Timisoara, Romania

**Background:** The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely. Although many treatments have been recommended for ITP, there are no evidence-based recommendations for when different treatments should be used, or when any treatment should be used rather than managing a patient by observation alone.

**Aims:** To evaluate the treatment of ITP patients in Department of Hematology, County Hospital, Timișoara.

**Methods:** A retrospective study for 350 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient's medical charts for the 15 months prior to their most recent visit.

**Results:** The mean age was 45.6 years with 58% women and 42% men. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Regardless of the presence of bleeding symptoms, for majority of patients we started treatment based on platelet count. Treatment was considered when platelet counts are less than  $20 \times 10^9/L$  in patients without bleeding, and less than  $30 \times 10^9/L$  in patients with bleeding. Prior to the observational period, 36% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (42%). Corticosteroids represented 52% of treatments, followed by IVIg (20%), azathioprine (12%) rituximab and 8% Nplate. Splenectomies (8% of patients) and platelet transfusions (27% of patients) were performed during the observational period. In the patient survey, 52% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than  $10 \times 10^9/L$  in 49% of patients. The most common symptoms of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. The side effects were most frequently associated with corticosteroid use (43%). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13,5 days.

**Summary/Conclusions:** The retrospective study of 350 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

## PB2125

**IMMUNOLOGICAL THROMBOCYTOPENIC PURPURA AND PREGNANCY: A RETROSPECTIVE STUDY OF 89 PREGNANCIES IN 59 PATIENTS**

H. Brahimi<sup>1,\*</sup>, S. Taoussi<sup>1</sup>, Z. Bouchetara<sup>1</sup>, K. Rekrout<sup>1</sup>, M. T. Abad<sup>1</sup>  
<sup>1</sup>Hematology, EHS ELCC CAC, Blida, Algeria

**Background:** Immunological thrombocytopenic purpura (ITP) occurs for about 1 case for 1000 pregnancies. The risk of onset, aggravation or relapse of ITP during pregnancy is not clearly established.

**Aims:** The aim is to describe the prevailing ITP progression profile in pregnant women and to evaluate the risk of neonatal thrombocytopenia in two situations, when ITP was known before pregnancy and when ITP was discovered for first time during pregnancy.

**Methods:** It is a retrospective study carried out in the hematology department of CAC Blida, Algeria, between 1993 and 2016. All patients (pts) who had a pre-pregnancy ITP or thrombocytopenia during pregnancy attached to an ITP were included.

**Results:** The development of 89 pregnancies (PG), including two twins, occurred in 59 women was analyzed. There were one PG in 40 pts, 2 PG: 13 pts, 3 PG: 5 cases, 4 PG: 1 case and 5 PG: 1 case. Of the 59 pts: in 42 cases it was a history of ITP before pregnancy (group 1: G1) with a history of splenectomy in 9 patients, and in 17 cases it was ITP discovered on the occasion of Pregnancy (group 2: G2). The average age at diagnosis=26.7 years (7-44) and that at delivery=30.4 years (19-44). The mean platelet count at diagnosis: G1:  $34000 / \mu L$ , G2:  $47000 / \mu L$ . In the first group (G1): At the beginning of pregnancy the ITP was chronic in 30 cases, newly diagnosed in 1 case, persistent in 2 cases and transient cured in 7 cases; treatments previously received were: corticosteroid therapy (n=34), splenectomy (n=9), Danazol (n=1), cyclosporine in 1 case and cyclophosphamide in 1 case, abstinence in 7 pts, 2 of whom required corticosteroids during pregnancy. The status of the ITP at the beginning of each pregnancy was: out of treatment (n=8), corticosteroid dependence (n=5), non-response (n=7), PR (n=11), CR (n=24). In the second group (G2): the discovery of thrombocytopenia was in the first trimester (T) in 4 cases, in the second T in 6 cases and in the third T in 7 cases; 17 pts had platelet counts  $< 80000 / \mu L$  and were included due to the persistence or even worsening and / or necessity to resort to treatment of thrombocytopenia after delivery. In both groups: in 26 pts (G1:16; G2: 10) variable dose and duration

treatment were required during pregnancy; at delivery, 19 patients needed a treatment, out of them, a bolus of corticosteroids (n=11)+transfusion of platelets (n=4), immunoglobulins in 4 cases and transfusion of platelets alone in 4 cases. At birth, thrombocytopenia was observed in 40 pregnancies (50.6%): platelets  $< 30000 / \mu L$  (n=7), between 31000 and 50000  $/ \mu L$  (n=13), between 51000 and 100000  $/ \mu L$  (n=20), between 100000 and 150000  $/ \mu L$  in 2 cases. All pregnancies were completed: 14 by caesarean section, one for thrombocytopenia, with an average platelet count=95000  $/ \mu L$  and 75 by natural delivery with a mean platelet count=100000  $/ \mu L$  with 4 deaths born, one anencephaly and 88 newborns. No hemorrhagic syndrome was observed in pregnancy; two postpartum hemorrhages were seen in G2 group. Eleven newborns (5 in G1 and 6 in G2) were thrombocytopenic with platelet count  $< 20000 / \mu L$  in 4 cases; between 20000 and 50000  $/ \mu L$  in 7 cases; neonatal thrombocytopenia occurred during the first 7 days. Only 4 newborns were treated, one by corticosteroid and 3 by immunoglobulins, with a good progression and only one of the untreated is always followed for thrombocytopenia.

**Summary/Conclusions:** The de novo ITP appearing during pregnancy is an etiological eventuality to be evoked in front of a thrombocytopenia of the pregnant woman after elimination of the other causes related to the pregnancy and in front of the non-resolution after the delivery. The pre-existing ITP does not necessarily.

## Quality of life, palliative care, ethics and health economics

#### QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH MULTIPLE MYELOMA

B. Sidi Mohamed El Amine<sup>1,\*</sup>, H. Asma<sup>1</sup>, O. Fouzia<sup>1</sup>, S.A. Najet<sup>1</sup>, C. Malika<sup>1</sup>, Z. Naima<sup>1</sup>, Z. Zahia<sup>1</sup>

<sup>1</sup>Hematology department, University hospital of Sidi Bel Abbés, Sidi Bel Abbés, Algeria

**Background:** Multiple myeloma (MM), the second most common hematological cancer, remains incurable. Its incidence is rising due to population ageing. Despite the impact of the disease and its treatment, not much is known about health-related quality of life (QoL) of patients with MM.

**Aims:** This study aimed to (1) Determine symptom prevalence in patients with MM on disease-modifying treatment, and identify the range and nature of these symptoms within the dimensions of physical, psychological, social well-being. (2) Measure the QoL of patients. (3) Compare the above-mentioned parameters to the general population.

**Methods:** Adults with multiple myeloma attending the hematology day unit in hematology department from November 2016 to January 2017 were eligible for inclusion in a cross-sectional. Consenting patients completed 2 validated questionnaires, the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) supplemented by the myeloma-specific module (EORTC QLQ-MY20).

**Results:** Forty-seven patients were included for analysis: 51, 1% were male and 48,9% were female. Mean age was 64,7 years (range 42-82, standard deviation 11,50). The QoL scores were significantly lower than the general population (54,7 vs 71,2). The most commonly reported physical symptoms were pain (72%), fatigue (70%) and insomnia (66%). About 61% of the patients were burdened by financial worries. On multivariate analysis, a good performance status (PS≤1) and a response of the disease to therapy (at least a partial response) were associated with high scores of QoL (P=0,01, P=0,03 respectively).

**Summary/Conclusions:** Patients with MM have a lower QoL than the general population and are symptomatic across physical, psychological and financial domains. They represent a polysymptomatic patient cohort with a complexity of need that merits a holistic multidisciplinary approach, and consideration of specialist symptomatic or palliative care review.

### PB2127

#### QUALITY OF LIFE IN ANEMIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

N. Romanenko<sup>1,\*</sup>, S. Bessmeltsev<sup>1</sup>, A. Romanenko<sup>2</sup>, N. Potikhonova<sup>1</sup>, M. Zenina<sup>1</sup>

<sup>1</sup>Clinical Hematology, Russian Research Institute of Hematology and Transfusionology, <sup>2</sup>Neurology, Children Hospital of St. Olga, Sankt-Peterburg, Russian Federation

**Background:** Anemia is a common complication of patients with hematological malignancies (HM), which may progress undergoing antitumor treatment significantly decreasing hemoglobin concentration and occur symptoms as fatigue, dizziness, palpitations, dyspnea markedly reduce patient activity, resulting in impaired Quality of Life (QoL).

**Aims:** To compare of QoL in HM's patients with different grades of anemia.

**Methods:** In this study were included following patients (n=326) in the age of 19-82 (Me=65) years: myelodysplastic syndrome (n=37), acute myeloid leukemia (n=20), acute lymphoid leukemia (n=7), primary myelofibrosis (n=23), chronic myeloid leukemia in blast crisis (n=6), multiple myeloma in II and III st. (n=126), Non-Hodgkin's lymphoma in III-IV st. (n=40) and chronic lymphocytic leukemia in B or C st. (n=67). Patients were examined: 1) clinical blood test (hemoglobin concentration) to assess anemia's grade; 2) the Functional Assessment of Cancer Therapy-Anemia (FACT-An) scale to measure of QoL. The FACT-An questionnaire consists of a general questionnaire (FACT-G), measuring domains of physical well-being (PW), social/family well-being (S/FW), emotional well-being (EW), functional well-being (FW), an anemia-specific questionnaire – Anemia subscale (AnS), measuring fatigue-associated items – Fatigue subscale (FS) and non-fatigue-associated items – Non-Fatigue subscale (NFS). Patients were divided into six groups according to the Hb concentration: 1) the first group – Hb was 4.0-6.4 g/dl (Me=5.7 g/dl); 2) the second – Hb 6.5-7.9 g/dl (Me=7.2 g/dl); the third – Hb 8.0-9.4 g/dl (Me=8.6 g/dl); the fourth – Hb 9.5-10.9 g/dl (Me=10.8 g/dl); the fifth – Hb 11.0-11.9 g/dl (Me=11.4 g/dl); the sixth – Hb 12.0-14.4 g/dl (Me=13.0 g/dl). The sixth group was control.

**Results:** In the first group of patients (n=34) with severe anemia grade 4 QoL was revealed too poor; number of points in the subscale of PW was 14.0±0.9, in S/FW – 14.2±0.7; EW – 10.3±0.9, FW – 18.5±0.8, AnS – 41.2±1.6, FS – 27.8±1.3, NFS – 13.4±0.6. In the second group of patients (n=53) with anemia

grade 3 QoL was poor too; in PW was 13.3±0.8, in S/FW – 14.4±0.6, EW – 9.9±0.7, FW – 18.2±0.6, AnS – 38.5±2.3, FS – 26.8±1.7, NFS – 12.0±0.7. In the third group of patients (n=72) with anemia grade 2 QoL in the subscale of PW was 11.5±0.7, in S/FW – 14.0±0.5, EW – 8.6±0.6, FW – 16.9±0.5, AnS – 36.1±1.9, FS – 25.5±1.4, NFS – 11.6±0.6. In the fourth group of patients (n=70) with anemia grade 1 QoL in PW was 11.3±0.7, in S/FW – 14.3±0.6, EW – 8.4±0.8, FW – 16.9±0.7, AnS – 34.7±1.6, FS – 23.0±1.2, NFS – 11.7±0.6. In the fifth group of patients (n=41) with anemia grade 0 QoL in PW was 11.1±0.9, in S/FW – 14.9±0.8, EW – 7.6±0.6, FW – 16.4±0.5, AnS – 34.6±2.2, FS – 23.7±1.6, NFS – 10.9±0.7. In the sixth group of patients (n=56) without anemia QoL in the subscale of PW was 7.5±0.7, in S/FW – 13.6±0.6, EW – 6.4±0.5, FW – 14.8±0.7, AnS – 23.4±1.5, FS – 14.9±1.0, NFS – 8.4±0.6.

**Summary/Conclusions:** QoL was found too poor in patients with Hb <8.0 g/dl. QoL wasn't satisfactory in patients with Hb 8.0-11.0 g/dl. But the QoL improvement were greater in patients with Hb levels >11.0-12.0 g/dl (p<0.05). These data suggest that early correct anemia with red blood cells transfusions and erythropoiesis-stimulating agents can improve QoL in a clinically meaningful way.

### PB2128

#### AN ANALYSIS OF THE IMPACT OF LOCAL COSTS OF MEDICINES ON COST EFFECTIVENESS OF THE TREATMENT OF CANCER ASSOCIATED THROMBOSIS.

E. Reimer<sup>1,\*</sup>, D.M.R. Lipp<sup>2</sup>, M. Gotfredsen<sup>1</sup>, M. Feuerbach<sup>3</sup>

<sup>1</sup>Thrombosis, LEO Pharma, Ballerup, Denmark, <sup>2</sup>Haematology and Oncology,

<sup>3</sup>Health Economy, German Oncology, Hamburg, Germany

**Background:** New research has surfaced in relation to health care resource utilization and costs in Cancer Associated Thrombosis (CAT). The studies originate from the US and are difficult to transfer directly to other countries. A few studies in Europe focusing on the total cost of CAT seem to indicate that the cost data in the field of CAT varies greatly between regions. To examine the importance of region specific cost elements in relation to research related to CAT, we studied the cost driver in the newest and most relevant health economic research and compared it with the costs from 6 European countries as well as Canada.

**Aims:** To highlight the importance of localized or regionalized cost inputs as cost drivers when considering cost effectiveness in relation to CAT.

**Methods:** The cost driver is the medication in a recent analysis by Connell 2016 and thus the focus of our analysis. The American paper incorporates outcomes from 6 RCTs for treatment with LMWH in patients with CAT. The annual medication costs of LMWH for daily treatment in 365 days were 32,120 USD in wholesaler acquisition cost (WAC). For VKA the annual medication cost for 365 days was 44 USD. LMWH is the cost driver but is not cost effective due to the cost of it. The study finds that "The one-way sensitivity analysis shows that LMWH would become the preferred strategy once its annual cost was less than \$7177". In the present analysis, the daily cost acquisition cost Wholesaler Purchasing Price (WPP) (which corresponds to the American WAC) for a LMWH (prefilled treatment syringes with Tinzaparin) was gathered in 7 large markets using a data retrieval from IHS global insights systems (Jan 2016). In addition to this, the role of the cost driver was also compared to other publications.

**Results:** Simply by applying the local unit cost for the treatment with LMWH for these countries, the conclusion becomes notably different. LMWH becomes the cost effective alternative in the European countries as well as in Canada with annual costs below 7177 USD. The price for VKA is comparable to that in the US, and does not change the cost effectiveness ratio.

The data from the retrospective cost of CAT study that the cost of the hospitalization of was 19% of the total cost of CAT and the CAT medication 11% of the total cost of CAT. This outlines hospitalization is a cost driver as well and not only the medication. Similar conclusions were reached in other studies. In summary, the role of the cost driver can change as a consequence of the localization of the costs. This outlines the great variation in costs in terms of CAT, and the caution it must be used with (Table 1).

Table 1.

Average Wholesaler Purchasing Price (WPP) in USD for Tinzaparin prefilled treatment syringes	Annual WPP cost (365 days of treatment)	Tinzaparin below threshold for Cost Effectiveness outlined by Connell, 2016; 7177 USD pr year
UK	USD 2.847	Yes
Germany	USD 3.358	Yes
Spain	USD 3.176	Yes
France	USD 3.869	Yes
Sweden	USD 2.811	Yes
Greece	USD 2.993	Yes
Canada	USD 6.879	Yes

**Summary/Conclusions:** The exercise shows that using local input changes the conclusion and could potentially influence local evaluations related to the access for LMWH treatment for CAT. Tinzaparin was found to be a cost effective LMWH over VKA in 6 European Countries as well as in Canada, when local medication costs were used. This was in contrast to the conclusion in the US. Not using localized or regionalized cost inputs could potentially lead misinterpretations about cost effectiveness of CAT treatments.

#### PB2129

##### MINIMIZING THE RISK OF MUCOSITIS IN HEMATOLOGIC PATIENTS WITH TOPICAL PRODUCTS

I. Ursuleac<sup>1,\*</sup>, Z. Varady<sup>1</sup>, A. Enache<sup>2</sup>, A. A. Tomescu<sup>2</sup>, R. Dragan<sup>2</sup>, D. Coriu<sup>1</sup>  
<sup>1</sup>Hematology, <sup>2</sup>Fundeni Clinical Institute, Bucharest, Romania

**Background:** Mucositis is a frequent severe complication associated to aggressive therapies of hematological malignancies with chemo and/or radiation (therapy), conditioning therapy in stem cell transplants. Regularly occurs at 3 to 10 days after chemotherapy and about 6 to 8 weeks after radiotherapy. It is self-limited within 2-4 weeks, but in this period the patient is vulnerable to systemic infections (bacterial and fungal). It could also compromise the optimal timing and dosage of the chemotherapy schedule, induce psychosocial distress, prolonged hospitalization and finally, higher costs.

**Aims:** Evaluating the efficacy of GelX® in chemotherapy induced mucositis. GelX® is a topical product that contains Zinc gluconate+taurine, with bacteriostatic and anti-inflammatory effect, easy to use for the patient, in order to prevent and reduce pain and severity of oral ulcers, making a barrier for mucosae

**Methods:** A retrospective analysis of 77 adult patients: 17 with hematological treatments and 60 with allogeneic stem cell transplantation. 17 were diagnosed and treated between January 2015 and December 2016 with various hematologic malignancies (5 AML, 2 ALL – 1 Ph positive, 2 blastic phases of CML, 3 ALLT (CHOP/DA-EPOCH), 2 DLBCL (RCHOP), 1 FL (RCVP), 1 MM (radiotherapy), 1 Hodgkin disease (ABVD). Treatment regimens used for acute leukemias/blastic phases of CML were: "3+7" (3 cases), MEC (1 case), high doses ARA-C (1), GMALL protocol (1), HyperCVAD (1), Idarubicine and ARA-C(1) HD-MTX(1). GelX® was indicated as prophylactic treatment for eight patients, because the risk of mucositis was high (aggressive chemotherapy, bad oral condition, risk of prolonged neutropenia). Curative treatment of grade 3-4 mucositis was indicated for 10 patients (one was initially treated with curative intention and after that with prophylaxis). In 60 patients allografted for various hematological conditions (35 unrelated, 4 haplo and 21 sibling) GelX® was prescribed for treating grade 3-4 mucositis. For the 35 cases with unrelated allotransplant (21 AML, 4 ALL, 2 SA, 2ATLL, 2 MMM, 2 CML, 1 MDS, 1 BH), 16 cases of grade 3-4 mucositis has appeared. The conditioning regimen was myeloablative(14 cases) and reduced intensity( 21 cases). There were 21 cases of sibling allotransplants (6AML, 3 ALL, 1 ATLL, 5 LMNH, 1CLL, 2 SAA, 2 CML, 1 mycosis)with 10 cases of mucositis grade 3-4. The regimens used were 6 myeloablative and 15 nonmyeloablative. 3 from 4 cases of haplotransplant with nonmyeloablative conditioning (2MDS, 1 AML and 1 SAA) had grade 3 mucositis.

**Results:** Prophylactic treatment induced a reduction in the grading of mucositis (grad 1-2) and a shorter period of evolution (5 days) versus grade 3-4 mucositis and prolonged duration of oral lesions for those with curative treatment. From 60 patients allotransplanted, 30 patients experienced grade 3 and 4 mucositis with a medium duration of five days. All of them received GelX® as prophylactic treatment.

**Summary/Conclusions:** Prophylaxis is the key of successful evolution in mucositis (time to heal shorter than 10 days). Identifying candidates for mucositis is mandatory and the product should be applied starting with the chemotherapy (or in the first 24 hours on the onset of chemotherapy) in order to minimize the risk of mucositis appearance.

#### PB2130

##### EUROBLOODNET: THE EUROPEAN REFERENCE NETWORK IN RARE HEMATOLOGICAL DISEASES

M.D.M. Mañu Pereira<sup>1,\*</sup>, V. Gutierrez Valle<sup>1</sup>, J.L. Vives Corrons<sup>1</sup>, B. Gulbis<sup>2</sup>, P. Fenau<sup>3</sup>

<sup>1</sup>Red Blood Cell Pathology and hematopoietic defects Unit, Josep Carreras Leukaemia Research Institute, Barcelona, Spain, <sup>2</sup>Laboratoire Hospitalier Universitaire de Bruxelles - ULB, Brussels, Belgium, <sup>3</sup>Service d'Hématologie Séniors, Hôpital Saint-Louis - Université Paris, Paris, France

**Background:** Almost all hematological disorders are rare diseases, affecting less than 1 in 2000 individuals, justifying their inclusion in a European Reference Network (ERN). ERN are networks created following the Directive 2011/24/EU on cross border health which include nationally recognized Centres of Expertise aiming to ensure the same level of access to health services of European citizens affected by a rare disease. EuroBloodNet, the ERN in Rare Hematological Diseases (RHD), results from a joint effort of the European Network on Rare and Congenital Anaemias (ENERCA), the European Hematology Association (EHA), and European hematology patient organisations represented in both the EURORDIS European Patient Advocacy Groups (ePAGS) and the EHA Patient Organisations Workgroup. EuroBloodNet gathers 66 highly skilled and multidisciplinary healthcare teams in 15 Member States, and advanced specialized medical equipment and infrastructures which will facilitate concentration of resources for the design, validation and implementation of high-quality and cost-effective services aimed at facing the challenges of RHD.

**Aims:** EuroBloodNet's main goal is to improve the healthcare and overall quality of life of patients with a RHD by 1) Improving equal access to highly specialized healthcare delivery for RHD across Europe 2) Promoting best practices in prevention, diagnosis and safe clinical care across Europe 3) Disseminating cutting-edge knowledge and facilitating continuous medical education in the field of RHD 4) Providing inter-professional consultation by sharing of expertise and safe exchange of clinical information 5) Fostering European cooperation in highly specialized procedures for diagnosis, promotion of clinical trials and innovative treatments and research.

**Methods:** RHD are covered in two main thematic groups: non-malignant diseases and malignant diseases, and six sub-thematic areas. Non-malignant diseases include 4 sub-thematic areas: 1) Rare red blood cell defects 2) Bone marrow failure (BMF) and hematopoietic disorders 3) Rare Bleeding-Coagulation disorders and related diseases and 4) Haemochromatosis and hereditary iron metabolism disorders. Malignant diseases include 2 sub-thematic areas: 1) Myeloid malignancies and 2) Lymphoid malignancies. Methods and tasks aiming to achieve EuroBloodNet specific objectives have been split into five categories of Transversal Field of action (TFA): 1) Cross border health 2) Best practices 3) Continuing medical education 4) Telemedicine 5) Clinical trials and research.

**Results:** Expected outcomes include reduction of healthcare inequalities for RHD in the EU by a) establishing a cross-border referral system allowing safe information, samples and patient mobility, b) provision of equal access to highly specialised procedures and innovative therapies resulting from best practice sharing, continuous medical education and virtual inter professional consultation for complex RHD cases, and c) facilitation of a timely and efficient translation of research results into patient oriented strategy at the clinical and the public health level.

**Summary/Conclusions:** EuroBloodNet, with the experience gained thanks to the EU-funded ENERCA and EHA, will seek to improve access to healthcare for RHD patients, to promote guidelines and best practice, to improve training and knowledge sharing, to offer clinical advice where national expertise is scarce, and to increase the number of clinical trials in the field.

#### PB2131

##### 2016 REVISION OF WHO CLASSIFICATION OF TUMOURS OF HAEMATOPOETIC AND LYMPHOID TISSUES: IMPACT ON INVESTIGATING PATIENTS WITH ISCHAEMIC STROKE

C. Philip<sup>1,\*</sup>, J.D. Pandian<sup>2</sup>, M.J. John<sup>1</sup>, P.N. Sylaja<sup>3</sup>, A. Mathew<sup>1</sup>, S. Kaul<sup>4</sup>, D. Khurana<sup>5</sup>, M. Padma<sup>6</sup>, D. Arora<sup>2</sup>, A. B. Singhal<sup>7</sup>

<sup>1</sup>Clinical Haematology, <sup>2</sup>Neurology, Christian Medical College & Hospital, Ludhiana, <sup>3</sup>Neurology, Sree Chitra Tirunal Institute of Medical Sciences and Technology, Thiruvananthapuram, <sup>4</sup>Neurology, Nizam's Institute of Medical Sciences, Hyderabad, <sup>5</sup>Neurology, Postgraduate Institute of Medical Education and Research, Chandigarh, <sup>6</sup>Neurology, All India Institute of Medical Sciences, New Delhi, India, <sup>7</sup>Neurology, Massachusetts General Hospital, Boston, United States

**Background:** Under diagnosis related to the earlier hemoglobin (Hb) or hematocrit (Hct) diagnostic criterion is one reason to the 2016 revision of the diagnosis of PV in the World Health Organization (WHO) classification of Tumours of Haematopoietic and Lymphoid tissues. Bone Marrow Biopsy (BM) and molecular markers (JAK2) are recommended to establish the diagnosis in those with the lower threshold (Arber DA et al.2016). This potentially could result in increased numbers and costs of investigations. The lower thresholds are aimed to identify those previously referred to as masked PV (mPV) who have been recognized to have an increased incidence of thrombosis (Barbui T et al, 2014 & 2015). We hypothesized that the revision would increase the incidence of patients with Ischaemic stroke and potential PV who would then require additional investigations.

**Aims:** To determine number of patients with young strokes with potential PV on application of the 2016 revised WHO criteria for PV.

**Methods:** We undertook an analysis of records of patients with ischemic stroke prospectively maintained in the The Indo-US Stroke Registry and Infrastructure Development Project. This registry enrolled adult patients admitted with imaging-confirmed ischemic stroke <2 weeks after symptom onset. The Indo-US Stroke Registry and Infrastructure Development Project, includes 5 geographically diverse centers in India and one in USA. The registry data was entered into a central web-based electronic database. From January, 2012 to March, 2014, 2076 patients with new onset ischemic stroke were evaluable in the Indian arm of the Indo-US Stroke registry. We compared the incidence of polycythemia as per the 2016 revision against the earlier (2008) Hb diagnostic criterion.

**Results:** There were 24 (1.2%) patients with potential PV which was revised to 107 (5.2%) on applying the 2016 Hb criterion. The exact McNemar's test determined that there was a statistically significant difference in the proportion of polycythemics, p=0.000. Considering the potential of comorbidities in the elderly to confound the association of polycythemia with Ischaemic stroke, we

separately analyzed only those with young stroke (Age <45). In this cohort there were 420 patients. A total of 6 (1.4%) patients had potential PV based on the 2008 Hb criteria. On applying the 2016 revision; 37 (8.8%) patients fulfilled the Hb criteria. An exact McNemar's test determined that there was a statistically significant difference in the proportion of polycythemics,  $p=0.000$ . Separate analyses by gender was not significant in females,  $P=0.5$ ; but significant in males,  $p=0.000$ . There were an additional 29 males with the revised criteria for polycythemia. The impact of cost in influencing treatment decision from resource limited countries with predominant out of pocket health expenditure has been earlier reported (Philip C et al, 2015). This revision promotes the routine use of BM and JAK-2. In our analysis we estimate this new criterion would add to the costs to each patient (□ 7000 per our centre estimate).

**Summary/Conclusions:** The present data shows that there exists a significant difference in the incidence of polycythemia in thrombosis (Ischaemic Stroke) on applying the revised criteria. The requirement to additionally investigate them with BM and molecular markers for PV has potential economic implications.

## PB2132

### PATHOPHYSIOLOGICAL MECHANISMS INVOLVED IN THE DEVELOPMENT OF ANEMIA IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA

M.-A. Gaman<sup>1,\*</sup>, A. Papoi<sup>2</sup>, A. M. Gaman<sup>3,4</sup>

<sup>1</sup>"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, <sup>2</sup>University of Medicine and Pharmacy of Craiova, <sup>3</sup>Hematology, Filantropia City Hospital, <sup>4</sup>Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

**Background:** Non-Hodkin's lymphomas (NHL) are a group of heterogeneous malignant lymphoid disorders that associate anemia either from diagnosis or during the evolution of the disease. The anemic syndrome can be present at the moment of diagnosis or can develop during the evolution of non-Hodgkin's lymphomas, with negative effects on the therapeutic regimen due to reduction of intensity and density of drug doses, overall survival and quality of life of these patients. Various pathophysiological mechanisms responsible for the development of anemia are depicted in literature: pro-inflammatory cytokines and hepcidin action on iron metabolism and erythropoiesis, bone marrow failure caused by infiltration of malignant lymphomatous cells, cytopenias secondary to chemotherapy, immune peripheral destruction of red blood cells, iron and folate deficiency due to chronic bleeding.

**Aims:** To evaluate the prevalence of anemic syndrome in patients with non-Hodgkin's lymphomas and the pathophysiological mechanisms involved in the development of anemia.

**Methods:** A retrospective study was conducted on 85 patients (informed consent obtained) with non-Hodgkin's lymphoma, who were admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, in between 2013 and 2015, in order to evaluate the prevalence and pathophysiological mechanisms involved in the development of anemia in this study group.

**Results:** In our study group, the median age at diagnosis of non-Hodgkin's lymphoma was 64 years, sex distribution was males:females=1,3, and the rural to urban area index=1,2. 85,88% of patients had B type NHL and 14,12% T type NHL. 20% of NHL were indolent lymphomas, aggressive lymphomas in 54% cases and very aggressive lymphomas in 26%. NHL repartition on stage of disease revealed: type I – 2.35%, type II – 18.81%, type III – 57.64%, and type IV – 21.16%. In our study group, 84% of patients enrolled had anemia, with the anemic syndrome affecting the 50-59 years and 70-79 years age groups. 59.73% of patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the development of anemia were: perturbations of iron metabolism and erythropoiesis under pro-inflammatory cytokines and hepcidin actions (47.25%), bone marrow failure induced by lymphomatous infiltration (25%), anemia induced by chemotherapy (18.05%), and autoimmune hemolysis (9.7%). Five patients with anemia induced by chemotherapy and three patients with lymphomatous infiltration of the bone marrow also associated iron and/or folate deficiency.

**Summary/Conclusions:** In our study, anemia was present in 84% of NHL cases, more frequently found in patients that associated comorbidities and belonged to the 50-60 years and 70-80 years age groups. In half of the cases, anemia was moderately severe. 47.25% of patients had simple chronic anemia due to perturbations of the iron metabolism and of erythropoiesis, and 25% of patients presented anemia due to bone marrow failure. Chemotherapy lead to an anemic syndrome in 18.05% of cases, whereas hemolysis of autoimmune cause was responsible for 9.7% of cases of anemia diagnosed. The management of anemia is extremely important in patients with NHL because it influences the administration of chemotherapy (dose intensity and density), prognosis and quality of life.

## PB2133

### SAFETY OF RITUXIMAB BIOSIMILAR (NOVEX®) IN THE ROUTINE USE TREATMENT IN ARGENTINA.

G. Milone<sup>1,\*</sup>, M. I. Penna<sup>2</sup>, F. Fernandez<sup>2</sup>, E. Spitzer<sup>2</sup>, S. Millan<sup>3</sup>, S. Mariani<sup>3</sup>, N. Español<sup>3</sup>, R. Gomez<sup>2</sup>

<sup>1</sup>Hematología, Centro Médico Hematológico, <sup>2</sup>Laboratorio Elea, Buenos Aires, Argentina, <sup>3</sup>Mabxience, Madrid, Spain

**Background:** Novex® is a biosimilar by design of the reference product Mabthera®/Rituxan®. Novex® was approved in Argentina following ANMAT's Biosimilar guidelines, having the same indications as the reference product, and is commercialized by Laboratorio Elea. As part of its Risk Management Plan (RMP), Laboratorio Elea implements an active pharmacovigilance program as defined in Argentina regulation. Periodically reports ANMAT RMP status and results.

**Aims:** To describe frequency and pattern of adverse events during the use of NOVEX® in treatments registered along an active pharmacovigilance program in order to oversee the safety profile of NOVEX® in the real clinical practice and maintain the benefit-risk evaluation.

**Methods:** A treatment Registry for NOVEX® was implemented from the beginning of NOVEX® commercialization as part of the RMP. The Data Lock Point for this report is Jan 31<sup>st</sup>, 2017. Physicians prescribing NOVEX® were requested to fill a form indicating age and gender, treatment start date, treated pathology, dosing and dose frequency. Such data was recorded in a database. After a preset time, physicians were contacted by Laboratorio Elea to ask them about the treatment outcome and Adverse Event occurrences. If adverse events were detected they reported each occurrence as Individual Case Safety Report (ICSR), they were registered using the MedDRA dictionary (version 19.1) for its codification.

**Results:** The total number of participating physicians was 151. During this period, they reported 638 treatment initiations, 389 of which had at least 1 follow up point and were included in further analysis. 53% male. Mean age 64.1 years. Hematological indications were more than 90%. More than 90% of indications were approved indications. Nevertheless, we detected off-label use. Total cycles received for any approved indication had a mean number of 5.7. Total received Individual Case Safety Reports were 17, indicating a relative frequency of 4.4% of Individual Case Safety Report. Occurrence rates were 1.2 Individual Case Safety Report per 100 administered cycles, and 0.020 per 100 treatment days. Eleven Individual Case Safety Reports were classified as serious (SAE) because they had at least one manifestation that prolonged hospitalization, endangered life or was death-associated. The most frequent AE reported was acute reaction related to infusion (9 cases), followed by cardiovascular manifestations (2 arrhythmia, 1 cardiac failure and 1 ischemic stroke), infections (1 pneumonia, 1 progressive multifocal leukoencephalopathy), neurologic (1 paresthesia), cytopenias (1 pancytopenia) and cutaneous (1 bullous dermatitis).

**Summary/Conclusions:** The activities developed under this active pharmacovigilance program showed great value allowing us not only to monitor the adverse event pattern but also to detect off-label use as part of real life treatments. This report showed a similar safety profile to that of the reference product concluding that NOVEX®, in terms of tolerability, is similar to the reference product. Pharmacovigilance is cornerstone in the development of biologicals, especially biosimilars, as a tool to assist in the knowledge about their safety profile.

## PB2134

### DEPRESSION AS THE PRESENTING SYMPTOM OF CENTRAL NERVOUS SYSTEM LYMPHOMAS IN NORTHWESTERN TURKEY

E.G. Umit<sup>1,\*</sup>, D.B. Esen<sup>1</sup>, M. Baysal<sup>1</sup>, A.M. Demir<sup>1</sup>

<sup>1</sup>Hematology, Trakya University Faculty of Medicine, Edirne, Turkey

**Background:** PCNSL represents approximately 4 percent of newly diagnosed primary central nervous system (CNS) tumors, with an age-adjusted incidence rate of four cases per million persons per year. Most cases of non-AIDS related PCNSL are diagnosed in patients between 45 and 65 years of age, with a median age at diagnosis in the fifth decade. The most notable risk factor for the development of PCNSL is immunodeficiency including HIV infection, iatrogenic immune suppression, and congenital immune deficiencies. Antecedent flu-like or gastrointestinal illnesses or a history of autoimmune diseases were reported. Presenting symptoms may include focal neurologic deficits, neuropsychiatric symptoms, signs of increased intracranial pressure, seizures or ocular symptoms. Neuropsychiatric symptoms like depression, apathy, psychosis, confusion, memory impairment, slowness of thought are generally undernoted or underestimated due to the increased rates of depression and tendency towards antidepressant use. Diagnosis is based on imaging of the central nervous system (CNS), ideally with contrast-enhanced magnetic resonance imaging (MRI), cerebrospinal fluid (CSF) analysis, unless contraindicated due to elevated intracranial pressure. The radiographic lesion tends to be a solitary non-hemorrhagic mass, situated in the deep white matter adjacent to the ventricular surface.

**Aims:** We aimed to evaluate the presence of depression and antidepressant use before the diagnosis of CNS lymphoma and emphasize the duration between the diagnosis of depression and lymphoma.

**Methods:** Data of 40 patients with CNS lymphoma were evaluated in a retrospective manner. From their national health records, prescription for antidepressant and anxiolytic drugs with their psychiatric diagnosis, time before the diagnosis of CNS lymphoma, the branch of the prescribing physician, presenting symptoms

from their medical files, type and treatment of lymphoma and survival were recorded. OECD international statistics as well as Turkish Statistical Institute data for national antidepressant use were collected and interpreted.

**Results:** Of the 40 patients, 14 were male (35%) while 26 were female (65%). Mean age was 60,5 years (38-78). 7 patients were alive (17.5%). Method for diagnosis was radiological imaging (magnetic resonance imaging) in 27 patients (67.5%) while in 13 patients, diagnosis was supported with histopathological confirmation (32.5%). Mean survival was 8,6 months (2-24 months). As the complaint for medical help seeking, 4 patients presented with neuropsychiatric symptoms while 16 patients presented with headache (40%) and 20 patients (50%) presented with neurological defects. On the other hand, prior to lymphoma diagnosis, 7 patients were diagnosed as anxiety disorder and 13 as depression (total, 19 patients, 47,5%) and were prescribed antidepressant and anxiolytic medications. The mean duration between prescription of antidepressants and diagnosis of lymphoma was 2,6 months (0-10 months). Within the patients who were on antidepressants, 6 were female and 14 were male. **Summary/Conclusions:** OECD Health at a Glance data revealed that in 2013, the defined dose per 1000 per day is 35, range of Europe is 21-88. According to our data of Ministry of Health, use of antidepressants in the general population is 10,52%, mostly in women. Within these patients, 42,37% were anxiety disorders and 22,99% were depression. In the last five years' statistics, 30% of our population was prescribed for an antidepressant. The major group of physicians prescribing these medications was family and general physicians (>45%). The most striking finding of our study was the majority of male patients receiving antidepressants before the diagnosis of CNS lymphoma with a mean delay of diagnosis as 2,6 months (0-10 months). Depression and anxiety disorders are the leading diseases of disability and the importance of organic and underlying conditions should not be underestimated relying on the increasing need of antidepressants.

#### PB2135

##### IMPACT OF U.S. FDA APPROVAL OF LENALIDOMIDE MAINTENANCE THERAPY IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT ON TOTAL HEALTHCARE COSTS

K. Parikh<sup>1</sup>, J. Xie<sup>2</sup>, C. Chen<sup>3</sup>, C. Yang<sup>4</sup>, A. Farrukh<sup>5</sup>, P. Cockrum<sup>1</sup>, A.B. Agarwal<sup>1</sup>, S. Abouzaid<sup>1</sup>.

<sup>1</sup>Celgene Corporation, Summit, NJ, <sup>2</sup>Analysis Group, Inc, Los Angeles, CA, <sup>3</sup>Analysis Group, Inc, Boston, <sup>4</sup>Analysis Group, Inc, Boston, MA, <sup>5</sup>Analysis Group, Inc., Los Angeles, CA, United States

**Background:** Lenalidomide maintenance therapy after autologous hematopoietic stem cell transplant (auto-HSCT) in the first-line treatment has been shown to improve progression-free survival (PFS) and overall survival (OS) in multiple myeloma (MM) patients.

**Aims:** This study assessed the budget impact of the United States (U.S.) Food and Drug Administration (FDA) approval of lenalidomide maintenance therapy on total healthcare costs of a U.S. health plan.

**Methods:** An economic model was developed to estimate the incremental (additional) total plan costs (in 2016 USD) of maintenance therapy in each year for the first 3 years after lenalidomide monotherapy (R) maintenance therapy approval. The number of post auto-HSCT adult MM pts eligible for initiating maintenance therapy was estimated from published epidemiological data and an analysis of Connect® MM Registry data. Clinical endpoints for R-maintenance, including time on treatment, PFS and OS, were obtained from a meta-analysis of published clinical trials (CALGB, IFM, and GIMEMA). The use of common off-label maintenance therapies was considered. Types of costs included in the model were drug, drug administration, adverse events (AE), AE monitoring, one-time progression and terminal care costs.

**Results:** In a hypothetical U.S. health plan with 1 million members, the number of adult MM pts eligible to initiate post-ASCT maintenance therapy was estimated to be 28. Among them, 14.8 pts initiated R-maintenance in Year 1, 15.2 in Year 2, and 15.3 in Year 3, representing an incremental increase of 2.9%, 4.2% and 4.4% after R-maintenance therapy approval, respectively. After considering additional costs of maintenance, as well as potential offsets resulting from delayed progression the incremental total healthcare costs by year are listed in the Table 1. Results were consistent across all total plan, per patient per year, and per member per month costs. Deterministic sensitivity analysis showed that the model results were robust to the variations of key model inputs.

Table 1.

	Healthcare Costs		
	Year 1	Year 2	Year 3
Incremental Plan total	\$67,617	\$176,262	\$271,929
Incremental Per patient per year	\$2,405	\$3,222	\$3,402
Incremental Per member per month	\$0.0056	\$0.0147	\$0.0227

**Summary/Conclusions:** Approval of lenalidomide monotherapy for maintenance after auto-HSCT in the first-line treatment of MM has minimal impact on

total plan costs, primarily due to the small incident population and the already common use of lenalidomide in post auto-HSCT maintenance.

#### PB2136

##### LAPAROSCOPIC APPROACH CAN EXTEND THE INDICATIONS OF SPLENECTOMY: ANALYSIS OF 31 CONSECUTIVE PATIENTS WITH MALIGNANT HEMOPATHIES

A. Salaroli<sup>1,\*</sup>, B. Cadiere<sup>2</sup>, C. Spilleboudt<sup>1</sup>, M. Vercauysen<sup>1</sup>, A. de Wind<sup>3</sup>, M. Maerevoet<sup>1</sup>, G. Dapri<sup>2</sup>, G. B. Cadiere<sup>2</sup>, D. Bron<sup>1</sup>

<sup>1</sup>Department of Hematology, Institut Jules Bordet, ULB, <sup>2</sup>Department of Digestive Surgery, Hôpital St Pierre, <sup>3</sup>Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

**Background:** Surgical resection of large spleens may eliminate a significant amount of tumor, allow definite diagnosis of malignant disorder, ameliorate abdominal symptoms and resolve cytopenia. However, because of short term perioperative events (25%) and long term immunosuppression (increased risk of infections caused by encapsulated bacteria) physicians can be reluctant to choose splenectomy, especially in older patients or patients with comorbidities. The role of laparoscopic splenectomy (LS) in patients with hematological malignancies is still unclear. Nevertheless, the ageing of the world's population and the increased incidence of Non-Hodgkin's Lymphoma are increasing the indications for splenectomy, requiring a well-tolerated and less invasive procedure.

**Aims:** The aim of this review is to analyze our single-center experience of LS performed for malignant Hemopathies. Results are compared with LS for benign splenomegaly and the risk of locoregional dissemination or inadequacy of fragmented histological sample were analyzed.

**Methods:** We retrospectively analyzed 50 patients who underwent LS between 2005 and 2016 at Saint-Pierre Hospital. Anterior approach was used in 12 patients whereas in the remaining 38 cases, a semi-lateral position was chosen. All the patients received the triple vaccination (Streptococcus pneumoniae, type B Haemophilus influenzae, and Neisseria meningitidis). Patients characteristics, safety data such as early (<30 days) and late (>30 days) morbidities and mortality and efficacy (hematological recovery, accuracy of histological diagnosis) were analyzed.

**Results:** 19 patients underwent splenectomy for benign hemopathies (SBH) and 31 patients for malignant hemopathies (SMH). Non-Hodgkin's lymphomas (12) and idiopathic myelofibrosis (10) were the most common causes of splenectomy followed by chronic lymphocytic leukemia (7), hairy cell leukemia (1) and Hodgkin's lymphoma (1). Patients' age (67 +/- 12 years, ranging from 36 to 87 in SMH, and from 11 to 71 in SBH), prior abdominal surgery (18/31) and spleen volume (1515 +/- 662 mL, ranging from 220 to 3000ml in SMH, and from 90 to 1500ml in SBH) were significantly higher in the SMH group (p <0.05). There was no significant difference in surgical time (150 vs 146 min, p=0.8), blood losses (243 vs 402 mL, p=0.26) and duration of hospitalization (5.4 vs 7.5 days, p=0.19) between SMH and SBH. No case of locoregional dissemination was experienced. The early morbidity of the SBH group was 10% and 13% for the SMH group (p=1). Late morbidity was 0% in the SBH group and 13% in the SMH group (p=0.28). This could be explained by a combination of underlying disease and immunosuppression (2 sepsis and 2 deep vein thrombosis). There was one conversion to open surgery and perioperative mortality in each group (p=1). There was no significant difference in efficacy of splenectomy, with respectively 83% and 79% (p=0.91) or quality of histological sample for pathological report between SBH and SMH. In the SMH group, 4 out of 31 patients received a pre-surgical corticosteroid treatment, with a pre-surgical platelets level of 156 +/- 108 x 10<sup>3</sup>/mL, white blood cell level of 15696 +/- 18950/mL and Hemoglobin level of 10.1 +/- 1.6 g/dL. Regarding the efficacy of LS in correcting hypersplenism in the SMH, a significant difference in term of platelets recovery after 1 month from the surgery was shown in patients efficiently Vs inefficiently operated (respectively 387 +/- 125 Vs 138 +/- 90 x 10<sup>3</sup>/ml, p <0,05). The median follow up is 39 +/- 37 months and 80% achieved a hematological recovery.

**Summary/Conclusions:** LS is a safe and less-invasive procedure in patients affected by Malignant Hemopathies. This approach is also well tolerated in older patients (median 67yrs) and in patients with large spleen (1515+/660 ml), extending the indication for laparoscopic SHM even in older patient and in patients with high volume spleen. Compared to historical data, LSy for Malignant Hemopathies shows better early and late morbidities. Our data shows however a trend for higher late morbidity in the SMH group, warranting a careful long term follow-up in this subset of patients.

#### PB2137

##### ARE WE AWARE OF ANXIETY AND DEPRESSION IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA?

M.H. Dogu<sup>1,\*</sup>, R. Eren<sup>1</sup>, N. Nizam<sup>2</sup>, O. Yukus<sup>1</sup>, E. Suyani<sup>1</sup>

<sup>1</sup>Hematology, <sup>2</sup>Internal Medicine, Istanbul Education Research Hospital, Istanbul, Turkey

**Background:** Acute leukemia poses a high risk of stress for the patient during the process of diagnosis. The process after the diagnosis is challenging for the

patient due to urgent admission, long duration of stay in hospital, chemotherapeutic agents used in the treatment and the disease itself. Evaluating this group of patients for anxiety and depression, providing necessary professional support and revising medical treatment is therefore substantial.

**Aims:** In our study, we aimed to assess the risks of anxiety and depression in newly diagnosed acute leukemia patients who were admitted to hematology clinic to receive chemotherapy and provide necessary professional support along with treatment revisions and follow-up according to our findings.

**Methods:** Our study was performed with newly diagnosed acute leukemia patients, who were admitted to our hospital hematology clinic in a six-month period to receive chemotherapy. Demographic characteristics were noted and Hospital Anxiety and Depression Scale (HADS) was used to assess depression. Hospital Anxiety and Depression Scale (HADS) is an assessment scale developed by Zigmond and Snaith to determine the risks and assess the severity of anxiety and depression (8). The validation and reliability studies of the scale in Turkey were carried out by Aydemir et al (9). The questionnaire has a total of 14 items; seven of which measure anxiety (odd numbers) and the remaining seven (even numbers) measure depression. Each item is scored from 0 to 3. The scoring order of each item in the questionnaire is different. Items numbered 1, 3, 5, 6, 8, 10, 11 and 13 indicate decreasing severity and are scored as 3-2-1-0. On the other hand; items numbered 2, 4, 7, 9, 12 and 14 indicate increasing severity and are scored as 0-1-2-3. The cut-off value for the total score of the odd-numbered questions assessing anxiety is 10; while it is 7 for the even-numbered questions assessing depression.

**Results:** 21 patients were included in the study. 13 of these patients (61.9%) were diagnosed with acute myeloid leukemia (AML) and 8 (38.1%) were diagnosed with acute lymphoblastic leukemia (ALL). Median age of the patients was 45 (range: 21-69). 11 patients (52.4%) were female and 10 (47.6%) were male. 5 patients (23.8%) had comorbidities while 16 (76.2%) had none. Anxiety evaluation revealed that 38.1% of all patients in the study experienced anxiety. The rate of anxiety was 38.5% in AML patients and similarly 37.5% in ALL patients. 45.5% of the female patients had anxiety while the rate was only 30% in male patients. The difference was not statistically significant ( $p > 0.05$ ). Depression evaluation revealed that 81% of all patients in the study. The rate of depression was 84.6% in AML patients and 75% in ALL patients. 81.8% of the female patients had depression while it was 80% in male patients. Neither anxiety nor depression had a significant correlation with comorbidities or gender ( $p > 0.05$ ). Correlation analysis revealed a positive correlation between anxiety and depression ( $r=0.846$ ;  $p < 0.01$ ).

**Summary/Conclusions:** In conclusion, assessing anxiety and depression in patients with acute leukemia at the time of hospital admission is substantial for the course of and adherence to treatment. In our study, depression was distinctively more common than anxiety and there was a positive correlation between depression and anxiety. We think that including a professional for psychological support in the medical team is important for the treatment of these patients.

## PB2138

### GENDER DIFFERENCE IN ANXIETY FOR THE FIRST BLOOD TRANSFUION

Y. Lu<sup>1,\*</sup>, X. Zhang<sup>1</sup>, X. Li<sup>2</sup>, Y. Zou<sup>1</sup>, Z. Lin<sup>1</sup>

<sup>1</sup>the third Affiliated Hospital of Sun Yat-Sen University, <sup>2</sup>The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Blood transfusion has several risks including allergic reaction, acute hemolysis, infectious disease and so on. Both physicians and patients are always cautious to decide on blood transfusion.

**Aims:** The purpose of this study was to explore whether there are gender difference in anxiety for the first blood transfusion in patients with different diseases.

**Methods:** 315 patients (153 men and 162 women) were enrolled in this prospective, comparative study and median age was 38 years (range 17-72). The disease consisted of 85 chronic hepatitis B, 73 leukemia, 69 gastric ulcer, 48 chronic renal failure and 40 gynecological oncology. Various blood products including plasma, red blood cells suspension and platelet were infused. Anxiety was evaluated according to the HAMA self-rating anxiety scale (SAS) during the first blood transfusion. Patients got 50 points below were divided into no anxiety group, 50 to 59 points were divided into mild anxiety group, 60-69 points were divided into moderate anxiety group and 70 points or more were divided into severe anxiety group.

**Results:** For patients with the same disease, more female patients were divided into moderate to severe anxiety group than male ones. The number of patients with mild anxiety was similar in female and male, and no one was divided into no anxiety group.

**Summary/Conclusions:** Women were more anxious than men during the first blood transfusion, which is independent of age, race, education level and kinds of blood product.

## PB2139

### A ROOM OF MY OWN

L. Gov Ari De-Vries<sup>1,\*</sup>

<sup>1</sup>Hematology day center, Shaare Zedek Medical Center, Jerusalem, Israel

**Background:** Three years ago, a unit for autologous bone marrow transplant for hematological patients has been established in Shaare Zedek medical center. The patients meet with the doctors for the treatment plan usually following the diagnosis. From the point of view of a part of the patients, the process appears simple, short term, and promises cure. In reality, the process is long term, including aggressive chemotherapy prior to the transplant. The treatment is highly aggressive and toxic with many physical and mental side effects for the patient and his/her family. The transplant process requires hospital admission for about a month in an isolation room. No one is allowed in the room except for close relatives and the medical staff. The social worker, part of the caring staff, accompanies patients and families from the initial diagnosis through this taxing and stressful process. Most patients are young, average 45 years, in the middle of their careers, from a broad spectrum of occupations, education as well as social status, representing Israeli society.

**Aims:** 1. To accompany and empower patients by means of giving them tools to cope with the transplantation process which is a crisis situation in the midst of their lives. 2. To teach patients self-awareness. 3. Promote quality of life for the patients especially during the stay in the isolation room by way of creating a safe domain.

**Methods:** The following tools had been utilized: 1. The "Empowerment method". An advanced view of the powers and experiences of patients that constitute resources in addressing crisis. 2. Work of hope- finding unique meaning in life crisis.

**Results:** This work is based on therapeutic conversations that took place inside the isolation room with about 30 patients, mostly men, average age was 50, during the past three years. With the understanding that a patient goes from the public sphere to a private one -the isolation room- my entrance into the room was based on the ability and willingness of the patients to go into a treatment dialogue at that point and time. From the narratives of the patients, a few themes were extracted that were repeatedly discussed by most patients. 1. Fear of death. 2. Post-traumatic issues. 3. Fear of isolation. 4. The issue of relationships. 5. Mind and body. 6. Children. 7. Faith. 8. Closure

As cited by S.A, a 49 year old man "I'm afraid to give in and die, help me to stay alive. And if I die, I want to know that I have left no unfinished business."

**Summary/Conclusions:** From the therapy sessions it appears that the central issues that bother the patients belong to the private space and the coping with it. The process of treatment helps patients to go from the private sphere back to the public one.

**Recommendations:** It seems essential for the patients in the isolation room, undergoing autologous bone marrow transplant, to have therapy sessions with a qualified social worker as part of the holistic care. 'Having a room of his own' in the process enables an opportunity to examine the inner self esteem and strengths of the patients thereby patients learn to contribute to themselves from themselves.

## Sickle cell disease

### PB2140

#### HYDROXYUREA INHIBITS MYELOID DIFFERENTIATION VIA NITRIC OXIDE SYNTHASE

T. Subotički<sup>1,\*</sup>, O. Mitrović Ajtić<sup>1</sup>, M. Diklić<sup>2</sup>, S. Vignjević Petrinović<sup>1</sup>, M. Budeč<sup>1</sup>, D. Djikić<sup>1</sup>, J. Santibanez<sup>2</sup>, V. Čokić<sup>2</sup>

<sup>1</sup>Laboratory of neuroendocrinology, <sup>2</sup>Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

**Background:** Hydroxyurea and nitric oxide (NO) inhibit erythroid differentiation, while hydroxyurea is NO-releasing agent used in therapy of sickle cell diseases.

**Aims:** To study the mechanism of hydroxyurea inhibition of erythroid differentiation by exploring NO synthase (NOS) dependence.

**Methods:** The erythroid differentiation is studied by methylcellulose colony assay in mice, whereas presence and activation of endothelial NOS (eNOS) by immunocytochemistry and immunoblotting, respectively in K562 erythroleukemic cell line.

**Results:** In *ex vivo* experiments, mice exposed 7 days to hydroxyurea demonstrated significant decrease in the number of nucleated cells per femur, partially reversed by NOS inhibitor N-nitro L-arginine methyl ester hydrochloride (L-NAME). The same, but less prominent reduction has been observed with NO metabolites nitrite (NO<sub>2</sub>) and nitrate (NO<sub>3</sub>). Moreover, hydroxyurea demonstrated a large diminution in the number of bone marrow derived myeloid colony-forming unit-granulocyte/macrophage (CFU-GM), burst-forming-units-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) colonies in methylcellulose cultures. L-NAME attenuated hydroxyurea reduction of myeloid and erythroid colonies, while by itself increased CFU-E and CFU-GM colonies and slightly BFU-E colonies. NO metabolites NO<sub>2</sub> and NO<sub>3</sub> generally inhibited myeloid and erythroid colonies, but the reduction was more prominent by NO<sub>2</sub> compound. Moreover, the hematological parameters and weight (before and after treatment) of mice did not show any significant difference among studied groups. Hydroxyurea increased NO production and the number of eNOS positive K562 erythroleukemic cells, while phosphorylation of eNOS and activation of AKT/mTOR signaling was not blocked by phosphatidylinositol 3-kinase inhibition.

**Summary/Conclusions:** NO prodrug hydroxyurea demonstrated NOS dependence in inhibition of myeloid / erythroid differentiation, not influencing the hematological parameters.

### PB2141

#### SLEEP DISORDERED BREATHING IN CHILDREN AND ADOLESCENT WITH SICKLE CELL DISEASE: IMPACT ON EXECUTIVE FUNCTION AND PROCESSING SPEED INDEX

M. Koelbel<sup>1,\*</sup>, J. Kawadler<sup>2</sup>, H. Stotesbury<sup>2</sup>, P. Balfour<sup>2</sup>, F. Kirkham<sup>1</sup>

<sup>1</sup>UCL Great Ormond Street Institute of Child Health <https://www.ucl.ac.uk/ich>, London, United Kingdom, <sup>2</sup>Developmental Imaging & Biophysics, UCL Great Ormond Street Institute of Child Health <https://www.ucl.ac.uk/ich>, London, United Kingdom

**Background:** Studies in non-syndromic children have shown that sleep-disordered breathing (SDB) increases the risk of neuropsychological deficits and neuronal brain injury. Few authors have investigated the role in cognitive deficits of SDB and the associated hypoxia in children with sickle cell disease (SCD). Snoring and SDB is very common in children with SCD and may affect cognitive function in very young children. Previous data suggested that executive function was worse in older children with SCD and low mean overnight oxygen saturation.

**Aims:** We aim to investigate if SDB could be a potential factor contributing to developmental problems in cognition in children and adolescent with SCD.

**Methods:** We have followed up children and adolescents in the Sleep Asthma cohort who underwent Polysomnography at two different time points (1) 2006-2009 and (2) 2011-2014 and compared the sleep data with subsequent neuropsychological assessment.

**Results:** Worse performance was found for processing speed: PSI ( $p < 0.01$ ) and general intelligence ( $p < 0.05$ ) compared to control siblings. SDB, measured as apnea and hypoxia index (*i.e.* AHI  $> 3\%$ : Apnoeas and hypopnoeas with more than  $\geq 3\%$  desaturation), was found to impact executive function, as measured with the Tower test, ( $p < 0.05$ ) and PSI ( $p < 0.05$ ). Mean oxygen saturation during total sleep time was significantly associated with lower PSI ( $p < 0.05$ ). Additionally, participants who showed a worsening of their SDB symptoms in their second sleep study had lower cognitive scores (*i.e.*, executive function,  $p < 0.05$  and PSI,  $p < 0.05$ ) (Figure 1).

**Summary/Conclusions:** SDB symptoms seem to worsen into adolescence and therefore, might have a neurodevelopmental impact if left untreated; appropriate intervention might improve cognition and quality of life.

### PB2142

#### LUNG FUNCTION IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL ANEMIA: A COMPARISON BETWEEN UK AND ITALY

C. De Pieri<sup>1,\*</sup>, M. Arigliani<sup>1</sup>, R. Colombatti<sup>2</sup>, L. Sainati<sup>2</sup>, K. Vecchiato<sup>3</sup>, S. Ndoro<sup>4</sup>, P. Cogo<sup>1</sup>, B. Inusa<sup>4</sup>

<sup>1</sup>Department of Clinical and Experimental Medical Sciences, University Hospital of Udine, Udine, <sup>2</sup>Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, <sup>3</sup>University of Trieste, Trieste, Italy, <sup>4</sup>Department of Pediatrics, Evelina Children's Hospital, London, United Kingdom

**Background:** Acute and chronic respiratory complications are common in sickle cell anemia (SCA). Subjects with SCA often have a progressive decline of lung function with age that could be influenced by the quality of healthcare and by environmental factors, such as the level of exposure to air pollution.

**Aims:** To compare lung function, evaluated cross-sectionally through spirometry, in children and adolescents attending sickle cell centers in UK and Italy.

**Methods:** Anthropometry and spirometry were recorded in patients with SCA (SS, S<sub>b</sub>) aged 6-17 years of African ancestry followed at the Evelina Children's Hospital, London, UK, and at the University Hospitals of Padova and Udine, northeast of Italy. Subjects from the British cohort lived in an urban area while those from Italy came from urban and non-urban areas. Exclusion criteria were the presence of SCA-related morbidity within the last two weeks and the inability to perform a spirometry meeting the *European Respiratory Society* acceptability and repeatability criteria (Miller, *Eur Respir J* 2005;26:319-338), modified for children (Kirkby, *Pediatr Pulmonol* 2008;43:1233-1241). Portable spirometers (Pony FX, Cosmed-IT, Easy-on PC, NDD-CH) were used. Z-scores of anthropometric and spirometric data were derived, respectively, from CDC2000 and from the *Global Lung Initiative 2012* predictive equations for African Americans (Quanjer, *Eur Respir J* 2012; 40:1324-1343). Spirometry patterns were classified as normal, obstructive ( $zFEV_1/FVC < -1.64$ ) or restrictive ( $zFVC < -1.64 + zFEV_1/FVC \geq -1.64$ ). Differences between groups were assessed by t-tests and considered statistically significant for p values  $< 0.05$ .

**Results:** A total of 101 children and adolescents were included (n. 62 in UK; n. 39 in Italy; 42% girls; age-range: 6.2-17.9 years). We didn't find significant differences in mean spirometry indices between the SCA cohort from London and northeast Italy (Table 1). Nevertheless while an obstructive spirometry pattern was more common in the British cohort compared to the Italian one (respectively 22.5% vs 7.7%), the picture was the opposite for the restrictive pattern (respectively 11.2% and 20.5%) (Table 1). In the whole sample age was negatively correlated with both zFEV1 (Spearman's rho-0.20) and zFVC (Spearman's rho-0.24).

Table 1.

Index	Sickle cell UK	Sickle cell ITA	Diff between means (95% CI)
n (%male)	62 (54%)	39 (61%)	
Age (years)	11.9 (2.7)	11.3 (3.5)	0.6 (-0.6 to 1.9)
Height z-score	-0.11 (1.23)	-0.08 (1.09)	-0.03 (-0.53 to 0.47)
BMI z-score	-0.11 (1.71)	-0.55 (1.17)	0.44 (-0.03 to 0.91)
FEV1 z-score	-1.10 (1.04)	-0.80 (0.97)	-0.30 (-0.72 to 0.10)
FVC z-score	-0.71 (1.03)	-0.71 (0.83)	0.00 (-0.43 to 0.39)
FEV1/FVC z-score	-0.43 (1.09)	-0.27(0.93)	-0.16 (-0.58 to 0.25)
<b>Spirometry pattern</b>			
Obstructive (% of total)	14 (22.5%)	3 (7.7%)	
Restrictive (% of total)	7 (11.2%)	8 (20.5%)	

**Summary/Conclusions:** Lung function of pediatric subjects with SCA living in London and in the northeast of Italy is overall comparable. Obstructive lung disease is more common among subjects with SCA living in London than in urban and non-urban areas in Italy. Differences in the level of exposure to ambient air pollution and in the prevalence of allergies between the rural and urban environment might have contributed to this finding and need to be further investigated.

### PB2143

#### SICKLE CELL DISEASE: A NEW DISEASE IN MADRID

E. J. Bardón-Cancho<sup>1,\*</sup>, M. García-Morín<sup>1</sup>, B. Ponce-Salas<sup>1</sup>, Y. Aguilar-de la Red<sup>1</sup>, A. Pérez-Corral<sup>2</sup>, G. Pérez-Rus<sup>2</sup>, E. Dulín<sup>3</sup>, C. Beléndez<sup>1</sup>, E. Cela<sup>1</sup>

<sup>1</sup>Section of Pediatric Hematology and Oncology, Department of Pediatrics, <sup>2</sup>Department of Hematology, <sup>3</sup>Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina - Universidad Complutense de Madrid, Madrid, Spain

**Background:** Sickle cell disease (SCD) was scarcely diagnosed 2 decades ago in Spain, and the Community of Madrid is a paradigm of the adjustments that had to be implemented to attend an increase of cases due to immigration.

**Aims:** The aim of our study was to find out the prevalence of SCD in the referral center for sickle newborn screening in the Community of Madrid, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

**Methods:** The study is observational, unicentric, descriptive and retrospective, carried out in February 2017 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with SCD and who had attended at least once to the hematology clinic for this reason were included. Demographic characteristics (date of birth, gender, country of birth) and clinical characteristics (genotype, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

**Results:** The total number of SCD patients included was 209. Ratio boy/girl is 1.3. Most of patients were born in Spain (85%), although 8% and 5.26% were born in Africa or America respectively. Seventy three percent of the progenitors came from Africa and 24% from America. Ninety two percent of those SCD patients born in Spain were detected in their first days of life due to universal screening detection implemented in Community of Madrid since 2003. Median age at first diagnosis was 1.42 years (0-21.4). Median age at the end of inclusion was 9.91 years (range 0.13 to 35.14). SS or S/Betathal<sup>0</sup> was reported in 86%. In addition, 2.39% associated alpha gen deletion, and 1 (0.48%) glucose 6 phosphate dehydrogenase deficiency. No patient had congenital thrombotic diathesis. Eighteen patients (8.65%) had human leucocyte antigen (HLA) identical siblings. Hydroxyurea was added to standard treatment in 65 patients (31%) of which 47 continue to be treated to date. Penicillin prophylaxis was communicated in 165 patients (79%). Vitamin-D prophylaxis was initiated in 128 patients (61%). Chronic exchange or simple transfusions existed in 26 cases (12%) and 9 children (4%) underwent splenectomy. None of these patients had sepsis or meningitis. Cholecystectomy was performed in 9 cases (4%). There were 18 progenitor stem cell transplantations (8.61%) performed between 2.09 to 13.97 years of age (median 6.77 years). Ten patients remained on complete chimerism, 6 on mixed chimerism and 1 attained a marrow rejection. One patient died of graft-versus-host disease. Patients lost in follow-up summed up 128: 23 for emigrating to other countries, 65 for continuing the monitor of their diseases in other centers or in adults units and 31 for unknown reasons. There were 9 deaths (2.87%).

**Summary/Conclusions:** Early diagnosis like universal neonatal screening allows an effective health education, and antibiotic and osteopenia prophylaxis with vitamin D and general and specific vaccination can be started.

**PB2144**

**COMPLEMENT ACTIVATION IN PATIENTS WITH SICKLE CELL DISEASE IS ASSOCIATED WITH HIGHER HbS LEVELS**

E. Gavriilaki<sup>1,\*</sup>, M. Mainou<sup>2</sup>, I. Christodoulou<sup>2</sup>, E.-E. Koravou<sup>1</sup>, A. Paleta<sup>1</sup>, T. Touloumenidou<sup>1</sup>, A. Papalexandri<sup>1</sup>, A. Athanasiadou<sup>1</sup>, C. Apostolou<sup>2</sup>, P. Klonizakis<sup>2</sup>, A. Anagnostopoulos<sup>1</sup>, E. Vlachaki<sup>2</sup>

<sup>1</sup>Hematology Department - BMT Unit, G. Papanicolaou Hospital, <sup>2</sup>Adults Thalassemia Unit, 2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokraton General Hospital of Thessaloniki, Thessaloniki, Greece

**Background:** Older studies have suggested activation of the alternative pathway of complement (APC) in sickle cell disease (SCD). Despite the renewed interest in SCD therapeutics, little is known about APC activation in the clinical setting of SCD, possibly due to the complexity of complement diagnostics.

**Aims:** We investigated firstly, whether complement activation can be detected in the sera of asymptomatic SCD patients using a simple functional assay, secondly whether it is associated with clinical parameters and thirdly whether it can be blocked *in vitro* by the complement inhibitor eculizumab.

**Methods:** Consecutive asymptomatic SCD patients were enrolled prospectively from November 2016 to January 2017. Patient history, clinical and laboratory data were recorded. Complement activation was detected in patient sera using the modified Ham test, a cell proliferation assay based on the susceptibility of a PNH (paroxysmal nocturnal hemoglobinuria)-like cell line to complement activated serum. Normal human serum (NHS) was used as a negative control and lipopolysaccharides (LPS)-incubated normal serum as a positive control. All samples were tested in triplicates and twice. Eculizumab containing serum (ECU) was collected from a PNH patient within 60 minutes after the infusion and used to test complement blockade by eculizumab in the modified Ham test.

**Results:** We studied 26 SCD patients (36±11 years of age, 12 male: 14 female, 8 HbS/S: 18 HbS/β-Thal). Among them, only 6 had a history of painful crisis and 15 a splenectomy, 15 were on hydroxyurea and 12 on antithrombotic treatment. Based on previous studies and present controls, percentage of non-viable cells higher than 20% was considered a positive modified Ham test, indicating increased APC activation in 4 SCD patients (Figure 1). Positive patients had significantly increased HbS levels (80.5±11 vs 61.8±16%, p=0.037), while 2/4 were homozygous (HbS/S) and 2/4 heterozygous (HbS/β-Thal). The majority (3/4) were not on hydroxyurea. No significant difference was found regarding age, gender, platelets, white blood cells, Hb, HbF, LDH and bilirubin levels between patients with and without complement activation. Then, we evaluated *in vitro* the efficacy of complement inhibition by eculizumab in the modified Ham

test. Mixing eculizumab serum (ECU) with complement activated sera demonstrated a dose-killing relationship that was consistent across the 4 patients.

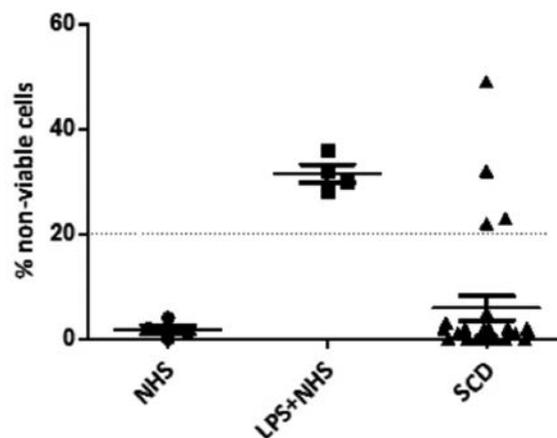

Figure 1.

**Summary/Conclusions:** Our results suggest that complement dysregulation is evident in asymptomatic SCD patients with increased HbS levels, an important tool in everyday clinical practice. APC activation during a painful crisis and the role of hydroxyurea need to be further investigated in larger series validating the role of different functional assays. Effective inhibition of complement activation *in vitro* is promising for future studies in selected patients.

**PB2145**

**THE ROLE OF EXECUTIVE DYSFUNCTIONS IN THE VERBAL LANGUAGE DEFICITS OF CHILDREN WITH SICKLE CELL DISEASE**

B. Arfe<sup>1</sup>, M. Montanaro<sup>2</sup>, E. Mottura<sup>2</sup>, R. Manara<sup>3</sup>, M. Scaltritti<sup>1</sup>, G. Basso<sup>2</sup>, L. Sainati<sup>2</sup>, R. Colombatti<sup>2,\*</sup>

<sup>1</sup>Department of Psychology, University of Padova, <sup>2</sup>Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, <sup>3</sup>Department of Radiology, University of Salerno, Salerno, Italy

**Background:** Children with Sickle Cell Disease (SCD) frequently present impairment of general and specific neurocognitive functions, even in the absence of clear neurological damage at brain neuroimaging. Verbal language deficits are also common, but the etiology of poor performance in the verbal domain is still not clear. The ability to speak and communicate verbally relies on a complex interaction of cognitive and linguistic functions as well as on environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

**Aims:** To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

**Methods:** In this study a cohort of bilingual children with SCD and socio-demographically matched healthy controls recruited from elementary schools of the same city, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Elithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and economically children at best. Analyses of variance (ANOVAs) were performed to test differences between the two groups in verbal language, attention and executive functions. Hierarchical regressions explored the contribution of linguistic knowledge and executive functions (*i.e.* inhibition) to the verbal language deficit of children with SCD.

**Results:** Thirty-two children with HbSS SCD aged 6 to 12 years (mean age= 9.03) and 35 controls (mean age= 9.14) were enrolled. Patients and controls were matched for gender (F 53 vs 61%), ethnicity (African 30 vs 29%),% of children born in Italy (81 vs 80%), number of years lived in Italy (8.09 vs 8.31) and Socio-Demographic Index (5.15 vs 4.59). Children's Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests are shown in Figure 1. The results overall showed significant differences between patients and controls in inhibition and planning (p= 0.001 and 0.001 respectively) and in verbal tasks that involved Executive Functions more (*i.e.* phonological fluency) (p=.004). The poorer verbal performance of children with SCD was not associated to visible lesions to Broca's area; in fact only 9 patients presented Silent Infarcts that were all in the white matter, in watershed areas. Regression analyses showed that in children with SCD inhibition skills explained unique variance in phonological fluency, suggesting that poor executive control

was a factor of the lower performance in this task. Figure 1. Children's Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests. P-values: Visuo-spatial intelligence: not significant(ns); Boston naming: ns; Phonol-Fluency: 0.004; Semantic fluency: ns.

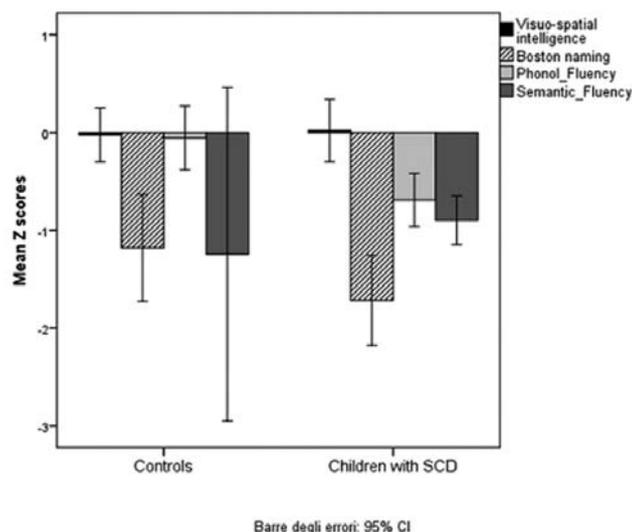

Figure 1.

**Summary/Conclusions:** Selective language problems may occur in children with SCD in the absence of clear neurological damage to language areas. These problems are explained by the executive dysfunction of patients with SCD and not by environmental factors like bilingualism. Cognitive rehabilitation or extra tuition may aid in overcoming these difficulties.

#### PB2146

##### UNDERSTANDING MEDICAL HISTORY, LIFESTYLE AND NEEDS FOR FUTURE THERAPIES FOR PEOPLE LIVING WITH SICKLE CELL DISEASE - IMPLICATIONS FROM A PATIENT SURVEY

A.M. Leitgeb<sup>1,\*</sup>, M. Robinson<sup>2</sup>, C. Herder<sup>1</sup>, L. Jendeborg<sup>1</sup>

<sup>1</sup>Modus Therapeutics, Stockholm, Sweden, <sup>2</sup>Micromattie Consulting Inc, Oviedo, Florida, United States

**Background:** Sickle Cell Disease (SCD) is an inherited blood disorder affecting millions of people. Sevuparin/DF02 is being developed to treat people suffering from SCD and is currently in clinical phase 2 for the treatment of the acute painful crisis in hospitalized SCD patients with intravenous infusion. This is called the Resolve program. In a second program called EASE, sevuparin/DF02 will be investigated as an on-demand treatment of early symptoms of painful sickle cell crisis in an at-home setting via a subcutaneous injection. Searching in the literature and discussing with health care providers, it becomes clear that little is known about how the SCD patients sense these early symptoms of a painful crisis. In order to gain increased understanding of how people living with SCD experience daily life, coping with disease, support by health care providers and the demand for new therapies, a patient survey addressing these areas was conducted.

**Aims:** The aim with this survey was to gain deeper understanding of different aspects of life with SCD by providing a channel for patients to air their own views. The outcome will provide important information and, in combination with future feasibility studies, will guide the design of the first clinical study aimed at treating the early symptoms of pain crises in SCD patients.

**Methods:** A 29-question survey was created to gather input on a wide variety of topics related to the lives of people living with SCD. This questionnaire was developed by Modus Therapeutics AB, Sweden, in conjunction with Micromattie Consulting Inc., USA. Experts and leaders of community-based organizations participated in two focus group sessions to ensure that the text and structure were ethical and appropriate for the intended purpose. The survey was hosted at [www.modustxpatientsurvey.com](http://www.modustxpatientsurvey.com). Patients answered the survey directly, or had their views entered in by a caregiver. The answers are anonymous. During the initial period, survey promotion occurred within the Sickle Cell Warriors online community and later, additional connections within the network of community-based organizations were leveraged. The survey was open for access during the period of January 10, 2017 through March 1, 2017.

**Results:** An interim analysis was conducted on January 31, 2017. Basic demographic data is presented in Table 1. Responders were located mainly in the US. Medical history related questions indicate that fatigue (40%), aches/pain (37%), irritability (27%) and appetite (20%) are early symptoms and increase just before the onset of a pain crises. However, 7% reported infrequent signs and 19% never experienced an indicator of pain crisis. Patients take initiative

at home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide "significant relief" and "prevent symptoms from happening" due to their SCD.

Table 1.

Demographic data from interim analysis January 31, 2017.	
Demographic data	
Number of responders	70
Age	4-74 years
Female	80%
Male	20%
SCD diagnosis	100%
Ethnicity	
• African American/African Descent	97%
• Other	3%

**Summary/Conclusions:** The survey collected feedback about topics for which the patient is the best source of information. It is obvious that people with SCD are willing to self-medicate by subcutaneous injections and that there is a need for new tools and medications. With support from the answers from the survey, specific aspects will be considered while designing a first clinical study for subcutaneous sevuparin/DF02 administration to treat early symptoms of painful crisis in an at-home setting.

#### PB2147

##### LONG-TERM USE OF HYDROXYUREA IN CHILDREN AND ADOLESCENTS WITH SICKLE /BETA THALASSEMIA

M. Economou<sup>1,\*</sup>, A. Teli<sup>1</sup>, E. Papadopoulou<sup>1</sup>, A. Papastergiopoulos<sup>1</sup>, S. Theodoridou<sup>2</sup>, F. Papachristou<sup>1</sup>

<sup>1</sup>Aristotle University of Thessaloniki, <sup>2</sup>Blood Bank, Hippokraton General Hospital, Thessaloniki, Greece

**Background:** Hydroxyurea (HU) has lately been used in the treatment of patients with severe sickle cell disease (SCD). Despite documented benefits on laboratory and clinical parameters in SCD patients, there are few reports about drug's long-term safety and efficacy in pediatric patients with SCD – even more so in the rare patient subgroup of sickle/beta thalassemia.

**Aims:** A prospective, long term evaluation of HU efficacy and safety in children and adolescents with sickle/beta thalassemia (S/b thal).

**Methods:** Ten patients with S/b thal aged 3.5-18 years were followed for a 6 year period (Jan 2011- Dec 2016). HU was given at a daily dose that ranged from 10 to 20 mg/kg, with a mean of 14.1 mg/kg. Laboratory follow-up consisted of WBC, Hb, Ht, RBC, reticulocyte count and PLT count measured every 2 weeks until dose escalation to a stable dose, biochemistry assessed every 2 months and Hb F measured every 2-3 months. Patients were clinically evaluated prior to HU treatment and every 12 weeks during the study period. Evaluated data on clinical course included frequency of vaso-occlusive crises, hospitalizations and transfusions, as well as presence of severe clinical events. Hematologic toxicity of hydroxyurea was defined as a more than 20% decline from baseline in Hb, as an absolute neutrophil count of less than 1,000/ $\mu$ l and/or a PLT count of less than 80,000/ $\mu$ l. Moreover, presence of alopecia, rash, skin hyperpigmentation or headache was reported as drug-related toxicity.

**Results:** A significant reduction in vaso-occlusive crises as compared to prior to HU treatment was noted (median: 1 episode per year before HU, range: 0-2.5 vs median: 0.24 episodes per study year after HU, range: 0-1.33,  $p=0.011$ ). A significant reduction in hospitalizations was also reported (median: 1 per year before HU, range: 0.3-2 vs median: 0.16 per study year after HU, 0-0.83,  $p=0.005$ ). None of the patients presented with severe clinical events such as acute chest syndrome, avascular bone necrosis, stroke or splenic sequestration during the study period. With regards to hematological parameters, a significant increase in HbF (10.2 $\pm$ 6.5% vs 16.6 $\pm$ 7.1%  $p=0.02$ ), MCV (66.1 $\pm$ 3.9fl vs 79.3 $\pm$ 8.4fl,  $p<0.001$ ) and MCH (20.9 $\pm$ 1.2pg vs 25.3 $\pm$ 2.2pg,  $p<0.001$ ), as well as a decrease in reticulocyte count (7.7 $\pm$ 3.3% vs 5.0 $\pm$ 1.9%,  $p=0.039$ ), WBC count (9,566 $\pm$ 3,674/ $\mu$ l, vs 7,466 $\pm$ 3,460/ $\mu$ l,  $p=0.009$ ) and PLT count (333,778/ $\mu$ l, $\pm$ 170,227 vs 272,111 $\pm$ 160,304/ $\mu$ l,  $p=0.007$ ) was noted. Concerning adverse events, one patient presented with mild transaminasemia, one with mild elevation of serum creatinine levels and one with pancytopenia. Due to persistent pancytopenia HU treatment was discontinued in the last mentioned patient, but was restarted a year later due to frequent vaso-occlusive events - despite the patient being put on transfusions after initial HU discontinuation. Besides the pancytopenia episode, the rest of the mentioned toxicities were short-term and dose-dependant.

**Summary/Conclusions:** The study indicates that HU has an overall safe profile and results in a marked improvement of clinical course in pediatric S/b thal patients.

**PB2148**

**IN VITRO AND IN VIVO EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K<sup>+</sup>-ISOTONIC SOLUTION**

O. I. Ajayi<sup>1,\*</sup>, O. Uchegbu<sup>2</sup>, F. Ozimede<sup>1</sup>

<sup>1</sup>Physiology, <sup>2</sup>Medical Lab Science, University of Benin, Benin city, Nigeria

**Background:** Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium chloride co-transport and calcium-activated potassium channel (Gardos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassaemia. We investigated the in-vitro and in-vivo effects of various concentration of K<sup>+</sup> ions in physiological solutions (PSS) as well as in *Cocos nucifera* water (CNw) which is known for its natural high potassium content and isotonicity.

**Aims:** This study was aimed at ascertain the efficacy of high potassium isotonic solutions in rehydrating sickle cell and possibly reversing the sickling phenomenon at *in vivo* and *in vitro* situations

**Methods:** Erythrocytes from twenty sickle cell anaemia (SCA) as well as 46 healthy subjects were studied. One part was treated with sodium metabisulphite (Na<sub>2</sub>S<sub>2</sub>O<sub>7</sub>) solution to induce maximum sickling as controls while the other was subjected to different high concentrations of K<sup>+</sup> in PSS as well as *Cocos nucifera* water (40mM, 80mM and CNw - 65mmol/L) respectively. The procedure was repeated for the normal HB AA subjects. Also, both groups of subjects were given 10ml/kg body weight of coconut water to drink as a single dose for the in-vivo experiment. Blood samples were collected longitudinally before and after the oral ingestion, at 1hr and at 24hrs for analysis of red cell indices as well as stained blood films used to ascertain the percentage sickled erythrocytes count before and after the treatment in both cases.

**Results:** Maximum percentage counts of sickled cells after the addition of Na<sub>2</sub>S<sub>2</sub>O<sub>7</sub> (45%) were observed which decreased significantly (P<0.05, respectively) to about 2% with *Cocos nucifera* and 10% with 80mM K<sup>+</sup>PSS. The count in 40mM K<sup>+</sup>PSS was not statistically significant. In both Hb AA and SS subjects, MCH and MCV remained relatively stable when compared with the pre-ingestion sample (P>0.05, respectively) while MCHC increased significantly in both groups as early as 1hr and sustained till the 24th hour. MCHC was equally raised in the in-vitro samples (P<0.05, respectively). The morphology of red cells also indicated a lesser count of sickled red cells after the oral ingestion

**Summary/Conclusions:** *Cocos nucifera* water and other high potassium ion solutions can activate the rehydration of sickled erythrocytes by probably de-activating the Gardos channel to increase the mean corpuscular haemoglobin concentration(MCHC) and thereby restoring the normal red cell shape. We suggest a probable pharmacological value of the *cocos nucifera* water as well as other formulated high potassium but isotonic fluids in SCA management.

**PB2149**

**VITAMIN D IN SPANISH CHILDREN WITH HEMOGLOBINOPATHIES.**

A.M. Bobes Fernández<sup>1,2,3,\*</sup>, B. Ponce<sup>1,2</sup>, Y. Aguilar<sup>1,2</sup>, C. Garrido<sup>1,2</sup>, M. García-Morín<sup>1,2</sup>, C. Beléndez<sup>1,2</sup>, E. Cela<sup>1,2</sup>

<sup>1</sup>Hospital Gregorio Marañón, <sup>2</sup>Facultad de medicina, Universidad Complutense de Madrid, <sup>3</sup>Hospital Clínico San Carlos, Madrid, Spain

**Background:** Although vitamin D deficiency has been documented as a frequent problem in studies of children, there are limited data on the prevalence of this nutritional deficiency among children who suffer from sickle cells disease (SCD) or thalassaemia. Vitamin D homeostasis is important to prevent osteopenia. Furthermore vitamin D deficiency has been associated with increased risk of common cancers, autoimmune diseases, hypertension, and infectious diseases. Vitamin D deficiency is now recognized as a pandemic. The major cause of vitamin D deficiency is the lack of sun. Although Spain has a high rate of sunny hours, we have found low levels of vitamin D in our patients with SCD or thalassaemia.

**Aims:** The purpose of this work is to assess the status of vitamin D in children with SCD and thalassaemia in our setting.

**Methods:** We have recruited children diagnosed with SCD and thalassaemia between 1998 and 2016 and we have reviewed their vitamin D levels. We have chosen the first vitamin value we obtained and the last one till today. Vitamin D was measured by quantitative determination of 25(OH) D. Deficit of vitamin D was defined by <30 ng/ml. The study enrolled 114 children. Most of them, with SCD diagnosis ( 94%). The type of anaemia was Hb SS (94 patients), Hb SC (8 patients), Hb Sβ0 (3 patients) and HbSβ+ (2 patients). The remaining 6% were diagnosed with Thalassaemia Maior. Mostly of the children were African or Central-South American. In our centre, vitamin D prophylaxis is made since the first year of life.

**Results:** 60% of the children had vitamin D deficiency. We have divided children into 4 groups depending on the age. When considering vitamin D first determination: mean vitamin D levels in children below 2 years old were 39.5±13.3 ng/dl. The group between two and five years old had a mean serum vitamin D of 35.5±14.8 ng/dl. Children aged between five and ten had 26.1±13.5 ng/dl of mean 25(OH)D. Finally in the group older than 10, we observed mean of 7.4±14 ng/dl. When having these low levels of vitamin D, we strongly recommend to

start treatment with Cholecalciferol 25000U/month. Regarding second levels of vitamin D, we have divided patients into those who presumably have the treatment against children who do not. We present the results in the following Table 1.

**Table 1.**

	<2 years old	2-5 years old	5-10 years old	>10 years old
Vit D treatment	33.7±9.02ng/dl	35.5±12.3ng/dl	34.3±7.3 ng/dl	26.4±11.2ng/dl
No Vit D treatment	-	33.8±1.5 ng/dl	27.3±4.9 ng/dl	6.6±2 ng/dl

**Summary/Conclusions:** The study found a high prevalence of vitamin D deficiency in children older than five years old(in the first determination) with SCD or Thalassaemia Maior and significant decrease of levels in those not having vitamin D therapy. It is not well known the physiopathology of this factor deficiency, although it is supposed to be multifactorial. However we confirm that living in a sunny geographical situation with a healthy diet is not enough to maintain an adequate 25(OH)D levels. Although it is difficult to reach correct levels of vitamin with oral treatment, vitamin D levels increase when having correct doses. We have also checked that older children have lower levels of vitamin D than younger boys. This could be explained by the fact that pre-teenagers spend lot of time at home instead of going out. If prophylaxis is made not only the vitamin levels will increase but bone growth also.

**PB2150**

**KNOWLEDGE OF SICKLE-CELL DISEASE IN HAUTE-NORMANDIE, SOCIO-DEMOGRAPHIC CONTEXT AND HEALTH CHARACTERISTICS: INTEREST OF THE IMPLEMENTATION OF A PATIENT EDUCATION IN SICKLE CELL DISEASE**

S. Ngo<sup>1,\*</sup>, H. Van Elslande<sup>2</sup>, A. Lahary<sup>3</sup>, J.-M. Kerleau<sup>4</sup>, H. Levesque<sup>2</sup>

<sup>1</sup>Internal Medicine, Hopital Delafontaine, Saint Denis, <sup>2</sup>Internal Medicine, <sup>3</sup>Hematology, CHU Rouen, Rouen, <sup>4</sup>Internal Medicine, Centre hospitalier de Dieppe, Dieppe, France

**Background:** Sickle cell anemia (SCA) is a genetic disease causing a severe disease manifesting by painful crisis but which can also be marked by organ complications. Mortality is still happening at a young age. Many of these complications may be better taken care of if treated early. The best way to manage this disease is probably through Patient Education (PE)

**Aims:** Patient Education for children with sickle cell anemia has been a subject of research, organized in France by association such as ROFSED, but PE in adult patients has been little studied. The main objective of this work was to evaluate SCA patients followed in Haute-Normandie, from a sociodemographic, health and socio-demographic perspective in order to establish a PE program. The secondary objective was to give them the opportunity to express their expectations of such a program.

**Methods:** We did an observational multicenter study. A self-questionnaire of 39 items was sent to all patients suffering from SCA followed in Haute-Normandie.

**Results:** Fifty patients (male / female ratio 0.92) out of 123 (40.6%) responded, mean age 33±10.5 years (SS genotypes [66%], SC[25%], S-beta-thalassaemia [9%]). 56% of them were born outside of Metropolitan France, 36% came from French speaking African countries. Aerate age was 18±10.9 years. Despite the fact that their education has been disrupted by the disease for the majority (69.4%), the level of education was "satisfactory": 68% of patients had graduated from high school or achieved a higher level, 18% had graduated from professional education, 10% had a primary / middle school level and 4% were illiterate. 68% of the patients had a job or were students. 48% of patients reported to practice physical activity at least once weekly. Tobacco was consumed on a daily basis by 14%, alcohol 2% and 4% for cannabis. Self-assessment of health status was 6.9 / 10, self-assessment of morale of 7.9 / 10 and impact of the disease on daily life was estimated at 5.4 / 10. The mean age at which specialized follow-up was started was 11±9 years. 88% of the subjects stated that they understood everything the doctor said during consultation. Missed appointments were reported by 26% which was justified by forgetfulness, lack of will or physical incapacity. Regarding sources of information regarding SCA, patients declared asking their specialist first and then looking on the internet. 68% of subjects had a first-degree relative suffering from the same disease, 71% were able to talk about the disease with their family. While the triggers of crises and the management of crises were well-identified by patients (average scores of 13.8 and 12/20), "standards" were not met with chronic complications, prenatal diagnosis, and long term treatment (mean scores respectively of 7.4; 4.2 and 2.2 / 20). Average score on the whole questionnaire was 9/20. Most patients showed interest in PE (52.1%) vs 31.3% that claimed were not interested, 17.7% did not decide.

**Summary/Conclusions:** A majority of SCA adults followed in Haute-Normandie are first-generation migrants. Even if the disease has heavy impact on everyday life and school access, their education level appeared correct. PE sessions will need to focus on chronic complications, prenatal diagnosis, and the long term treatment. The majority of adults with SCA are motivated by PE, we will have to adapt to a heterogeneous population in terms of educational level, ethnic origin and knowledge of the disease.

## PB2151

**DELAYED HAEMOLYTIC TRANSFUSION REACTIONS: A MASQUERADE OF SICKLE CELL COMPLICATIONS**H.N. Fernandez - Leyva<sup>1,\*</sup>, S. Kotsiopolou<sup>1</sup>, N. Osuji<sup>1</sup>, J. Maitland<sup>1</sup>  
<sup>1</sup>Haematology, Croydon University Hospital, London, United Kingdom**Background:** Patients with sickle cell disease (SCD) may require repeated red blood cells (RBCs) transfusion, putting them at risk from minor blood group alloimmunization and the development of delayed haemolytic transfusion reactions.**Aims:** Reported a prevalence of recognized DHTR syndrome in patients with SCD.**Methods:** We reviewed the cases of (DHTR) in SCD patients in a 5-year period (2010- 2016). A total of 10 patients had a clinical picture compatible with DHTR and underwent treatment with high dose steroids, intravenous immunoglobulins (IVIG) or erythropoietin. Any patient received Rituximab.**Results:** The most common indications for transfusion were anaemia due to vasoocclusive sickle cell crisis or preoperative anaemia optimization. The cohort received partial exchange transfusion and phenotypically matched RBCs. Before transfusion the median of Hb level was 69 g/L (baseline range 80g/L) and the nadir at haemolysis episode was 38 g/L, Ht was 21.9%, WBC was  $17.3 \times 10^9$  cells/L and mean LDH 1290 IU/L. The median time to develop DHTR was seven days after the transfusion and approximately 6 days after the surgical interventions (range: 4–12 days) and all cases presented with symptoms of anaemia, jaundice, tiredness and tachycardia. The median age was 29 years with female predominance (6:4). Blood cultures were negative in 80% of patients and only positive in 2 cases. 30% of patients tested positive for viral infection on PCR. Mortality rate in our series was low (zero). Pain episodes and other complications associated with DHTR was treated as required and four cases were successfully monitored in HDU. One patient required noninvasive ventilations and inotropic support. Two patients received RBCs transfusion (median 1.5 unit of packed RBCs). Possibly as their presentation mimics an acute vaso-occlusive crisis. In all cases haemoglobin stabilized and improved, symptoms resolved and patients were discharged on small course of oral antibiotics (median admission 6 days).**Summary/Conclusions:** The symptoms of DHTR can easily be mistaken for other SCD complications, including infection and vaso-occlusive crisis.

The diagnosis of DHTR is based on clinical suspicion, when there is a rapid Hb drop after a recent RBC transfusion with clinical signs of haemolysis. To support the diagnosis, laboratory tests (serial FBCs, haemolysis screen, DAT, measurement of Hb S levels) and exclusion of other aetiologies are useful. Whenever a DHTR is suspected, further RBC transfusion should be withheld unless absolutely necessary, as it may precipitate acceleration of the hemolytic reaction. Patients in whom the diagnosis of DHTR is missed may receive repeat transfusions, which may contribute to the complications associated with SCD. The use of more extensive phenotypic matching of blood and minimizing RBC transfusion help to prevent DHTR. The present series emphasize the importance of early recognition of symptoms and signs in correlation with a recent history of RBC transfusions, as DHTR can be a potentially life-threatening complication.

## PB2152

**HbS MONITORING ON TOSOH G8 IN VARIANT HbA1c MODE IN CASE OF URGENT RCE**S. Van Aelst<sup>1</sup>, E. Nackers<sup>1</sup>, K. Desmet<sup>1,2</sup>, D. Kieffer<sup>1,3,\*</sup><sup>1</sup>Department of Laboratory Medicine, University Hospitals Leuven, <sup>2</sup>Department of Cardiovascular Sciences, <sup>3</sup>Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium**Background:** Pre- and post-transfusion HbS levels are used to document the efficacy of red blood cell exchange (RCE) in patients with sickle cell disease (SCD). In case of urgent RCE a 24/7 STAT analysis, with the ability to identify and quantify hemoglobin (Hb) S, is warranted.**Aims:** We evaluated the use of Tosoh Automated Glycohemoglobin Analyzer HLC-723G8 (Tosoh Europe, Amsterdam, The Netherlands) for this purpose, using the variant HbA1c mode. Results were compared to our routine CZE Minicap Flex Piercing (Sebia, Lisses, France).**Methods:** Within- and between-run imprecision were assessed using a sickle cell trait and a sickle cell anemia sample, aliquoted and stored at -80°C, twice daily in duplicate for ten days. A linearity study was performed using duplicate measurements of a dilution set of 11 samples (HbS range: 0% - 88%). Additionally, a comparison study was conducted between TOSOH G8 and Minicap Flex Piercing using 32 whole blood left-over HbS samples (HbS range: 9% - 93%). Data analysis was performed using Microsoft Excel Analyze-it version 4.65.3 and differences were considered as statistically different if the P-value was <0.05.**Results:** Within- and between-run imprecision were <2% and an acceptable linearity was observed. Passing-bablok regression analysis comparing TOSOH G8 and Minicap Flex Piercing showed an acceptable correlation coefficient of 0.998 (>0.95) and a slope and intercept of 0.94 (95%CI: 0.92 to 0.98) and 0.057 (95% CI: -2.5 to 1.3), respectively. Differences in HbS results between TOSOH G8 and Minicap Flex Piercing ranged from -8.76% to +0.36% (mean difference: -3.54%). More specifically, for samples with a HbS concentration

&lt;25% HbS results on TOSOH G8 differed between -0.34% to +0.36% compared to Minicap Flex Piercing. For samples with a HbS concentration &gt;25%, differences in HbS results ranged from -8.76% to -0.43%.

**Summary/Conclusions:** In our clinical laboratory, TOSOH G8 is used in variant HbA1c mode to quantify HbA1c. Previous studies demonstrated reliable HbS identification using TOSOH G8 in variant HbA1c mode. Our study showed a good analytical performance for HbS quantification using TOSOH G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant HbA1c mode generates lower HbS results in samples with a high HbS concentration (>25%) compared to our routine analyzer. However, the goal of RCE is to achieve a post-transfusion HbS level of 30% or less. Therefore, results obtained with TOSOH G8 are clinically acceptable to monitor post-transfusion HbS levels. Importantly, HbS on TOSOH G8 can only be requested in case of urgent RCE. Our routine hemoglobinopathy screening will still be performed using CZE Minicap Flex Piercing in combination with CE-HPLC Variant <sup>11</sup>TM.

## PB2153

**GENDER DIFFERENCES IN THE DEVELOPMENT OF CMR ABNORMALITIES AND CARDIAC COMPLICATIONS: A MULTICENTRIC PROSPECTIVE STUDY IN A COHORT OF SICKLE CELL DISEASE PATIENTS**A. Meloni<sup>1,\*</sup>, L. Pistoia<sup>1</sup>, C. Gerardi<sup>2</sup>, E. Facchini<sup>3</sup>, M. Allò<sup>4</sup>, M. P. Smacchia<sup>5</sup>, S. Campisi<sup>6</sup>, S. Maffei<sup>1</sup>, V. Vinci<sup>7</sup>, G. Restaino<sup>8</sup>, V. Positano<sup>1</sup>, A. Pepe<sup>1</sup><sup>1</sup>Fondazione G. Monasterio CNR-Regione Toscana, Pisa, <sup>2</sup>Presidio Ospedaliero "Giovanni Paolo II" - Distretto AG2 di Sciacca, Sciacca, <sup>3</sup>Azienda Ospedaliero-Universitaria di Bologna - Policlinico "S. Orsola-Malpighi", Bologna, <sup>4</sup>Presidio Ospedaliero ASL 5, Crotone, <sup>5</sup>Policlinico Umberto 1, Roma, <sup>6</sup>Presidio Ospedaliero "Umberto I", Siracusa, <sup>7</sup>Azienda Ospedaliera "Garibaldi" Presidio Ospedaliero Nesima, Catania, <sup>8</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy**Background:** No data are available in literature about the relationship between gender and the development of CMR abnormalities and/or cardiac complications in sickle cell disease (SCD).**Aims:** This prospective and multicentre study aimed to assess if there was an association between gender and risk of cardiac iron overload, heart dysfunction and dilation, left ventricular (LV) hypertrophy, and myocardial fibrosis, assessed by Cardiovascular Magnetic Resonance (CMR), and of cardio-vascular complications in sickle cell disease (SCD) patients.**Methods:** We considered 115 SCD patients (58 females, 34.79±13.26 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Myocardial iron overload was assessed by the multislice multiecho T2\* technique. Biventricular function parameters and atrial areas were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.**Results:** Table 1 shows the comparison between sexes in the development of cardiac outcomes. Males and females showed a similar risk of accumulating cardiac iron, but both patients with cardiac iron were females. Compared to females, males showed a significant lower risk of developing LV hypertrophy, although having a similar risk for biventricular dilation and dysfunction and for myocardial fibrosis. No patients with less than 31 years developed LV hypertrophy and age at the CMR was significantly higher in patients with LV hypertrophy versus patients without it (41.24±75.98 years versus 34.47±13.37 years; P=0.003). We recorded 12 (10.4%) cardiac events: 4 ischemic strokes, 5 arrhythmias (4 supraventricular and 1 ventricular), two pulmonary hypertension and one pulmonary embolism. No prospective association was detected between gender and cardiac complications.

Table 1.

	N(%) with positive outcome	Cox Regression	
		HR (95%CI)	P
<b>Global heart T2* &lt;20 ms:</b>			
Female sex	2 (3.4)	Reference	0.506
Male sex	0	0.02	
<b>Ventricular dilatation</b>			
Female sex	10 (17.2)	Reference	0.162
Male sex	4/55 (7.3)	0.44 (0.14-1.39)	
<b>LV hypertrophy</b>			
Female sex	12 (20.7)	Reference	0.02
Male sex	1/55 (1.8)	0.09 (0.01-0.66)	
<b>Ventricular dysfunction:</b>			
Female sex	12 (20.7)	Reference	0.965
Male sex	11/55 (20.0)	1.02 (0.44-2.37)	
<b>Myocardial Fibrosis:</b>			
Female sex	7/39 (17.9)	Reference	0.338
Male sex	3/35 (8.3)	0.50 (0.12-2.05)	
<b>Atrial dilatation</b>			
Female sex	9/36 (25.0)	Reference	0.990
Male sex	7/52 (21.9)	1.01 (0.37-2.71)	
<b>Cardiac complications</b>			
Female sex	9 (13.6)	Reference	0.204
Male sex	4 (7.0)	0.42 (0.11-1.59)	

**Summary/Conclusions:** In SCD male and female seem to show a comparable risk in developing cardiac complication, although compared to females, males showed a significant lower risk of developing LV hypertrophy. There are no specific guidelines for SCD patients and, as a consequence, the cardiovascular follow-up is conformed to that one of thalassemia patients (complete cardiac evaluation performed annually for both genders). Our data not support a different follow up time based on the gender.

**PB2154**

**SICKLE CELL PAIN IN CHILDREN: TARGETS FOR ADMINISTRATION OF ADEQUATE INITIAL ANALGESIA**

A. Rushd<sup>1,\*</sup>, A. Ramanathan<sup>2</sup>, B. Inusa<sup>3</sup>

<sup>1</sup>KCL, <sup>2</sup>GSTT, <sup>3</sup>Paediatric haematologist, Guys St Thomas Hospital, London, United Kingdom

**Background:** Acute pain is a hallmark presentation in sickle cell disease (SCD) and frequently requires attendance to the emergency department (ED).

**Aims:** Here we report our findings following a complete retrospective audit cycle, documenting the timeliness of analgesia administration and post-treatment pain review as per National Institute of Clinical Excellence and College of Emergency Medicine guidelines, in children with SCD presenting to a single inner city London ED over a 14 month period.

**Methods:** In 2014, we evaluated 48 patient records of children presenting to the ED, with respect to mild, moderate and severe pain scores, time of analgesia administration and pain review. Completing the audit cycle, 97 records were re-audited in 2015. A total of 145 admission records were evaluated.

**Results:** In 2014 the ED met CEM criteria for the timeliness of analgesia administration in 100% of severe and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.

**Summary/Conclusions:** We conclude CEM guidelines promote timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

**PB2155**

**DIAGNOSTIC CHALLENGES IN A POPULATION WITH INCREASED IMMIGRATION: HEMOGLOBINOPATHIES IN THE NEW CENTURY**

J. Zanabill Al-Sibai<sup>1,\*</sup>, A. Fonseca Mourelle<sup>1</sup>, T. Arias Fernández<sup>1</sup>,

L.R. Morais Bras<sup>1</sup>, L.F. Ávila Idrovo<sup>1</sup>, C. Castañón Fernández<sup>1</sup>,

A. Solé Magdalena<sup>1</sup>, A. Bernardo Gutiérrez<sup>1</sup>, R. Llorente de Jesus<sup>1</sup>

<sup>1</sup>Hematology, HUCA, Oviedo, Spain

**Background:** The diagnosis of hemoglobinopathies (Hbpts) has changed in recent years due to immigration, with an increase in structural Hbpts. In our region, Asturias, population census is 1,061.756 habitants; 48,097 out of them are immigrants.

**Aims:** Review the incidence of structural Hbpts and thalassemias in our region in the last 10 years.

**Methods:** A retrospective analysis was performed with 1202 hemoglobin (Hb) studies at Hospital Universitario Central de Asturias between January 2006 and March 2016. The studies came from medical applications, the finding of abnormal Hb patterns in the HbA1c test or suggestive results of thalassemia on hematology test. Studies were performed by high-performance liquid chromatography (HPLC) with the Variant Hemoglobin Testing machine of Bio Rad, and Hb electrophoresis with Paragon plates until May 2013. Since then, it has been performed by capillary electrophoresis (CE) with the MINICAP System of the Sebia Laboratory.

**Results:** We analyzed 1202 patients, 49% were males and the median age was 33 years (range 0-85). We found 562 pathologic studies. - Thalassemia were detected in 390; 337 were  $\beta$  or  $\delta\beta$  (86.4%); 54% came from Spain. The cases of  $\beta$ -thalassemia were: 5 intermedia, 3 major, 1  $\delta\beta$ -homozygote and the remainder were minor (97%). All thalassemia major, 3 intermedia and 74% of minor were Caucasian. Anemia was found in all of major thalassemia (median Hb 6.2g / dL, range 6-6.5), in 3 of intermedia (11.4g / dL, range 6-10), and in 197 of minor (10.87g / dL, range 6.9-11.9). - Structural Hbpts were found in 170, the predominant was Hb S (n=125). Only 17 sickle cells (Hb SS and Hb SC). Most of them black (n=14) coming from Africa (n=10) and South America (n=5). Eighty six percent (n=108) were heterozygous (Hb SA), mainly from Africa (n=56) and South America (n=23). Anemia were seen: 4 Hb SC (median Hb 10.5g / dL, range: 9.4-11.2), 9 Hb SS (7.94g / dL, range 5.2-9.7) and 37 heterozygotes (10.15g / dL, range 6.7-11.9). There are two peaks of higher incidence of structural Hbpts, in 2008 coinciding with the creation of the Tropical Diseases Unit and since 2013 when detection increases with the introduction of HbA1c test. The increase in thalassemias was due to the decision to extend studies due to pathological findings in hematology results (Figure 1).

**RESULTS EVOLUTION**

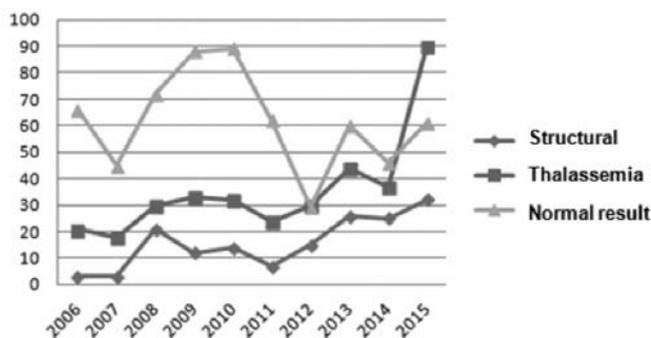

Figure 1.

**Summary/Conclusions:** In our area there is a predominance of  $\beta$ -thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and EC are simple, fast and efficient methods in the diagnosis of Hbpts. In our area there is a predominance of  $\beta$ -thalassemia minor. Structural Hbpts are the main diagnosis in immigrants. The incidence is still small, although increasing in the last 3 years, so a neonatal screening program is being implemented. Both HPLC and CE are simple, fast and efficient methods in the diagnosis of Hbpts.

**PB2156**

**EFFECT OF SUSTAINED-RELEASE SUPPLEMENTATION OF L-ARGININE AMONG CHILDREN WITH SICKLE CELL DISEASE IN FEDERAL TEACHING HOSPITAL GOMBE, NORTH EASTERN NIGERIA**

O. Erhabor<sup>1,\*</sup>, V.D. Knox<sup>2</sup>, S. Abubakar<sup>3</sup>, S. Yuguda<sup>3</sup>

<sup>1</sup>Haematology and Blood Transfusion Science, Usmanu Danfodiyo University Sokoto, Nigeria, Sokoto, Nigeria, <sup>2</sup>Department of Biochemistry and Molecular Pharmacology, West Virginia University Medical School, Morgantown, United States, <sup>3</sup>Department of Haematology, Federal Teaching Hospital Gombe, Gombe State, Nigeria, Gombe, Nigeria

**Background:** Sickle cell disease is a global public health problem. As of 2013 about 3.2 million people have sickle-cell disease with 176,000 deaths

**Aims:** In this present study, we investigated the effect of 8 weeks, low dose supplementation of sustained-release of nitric oxide generating L-arginine supplement (350mg) given two times daily on the full blood count, L-arginine, nitric oxide, Pantothenic acid, plasma malondaldehyde, glutathione and total antioxidant capacity of children with sickle cell disease.

**Methods:** This study included children with sickle cell disease (HbSS) aged 1-14 years with mean age 7.4500±0.50613 years presenting to the sickle cell clinic unit of Federal Teaching Hospital Gombe, Gombe State. Subjects received sustained release oral L-arginine supplementation of 350mg twice daily for 8 weeks.

**Results:** L-arginine and nitric oxide levels were significantly higher among sickle cell disease children. There were no statistically significant differences between the baseline and post L-arginine supplementation in the PCV, WBC, RBC and LYM levels of subjects (p>0.05). There was a statistically significant difference between the baseline and post L-arginine supplementation in the MCV, MCH, MCHC, PLT, NEU, EOS, MON and RDW-SD levels of subjects (p<0.05). The L-arginine and nitric oxide levels was significantly higher post supplementation compared to baseline levels (p=0.002 and 0.000 respectively). The pantothenic acid level was significantly higher at baseline compared to post supplementation levels (p=0.00). The L-arginine, nitric oxide and Total Antioxidant Capacity was significantly higher post supplementation compared to baseline levels among sickle cell disease subjects with vaso-occlusive crisis (p= 0.001, 0.01 and 0.05 respectively). The pantothenic acid and malondaldehyde levels at baseline were significantly higher than the post supplementation levels among subjects with vaso-occlusive crisis (p=0.002 and 0.000 respectively). The Total Antioxidant Capacity and Glutathione levels were significantly higher post supplementation compared to baseline levels among the sickle cell subjects (p= 0.05 and 0.000 respectively). The baseline plasma malondaldehyde level was significant higher than the post supplementation levels among the sickle cell disease subjects. There is need for more effort and resources to be dedicated to research especially in supplementation studies involving a larger population aimed at establishing specific treatment for sickle cell disease. It is recommended that L-arginine supplementation be included in the management of patients with sickle cell disease particularly those with vaso-occlusive crisis. We observed a statistically significant negative correlation between the L-arginine levels and the red cell count among sickle cell disease subjects (r=-0.350, p=0.043).

**Summary/Conclusions:** L-arginine supplement should be made available in the paediatric emergency unit, clinic and pharmacy department in high risk communities to obviate the negative effects during vaso-occlusive crisis and potentially reduce the length of stay in the hospital. L-arginine, nitric oxide, total antioxidant capacity, malondaldehyde and glutathione levels should be routinely monitored in sickle cell disease patients particularly those presenting with vaso-occlusive crisis.

## Stem cell transplantation - Clinical

Saint-Justine, University of Montreal, Montreal, Canada, <sup>11</sup>Hematology Department, Hospital Infantil Universitario Nino Jesus, Madrid, Spain, <sup>12</sup>Institute of Hematology and Oncology Paediatrics, Hospices Civils de Lyon, Lyon, France, <sup>13</sup>Hospital Sírío Libanês, San Paulo, Brazil, <sup>14</sup>Division of Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents of Frankfurt, Frankfurt, Germany

**Background:** Body mass index (BMI) may influence outcome after allogeneic transplantation. Previous studies have demonstrated that being obese or underweight may have a detrimental effect on survival rates after chemotherapy induction in children with acute leukemia. However, the impact of BMI of transplanted patients on survival is still not clear, with conflicting results being reported on this issue.

**Aims:** To analyze the effect of BMI on UCBT outcomes in children with acute leukemia

**Methods:** We retrospectively analyzed 517 patients aged from 2 to 20 years with acute leukemia who underwent umbilical cord blood transplantation (UCBT) from 1990 to 2015. Patients were classified according to BMI as normal (5<sup>th</sup>-85<sup>th</sup> percentile), underweight (<5<sup>th</sup> percentile), overweight (85<sup>th</sup>-95<sup>th</sup> percentile) and obese (>95<sup>th</sup> percentile) by using growth charts for age and gender.

**Results:** Sixty-one percent (n=314) of patients were in the normal category, 12% (n=63) were underweight, 15% (n=80) overweight and 12% (n=60) obese. All patients received single-unit UCBT after a myeloablative conditioning regimen. Diagnosis was acute lymphoid leukemia in 70% (n=363) and acute myeloid leukemia in 30% (n=154). Median age at UCBT was 7.4 years (range 2-19.6). Cytomegalovirus (CMV) serology was positive in 45% patients; 60% of patients were male. Most patients (92%) were in complete remission at UCBT. Median follow-up was 52 months (range 2-201). Total body irradiation (>6 Gy) was used in 58% of cases; antithymocyte globulin (ATG) in 68% of cases. Median infused total nucleated cell (TNC) dose was 4.2x10<sup>7</sup>/Kg (0.3-17.8); 56% of patients received a graft with 0-1 HLA mismatch donor. Four-year overall survival (OS), leukemia-free survival (LFS) and graft-versus-host disease-free, relapse-free survival (GRFS) were 45±2%, 43±2% and 35±2%, respectively. Cumulative incidence function (CIF) of neutrophil engraftment was 88.6% (85.9-91.4%). CIF for acute GVHD was 34% (30.1-38.4%) at 100 days. At 4 years chronic GVHD was 19.1% (15.7-23.3%), relapse incidence was 34.5% (30.1-38.9%) and non-relapse mortality (NRM) was 22.8% (19.2-26.7%). In univariate analysis, no statistically significant difference in OS, LFS, GRFS, neutrophil engraftment, NRM and chronic GVHD between the 4 groups identified according to BMI was identified. Conversely, acute GVHD was 44.3% (33.3-58.8%) for underweight, 36% (31-41.8%) for normal, 26.2% (18.1-38%) for overweight and 23.3% (14.7-37.1%) for obese (p=0.03). Among patients underweight who experienced acute GVHD (n=27), 37.5% had grade III-IV acute GVHD with gut involvement. In multivariate analysis, infused TNC dose>4.2x10<sup>7</sup>/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.18-1.82, p=0.001). Positive CMV serology (HR=1.5, CI 95% 1.04-2.26, p=0.03) and female gender (HR=1.5, CI 95% 1.03-2.23, p=0.03) were associated with higher NRM. ATG use (HR=1.6, CI 95% 1.05-2.31, p=0.03) was associated with higher relapse incidence. Moreover, ATG use and a positive CMV serology were associated with worse OS (HR=1.6, CI 95% 1.15-2.17, p=0.04 and HR=1.3, CI 95% 1.01-1.69, p<0.001, respectively) and LFS (HR=1.6, CI 95% 1.17-2.16, p<0.001 and HR=1.34, CI 95% 1.04-1.72, p=0.02, respectively). Infused TNC >4.2x10<sup>7</sup>/Kg (HR=1.5, CI 95% 1.07-2.14, p=0.02), lack of ATG in the conditioning (HR=2.72, CI 95% 1.6-3.1, p<0.001) and BMI <5<sup>th</sup> percentile (HR=1.8, CI 95% 1.19-2.78, p<0.001) were associated with higher incidence of acute grade II-IV GVHD.

**Summary/Conclusions:** In conclusion, we did not find association of obesity with transplant outcomes in this study population. However a BMI <5<sup>th</sup> percentile at UCBT was found to be associated with higher risk of acute GVHD, highlighting the importance of nutritional status before UCBT.

Tsurumi<sup>2</sup>  
<sup>1</sup>Hematology, Gifu Municipal Hospital, <sup>2</sup>Hematology, Gifu University Graduate School of Medicine, <sup>3</sup>Hematology, Gifu Red Cross Hospital, <sup>4</sup>Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

**Background:** Allogeneic hematopoietic stem cell transplantation (allo-SCT) using reduced intensity conditioning (RIC) has been widely applied to elderly or frail patients who are not eligible for conventional conditioning regimen. However, benefit provided by reduced toxicity has been often offset by increased incidence of relapse. So far, the optimal conditioning for those patients has not been established.

**Aims:** Here, to investigate whether addition of high dose cytarabine (AraC) to RIC regimen consisting of fludarabine (Flu) and cyclophosphamide (Cy) +/- total body irradiation (TBI) can be available for elderly or frail recipients, phase II study has been designed.

**Methods:** This study was conducted from April 2011 to December 2015. The protocol was approved by each institutional review board (Trial identifier: UMIN000007281). Patients aged from 55 to 70, or patients who have some organ damage or a history of SCT aged from 20 to 54 with hematologic malignancies were enrolled after obtaining written informed consent. Bone marrow (BM), peripheral blood (PB), or cord blood (CB) was used as stem cell sources. Pretransplant conditioning regimen consisted of 30 mg/m<sup>2</sup> of Flu for 5 days (total 150 mg/m<sup>2</sup>), 4 g/m<sup>2</sup> of AraC for 2-4 days (divided by 2 daily, total 8-16 g/m<sup>2</sup>) and 50mg/kg of Cy for a day. Four gray of TBI was used for all CB transplant recipients, whereas 2 gray of TBI was used in other stem cell sources except a matched related donor according to each institutional policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

**Results:** Thirty nine patients including 7 recipients with a history of SCT were enrolled. Median age was 61 (28-69), 21 were male, and 18 were female. Nineteen were acute myeloid leukemia, 11 myelodysplastic syndrome, 6 malignant lymphoma and 3 acute lymphoblastic leukemia. Donors were 4 matched related PB, 8 matched unrelated BM, 5 1-Ag/allele-mismatched unrelated BM, and 22 ≤2-Ag-mismatched CB. Thirty seven (94.9%) patients have passed 60-day-point post-transplant. In 38 (97.4%) recipients, engraftment was obtained, a patient died before engraftment due to sepsis caused by enterococcus faecium (male CB recipient, 55y, day15). Median neutrophil recovery to over 500/μl was obtained on day 19 (16-38). Fourteen blood stream infections (13 bacteremias and 1 candidemia) judged as grade 3 toxicity and 2 cases (1 sepsis and 1 endotoxemia) of grade 4 toxicity were observed within 60 days post-transplant. There were 2 deaths of post-engraftment due to cerebral bleeding (1 female CB recipient, 64y, day 46) and GVHD (1 male CB recipient, 60y, day 77) within 100 days. Although no relapse was observed up to day 60, 7 relapses were observed up to 1 year. Overall survival and disease-free survival were estimated to be 82.1% and 73.8% at 1 year post-transplant, respectively.

**Summary/Conclusions:** RIC using Flu/high dose AraC /Cy +/- TBI was well tolerated with acceptable low toxicities and was sufficient to allow donor cell-engraftment post allo-SCT for elderly or frail patients with hematologic malignancies. Longer follow up and another prospective study enrolling more patients are required to evaluate the eventual survival benefit by reducing relapse.

**LATE COMPLICATIONS OF CONDITIONING REGIMENS (CYCLOPHOSPHAMIDE - TOTAL BODY IRRADIATION vs BEAM) FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN LYMPHOMA.**

S. Novelli<sup>1,\*</sup>, A.C. Caballero<sup>1</sup>, A. Monter<sup>1</sup>, G. Gomez Segura<sup>2</sup>, I. Garcia Cadenas<sup>1</sup>, A. Esquirol<sup>1</sup>, R. Martino<sup>1</sup>, J. Sierra<sup>1</sup>, J. Briones<sup>1</sup>  
<sup>1</sup>Hematology, <sup>2</sup>Radiotherapy, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Autologous stem cell transplantation (ASCT) is a frequently used procedure for the treatment of patients with relapsed non-Hodgkin lymphoma (NHL). While chemotherapy-based regimens are now commonly administered, total body irradiation (TBI) was largely used in the past. The current conditioning regimen in our center is BEAM (a combination of carmustine (BCNU), etoposide, cytarabine and melphalan) although we also have a large experience with cyclophosphamide (CFM)-total body irradiation (TBI) since this was the usual conditioning until year 2000.

**Aims:** To analyze the cumulative incidence of secondary neoplastic complications and non neoplastic complications (grade 3-4 infections, cardiovascular and pulmonary toxicity) after the two conditioning regimens (CFM-TBI vs BEAM) for ASCT.

**Methods:** We performed a retrospective analysis of patients with NHL that

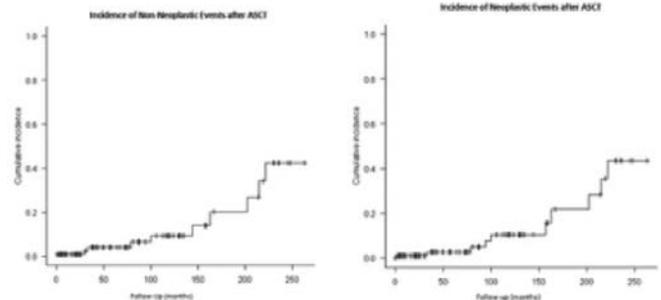

received an ASCT between October 1992 and December 2012. The late complications were defined as those to other previous comorbidity or to aging. Statistical analysis was performed using the IBM SPSS Statistics version 21.0. Cumulative incidences were estimated using EZR version 1.27 (Saitama Medical Center, Jichi Medical University, Omiya, Japan), a graphical user interface for R (version 3.1.1).

**Results:** A total of 105 autografted patients were analyzed. Patient's characteristics are in Table 1. The median follow up since ASCT was 73 months (0 – 274 months). Thirty-one percent (n=33) of patients were conditioned with CFM-TBI. The overall 5-years survival (OS) was 68.3% (58-77% - CI 95%) and the 5-year disease free survival (DFS) was 52% (42 61% - CI 95%). There were no differences regarding OS and DFS between the two conditioning regimens. The 5-years cumulative incidence (CI) of relapse was 0.48 (0.37-0.57, CI 95%). We detected 10 secondary neoplasm (myelodysplasia n=1, skin carcinoma n=2, lung carcinoma n=3, oropharyngeal carcinoma n= 1, intestinal adenocarcinoma n=1, renal neoplasia n=1, bladder neoplasia n=1). The median time for the neoplastic event was 10.5 years (0-18.5 years). The CI of secondary neoplasias (2nd neoplasia) at 10 years was 10% (1-20%, CI 95%) and at last point of follow up (18.5 years) was 40% (13%>63%, CI 95%). There were no differences in the CI of 2nd neoplasias between BEAM and CFM-TBI. Non-neoplastic complications were present in 10% of patients (n=11). Three cases were infections grade 3-4 related to ASCT. Six cases had cardiac complications (5 acute coronary syndrome, 1 myocardiopathy) and 2 had pulmonary toxicity. CI of non-2nd neoplastic complications at 10 year was 10% (1 – 25%, CI 95%). No differences were detected between the two conditioning regimens regarding non-neoplastic complications. (see Figure 1).

**Table 1. Patient's characteristics.**

	Frequency (n)	Percentage
Age (years)	51 years old (18-70 years)	
Gender	Male: 62	59%
Histology	Diffuse Large Cell Lymphoma: 40	38%
	Follicular Lymphoma: 65	62%
Prognostic Index (IPI or FLIPI) (when available, n=103)	Low risk: 23; Intermediate risk: 67; High risk: 13	22%/65%/13%
Response pre-ASCT	Complete Remission: 58	55%
	Partial Remission: 46	44%
	Stable disease: 1	1%
Number of Lines pre-ASCT	1 line: 11; 2 lines: 69; 3 lines: 18; 4 lines: 7	10%/66%/17%/7%
Conditioning	CFM-TBI: 33; BEAM: 74	31% / 69%

**Cumulative Incidence of Neoplastic and Non Neoplastic Events After ASCT**

**Figure 1.**

**Summary/Conclusions:** Autologous stem cell transplantation offers long disease free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events

**PB2160**

**THE MANAGEMENT OF RELAPSED HODGKIN'S LYMPHOMA AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION: DONOR LYMPHOCYTE INFUSION AND BRENTUXIMAB.**

I. Sánchez Bazán<sup>1,\*</sup>, A.L. Contento Gonzalo<sup>1</sup>, M.J. Pascual Cascón<sup>1</sup>, A.R. Martín Cerezo<sup>1</sup>, M.Á. Cuesta Casas<sup>1</sup>, A.I. Heiniger Mazo<sup>1</sup>  
<sup>1</sup>Hematology, Hospital Regional de Málaga, Málaga, Spain

**Background:** Hodgkin's lymphoma, is a heterogeneous malignancy which is possible to cure. For those patients who relapse, chemotherapy followed by an autologous transplantation (autoTPH) may conduce to a complete remission. Allogeneic transplantation (alo-SCT) is used for patients in relapse after auto-SCT or those with refractory advanced disease. Since 2012, with the experience of the Baltimore group, our Center has chosen the haploidentical family donor as a source for aloSCT in Hodgkin's disease. Despite the promising results, the rate of relapse is between 25 and 35%, and there is not standardized treatment for this situation.

**Aims:** To analyze the outcome of post-transplant relapse treatment of haploidentical donor haematopoietic progenitors (haploTPH).

**Methods:** We studied 18 patients with the diagnose of Hodgkins lymphoma in our center between August 2004 and July of 2013. All of them were submitted to haploSCT with a median follow-up of 495 days (455-1054).

**Results:** The median age was 32 years (21-60). 44% (8 patients) relapsed. 60% of them (5 patients) were nodular sclerosis histological subtype and 40% (3) lymphocytic predominance. 2 patients (25%) were diagnosed in stage IV and 75% (6) stage II. The median of number of treatment lines received before transplantation was 5.5 (4-7); Compared to 7 in the non-relapsed group (4-11). 5 patients (60%) of the patients who relapsed had reached haploTPH in complete remission and 40% in partial remission, we did not observe differences related to the pre-SCT status. Peripheral blood was used as progenitors source in 75% (6) of the patients who relapsed and in 70% (7) in the non-relapsed group. 38% of the whole group of patients, had a donor/recipient KIR alloreactivity without differences between the two groups of the study. 88% (7) of the relapses occurred before 6 months of the SCT. The mean time to relapse was 316 days (range 181-446). Between the 8 relapsed patients, one was treated by another center with Vimblastine / Dexamethasone and died by infection, another patient died by abdominal sepsis before starting any treatment. Brentuximab was administered in 63% (5) of the patients. One of them received a single Brentuximab cycle with no tolerance, and changed to RT, GPD+Donnor lymphocyte infusions (DLI) and had reached complete response after 5 DLI. The rest (4) received between 3 and 7 doses with adequate tolerance. According to the re-evaluation (PET-TC) after 3rd Brentuximab, 4 were in partial remission and one reached complete response. We associated Donor lymphocyte infusion in 6 patients. The mean of DLI received was 10; the median was 8, with a range between 2-3. Four patients reached complete remission, two of them maintain a partial response. All of them presented good tolerance to DLI. We observed Graft *versus* host disease in four patients, 3 of them presented moderate cutaneous affection, and one of them suffered hepatic graft *versus* host disease stage III, with adequate evolution after treatment.

**Summary/Conclusions:** Is possible to treat patients who relapsed after haploidentical stem cell transplantation with Brentuximab+DLI, with a very good tolerance. We observed cutaneous graft *versus* host disease in most of the patients who reached completed response after DLI. Despite this findings, we need multicentric studies to perform standardized treatments and protocols.

### CONDITIONING REGIMENS BEFORE AUTOLOGOUS STEM CELL TRANSPLANT FOR PATIENTS WITH MALIGNANT LYMPHOMA – LEED vs MCEC –

H. Shimizu<sup>1,\*</sup>, C. Naitoh<sup>2</sup>, Y. Osaki<sup>1</sup>, Y. Miyazawa<sup>3</sup>, K. Toyama<sup>2</sup>, H. Koiso<sup>1</sup>, A. Yokohama<sup>1</sup>, M. Morio<sup>3</sup>, H. Ogura<sup>4</sup>, N. Tsukamoto<sup>1</sup>, H. Handa<sup>1</sup>

<sup>1</sup>Gunma University, Maebashi, Gunma, <sup>2</sup>Fujioka General Hospital, Fujioka, Gunma, <sup>3</sup>Shibukawa Medical Center, Shibukawa, Gunma, <sup>4</sup>Maebashi Sekijui Hospital, Maebashi, Gunma, Japan

**Background:** High-dose chemotherapy before ASCT has been established as an effective treatment option for high-risk patients with chemo-sensitive ML. Although the therapeutic efficacy of this strategy highly depends on the conditioning regimens before ASCT, the appropriate regimen has been controversial. Thus, we performed a multi-center retrospective study of ASCT recipients with ML to compare the safety and efficacy of the conditioning regimens LEED and MCEC, which are widely used in Japan.

**Aims:** The primary objective was to determine the preferable conditioning regimen before ASCT: LEED or MCEC.

**Methods:** This study analyzed 127 adult patients who underwent ASCT following LEED or MCEC as the conditioning regimen against chemo-sensitive ML at four institutions in Japan between 1997 and 2015. Any type of pathological diagnosis was considered. The LEED regimen consisted of 140 mg/m<sup>2</sup> L-PAM (day -1), 500 mg/m<sup>2</sup> etoposide (days -4 to -2), 60 mg/kg cyclophosphamide (days -4 to -3), and 40 mg/body dexamethasone (days -4 to -1). The MCEC regimen consisted of 200 mg/m<sup>2</sup> MCNU (days -8 and -3), 300 mg/m<sup>2</sup> carboplatin (days -7 to -4), 500 mg/m<sup>2</sup> etoposide (days -6 to -4), and 50 mg/kg cyclophosphamide (days -3 to -2). Fisher's exact test was used to compare binary variables. OS rates were estimated by the Kaplan-Meier method and compared using the log-rank test. Cumulative incidences (CIs) of relapse and non-relapse mortality (NRM) were compared using the stratified Gray test. The Cox proportional hazards regression model was used for multivariate analysis of OS. Values of p <0.05 were considered significant.

**Results:** Of the 127 patients, 76 were male and 51 were female, and the median age was 56 years (range: 18 to 68 years). Underlying diseases were DLBCL in 74 patients, mantle cell lymphoma in 16, other B-cell lymphoma in 14, Hodgkin lymphoma in 9, and T-NK-cell lymphoma in 14. The disease status at the time of transplant was first complete remission (CR) in 68, advanced CR in 27, and partial remission in 32. As the conditioning regimens before ASCT, 81 patients (64%) received the LEED regimen, and 46 (36%) received the MCEC regimen. No significant differences in patient characteristics, disease features, or transplant procedures were present between the two groups except for the following three factors: (1) ASCT in the later period (2007–2015) in the

LEED group compared with the MCEC group (72% vs 13%; p <0.01); (2) more frequent administration of rituximab before ASCT in the LEED group (84% vs 59%; p <0.01); and (3) less frequent radiation therapy before ASCT in the LEED group (17% vs 37%; p=0.02). The 5-year OS rates were not significantly different between the LEED and MCEC groups (77% vs 68%; p=0.35). Likewise, both the 5-year CIs of relapse and NRM were similar in the two groups (relapse: 39% vs 33%; p=0.61, NRM: 1% vs 5%; p=0.71). In multivariate analysis that included the transplant periods, rituximab administration, and radiation therapy as independent variables, two or more prior regimens was extracted as an independent unfavorable prognostic factor for OS, but not conditioning regimens. Regimen-related toxicities within 100 days after ASCT were assessed. The incidences of grade 3-4 nausea (36% vs 78%; p <0.01), vomiting (4% vs 28%; p <0.01), diarrhea (36% vs 56%; p=0.02), and liver dysfunction (4% vs 36%; p <0.01) were significantly decreased in the LEED group. The 5-year CIs of secondary MDS/AML were similar between the two groups (4% vs 3%; p=0.62).

**Summary/Conclusions:** Our findings demonstrated that both the LEED and MCEC regimens showed sufficient anti-lymphoma effect as conditioning regimens before ASCT, with a 5-year OS rate of more than 70% in patients with chemo-sensitive ML. However, the LEED regimen is considered more preferable in comparison with the MCEC regimen based on the low frequency of severe regimen-related toxicities. A large-scale prospective study is warranted to confirm these findings.

### ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SECONDARY HAEMATOLOGICAL NEOPLASIA: A SINGLE CENTER EXPERIENCE

E. Metafuni<sup>1</sup>, P. Chiuloso<sup>1</sup>, L. Laurenti<sup>1</sup>, F. Sorà<sup>1</sup>, S. Giammarco<sup>1</sup>, G. Leone<sup>1</sup>, A. P. Bacigalupo<sup>1</sup>, S. Sica<sup>1,\*</sup>

<sup>1</sup>Hematology Department, Fondazione Policlinico agostino Gemelli, Rome, Italy

**Background:** Therapy related haematological neoplasms (t-HN) occur due to direct mutational events of chemotherapeutic agents and radiotherapy. Disease latency, mutational events and prognosis vary with drugs categories.

**Aims:** The aim of this retrospective study was to assess the outcome of t-HN after hematopoietic stem cell transplantation (HSCT).

**Methods:** We describe a cohort of 31 patients, 19 females (61.3%) and 12 males (38.7%), with median age of 53 years (range, 20 to 64), who received an allogeneic HSCT in our Unit, between September 1999 and July 2016. Patients had a history of solid tumor in 15 cases (48.4%), haematological malignancies in 15 cases (48.4%) and both of them in one case (3.2%). All but one received a median of 2 (range, 1 to 6) lines of therapy. After a median of 36 months (range 12-190) from the first neoplasia, patients developed t-AML (n=19) (61.3%), t-Ph+ ALL (n=1) (3.2%), or t-MDS (n=11) (35.5%). Molecular abnormalities were detected in 7 (46.7%) out of 15 evaluable patients: BCR/ABL (1), ITD FLT3 (2), inv16 (1), NPM1 (2), NPM1+ITD FLT3 (1). Karyotype aberrations were found in 18 (64.3%) out of 28 evaluable patients: 16.7% was favourable risk (n=3), 27.8% was intermediate risk (n=5) and 55.5% was adverse risk (n=10). The disease status at transplant was as follows: complete remission (n=13) (42%), refractory disease (N=10) (32%), stable disease (n=3) (10%). Patients received conventional chemotherapy in 14 cases (45.2%), azacitidine in 11 cases (35.5%), both of them in one case (3.2%), whereas 5 patients (16.1%) were untreated. The conditioning was myeloablative (MAC) in 20 patients (64.5%) or reduced intensity (RIC) in 11 patients (35.5%); the donor was a family member (REL) in 17 patients (54.8%) or unrelated (MUD) in 14 patients (45.2%). The hematopoietic cell transplantation comorbidity index (HCT-CI) was as follows: 14 patients (45.2%) had a score of 3 and 17 patients (54.8%) had a score of 4 or more. Overall survival was calculated with Kaplan-Meier method. Transplant-related mortality (TRM) and relapse-related mortality (RRD) rates were estimated by cumulative incidence (CI), both considering the opposite event as competing. Fine and Gray's method for CI of TRM and RRD was used to evaluate the risk factors on univariate analysis.

**Results:** Twenty-three patients were in remission on day +30, by bone marrow cytology, 3 patients were classified as resistant disease and five patients were not evaluable because of early death. Five patients (21.7%) relapsed after a median 6 months (range, 3 to 15). At the time of this analysis (December 2016) 14 patients were alive with a median OS of 53 months (range 8-190), while 17 patients died after a median of 4 months (range 1-27): RRD was 16% (n=5) and TRM was 39% (n=12). Non relapse causes of death were as follows: GvHD (n=3), infectious complications (n=8) and EBV-related PTLD (n=1). One patient experienced a third tumor (breast cancer) thirteen years from HSCT. TRM was higher for patients transplanted from MUD (66%) as compared to REL donor (16%) (p=0.01). The overall survival was 45.2% (Figure 1) and 58% maintained a complete remission.

**Summary/Conclusions:** This report confirms that allogeneic HSCT is a curative approach in approximately 50% of patients with therapy related haematological neoplasms, especially for those patients who benefit from a familial donor.

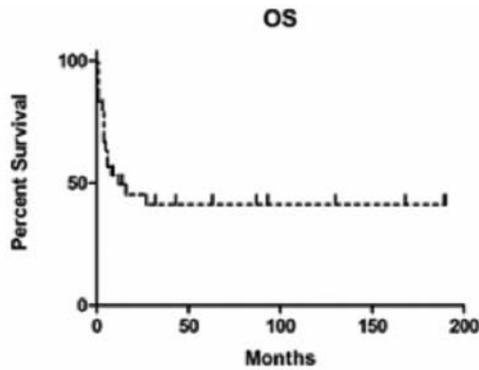

Figure 1.

**PB2163**

**IMPROVEMENT IN BIVENTRICULAR CARDIAC MECHANICS NOTED IN PATIENTS UNDERGOING MYELOABLATIVE AUTOLOGOUS-HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AL AMYLOIDOSIS**

S. Heitner<sup>1,\*</sup>, C. Purtell<sup>2</sup>, E. Scott<sup>3</sup>

<sup>1</sup>Knight Cardiovascular Institute, <sup>2</sup>Department of Medicine, <sup>3</sup>Knight Cancer Institute, Oregon Health and Science University, Portland, United States

**Background:** Primary amyloidosis (AL) is characterized by extracellular deposition of insoluble protein fibrils often with multisystem organ involvement. The Mayo staging model for determining prognosis in patients with cardiac amyloidosis takes into account troponin, NT-proBNP, and serum free-light chain difference in order to stage patients prior to undergoing autologous hematopoietic stem cell transplant (Auto-HCT). Since amyloidosis often involves the kidneys, serum biomarkers that require renal clearance are less reliable in the setting of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.

**Aims:** Our hypothesis is that strain imaging is a feasible biomarker for cardiac response after Auto-HCT in AL amyloidosis.

**Methods:** Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using EchoInsight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

**Results:** Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed an improvement (baseline -14.69%; follow-up -16.84%; mean absolute improvement 2.15%;  $p < 0.05$ ) across all four Mayo Stages. There was no difference in GLS within individual stages. In patients with stable NYHA classification after transplant, there was also a significant improvement in Right Ventricular Free-Wall Strain (RVFWS) with a mean absolute improvement of 6.2% ( $p < 0.05$ ). There was no significant change in left ventricular ejection fraction (LVEF) (Figure 1).

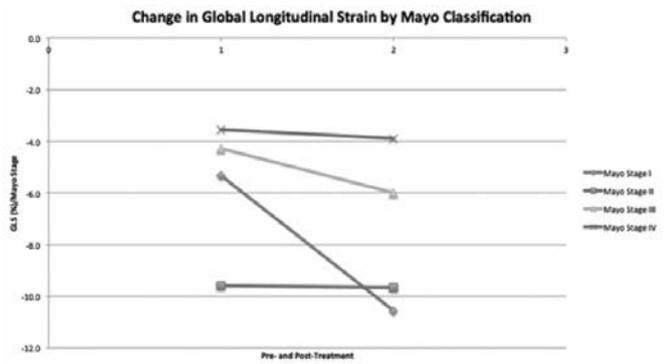

Figure 1.

**Summary/Conclusions:** We demonstrate that there is a clinically meaningful improvement in cardiac mechanics one year after Auto-HCT, despite no alter-

ation in LVEF. This metric may prove useful in assessing organ response, especially when serum biomarkers are less reliable. Changes in left ventricular GLS occur independent of pre-transplant Mayo stage, although prospective studies are needed for confirmation. We further believe that improvements in RVFWS may predict clinical improvement.

**PB2164**

**AN ABSOLUTE NUMBER OF CD34+ CELLS IN BLOOD AS A PREDICTOR OF A SUCCESSFUL HARVEST OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS**

I. Galtseva<sup>1,\*</sup>, Y. Davydova<sup>1</sup>, T. Gaponova<sup>1</sup>, N. Kapranov<sup>1</sup>, L. Kuzmina<sup>1</sup>, V. Troitskaya<sup>1</sup>, E. Zvonkov<sup>1</sup>, E. Parovichnikova<sup>1</sup>, L. Mendeleeva<sup>1</sup>, V. Savchenko<sup>1</sup>

<sup>1</sup>Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

**Background:** Autologous stem cells transplantation (ASCT) has become necessary part in therapy of hematological diseases. Transfusion of at least  $2 \times 10^6$  CD34+ HSCs per kg of patient's weight allows achieving an adequate hematopoiesis after high-dose chemotherapy. The most optimal is to collect  $\geq 2 \times 10^6$  CD34+ cells/kg with single harvest apheresis. Different mobilization regimens lead to variations in white blood cell count (WBC) and the number of circulating HSCs. Deciding on the time of the first leukapheresis is very important. **Aims:** The aim was to identify significant parameter predicting efficiency of CD34+ cells collection.

**Methods:** The study included 142 patients (pts) who undergo ASCT (80 m, 62 f, median age 53 y.o., 81 were diagnosed with multiple myeloma, 10 - Hodgkin's lymphoma, 51 - non-Hodgkin's lymphomas). WBC and absolute CD34+ number in the blood before the first apheresis and the number of CD34+/kg in the apheresis product were determined for each patient. There were three different mobilization regimens: 12 pts received 10 µg/kg/day G-CSF in the stable hematopoiesis for 5-6 days; 86 pts - 4 g/m<sup>2</sup> cyclophosphamide and 5-10 µg/kg/day G-CSF (Cph+G-CSF); 44 pts - DHAP: 40 mg dexamethasone, 100 mg/m<sup>2</sup> cisplatin, 2g/m<sup>2</sup> cytarabine and 10 µg/kg/day G-CSF (DHAP+G-CSF). CD34+ HSCs were evaluated with ISHAGE-protocol by BD FACSCanto II flow cytometer. Results are presented as mean±SEM. ROC-analysis was performed for WBC and the absolute number of CD34+ HSCs in the blood as the predictor markers for HSCs successful harvesting ( $\geq 2 \times 10^6$  CD34+/kg for first apheresis).

**Results:** WBC mean was higher in pts with G-CSF mobilization scheme compared to Cph+G-CSF and DHAP+G-CSF (28.5±3.5 vs 10.4±0.9 and 9.0±1.8×10<sup>9</sup>/l, respectively,  $p < 0.0001$ ), but the absolute number of CD34+ HSCs in the blood (26.3±9.3 vs 55.5±5.6 and 93.1±22.3/µl,  $p = 0.03$ ) and the number of CD34+/kg in the leukapheresis product (1.9±0.7 vs 5.2±0.6 and 6.9±1.3×10<sup>6</sup>/kg,  $p = 0.01$ ) were lower. Differences between Cph+G-CSF and DHAP+G-CSF in all parameters were not found. There was not any relationship between WBC and the number of CD34+/kg: the area under ROC-curve (AUC) didn't differ from 0.5 for all mobilization regimens. Then absolute number of CD34+ in blood was investigated as predictor for harvest success, AUCs were 0.964, 0.938 and 0.979 ( $p < 0.0001$ ) for G-CSF, Cph+G-CSF and DHAP+G-CSF, respectively. In the ROC-analysis showed the optimal CD34+ number in blood than most likely to collect  $\geq 2 \times 10^6$  CD34+/kg for first leukapheresis. It was 29 CD34+cells/µl in G-CSF mobilization, 24 CD34+cells/µl - in Cph+G-CSF and 27 CD34+cells/µl - in DHAP+G-CSF. To calculate universal level of absolute CD34+ number all data from 142 pts was used. In this case AUC was 0.952 and a threshold of successful harvesting was 20 CD34+cells/µl in blood before apheresis with sensitivity of 96% and specificity of 81%.

**Summary/Conclusions:** Various mobilization regimens differ in count of leucocytes and CD34+ HSCs in peripheral blood: WBC was significant higher in G-CSF than in Cph+G-CSF and DHAP+G-CSF, but the absolute number of CD34+ cells was higher in chemotherapy-based mobilization and G-CSF than in G-CSF alone. The absolute number of leucocytes in blood before apheresis was not a predictor factor of harvest success in all variants of mobilization regimens. If there is at least 20 CD34+cells/µl in blood before apheresis it is possible to collect  $\geq 2 \times 10^6$  CD34+/kg for single leukapheresis with high sensitivity and specificity independent of mobilization regimen.

**PB2165**

**QUANTIFICATION OF CD34+ CELL AND ITS VIABILITY OF FRESH OR CRYOPRESERVED NUCLEATED CELLS BY IMAGE-BASED CELL COUNTER IS COMPARABLE TO STANDARD FLOW CYTOMETER**

Y.-H. Lee<sup>1,2,\*</sup>, W.-J. Rah<sup>1</sup>, H. Koh<sup>1,2</sup>, J.Y. Suh<sup>2</sup>, H.J. Eom<sup>2</sup>, E.-K. Shin<sup>1</sup>, J. Uhm<sup>2,3</sup>, J.H. Oh<sup>4</sup>, J.-Y. Lee<sup>4</sup>, S.R. Bong<sup>4</sup>, J.Y. Kim<sup>4</sup>, S. Han<sup>4</sup>, C. Chung<sup>4</sup>, H.J. Park<sup>4</sup>, J.K. Yoon<sup>4</sup>

<sup>1</sup>Department of Pediatrics, <sup>2</sup>Blood & Marrow Transplantation Center, <sup>3</sup>Department of Internal Medicine, Hanyang University Medical Center, <sup>4</sup>NanoEntek, Seoul, Korea, Republic Of

**Background:** As a standard method for quantification of CD34+ stem cells, flow cytometry has been widely used. However, it has some limitations such as

expensive instrumentation, high reagent costs, and poor reproducibility between technicians and laboratories.

**Aims:** We developed and assessed an instrument performance of a newly-developed image-based microscopic cell counter (ADAM II<sup>TM</sup>) for enumeration of CD34+ cell and its viability.

**Methods:** We used samples of fresh and cryopreserved nucleated cells from G-CSF mobilized peripheral blood stem cells (PBSCs) as well as cord blood (CB). We assessed the reproducibility and linearity of the new device and compared numbers and viabilities of CD45+ cells and CD34+ cells determined with the ADAM II<sup>TM</sup> and flow cytometer.

**Results:** Each analysis used 10 aliquots from one sample to assess the reproducibility of ADAM II<sup>TM</sup>, with expected values of 14.77~172.06 CD34+ cells/0.08~0.56 CD34(%) / CD45. The number of CD34+ cells determined by ADAM II<sup>TM</sup> was sufficiently accurate over the expected range, and the intra-assay coefficient of variation (CV) was ≤10.8%. The linearity of CD34+ cell counts was confirmed over a range of dilutions (0.58~280 cells/□ of sample). Linearity was satisfactory (R<sup>2</sup>=0.99). The numbers and viabilities of CD45+ cell and CD34+ cell obtained with the ADAM II<sup>TM</sup> were highly correlated with those obtained with the flow cytometer (R<sup>2</sup>>0.9841, p<0.0001). In all samples from fresh/cryopreserved PBSC and fresh/cryopreserved CB, there were no significant differences of total numbers and viabilities of CD45+ cell and CD34+ cell count analyzed from ADAM II<sup>TM</sup> as well as flow cytometer.

**Summary/Conclusions:** The newly developed image-based microscopic cell counter (ADAM II<sup>TM</sup>) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

**EXTRACORPOREAL PHOTOPHERESIS IN STEROID-DEPENDENT OR REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE**

I. Sakellari<sup>1</sup>, I. Batsis<sup>1</sup>, E. Gavrilaki<sup>1,\*</sup>, A. Panteliadou<sup>1</sup>, A. Lazaridou<sup>1</sup>, K. Leontopoulos<sup>1</sup>, D. Mallouri<sup>1</sup>, A. Bouinta<sup>1</sup>, V. Constantinou<sup>1</sup>, E. Yannaki<sup>1</sup>, C. Smias<sup>1</sup>, A. Anagnostopoulos<sup>1</sup>

<sup>1</sup>Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

**Background:** Extracorporeal photopheresis (ECP) has been incorporated in the management of graft-versus-host disease (GVHD) post allogeneic haematopoietic cell transplantation (alloHCT) in many centres. The introduction of ECP as an early second-line treatment in steroid-dependent or refractory patients with acute GVHD (aGVHD) remains under study. The rationale of its early use is based on the low incidence of complete responses to corticosteroids and the profound immunosuppression caused by traditional secondary treatments.

**Aims:** Based on our long-lasting experience in chronic GVHD, we aimed to prospectively assess the role of ECP in this high-risk population.

**Methods:** We enrolled consecutive patients with steroid-dependent or refractory grade (gr) II-IV aGVHD post alloHCT from January 2013 to August 2016. All patients with unrelated or haploidentical donors received thymoglobulin (ATG) 5mg/kg as prophylaxis. Post-transplant GVHD prophylaxis included cyclosporine – methotrexate in myeloablative and cyclosporine – mycophenolate mofetil in reduced toxicity or intensity regimens. ECP was commenced after assessment of response to 5 days of steroid treatment according to our protocol: 2 sessions/week for 1 month, 1 session/2 weeks for 3 months, evaluation of response and 1 session/month for 6 months.

**Results:** We studied 20 patients, aged 35 (18-65), post alloHCT with myeloablative (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (3), matched (8) or one locus mismatched (8) volunteer unrelated and haploidentical (1) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +17 (8-50) in 15 patients, late-onset at +130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GrII, 7 with GrIII aGVHD) were steroid-dependent and 11 (8 with GrIII, 3 with GrIV) steroid-refractory. ATG was administered simultaneously with ECP initiation in 6 refractory patients that further developed EBV reactivation (p=0.032) treated pre-emptively with rituximab. ECP was commenced at day +51 for 16 (4-20) sessions. The majority of patients (16/20) presented partial (6), very good (9) or complete (1) response to ECP. With 9.3 (1.8-54.7) months of follow-up, immunosuppression was reduced in 10/20 and ceased in 1 patient. Clinically significant bacterial infections were found in 17 patients, fungal in 2, CMV and EBV reactivation in 14 and 13 respectively and other viral in 5 patients. Cumulative incidence (CI) of chronic GVHD was 77.4 at 1-year. 1-year CI of aGVHD-related mortality was 20%. 1-year overall survival (OS) was 53% and significantly increased in steroid-dependent versus refractory patients (76% vs 36%, p=0.041). Reduction of immunosuppression (p=0.026) and steroid dependence (p=0.023) were associated with improved OS, irrespectively of other factors.

**Summary/Conclusions:** Our study supports that ECP should be considered early in the course of steroid-dependent or refractory aGVHD, before significant irreversible end organ damage has been established. Optimal timing of intervention, frequency, duration and tapering schedule of ECP need to be investigated in future studies.

**RAPID RECONSTITUTION OF NK1 CELLS IS ASSOCIATED WITH THE LOWER INCIDENCE OF GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENEIC TRANSPLANTATION**

X. Zhao<sup>1,\*</sup>, L. Xu<sup>1</sup>, X. Yu<sup>1</sup>, Y. Chang<sup>1</sup>, X. Huang<sup>1</sup>

<sup>1</sup>Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

**Background:** The balance between immunostimulation and immunoregulation in T cell immunity is achieved by a Th1/Th2/Th3/Tr1 and CD4+CD25+ regulatory T (Treg) cell paradigm.

**Aims:** We investigated the production of type1 (IFN-gamma, NK1), type2 (IL-13, NK2), type3 (TGF-beta, NK3) and regulatory cytokines (IL10, Nkr) from human peripheral blood to discuss the cytokine paradigm of NK cells in human allogeneic hematopoietic stem cells transplantation (allo-HSCT).

**Methods:** Forty patients undergoing haploidentical (n=27) and HLA-identical sibling (n=13) allo-HSCT between August 2009 and December 2009 were enrolled in this analysis after being originally selected using a protocol exploring the association of reconstituted donor derived NK1/NK2/NK3/Nkr cells to GVHD and CMV reactivation.

**Results:** Expansion of NK2 and NK3 were found post allo-HSCT compared to healthy donor. The levels of Nkr reconstituted to donor's level since day 15 post allo-HSCT, and the levels of NK1 in recipients post transplantation were consistently lower compared to donors' levels until day 60 post allo-HSCT. Multivariate analysis showed that the higher levels of NK1 by day 15 were associated with lower overall acute GVHD (HR 0.157, 0.039-0.642, P=0.010) as well as II-IV acute GVHD (HR 0.260, 95%CI, 0.064-1.053, P=0.059). Meanwhile, the higher levels of NK1 by day 15 correlated with lower CMV reactivation (HR 0.040, 0.005-0.348, P=0.003).

**Summary/Conclusions:** These results indicate that rapid reconstitution of NK cells; especially NK1 cells would be help to prevent the development of graft-versus-host disease as well as CMV reactivation after allogeneic transplantation.

**PB2168**

**BORTEZOMIB FOR STEROID-REFRACTORY RITUXIMAB AUTOIMMUNITY AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION**

M. Zine<sup>1,\*</sup>, T. Khalid<sup>1</sup>, S. Kafka<sup>1</sup>, D. Bonney<sup>1</sup>, S. Hughes<sup>1</sup>, S.H. Lum<sup>1</sup>, R. Wynn<sup>1</sup>

<sup>1</sup>Bone Marrow Transplant Unit, Royal Manchester Children's Hospital, Manchester, United Kingdom

**Background:** Therapy of post-transplant autoimmunity manifestations remains a challenge. Many cases are steroid and rituximab refractory and continuing intensified immune suppression increase the risk of infection in the post-HSCT patient. In our institution, we have used bortezomib as our third agent after failure of steroids or rituximab, or in cases of steroid-dependence since Bortezomib appears to be effective in cases with refractory autoimmunity.

**Aims:** In our series, we assessed the therapeutic response to proteasome inhibitor in 4 cases of post-transplant refractory autoimmunity

**Methods:** Three of the 4 cases received Bortezomib for autoimmune cytopenia (autoimmune haemolytic anaemia AIHA (n=2), AIHA with acquired red Cell Aplasia (n=1)). At least 2 therapy lines had failed to resolve the cytopenia. One to two courses of Bortezomib were administered at a dose of 1.3 mg/m<sup>2</sup> at day 1, 4, 8, 11 each course. In two cases this treatment was combined with immunosuppressive agents: Mycophenolate mofetil (MMF) alone in one case and associated with sirolimus in the other case.

**Results:** Resolution of autoimmune cytopenia was observed in the three cases after a median of 33 days from the first day of administration. The fourth case received 1 course of Bortezomib for persistent anti-enzyme antibodies after allogeneic transplant for Wolman disease. Therapeutic response was obtained after 25 days reflected by a complete regression of circulating anti-enzyme antibodies. In all cases, no Bortezomib related toxicity was noticed. The response was maintained in all cases.

Table 1 summarizes the clinical data and the results of the four cases.

**Table 1.**

patients	Age at Allogeneic HSCT	Diagnosis	post-transplant bortezomib indication	Previous treatments	bortezomib courses (n)	Response	Time to response	bortezomib-related toxicity	loss of response at last follow up
1	14	Beta thalassemia	AIHA	IVIg, Sirolimus, Steroids, Rituximab, Cyclophosphamide, Splenectomy	2	Yes	33	None	No
2	91	myelodysplastic syndrome trisomy 8	AIHA	IVIg, Steroids, Rituximab, MMF	2	Yes	57	None	No
3	14	Mucopolysaccharidosis type I	AIHA with Acquired Red Cell Aplasia	Rituximab, MMF	1	Yes	14	None	No
4	25	Wolman disease	Anti-enzyme antibodies	None	1	Yes	25	None	No

**Summary/Conclusions:** Our study shows that Bortezomib is a promising therapeutic option for refractory post-transplant autoimmunity with high tolerance and no related toxicities.

## PB2169

**POST-THAW CELL COUNT PREDICTS ENGRAFTMENT RATE IN CORD BLOOD TRANSPLANTATION**K. Isobe<sup>1,\*</sup>, K. Koh<sup>1</sup>, R. Kawakami<sup>1</sup>, T. Itabashi<sup>1</sup>, M. Yanagi<sup>1</sup>, K. Sasaki<sup>1</sup>, K. Watanabe<sup>1</sup>, M. Mori<sup>1</sup>, Y. Arakawa<sup>1</sup>, R. Hanada<sup>1</sup><sup>1</sup>Hematology/Oncology, Saitama Children's Medical Center, Saitama, Japan

**Background:** The infused cell count in cord blood transplantation (CBT) is an important element for engraftment; however, this number in the prior reports has been based on the pre-thaw cell count. Therefore, the association between post-thaw cell count and engraftment rate, especially in pediatric patients, is unclear.

**Aims:** The Aim of this study is to reveal the association between post-thaw cell count and engraftment rate in pediatric patients in the setting of CBT at our institution.

**Methods:** We retrospectively reviewed the medical records of 78 patients who underwent CBT between June 1998 and April 2016. We excluded the cases of CBT that required rescuing after engraftment failure.

**Results:** Underlying disease was acute leukemia (AL) in 63 (ALL, 38; AML, 25) patients, chronic myeloid leukemia in one, malignant lymphoma (ML) in two, myelodysplastic syndrome (MDS) in three, aplastic anemia in one, and others (such as primary immunodeficiency syndrome) in eight. In terms of conditioning regimens, myeloablative conditioning was administered to 62 patients and reduced intensity conditioning was administered to 16 patients. The median age at CBT was 3 (range, 0–19) years, and the median follow-up period was 898 (range, 47–6236) days. The engraftment rate was 84.6%, primary engraftment failure was observed in 11 patients (AL, seven; ML, one; MDS, one; neuroblastoma, one; and others, one) and secondary graft failure was observed in one patient (severe congenital neutropenia). The 3-years overall survival rate was 55.1%, and 32 patients had died (cause of death: progressing disease in 19 patients). We analyzed the data on 34 patients of whom both of pre- and post-thaw CD34+ cell counts in the cord blood samples were available. The median pre- and post-thaw CD34+ cell counts were  $1.67 \times 10^5/\text{kg}$  and  $1.51 \times 10^5/\text{kg}$ , respectively, and they were significantly correlated with each other ( $r=0.73$ ,  $p=0.52$ ). In our study cohort, the engraftment failure occurred in five patients (primary in all patients). The median post-thaw CD34+ cell count was  $1.60 \times 10^5/\text{kg}$  in the patients who achieved engraftment and  $1.01 \times 10^5/\text{kg}$  in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups ( $p=0.30$ ). When we defined the cut-off value of the pre-thaw CD34+ cell count as  $1.2 \times 10^5/\text{kg}$  in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as  $0.7 \times 10^5/\text{kg}$  in the patients who were infused with CD34+ cells more than the cut-off value, the specificity and sensitivity of graft failure was 96.6% and 40%, respectively.

**Summary/Conclusions:** We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+ cell count and that if the post-thaw CD34+ cell count is more than  $0.7 \times 10^5/\text{kg}$ , the risk of graft failure is very low.

## PB2170

**COLONYFORMING CAPACITY OF HEMATOPOIETIC STEM CELLS MOBILIZED INTO PERIPHERAL BLOOD WITH VINORELBINE AND GRANULOCYTE COLONY STIMULATING FACTOR**V. Balashova<sup>1</sup>, I. Kostroma<sup>2,\*</sup>, I. Zapreeva<sup>2</sup>, V. Rugal<sup>1</sup>, S. Bessmeltsev<sup>2</sup>, A. Chechetkin<sup>2</sup>, S. Gritcaev<sup>2</sup><sup>1</sup>Laboratory of Leukemia Study, <sup>2</sup>Hematological Clinic, Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

**Background:** One of the alternative method to mobilize stem cells from bone marrow to peripheral blood is using of vinorelbine with granulocyte colony stimulating factor (G-CSF). The specific features of vinorelbine are absence of hospitalization necessity and predictability of leukocytapheresis' optimal time. But there is not enough data to conclude whether vinorelbine is safe for haematopoietic stem cells.

**Aims:** The aim of the study was to determine the colonyforming capacity of haematopoietic stem cells mobilized into peripheral blood with vinorelbine and G-CSF.

**Methods:** Data of 11 patients with multiple myeloma (MM) and 1 patient with Hodgkin lymphoma (HL) were analyzed. Vinorelbine was injected IV in dose 50-70 mg (35 mg/m<sup>2</sup>). Daily lenograstim dose was 10 mcg/kg. The number of BFU-E, CFU-GM, CFU-GMME and CFU-Macrophage was studied in 14-days culture:  $1 \times 10^5$  cells of leukocytapheresis product were set into Petri dish with MethoCult H 4435 full medium. Control group was consisted of hematopoietic stem cells donors' data in which G-CSF monotherapy was used for mobilization.

**Results:** The median patients' age was 55 (43-64) y. Induction courses for MM treatment included bortezomib (11 patients), lenalidomide (5 patients) and carfilzomib (1 patient) in combination with steroids. A patient with HL was treated with ABVD scheme. Leukocytaphereses were started on 6-8 day, here-with in 9/11 (75%) patients on 7 day. The number of gained CD34+ was  $1.7-7.8 \times 10^6/\text{kg}$  (Me  $3.3 \times 10^6/\text{kg}$ ). Median number of BFU-E, CFU-GM, CFU-GMME

and CFU-Macrophage in patients' group was 207, 180, 14 and 9 accordingly. The results were not significantly different from control group data: 168, 170, 10 and 12 accordingly;  $p < 0.05$ .

**Summary/Conclusions:** We conclude that mobilization regimen with vinorelbine in combination with G-CSF does not damage colonyforming capacity of hematopoietic stem cells.

## PB2171

**URIC ACID LEVEL MIGHT BE A PROGNOSTIC INDICATOR FOR SURVIVAL IN PATIENTS WHO UNDERWENT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION. SINGLE CENTER EXPERIENCE**N. Mandaci Şanlı<sup>1,\*</sup>, S. Şıvgın<sup>1</sup>, L. Kaynar<sup>1</sup>, B. Eser<sup>1</sup>, M. Çetin<sup>1</sup>, A. Ünal<sup>1</sup><sup>1</sup>Hematology and Bone Marrow Transplant Center, Erciyes University School of Medicine, KAYSERİ, Turkey

**Background:** Uric acid (UA) is an abundant aqueous antioxidant that accounts for almost two thirds of all free-radical-scavenging activity in human serum. It is released from injured cells during conditioning for allogeneic hematopoietic stem cell transplantation (AHSCT).

**Aims:** The aim of this study was to evaluate the prognostic impact of pre transplantation uric acid levels on survival and mortality in allogeneic HSCT patients.

**Methods:** We retrospectively analyze 273 patients with hematologic diseases undergoing AHSCT. The patients were categorized as patients with acute leukemia, myelodysplastic syndrome, lymphoma patients and other hematologic disease diagnoses. A serum uric acid concentration 3.4 mg/dl was considered hypouricemia. Pretransplantation uric acid, creatine, total protein and albumin were analyzed. Univariate, multivariate Cox regression models and Kaplan-Meier curves were performed to uric acid, creatine, total protein and albumin associated with disease-free survival (DFS), over all survival (OS), early non relaps mortality (+30 day) and late non relaps mortality (+100 day).

**Results:** Pretransplantation low uric acid levels were detected in 57 (%20.8) patients. Low UA levels were significantly associated with DFS (HR: 0.52;  $p=0.027$ ). None of the creatine, total protein and albumin were significantly associated with DFS (HR: 0.98;  $p=0.98$ , HR: 0.87  $p=0.60$ , HR: 1.15;  $p=0.66$ ). There was no significant association between UA, creatine, total protein and albumin levels and overall survival (HR: 0.84;  $p=0.46$ , HR: 2.10;  $p=0.057$ , HR: 0.88;  $p=0.52$ , HR: 0.78;  $p=0.26$ ), early relapse mortality (HR: 1.38;  $p=0.54$ , HR: 2.16;  $p=0.29$ , HR: 0.61;  $p=0.25$ , HR: 0.53;  $p=0.13$ ) and late non-relapse mortality (HR: 0.57;  $p=0.35$ , HR: 0.21;  $p=0.29$ , HR: 1.04;  $p=0.94$ , HR: 1.07;  $p=0.92$ ).

**Summary/Conclusions:** Uric acid is a natural antioxidant compound. UA reacts with oxygen-derived free radicals and becomes oxidized. Since humans are unable to catabolize UA to the more soluble compound allantoin due to lack of urate oxidase or uricase, the serum UA concentration is higher in humans than almost all other mammals. However, this high UA level in humans has been regarded as being beneficial in the presence of elevated oxidative stress. Our study supports that the uric acid is a antioxidant compound. Because disease-free survival is lower in patients with low uric acid levels before transplantation. This is the first report demonstrating a positive association between UA levels and survival analyses in allogeneic HSCT patients. Our findings are potentially clinically relevant. Confirmation in independent cohorts and further investigations into underlying mechanisms, such as reduced antioxidant capacity in hypouricemia, are warranted. In the coming years, as a result of increased works on this subject, uric acid may be considered a possible prognostic marker in allogeneic hematopoietic stem cell transplantation.

## PB2172

**RISK FACTORS FOR HERPES SIMPLEX VIRUS-1/2 VIREMIA AND CLINICAL OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HAEMATOPOIETIC STEM CELL TRANSPLANTATION**F.-F. Tang<sup>1</sup>, L.-P. Xu<sup>1</sup>, X.-H. Zhang<sup>1</sup>, H. Chen<sup>1</sup>, Y.-H. Chen<sup>1</sup>, X.-D. Mo<sup>1</sup>, Y.-Q. Sun<sup>1</sup>, K.-Y. Liu<sup>1</sup>, X.-J. Huang<sup>1,\*</sup><sup>1</sup>Peking University People's Hospital, Peking University Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

**Background:** Herpes simplex virus(HSV)-1/2 can still be reactivated after allogeneic haematopoietic stem cell transplantation (allo-HSCT) even when the prophylactic acyclovir used. However, the risk factors for HSV-1/2 viremia and the clinical outcomes following unmanipulated haploidentical HSCT remain unknown.

**Aims:** The aim of this study was to explore the risk factors for HSV-1/2 viremia and to evaluate clinical outcomes following haplo-HSCT.

**Methods:** Nineteen patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia which were selected using the case-pair method after haploidentical HSCT were enrolled. We analysed the risk factors for HSV-1/2 viremia and compared clinical outcomes between the two patient groups.

**Results:** The risk factors for HSV-1/2 viremia included HLA disparity  $\geq 2$  loci ( $p=0.049$ ) and cytomegalovirus (CMV) reactivation ( $p=0.028$ ). The incidences of platelet engraftment, oral mucositis and severe haemorrhagic cystitis (HC) in patients with and without HSV-1/2 viremia were 77% and 94% ( $p=0.003$ ),

78% and 13% ( $p=0.000$ ), and 25% and 6% ( $p=0.04$ ), respectively. Moreover, the median time to platelet engraftment in patients with and without HSV-1/2 viremia was 25 d (range, 11–80 d) and 17 d (range, 8–67 d) ( $p=0.004$ ). In a multivariate analyses, HSV-1/2 viremia was associated with delayed platelet engraftment ( $p=0.038$ ), a higher incidence of oral mucositis ( $p=0.000$ ) and severe HC ( $p=0.038$ ). However, HSV-1/2 viremia was not associated with non-relapse mortality (34.0% vs 31.5%,  $p=0.26$ ), leukaemia-free survival (60.9% vs 57.9%,  $p=0.46$ ) and overall survival (61.2% vs 60.7%,  $p=0.37$ ) (Figure 1).

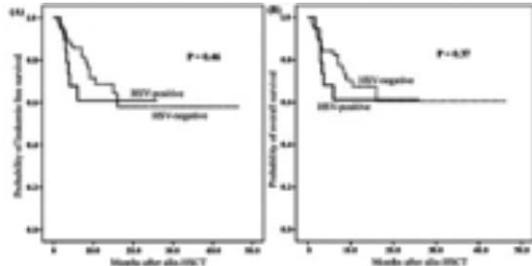

Figure 1.

**Summary/Conclusions:** Based on our study results, we recommend that HSV-1/2 PCR should be performed on clinical suspicion.

#### PB2173

##### FACTORS PREDICTING GRAFT-VERSUS-HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AND OUTCOMES AFTER REDUCED INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA OR MYELODYSPLASTIC SYNDROMES

H. Kanamori<sup>1</sup>, J. Aoki<sup>1</sup>, A. Negoro<sup>1</sup>, S. Koyama<sup>1</sup>, T. Tachibana<sup>1</sup>, H. Nakajima<sup>2</sup>, M. Tanaka<sup>1</sup>

<sup>1</sup>Hematology, Kanagawa Cancer Center, <sup>2</sup>Hematology and Clinical Immunology, Yokoham City University, Yokohama, Japan

**Background:** Reduced intensity allogeneic stem cell transplantation (RIST) is now commonly applied for elderly patients with acute leukemia (AL) or myelodysplastic syndromes (MDS). However, the factors affecting graft-versus-host disease-free, relapse-free survival (GRFS) and overall survival (OS) remain obscure.

**Aims:** To identify such factors and to clarify the clinical significance of RIST with various graft sources, we retrospectively analyzed patients with AL or MDS who received RIST in our hospital.

**Methods:** The study included patients with acute myeloid leukemia ( $n=73$ ), acute lymphoid leukemia ( $n=31$ ) or MDS ( $n=25$ ), who received fludarabine (Flu)/melphalan (Mel)-based RIST between 2004 and 2015 as the first transplantation.

**Results:** There were a total of 129 patients, including 3 in low risk (L), 74 in intermediate risk (I), 36 in high risk (H) and 16 in very high risk (V), classified by the refined disease risk index (rDRI). The median age was 58 years (range: 18-68 years), with 73 males and 56 females. Conditioning regimens contained Flu ( $125\text{mg}/\text{m}^2$ ) combined with Mel ( $80\text{mg}/\text{m}^2$ ,  $n=21$  or  $140\text{mg}/\text{m}^2$ ,  $n=108$ ). Total body irradiation (4Gy) was used in 96 patients who received transplantation from unrelated donors or HLA mismatched related donors. Bone marrow (BM) or peripheral blood stem cell (PB) from related donors was used in 40 patients, BM or PB from unrelated donors in 33 and cord blood (CB) from unrelated donors in 56. Primary graft failure occurred in 7 patients and death before engraftment was observed in two. After a median follow-up of 46 months (range: 15-144 months) for the survivors, the 1-year GRFS, disease free survival (DFS) and OS were 57%, 61% and 70%, respectively. On univariate analysis for all patients, pre-transplant factors associated with the 1-year GRFS included stem cell sources (BM/PB vs CB: 44% vs 68%,  $p=0.005$ ), donors (related vs unrelated: 38% vs 62%,  $p=0.012$ ), disease (AL vs MDS: 60% vs 28%,  $p<0.001$ ) and rDRI (L/I vs H/V: 65% vs 38%,  $p=0.003$ ). On multivariate analysis, BM/PB (HR 2.0, 95% CI 1.0-4.0,  $p=0.039$ ), MDS (HR 2.6, 95% CI 1.5-4.6,  $p=0.001$ ) and H/V rDRI (HR 2.1, 95% CI 1.2-3.5,  $p=0.006$ ) were associated with a worse GRFS. The 5-year OS, cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) were 55%, 36% and 18%, respectively. On univariate analysis, significant prognostic factors were hematopoietic cell transplantation-specific comorbidity index (HCT-CI) (score 0 vs  $\geq 1$ : 78% vs 48%,  $p=0.007$ ), disease (AL vs MDS: 59% vs 40%,  $p=0.004$ ) and rDRI (L/I vs H/V: 64% vs 43%,  $p=0.003$ ) for the 5-year OS, donors (related vs unrelated: 53% vs 27%,  $p=0.005$ ) and rDRI (L/I vs H/V: 27% vs 48%,  $p=0.005$ ) for CIR, and age ( $<60$  vs  $\geq 60$ : 10% vs 28%,  $p=0.021$ ), donors (related vs unrelated: 8% vs 23%,  $p=0.034$ ) and disease (AL vs MDS: 13% vs 36%,  $p=0.003$ ) for NRM. On multivariate analysis, HCT-CI score  $\geq 1$  (HR 3.1, 95% CI 1.3-7.4,  $p=0.009$ ) and MDS (HR 2.4, 95% CI 1.3-4.5,  $p=0.005$ ) were adversely associated with OS, so were H/V rDRI (HR 2.5, 95% CI 1.4-4.7,  $p=0.003$ ) and MDS (HR 3.7, 95% CI 1.6-8.8,  $p=0.002$ ) for CIR and NRM, respectively.

**Summary/Conclusions:** Our data suggest that Flu/Mel-based RIST was a promising strategy for patients with hematologic malignancy, irrespective of (?) donor or stem cell sources. However, GRFS and OS of MDS were significantly worse than those of AL, and MDS is strongly associated with high NRM even with RIST. This indicates that we should pay more attention to NRM in MDS.

#### PB2174

##### INCIDENCE AND RISK FACTORS FOR THE DEVELOPMENT OF HEMORRHAGIC CYSTITIS ON HAPLOIDENTICAL TRANSPLANTATION

M. Saez-Perdomo<sup>1</sup>, M. Perera<sup>1,\*</sup>, J. Viedma<sup>1</sup>, C. Rodriguez<sup>1</sup>, A. Suarez<sup>1</sup>, L. Guerra<sup>1</sup>, J. Lopez<sup>1</sup>, T. Molero<sup>1</sup>, S. Jimenez<sup>1</sup>

<sup>1</sup>Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

**Background:** Hemorrhagic cystitis (HC) is a serious complication occurring after allogeneic hematopoietic stem cell transplantation (HSCT) more frequent on haploidentical (haplo) HSCT, with an incidence of 10% to 70% (Silva et al Haematologica 2010;95(7):1183–1190) associated mainly with the effect of cytotoxic agents such as Cyclophosphamide (Cy). The conditioning regimen, BKPyV infection and graft versus host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development (Ruggeri et al Transplant Infectious Disease 2015;17:822–830).

**Aims:** With this study we aim to describe the HC incidence and risk factors in all haplo-HSCT performed in the Canary Islands.

**Methods:** We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation (PTCy). We used HC prophylaxis intense hydration on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginning 15 minutes before the Cy administration on 16 pts and at 20% of the last dose at 0, 4 and 8 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.

**Results:** We performed 20 haplo-HSCT, of which 10 were males (1 was transplanted 3 times) and 8 were women. The mean age was 40 (range 16-64). The pts presented the following diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). 45% of pts received the haplo-HSCT in remission, 50% with refractory disease and 5% of pts did not receive previous treatment. 6 pts developed HC (36.5% CI at day +80) (Figure 1a) with a median time from haplo-HSCT to onset of 23 days (range 3-42), 1 (17%) was grade I, 4 (66%) grade II and 1 (17%) grade IV. The grade I case did not receive the MESNA infusion like most of the other pts. No pts died due to HC and all cases resolved without sequelae. 12 pts received Cy pre- and post-transplant and only 8 pts received PTCy. The CI at day +80 for the pts with PTCy was 33.3% and for Cy pre- and post-transplant 38.3% (Figure 1b). We found no statistically significant difference on the CI of HC between these two groups. The development of HC was related to Cy in 1 patient, who suffered from this complication on the second and third haplo-HSCT. For the rest of the pts (after day +30) the HC was related to BKPyV infection, as a consequence of the immunosuppression state of the patient, we also observed all these pts had positive serum viral load for CMV.

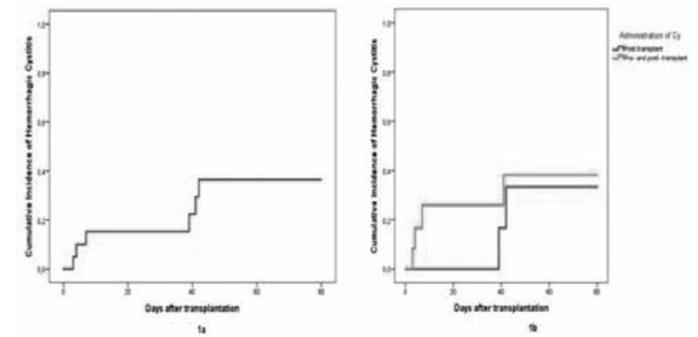

Figure 1.

**Summary/Conclusions:** The incidence of HC associated to post-HSCT high Cy dose in our series is 15% lower than other ones. Most of them on grade 1 or 2 and without mortality associated. The risk of HC is high, particularly in the setting of highly pre-treated patients (especially those undergoing a 2<sup>nd</sup> transplant). The development of HC after day +30 is evidently associated to BKPyV as a contributing factor for continuous inflammation and CMV reactivation (as an immunosuppression marker). In our study, HC did not have an impact on mortality of high-risk patients after haplo-HSCT. The HC remains frequent with a high morbidity in particular when it is severe, often causing prolonged hospitalization and resource use. We need further studies to recognize the at-risk population early.

**PB2175**

**OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDERGOING NON-MYELOABLATIVE ALLOGENIC STEM CELL TRANSPLANTATION AFTER TREATMENT WITH THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB**

F. Ramdohr<sup>1,\*</sup>, G.-N. Franke<sup>1</sup>, M. Jentzsch<sup>1</sup>, W. Pönisch<sup>1</sup>, C. Michael<sup>1</sup>, S. Heyn<sup>1</sup>, S.-Y. Wang<sup>1</sup>, G. Behre<sup>1</sup>, S. Leiblein<sup>1</sup>, S. Schwind<sup>1</sup>, D. Niederwieser<sup>1</sup>, V. Vucinic<sup>1</sup>

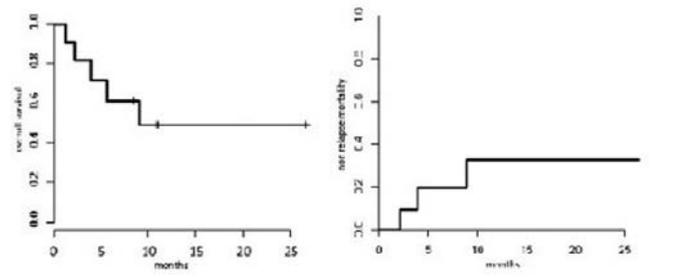

<sup>1</sup>Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

**Background:** Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematological stem cell transplantation (HCT) remains the only curative option for the underlying disease. Data on pre-transplant treatment of CLL with ibrutinib are very limited.

**Aims:** Here we present our experience of HCT in pts previously treated with ibrutinib.

**Methods:** 11 CLL pts (median age at HCT 57 years [y], range 52-66 y) treated between 2014 and 2016 in our unit with non-myeloablative (nma) HCT after ibrutinib were included. Ibrutinib treatment lasted median 4.03 months (range 1 - 28). Conditioning regimen was Fludarabine 30 mg/m<sup>2</sup> on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=3) or Binet C (n=8). Two pts had Richter's transformation (RT) diagnosed before nma-HCT. Ten pts were in partial remission (PR) at nma-HCT (PR1 n=4; PR2 n=3; PR3 n=2, PR4 n=1) while one was in first relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cytogenetic analysis and fluorescence *in situ* hybridization (FISH) was carried out for every pt. Five pts had a deletion (del)(17p13) and one a del(11q22.3).

**Results:** The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13, p=0.98). OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn't reach significance (p=0.39). EFS was median 125 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.055). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our group (30% at 4y). The acute GvHD Grade 3-4 was present in 3 pts (27.2%).

**Figure 1.**

**Summary/Conclusions:** The outcome in this small group is comparable to studies of CLL-pts undergoing nma-HCT without receiving ibrutinib upfront. Previous data from our unit (Hebenstreit *et al.*, Leuk Lymphoma 2014) showed OS 51% and NRM 30% at 4y. Ibrutinib appears to be a feasible option in a transplantation setting, although further testing with larger numbers of patients and a longer follow up is required.

**SHORT-TERM CHIMERISM IN T-HELPER CELL SUBSETS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION**

D. Dubnyak<sup>1,\*</sup>, N. Risinskaya<sup>2</sup>, M. Drokov<sup>1</sup>, N. Kostriksa<sup>3</sup>, L. Kuzmina<sup>1</sup>, N. Popova<sup>1</sup>, E. Mikhalcova<sup>1</sup>, V. Vasilyeva<sup>1</sup>, O. Koroleva<sup>1</sup>, Z. Konova<sup>1</sup>, I. Fevraleva<sup>2</sup>, I. Galtseva<sup>4</sup>, J. Davydova<sup>4</sup>, N. Kapranov<sup>4</sup>, A. Sudarikov<sup>2</sup>, E. Parovichnikova<sup>1</sup>, V. Savchenko<sup>1</sup>

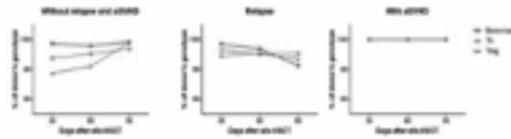

<sup>1</sup>Bone marrow transplant department, <sup>2</sup>of Molecular Hematology, National Research Center for Hematology, <sup>3</sup>school of medicine, Lomonosov Moscow State University, <sup>4</sup>Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Despite the fact that almost all studies in transplant biology dedicate T-cells the chimerism in T-helper (Th) cells and its subsets such as T-regulatory (Treg) cells after allogeneic hematopoietic stem cell transplantation (allo-HSCT) has never been evaluated.

**Aims:** To evaluate Th, Treg and bone marrow cell short-term chimerism in allo-HSCT patients.

**Methods:** Between May 2015 and November 2016 there was 109 transplants in our center. The research included 24 patients with hematological malignancies (AML =14, ALL =7, MDS =2, CMML -1). The median age of patients was 33,5 (range 19 to 60) years old, female=16, male=8. Myeloablative conditioning regimen was used for 11 patients. The other 13 patients underwent reduced intensity conditioning regimen. Peripheral blood stem cells (PBSCs) as graft source was used in 9 patients, BM in 15 patients. 9 patients were transplanted from HLA-identical related donor, 15 - from unrelated matched. Chimerism was evaluated at +30, +60, and 90-day in blood and bone marrow. Peripheral blood mononuclear cells (PBMC) were isolated using standard protocol. Cells were sequentially incubated with CD4-biotin and anti-biotin microbeads (Milteney Biotech, Germany). Next pure fraction of Treg cells (CD4<sup>+</sup>CD25<sup>high</sup>) was obtained by positive selection with the use of anti-CD25 microbeads. DNA was isolated by AmpliSens DNA-sorbB nucleic acid extraction kit. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats).

**Results:** For detailed result see Figure 1. 18 patients didn't have any signs of relapse, graft failure or acute graft-versus host disease at all observation time. In this group on day 30% of cells with donors genotype was - 97,17±0,75; on day 60 - 95,75±2,15; on day 90- 98,21±0,80. On day 30 T-helper - 87,51±3,12; on day Th 60- 90,43±3,18; on day 90 Th - 93,71± 3,03. On day 30 T-regulatory - 77,36±4,50; on day 60Treg - 82,08± 5,94; on day 90Treg - 97,71± 1,18. Four patients were diagnosed with relapse at +4 and +6 months after allo-HSCT. Two patients were diagnosed with acute GVHD.

**Figure 1.**

**Summary/Conclusions:** Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.

**PB2177**

**ADIPOSE TISSUE CHANGES IN LYMPHOMA PATIENTS IN THE PERI TRANSPLANTATION PHASE**

J. Jabbour<sup>1,2</sup>, B. Manana<sup>3</sup>, A. Zahreddine<sup>4</sup>, C. Saadeh<sup>5</sup>, C. Maya<sup>3</sup>, A. Bazarbachi<sup>4</sup>, D. Blaise<sup>6</sup>, J. El Cheikh<sup>3,\*</sup>

<sup>1</sup>Clinical Nutrition, American University of Beirut Medical Center, Beirut, Lebanon, <sup>2</sup>Ecole Doctorale Sciences de la vie et de la santé, Aix Marseille Université, Marseille, France, <sup>3</sup>Division of Hematology/Oncology, <sup>4</sup>Bone Marrow Transplantation Program, <sup>5</sup>Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon, <sup>6</sup>Programme de Transplantation et Thérapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France

**Background:** Abdominal Visceral Adipose Tissues (VAT) have been shown to have inflammatory activity and have been used to predict cancer outcomes. The ratio of VAT/Total Adipose Tissues (TAT) is a negative predictor of progression free survival in Lymphoma patients on chemotherapy.

**Aims:** Assess the changes in adipose tissues among stem cell lymphoma recipients in the peri-transplantation phase.

**Methods:** Institutional Review Board approved this retrospective study for adult patients (age>16 years) having B and T lymphoma who underwent Stem Cell Transplantation (SCT). Each patient was imaged by PET/CT scan pre-SCT and in the first 3 months post transplantation. A cross sectional image was analyzed at the level of the L3 to calculate TAT, VAT and Waist Circumference (WC). Data was analyzed by gender since body composition parameters differed significantly between the two categories in the literature.

**Results:** The study sample consisted of 91 patients [mean age: 37.7±13.5 years, n=52 (57%) males, n=81(87%) autologous SCT, n=12(13%) allogeneic SCT, median overall survival in months: 12 in males and 19 in females]. Death was observed in 6 (11.5%) males and 1(2.4%) female. Patient characteristics were similar across gender categories except for weights (kg) and Body Mass Index (kg/m<sup>2</sup>): 88.1 and 28.6 vs 65.2 and 25.0, in males and females respectively (p<0.05). Changes from pre-SCT to 3 months post SCT revealed that TAT and VAT decreased with mean differences of 33±56 cm<sup>2</sup> (p<0.01) and 7.0±36 cm<sup>2</sup> (p=0.17) in males and 16±44 cm<sup>2</sup> (p<0.01) and 4±14 cm<sup>2</sup> (p=0.056) in females, respectively. Waist circumference decreased significantly with mean

differences of  $3.9 \pm 4.9$  cm and  $2.8 \pm 4.4$  cm in males and females, respectively ( $p < 0.01$ ). VAT/TAT withnissed a slight increase in males and reduction in females ( $p > 0.05$ ). In multivariate analysis, no significant associations were shown with mortality and progression rates (Figure 1).

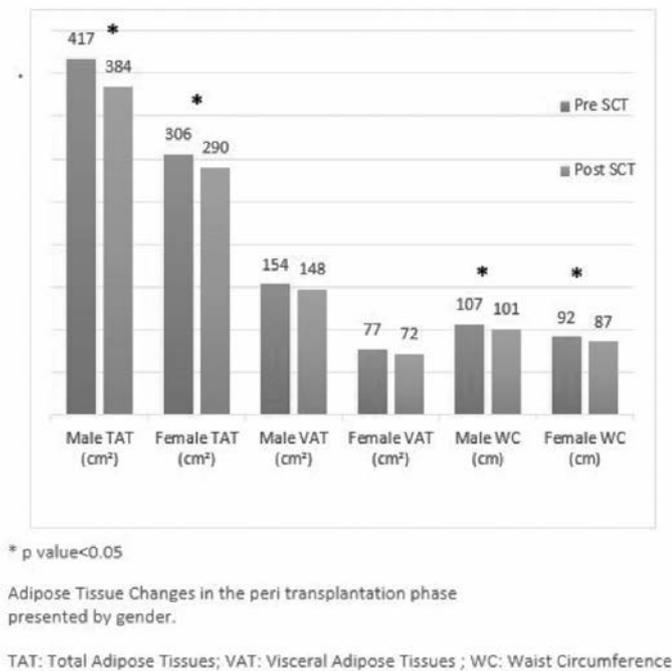

Figure 1.

**Summary/Conclusions:** This study provides data on the evolution of adipose tissues parameters in the peri-transplantation phase. TAT, VAT and WC decrease 3 months post transplantation. Future studies should evaluate the associations of these parameters with major outcomes on larger sample sizes.

#### PB2178

##### NON RELAPSE MORTALITY (NRM) ANALYSIS IN 93 UNRELATED DONOR TRANSPLANTATION - SINGLE CENTRE EXPERIENCE - HLA HAPLOTYPE ROLE?

P. Mensah-Glanowska<sup>1,2,\*</sup>, B. Piątkowska-Jakubas<sup>1,2</sup>, A. Radziszewska<sup>2</sup>, A.B. Skotnicki<sup>1,2</sup>

<sup>1</sup>Department of Haematology, Krakow University Hospital, <sup>2</sup>Department of Haematology, Collegium Medicum Jagiellonian University, Krakow, Poland

**Background:** Unrelated donor stem cell transplantation has a curative potential against haematological malignancies. However there are concerns about associated risk of non-relapse mortality. We performed a retrospective single centre study of causes of non-relapse mortality over four year period - 2012-2016.

**Aims:** Purpose of the study was to analyse non-relapse mortality (NRM) in patients subjected to unrelated donor transplantation in four-year-period: 2012 to 2016 - 93 transplant procedures in 86 patients.

**Methods:** Study cohort was analysed - relapse rate and non-relapse mortality were assessed. Causes of both - early and late NRM were studied.

**Results:** There were 23 relapses in the group of assessed patient cohort (24,7%). 7 patients undergone the second transplant - five patients - because of AML relapse, later two - because of secondary graft failure. Out of re-transplanted 7 patients - 3 patients are alive - 2 patients with graft failure and one with post-transplant AML relapse in 2nd CR. Out of 93 procedures of unrelated donor transplantation there were 16 cases of death - assumed as non relapse mortality NRM (17%). There were 9 early deaths (before day +100) - 6 cases in patients with relapsed/refractory acute leukaemia without remission after conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active antileukaemic treatment can be reason for higher treatment related toxicity and elevated risk of death. Later two patients developed infectious bacterial complications with septic shock. In one patient - antiviral treatment refractory CMV encephalitis with massive macrophage activation syndrome was diagnosed. Analysis of NRM after day100 revealed 7 affected patients. All these patients GVHD 2-4 was diagnosed previously, accompanied by transplant associated microangiopathy (TAM) and infections - both viral and fungal. Additionally to factors connected to NRM - age, comorbidity score, patient/donor HLA allelic and antigen and sex mismatches, HLA patient/donor haplotypes were analysed. It was possible to categorise 15 out of 16 NRM patients into 5 HLA class II haplotype groups connected with autoimmune diseases in Caucasian

population - rheumatoid arthritis and lupus erythematosus: DRB1 01:01 DQB1 05:01 (5 patients), DRB1 03:01 DQB1 02:01 (4 patients), DRB1 11:01 DQB1 03:01 (3 patients), DRB1 15:01 DQB1 06:02 (2 patients), DRB1 04:01 DQB1 03:02 (1 patient).

**Summary/Conclusions:** Based on these results we create working hypothesis that HLA class II haplotype may predispose to severe post-transplant infectious or/and non-infectious complications and affect the risk of NRM. Because small number of analysed patients and documented high frequency of these haplotypes in population, further analysis is required.

#### PB2179

##### HAPLOIDENTICAL STEM CELL TRANSPLANTATION WITH HIGH DOSE CYCLOPHOSPHAMIDE POST-TRANSPLANT IN HIGH RISK HEMATOLOGIC MALIGNANCIES: RISK FACTOR AND OUTCOME ANALYSES IN OUR CENTER

J. Viedma<sup>1,\*</sup>, M. Saez-Perdomo<sup>1</sup>, M. Perera<sup>1</sup>, A. Suarez<sup>1</sup>, J. Lopez<sup>1</sup>, C. Medina<sup>1</sup>, L. Guerra<sup>1</sup>, M. T. Gómez-Casares<sup>1</sup>, H. Luzardo<sup>1</sup>, T. Molero<sup>1</sup>, S. Jimenez<sup>1</sup>

<sup>1</sup>Hematology, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

**Background:** Allogenic hematopoietic stem cell transplantation (allo-HSCT) is an effective therapy for a variety of hematological malignancies. However, a lack of HLA-identical sibling donors or unrelated donors has restricted the application of allo-HSCT in hematological malignancies. Haploidentical HSCT (Haplo-HSCT) offers the benefits of rapid and nearly universal donor availability and, in the past decade, has been accepted worldwide as an alternative treatment for patients with hematological malignancies who do not have an HLA-identical sibling donor or who require urgent transplantation.

**Aims:** The purpose of this study was to investigate the incidence, causes and factors influencing overall and transplant-related mortality after Haplo-HSCT.

**Methods:** We analyzed all consecutive patients receiving Haplo-HSCT from family donors at our hospital from 2013 to 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation. We classified the patients before the Haplo-HSCT according to disease risk index (DRI), ECOG, Sorror score and EBMT risk score to evaluate the correlation between the physical state of the patients before the transplant and the survival (overall mortality (OM) and transplant-related mortality (TRM)). We used SPSS V.23 to calculate the cumulative Mortality incidence by the KM test and the Cox proportional hazards model.

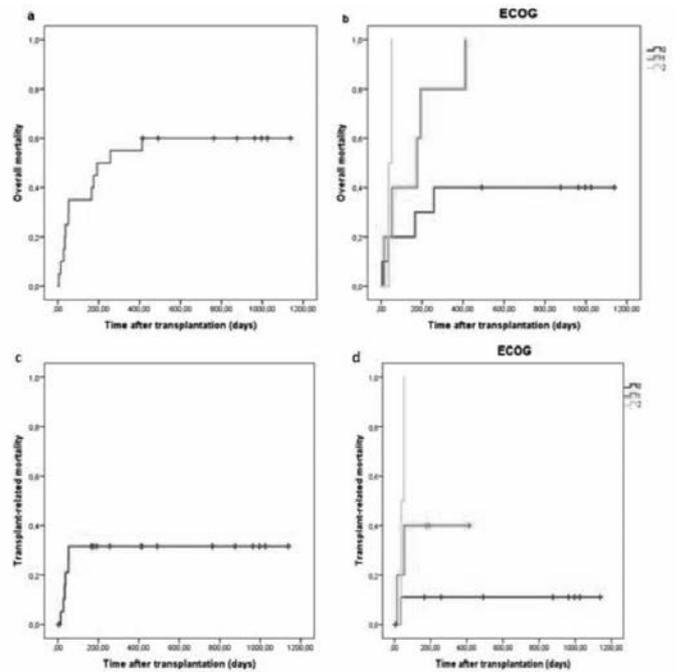

Figure 1.

**Results:** We performed 20 haplo-HSCT, 10 were males (1 was transplanted 3 times) and 8 were females mean age of 40 (range 16-64). Diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). Forty five percent of patients received the haplo-HSCT in remission, 50% with refractory disease and 5% of patients did not receive previous treatment. Of the 20 patients from our series, 12 died post transplant with an OM of 60%. The cumulative incidence (CI) of OM was 15% at 1 month (m), 35% at 3 m, 45% at 6 m, 55% at 1 year, and 40% at 2 and 3 years (Figure 1a). When we analyzed the OM depending on the different physical status scores we found no statistically significant differ-

ence between OM from the different states of EBMT (p=0.356) and DRI (p=0.07), however we found a statistically significant difference for ECOG (p=0.028) (Figure 1b) and Sorror (p=0.016). On a pairwise analysis of the OM we found no statistically significant for EBMT, and found a statistically significant difference between the patients with low-high DRI (p=0.01), intermediate-high DRI (p=0.01), ECOG 0-1 (p=0.046) and Sorror 0-5 (p=0.003). The multivariate analysis showed that ECOG 2 vs 0 (p=0.013, HR=46.59), Sorror 2-3 vs 0-1 (p=0.041, HR=19.55) and Sorror 4-5 vs 0-1 (p=0.005, HR=282.48) were significantly related with a higher incidence of OM. Five patients died of infection (41.67%), 3 of disease progression (25%), 1 of relapse (8.33%) and 3 of other causes (25%). Six patients died of TRM (50%). The CI of TRM was 10.5% at 1 m and 31.6% at 3 m, 6 m, 1, 2 and 3 years (Figure 1c). When we analyzed the TRM depending on the different physical status scores we only found a statistically significant difference between TRM incidence from the different states of ECOG (p=0.038) (Figure 1d) and no statistically significant difference for EBMT (p=0.386), DRI (p=0.372) and Sorror (p=0.073). On the pairwise analysis we also found statistically significant differences between ECOG 1-2 (p=0.018) and EBMT 1-5 (p=0.046), for Sorror we found a marginal statistical signification between 0-1 (p=0.052), 0-2 (p=0.052) and 0-5 (p=0.052), for DRI we found no statistically significant difference. On the multivariate analysis we found no statistically significant correlation between TRM and the physical status scores.

**Summary/Conclusions:** Despite the fact that Sorror, EBMT and DRI scores are widely validated to establish the risk of patients undergoing HSCT, in our experience ECOG remains a useful score for assessing the risk of TRM on patients receiving Haplo-HSCT. We think further studies with a larger sample would be necessary to confirm our results.

**PB2180**

**A SIMPLIFIED METHOD OF CRYOPRESERVATION OF PERIPHERAL BLOOD STEM CELLS WITH OVER 10% GRANULOCYTE CONCENTRATION FOR LESS THAN 36MONTHS**

T. Akagi<sup>1,\*</sup>, K. Ota<sup>2</sup>, T. Fujii<sup>2</sup>, K. Kamata<sup>3</sup>, K. Mayama<sup>3</sup>, K. Yamaguchi<sup>3</sup>, K. Yamagata<sup>3</sup>, S. Fukuda<sup>3</sup>, K. KUbo<sup>2</sup>

<sup>1</sup>Transfusion and Cell Therapy, <sup>2</sup>Hematology, Aomori prefectural central hospital, Aomori, <sup>3</sup>Gastroenterology and Hematology, Hirosaki University Hospital, Hirosaki, Japan

**Background:** The long-term stability of cryopreserved peripheral blood stem cells (PBSCs) is an important concern for patients experiencing disease relapse. However, the quality of long-term cryopreserved PBSCs stored at -80°C by using simplified method has not been elucidated in detail. Cryopreserved PBSCs undergo cell damage and decrease in viability, and those containing granulocytes might influence cell loss.

**Aims:** The aim of this study was to evaluate the effect of cryopreservation for less than 36 months and the number of granulocytes in the cryopreserved PBSC products on CD34<sup>+</sup> cells.

**Methods:** We examined the effects of cryopreservation on the viability of CD34<sup>+</sup> cells that were stored for less than six months and those stored for 7–24 months, and 25–36 months, and the change of CD34<sup>+</sup> cell viability with higher granulocyte content. We also evaluated the correlations between the number of granulocyte in the cryopreserved PBSC products and the time to engraftment of leukocyte or platelet. Informed consent was obtained prior to the procedure from all the patients following institutional guidelines.

**Results:** A total of 65 PBSC samples were collected. We compared three groups based on the cryopreservation period: (1) less than 6 months, (2) 7–24 months, and (3) 25–36 months. The median (range) viability of CD34<sup>+</sup> cells after thawing was 81.8% (58.2–94.4), 80.5% (56.6–92.8), and 76.1% (54.5–89.6) in the three groups, respectively. No significant difference in the viability of the cells in either frozen period was observed (p=0.14, respectively). We compared the effect of granulocyte concentration (over 10% concentration against less than 10% concentration) on CD34<sup>+</sup> cells viability. The median (range) viability of CD34<sup>+</sup> cells containing >10% granulocytes was 76.6% (54.5–93.0%), and that for cells containing <10% granulocyte was 82.1% (59.1–94.4%), respectively. There was significant difference in the viability of CD34<sup>+</sup> cells between the two groups (p=0.02, respectively). Second, we analyzed 81 autologous PBSC transplants after stored at -80°C by using simplified method. We compared two groups based on the granulocyte concentration (>10% concentration against <10% concentration). No significant difference in the days to leukocyte >1.0x10<sup>9</sup>/L and to platelet >20x10<sup>9</sup>/L in either granulocyte concentration was observed. However, the median (range) time to platelet >50x10<sup>9</sup>/L containing >10% granulocytes was 27.2(12-87), and that for cells containing <10% granulocyte was 20.3(10-51), respectively. There was significant difference in the day to platelet >50x10<sup>9</sup>/L between the two groups (p=0.04, respectively).

**Summary/Conclusions:** Long-term cryopreservation represents a means of holding a potential therapeutic modality in reserve for use at a future date. In this study, PBSCs can safely be stored for at least 36 months by the simplified method at -80°C. The loss of the viability of CD34<sup>+</sup> cells was greater when the granulocyte content was over 10% than in cells with less than 10% of granulocytes. The effect of reduced CD34<sup>+</sup> cells viability seems important for engraft-

ment. Difference in the day to platelet >50x10<sup>9</sup>/L between the two groups based on the granulocyte concentration (>10% concentration against <10% concentration) was observed. Thus, a lesser granulocyte content could give a more reliable graft with better quality. Further research is necessary to observe the effect of long-term cryopreservation period and granulocyte content on the viability of stored CD34<sup>+</sup> cells.

**PB2181**

**LYMPHOCYTE RECONSTITUTION AFTER ALOGENIC TRANSPLANTATION, DOES EARLY RECOVERY HAVE ANY INFLUENCE IN SURVIVAL RATES?**

V. Verdugo<sup>1,\*</sup>, M.A. Correa Alonso<sup>1</sup>, V. Rubio Sanchez<sup>1</sup>

<sup>1</sup>Hematology, Hospital Jerez de la Frontera, El Puerto de Santa María, Spain

**Background:** Immune reconstitution after AlogTPH has significant influence on the procedure final success. Studies have established that early lymphocyte recovery can influence survival rates, associated to a reduction in mortality unrelated relapse (NMR) and, in some studies, also to a reduction in relapse rate.

**Aims:** Analyze our patients survival rates in terms of lymphocyte reconstitution in absolute value on day+30 and+60 post-HSCT. Check if there is any relationship between the number of transfused CD34<sup>+</sup> progenitors and LT3<sup>+</sup> and see if that possible link affects the speed of recovery after transplant t- lymphocyte count.

**Methods:** Analysis of the lymphoid recovery in a retrospective study of 63 of 71 patients transplanted (ALO, and Haplo Unrelated Donor) by AML and ALL between 2008- 2015. (8 died before the day+60). Table 1 shows the characteristics of the pre-transplanted patients and analyze the influence of the parameters of the infused product (CD34x10<sup>6</sup> and LTx10<sup>8</sup>/kg r), type of transplant, GVHD presentation. treatment and reactivation of CMV on the recovery of absolute lymphocyte numbers in s+30 and +60 days post transplantation using as cutt off <0.3x10<sup>3</sup>/ml. We have analyzed the ratio of the number of lymphocytes on day +60 with survival after transplantation. It has made a statistical - analysis of OS and DFS in relation to the number of lymphocytes on day +30 and day +60 with Kaplan Meier compared the results with long-rank test and subsequent analysis of the variables collected with Cox Regression.

**Results:** After analyzing the product infused we observe a relationship between LT and lymphocyte recovery on day+30 (p: 0097, cor: 0223) and day +60 (p=0.059, cor: 0257) but not with the CD34+/Kg r. Table 2 shows the patient characteristics in lymphocyte absolute count in the day +60. We analyzed the overall survival (OS) and disease - free survival (DFS) and a decrease in OS with statistical difference was evident in patients with <.300 (p=0.0029) on day +60 and day+30 (p: 0.05), a decline also in DFS, with no statistically significant difference (p=0.1). Multivariate analysis to determine which factors could influence the lymphoid recovery on day +60 and SG, we observed that the type of unrelated donor, myeloablative conditioning and ATG administration can influence a delay in this recovery. No differences were observed in the rest of the variables.

**Table 1.**

CHARACTERISTICS OF THE PATIENT S:	
SEX:	<ul style="list-style-type: none"> <li>- Male: 44 (62%)</li> <li>- Female: 27 (38%)</li> </ul>
AGE: Median:	41 (14-69)
DIAGNOSIS:	<ul style="list-style-type: none"> <li>- LLA: 22 (31%)</li> <li>- LMA: 47 (68.2%)</li> <li>- THE Biphentotype: 1 (1.4%)</li> <li>- Bilinear: 1 (1.4%)</li> </ul>
STATE OF ILLNESS TO TRANSPLANTATION:	<ul style="list-style-type: none"> <li>- RC: 55 (77.4%)</li> <li>- RP / EMR +10 (14%)</li> <li>- Refractoriness: 8 (8.45%)</li> </ul>
STEM CELL:	<ul style="list-style-type: none"> <li>- SP: 66 (92.95%)</li> <li>- MO: 2 (2.8%)</li> <li>- SCU: 3 (4.2%)</li> </ul>
DONOR:	<ul style="list-style-type: none"> <li>- DE: 48 (67.6%)</li> <li>- DNE: 20 (28.16%)</li> <li>- Haploidentical: 3 (4.2%)</li> </ul>
CONDITIONING:	<ul style="list-style-type: none"> <li>- MIELOBLATIVO: 46 (64.8%)</li> <li>- Low intensity: 25 (35.2%)</li> </ul>

**Summary/Conclusions:** A delay in lymphocyte recovery is associated with a decrease in survival rates in our patients. Measures favoring an accelerated lymphocyte recovery (judicious use of thymoglobulin, adequate donor selection, and transplantation modality) could affect the post-transplant survival. It appears that the amount of infused product could play an important role in reconstitution, so it would be a factor to take into account prior to infusion.

and 74.5% and PFS was 76.8% and 58.2%, respectively. Before ASCT, 60 patients (72.3%) were in CR and 23 (27.7%) were in PR. After ACST, 4 patients were not assessed for response due to early death by toxicity. Of the remaining, 70 (88.6%) achieved a CR, 4 (5.1%) a PR and 5 (6.3%) failed to respond. Patients in CR before ASCT presented significantly longer PFS compared with those in PR (107.9 vs 44.0 months,  $p=0.01$ ). Besides that, patients that obtained CR after ASCT also had longer OS and PFS compared with those in PR (107.9 vs 8.0 and 107.9 vs 7.3 months,  $p<0.001$ ). However, these patients had significantly lower PFS compared to patients that continued in CR after ASCT (45.3 vs 107.9 months,  $p=0.041$ ). Univariate analysis indicated that remission status pre-ASCT (CR vs PR) is a significant predictor of PFS after ASCT (HR 0.39; 95% CI 0.19-0.82,  $p=0.013$ ). Multivariate Cox regression model showed that this factor retains prognostic value after adjustment for age, histological subtype, Ann Arbor stage and number of previous lines of treatment.

**Summary/Conclusions:** Our results highlight the relevance of the obtained CR after ASCT in the OS. Furthermore, we conclude that patients with NHL who are in CR before ASCT have a better PFS than those in PR before ASCT. Additionally, continued CR after ASCT may also be an important prognostic factor. Our results suggest that the use of more effective induction regimens in order to improve initial response may be advantageous in terms of clinical benefits post-ASCT.

## PB2185

### AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MANTLE CELL LYMPHOMA: SINGLE CENTER EXPERIENCE

S.K. Toprak<sup>1,\*</sup>, E. Atilla<sup>1</sup>, P. Ataca Atilla<sup>1</sup>, S. Civriz Bozdogan<sup>1</sup>, M. Kurt Yuksel<sup>1</sup>, P. Topcuoglu<sup>1</sup>, T. Demirer<sup>1</sup>, O. Arslan<sup>1</sup>, M. Ozcan<sup>1</sup>, M. Arat<sup>2</sup>, O. Ilhan<sup>1</sup>, H. Akan<sup>1</sup>, M. Beksac<sup>1</sup>, N. Konuk<sup>1</sup>, A. Uysal<sup>3</sup>, G. Gurman<sup>1</sup>

<sup>1</sup>Ankara University School of Medicine Department of Hematology, Ankara, <sup>2</sup>Florence Nightingale Hospital, Istanbul, <sup>3</sup>Koru Hospital, Ankara, Turkey

**Background:** Mantle cell lymphoma accounts for relatively small proportion (3%>10%) of non-Hodgkin lymphoma. High-dose chemotherapy (HDT) and autologous-stem cell transplantation (ASCT) has played a critical role in the treatment of mantle cell lymphoma. Regardless of that, mantle cell lymphoma remains largely a relapsing/remitting disease.

**Aims:** Our aim is to present our mantle cell lymphoma patients who underwent ASCT.

**Methods:** We retrospectively evaluated our 21 mantle cell NHL patients. The patients were followed after ASCT for relapse

**Results:** Patients were followed by a median time of 56.9 months (range, 6-170 months). The median age at diagnosis was 45 (range, 18-69), female to male ratio:5/16. The stages and MIPI scores at diagnosis were as follows: 5% stage II, 19% stage III, 76% stage IV; Low MIPI 29%, intermediate MIPI 48% and high MIPI 23%. First line treatments were R-CHOP for 6 cycles in 6 patients (29%) and R-CHOP for 3 cycles followed by R-DHAP in 15 patients (71%). The median time to ASCT was 20 months (range, 7-48 months). All patients were in at least partial remission at the time of ASCT. The transplant conditioning regimen was CVB in 5 patients (24%) and R+/-ICE in 5 patients (24%), R+/-BEAM in 11 patients (52%). Six patients (29%) achieved complete remission. Four patients (19%) died within three months of ASCT due to infection. Eleven patients (52%) was relapsed with a median time of 39 months (range, 4-123 months). Ten patients received BORID (bortezomib, rituximab, dexamethasone) and 1 patient received lenalidomide as salvage therapy and six of them achieved complete remission. Three patients underwent allogeneic hematopoietic stem cell transplantation as well as two patients received ibrutinib as fourth line therapy and followed in remission. The 3 year overall survival was 71%.

**Summary/Conclusions:** ASCT is a part of initial treatment strategy in fit patients with mantle cell lymphoma however 19 patients in our series had transplant related toxicity. Today, novel agents may present a less intensive approach for achieving response.

## PB2186

### ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH AUTISM

A. Gomes<sup>1,\*</sup>, A. B. Mafra<sup>1</sup>, A. Zanette<sup>1</sup>, V. Rocha<sup>1</sup>

<sup>1</sup>Hematopoietic Stem Cell Transplantation, Hospital Sirio Libanês, Sao Paulo, Brazil

**Background:** Autism Spectrum Disorders (ASD) are severe heterogeneous neurodevelopmental abnormalities characterized by dysfunctions in social interactions and communication skills, restricted interests, repetitive, and stereotypic verbal and non-verbal behaviors. The etiology of ASD remains unknown, but recent studies suggest a possible association with altered immune responses and ASD. Inflammation in the brain and Central Nervous System has been reported with microglia activation and increased cytokine production in post-mortem brain specimens of individuals with ASD. Other studies have established a correlation between ASD and family history of autoimmune diseases, associations with MHC complex haplotypes, and abnormal levels of various inflammatory cytokines and immunological markers in the blood. The

paracrine, secretome, and immunomodulatory effects of stem cells would appear to be the likely mechanisms of application for ASD therapeutics.

**Aims:** Evaluation the benefits of HSCT in patients with ASD.

**Methods:** We describe two cases of patients with ASD who underwent HSCT for acute lymphoblastic leukemia (ALL) and whose symptoms were markedly decreased like an improvement of social interaction, communication, and behaviors.

**Results:** The first patient is an 11-year-old girl with ASD who was diagnosis with Ph-positive ALL in October 2011 (at the end of treatment, BCR-ABL remained positive). She underwent a matched sibling HSCT in March 2015. The conditioning regimen was total body irradiation (TBI) and cyclophosphamide. During the 20-month follow-up period, we observed improvement in social interaction, communication, and behaviours. According to The Childhood Autism Rating Scale – CARS, prior to HSCT, she had a score of 39 (Severe Symptoms of ASD disorder), and she currently scores 30 (Mild-to-Moderate Symptoms of ASD). The second case is a 7-year-old boy with ASD, Asperger Syndrome, who was diagnosis with ALL in September 2012. He presented with bone marrow and testicular relapse in May 2015 and underwent a matched unrelated HSCT in November 2015. The conditioning regimen was Etoposide, ATG and TBI. During the 12-month follow-up period, we observed improvement in social interaction, communication, and behaviours. According to CARS, prior to HSCT he had a score of 30 (Mild-to-Moderate Symptoms of ASD), and he currently scores 24 (Minimal-to-No Symptoms of ASD). There is no treatment for ASD thus every effort to minimize the symptoms are valuable. In both cases, social interaction was significantly increased, and the aggressive behaviors decreased. Clinical cases have reported responses in autistic children receiving cord blood CD34+ cells.

**Summary/Conclusions:** Several incurable neurological disorders have shown benefits with cellular therapy. Thus, autism should be explored as an indication. Clinical studies are an immediate need to fully explore its potential in autism.

### ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE FROM TURKEY

D. Atay<sup>1,\*</sup>, F. Erbey<sup>1</sup>, A. Akcay<sup>1</sup>, G. Ozturk<sup>1</sup>

<sup>1</sup>Pediatric Hematology Oncology Bone Marrow Transplantation Unit, Acibadem University Medicine Faculty, Istanbul, Turkey

**Background:** Myelodysplastic syndrome (MDS) in childhood is a rare disorder and hematopoietic stem cell transplantation (HSCT) is the only known curative treatment option. However, there exist few reports regarding the outcome of transplantation for children with various types of MDS.

**Aims:** We analyzed the outcome of pediatric patients who underwent HSCT in our center.

**Methods:** We reviewed retrospectively 14 pediatric MDS patients who received HSCT at a single center. Median age at time of HSCT of the patients was 4.3 years and disease duration from diagnosis to transplantation ranged from 3 to 36 months with a median of 10 months. Five patients had primary and one had secondary MDS. Four patients had juvenile myelomonocytic leukemia (JMML) and 4 patients had myelodysplastic related acute myeloid leukemia (MDR-AML). Diagnostic cytogenetics included monosomy 7 (n=2), trisomy 8 (n=3), KRAS (n=1) or normal/other (n=8). Patients received a median of  $6.8 \times 10^6$  CD34+cells/kg. Eight patients received a bone marrow, 5 had peripheral blood graft and one an unrelated cord blood (UCB) transplant; five patients were transplanted from a matched sibling donor (MSD), 5 from a matched unrelated donor (MUD) and 4 from haploidentical donor. Conditioning regimen consisted of busulfan/cyclophosphamide in MSD/MUD patients. The patients transplanted from MUD and UCB also received antithymocyte globulin (ATG) for 3–5 days pretransplantation. Haploidentical transplantation was performed with RIC regimen and TCR $\alpha\beta$ /CD3 depletion.

**Results:** Graft failure occurred in three patients with JMML (n=1), secondary MDS (n=1) and MDR-AML (n=1). Except one, all of the JMML patients relapsed at a median 83.5 days post-transplant and two of them died. One patient with MDR-AML underwent second transplantation from another MUD one year after first transplant and died from GVHD. Ten patients are alive with a median follow-up of 19.5 months (range 3-61). All patients with primer MDS are alive and well. Four patients died from transplant-related toxicity (n=2) and relapse (n=2). For the entire group, estimated five-year relapse-free survival (RFS), event-free survival (EFS) and overall survival (OS) were 78.6%, 64.3% and 70.7%, respectively.

**Summary/Conclusions:** These data demonstrate that especially children with primer MDS may achieve encouraging OS and RFS following HSCT. Relapse remains the main cause of treatment failure in children with JMML given HSCT. All children with MDS should be referred for allogeneic HSCT soon after diagnosis.

### RELATIONSHIP BETWEEN URIC ACID LEVELS AND CARDIAC FINDINGS IN A LARGE COHORT OF B-THALASSEMIA MAJOR: GENDER-RELATED DIFFERENCES

A. Meloni<sup>1,\*</sup>, C. Vassalle<sup>1</sup>, L. Pistoia<sup>1</sup>, T. Grippo<sup>2</sup>, M. G. Bisconte<sup>3</sup>, G. Palazzi<sup>4</sup>, M. P. Smacchia<sup>5</sup>, N. Dello Iacono<sup>6</sup>, R. Ndreu<sup>1</sup>, A. Olivi<sup>1</sup>, V. Positano<sup>1</sup>, A. Pepe<sup>1</sup>  
<sup>1</sup>Fondazione G. Monasterio CNR-Regione Toscana, Pisa, <sup>2</sup>Azienda Ospedaliera Regionale San Carlo di Potenza, Potenza, <sup>3</sup>Azienda Ospedaliera Cosenza - Presidio Ospedaliero "Annunziata", Cosenza, <sup>4</sup>Modena, Policlinico di Modena, <sup>5</sup>Policlinico Umberto 1, Roma, <sup>6</sup>Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo, Italy

**Background:** Iron overload, secondary to recurrent transfusions and ineffective erythropoiesis, induces oxidative stress in thalassemia (TM). Uric acid (UA), a major blood antioxidant, may act either as an antioxidant or pro-oxidant.

**Aims:** Our aim was to evaluate the role of UA in TM and its association with cardiac iron, dysfunction, fibrosis, and complications, and cardiovascular risk factors in a large cohort of TM patients of both sexes.

**Methods:** 397 TM patients (200 men, mean age 32±8 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. Myocardial and hepatic iron burdens were quantified by the T2\* technique. Atrial dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

**Results:** As expected, UA resulted significantly higher in male respect to female TM patients (4.74.7±1.3 vs 4.0±1.0 mg/dL; P<0.0001).

UA levels directly correlated with BMI (R=0.25, P=0.0003), and triglycerides (TG) (R=0.20, P=0.005) in female patients. Moreover, female which presented myocardial fibrosis showed higher levels of UA (4.4±1.3 vs 3.9±0.9 mg/dL, P=0.03). The multiple regression model identified BMI (T-value 3.7, P=0.0003), TG (2.1, P=0.04) and cardiac fibrosis (2.5, P=0.01) as independent correlates of UA level in women. In men, UA levels were positively correlated with BMI (R=0.17, P=0.02), TG (R=0.38, P<0.001), and inversely with HDL (R=-0.20, P=0.006) and glycemia (R=-0.15, P=0.04). Interestingly, UA was also directly correlated with global heart T2\* values (R=0.3, P<0.001). After multivariate analysis adjustment, global heart T2\* (T-value 2.6, P=0.01), TG (4.7, P<0.001), and BMI (1.9, P=0.05) remained as independent determinants of UA in male TM patients.

**Summary/Conclusions:** UA levels correlates with factors related to metabolic dysfunction in TM patients of both sex, while a more strong correlation between UA and cardiac fibrosis was observed only in females, and a direct relationship between UA and T2\* global heart only in males. The differences in male and female TM patients imply some gender-specific mechanisms, providing biochemical basis for the epidemiological differences between sexes.

PB2189

### CHARACTERIZATION OF HEMORHEOLOGICAL ALTERATIONS IN THALASSEMIA BY A CHEMOMETRIC APPROACH

P. Caprari<sup>1,\*</sup>, C. Bozzi<sup>1</sup>, S. Materazzi<sup>2</sup>, R. Risoluti<sup>2</sup>

<sup>1</sup>Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, <sup>2</sup>Department of Chemistry, "Sapienza" - University of Rome, Rome, Italy

**Background:** Several studies reported a high incidence of thromboembolic events in β - thalassemia, more frequent in thalassemia intermedia than in regularly transfused thalassemia major. In these patients a chronic hypercoagulable state is evident and the red blood cells exhibit impaired flow properties that facilitate micro-circulatory disorders.

**Aims:** Since many abnormalities described in thalassemia may determine rheological alterations, in this study we have investigated the viscoelastic profiles of red blood cells from patients with β-thalassemia. The hemorheological profiles of blood samples obtained from healthy subjects and thalassemic patients were studied by chemometric tools in order to develop a model of prediction of circulatory disorders according to the viscoelastic behaviour.

**Methods:** Blood samples from 45 β-thalassemia patients and 48 healthy individuals, after informed consent, were analyzed. Hemorheologic profiles were investigated at 37 °C at native and normalized hematocrit. The evaluation of RBCs viscoelastic properties was performed by determining storage modulus G', loss modulus G'' and complex modulus G\* in oscillation mode as a function of angular frequency ω in the range 0.1-10 Hz. Multivariate statistical analysis was performed on the resulting G', G'' and G\* curves and Principal Components Analysis was used as display method.

**Results:** The hemorheological profiles of patients affected by β-thalassemia and healthy subjects showed significant differences and the chemometric analysis demonstrated a clearly identification of anemic status according to viscoelastic profile. Increased G', G'' and G\* modula were observed in thalassemic patients demonstrating a reduction in deformability and impaired flow properties.

**Summary/Conclusions:** In this study a characterization of haemorheological alterations in thalassemia patients has been performed by a chemometric approach. The achieved results permit to consider the viscoelastic properties as promising predictive new indices of microvascular damage in β-thalassemia and to explain the increased incidence of vascular complications in these disorders.

PB2190

### HEPATITIS E IN TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS, IN GREECE. A SINGLE CENTER EXPERIENCE

P. Klonizakis<sup>1,\*</sup>, G. Gioula<sup>1</sup>, A. Melidou<sup>1</sup>, M. Exindari<sup>1</sup>, G. Karavalakis<sup>2</sup>, C. Apostolou<sup>1</sup>, E. Gigi<sup>1</sup>, E. Vetsiou<sup>1</sup>, A. Kotsiafi<sup>1</sup>, E. Vlachaki<sup>1</sup>

<sup>1</sup>Aristotle University of Thessaloniki, <sup>2</sup>Papanikolaou General Hospital, Thessaloniki, Greece

**Background:** Hepatitis E (HE) is nowadays considered an emerging disease that may be a threat in both developing and industrialized countries all over the world. The causal agent is an RNA virus, transmitted mainly through the fecal-oral route. Nevertheless, there are additional patterns of transmission, including the transfusion of infected blood products. The risk of developing chronic HE infection following transfusion of infected blood-derived products is higher among immune-compromised individuals. Transfusion-dependent Thalassemia patients consist a distinct category of immune-compromised patients, but the data regarding transfusion-transmitted HE infection are limited for this group of patients. Accordingly, there is, as yet, no consensus on whether blood products should be systematically screened for markers of the HE virus.

**Aims:** The aim of this study was to assess the status of Hepatitis E infection in 96 transfusion-dependent Thalassemia patients, followed up in a single Thalassemia Unit, in Northern Greece.

**Methods:** Over a one-month period, we retrospectively evaluated 96 consecutive patients, from a registry of 150 adult TDT patients followed at a single Thalassemia Unit, in Northern Greece. The mean age of the study population was 36±10 years, 42% were male and 58% female. According to the patients' blood transfusion history, the participants had been transfused with 47.376 blood units during the last 14 years, whereas during the last year the same patient population had been transfused with 3.384 blood units. The detection of HEV RNA was performed by Real-Time RT-PCR method (hepatitis2@ceer-amTools kit, Applied Biosystems ABI), according to the instructions. The detection of HEV was based on the identification of the "a" region of ORF2. The detection of IgG anti-HEV antibodies and their titration were performed in 92/96 samples using a commercially available enzyme-linked immunosorbent assay kit (CUSABIO BIOTECH kit), according to the manufacturer's instructions. The cut-off value was calculated according to the manufacturer's instructions.

**Results:** HE RNA was not detected in any of the 96 samples, whereas the IgG anti-HEV antibodies were also negative in all measured samples. The negative HEV RNA, in all the participants of this study, indicates the absence of an active HE infection, whereas the negative IgG anti-HEV antibody titre implicates that there was no history of previous HE infection. According to the literature, IgG antibodies may be detectable following an HE infection for a time period that varies from one year to 14 years.

**Summary/Conclusions:** This is the first assessment of the HE virus seroprevalence in the population of TDT patients in Greece, over the last two decades. Our results suggest that TDT patients are not at a high risk for HE infection. Further studies are necessary to evaluate the clinical importance of the transfusion-transmitted HE infection in TDT patients and clarify whether screening of blood donors is necessary for countries with a lower or higher prevalence of HE.

PB2191

Abstract withdrawn.

PB2192

### A PRELIMINARY STUDY OF THE CARDIAC EFFECT OF PPAR GAMMA IN BETA THALASSEMIA MAJOR WITH IRON OVERLOAD

P.M. Eldefrawy<sup>1,\*</sup>, P.N.A. Hamed<sup>1</sup>, D.D. Elnileey<sup>2</sup>, D.O. Ghallab<sup>1</sup>, M.A. Khalifa<sup>1</sup>

<sup>1</sup>Hematology, <sup>2</sup>Clinical Pathology, Alexandria Faculty of Medicine, Alexandria, Egypt

**Background:** Peroxisome proliferator-activated receptor (PPAR)-gamma is a transcription factor belonging to the same family of nuclear receptors as steroid and thyroid hormone receptors. PPAR-gamma is a master transcriptional regulator involved in the expression of probably hundreds of genes. One of PPAR gamma gene polymorphisms is Pro12Ala which is present in at least 80% of humans. Pro12Ala polymorphism may reduce the risk of cardiovascular complications. Consistently, Ala12 allele carriers were found to have lower carotid intima-media thickness and reduced risk of myocardial infarction in type 2 diabetes patients. Pharmacological agonists of PPAR-gamma leads to a molecular

switch providing alleviating myocardial injury through modulating oxidative, inflammatory and apoptotic signaling pathway.

**Aims:** Our aim was to investigate the frequency of Pro12Ala polymorphism (substitution of proline to alanine at codon 12 in exon B of PPAR $\gamma$  gene in Egyptian  $\beta$ -thalassemia major ( $\beta$ -TM) with iron overload. Untreated transfusion induced iron overload in thalassemia major is fatal, usually as a result of cardiac complications.

**Methods:** 30  $\beta$ -TM patients and 10 healthy volunteer matched for age, sex and body weight were involved in this study.  $\beta$ -TM patients followed up was in the "outpatient clinic of Hematology unit, at Alexandria main university hospital". Seventeen were males and thirteen were females with ages ranging from 16 – 39 years (21.53 $\pm$ 5.44). Blood samples from  $\beta$ -TM patients and healthy controls were analyzed for PPAR $\gamma$  gene polymorphism using polymerase chain reaction-restriction fragment length polymorphism.

**Results:** The mean value of serum ferritin in  $\beta$ -TM was 4976.30 $\pm$ 2216.41 ng/L which was significantly higher than that in controls (102.60 $\pm$ 12.69 ng/L). The mean value of ejection fraction were 62.23 $\pm$ 3.46% and 63.80 $\pm$ 4.34 in cases and controls respectively. Pro12Ala polymorphism was present in 2 out of 30 (6.67%)  $\beta$ -TM patients with osteoporosis. One patient had heterozygous 12Ala polymorphism and the other had homozygous 12Ala polymorphism. Both had normal body mass index, lipid profile, ejection fraction and elevated serum ferritin (4923 ng/l in heterozygous patient and 4886 ng/l in homozygous patient). Ejection fraction was 70% in heterozygous patient and 68% in homozygous patient. Only one male control (10%) has homozygous 12Ala polymorphism (Table 1).

Table 1.

Comparison between the two studied groups according to PPAR gamma genotyping

Parameter	Cases (n = 30)		Control (n = 10)		$\chi^2$	McP
	No.	%	No.	%		
<b>Genotyping</b>						
Normal	28	93.3	9	90.0	1.509	0.585
Heterozygous	1	3.3	0	0.0		
Homozygous	1	3.3	1	10.0		

Data of the two cases with PPAR gamma polymorphism

Parameter	Homozygous	Heterozygous
Age (years)	20	18
Sex	male	Female
Body mass index	19.83	20.20
Ferritin (ng/ml)	4886	4923
FBG (mg/dl) kg/m <sup>2</sup>	79	87
Triglyceride (mg/dl)	128	97
Total cholesterol (mg/dl)	130	161
HDL (mg/dl)	8	25
LDL (mg/dl)	80	71
Ejection fraction (%)	68	70
BMD	-6	-2.4

**Summary/Conclusions:** This study suggests that Pro12Ala polymorphism may have a cardioprotective effect in Egyptian thalassemic patients since we find the highest value of ejection fraction among the two positive cases. Further studies on a larger population of patients are still needed to confirm this finding.

PB2193

THALASSEMIA MAJOR AND INTERMEDIA IN PATIENTS OLDER THAN THIRTY-FIVE YEARS - FROM A FATAL TO A CHRONIC DISEASE

O. Pasvolsky<sup>1,\*</sup>, L. Shargian Alon<sup>1</sup>, P. Raanani<sup>1</sup>

<sup>1</sup>Beilinson Hospital, Petach Tikva, Israel

**Background:** During the past four decades beta thalassemia major (TM) and beta thalassemia intermedia (TI) have transformed from a universally fatal disease at a young age, into a chronic disease, with a constantly increasing life expectancy. This is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.

**Aims:** We aimed to characterize disease and patients' characteristics in patients above 35 years of age in an adult thalassemia center in Israel.

**Methods:** We conducted a retrospective analysis of 14 adult patients over the age of 35 years with TM (N=10) and TI (N=4) treated in a single center, spe-

cializing in the care of adult thalassemia patients. We used descriptive statistics to describe characteristics of disease and patients and the Mann-Whitney test to compare between patients with TI and patients with TM.

**Results:** Between 2006 and 2016, 14 adult patients older than 35 years with TM (n=10) & TI (n=4) were followed and treated in our center. Median patients' age was 37 (range, 35-51) years, with 66% males and 50% of Arab ethnicity. Most of the patients had at least high school education (85%), and 78% were employed. Thirteen patients (all TM patients and 3 out of the 4 TI patients) were treated regularly with blood transfusions. All patients received chelation treatment. Median hemoglobin (Hb) levels and mean corpuscular volume (MCV) levels were lower in patients with TI compared to TM (8.1 vs 10 g/dl, p=.002 and 72.4 vs 84 fl, p=.004, respectively). Median LDH levels and indirect bilirubin levels were higher in patients with TI compared to TM (603 vs 330 u/L, p=.004 and 2.02 vs 1.1 mg/dl, p=.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferoxamine (DFO), deferiprone (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating temporary discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had good compliance with current chelation therapy. Four patients with acute heart failure secondary to cardiac iron overload, and all four improved with intensified chelation treatment. Four TM patients (40%) were hypothyroid, half of them requiring thyroid hormone replacement therapy. All TM patients had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symptomatic cardiac iron overload and endocrine dysfunction in the cohort. Three patients (21.4%) had significant liver overload according to liver T2\* MRI, necessitating chelation treatment intensification. None of the patients in our cohort underwent allogeneic hematopoietic stem cell transplantation and none developed secondary malignancy during follow-up.

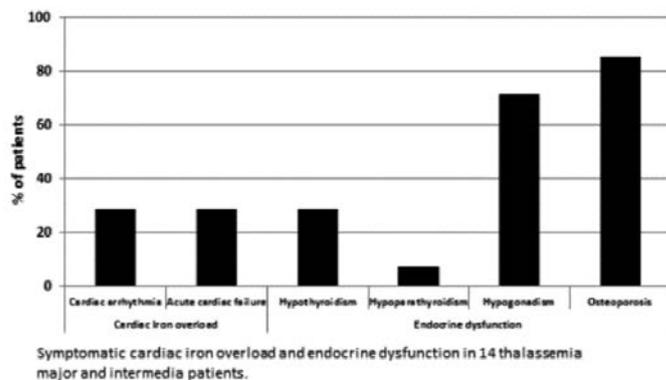

Figure 1.

**Summary/Conclusions:** Advances in the treatment of thalassemia patients have enabled the majority of these patients prolonged survival into adulthood. However, this has brought a new set of challenges for both patients and health-care. This study delineates the challenges faced while treating adult patients with TI and TM in the new era.

PB2194

EVALUATION OF LIVER IRON CONCENTRATIONS IN CHILDREN WITH BETA THALASSEMIA INFECTED WITH HEPATITIS C VIRUS BEFORE AND AFTER SPIRULINA THERAPY BY MAGNETIC RESONANCE IMAGING

M. El-Shanshory<sup>1,\*</sup>, M. Awad<sup>1</sup>, R. El-Shafey<sup>2</sup>, A. Alsharkawy<sup>3</sup>

<sup>1</sup>Pediatrics, <sup>2</sup>Radiology, Faculty of Medicine, Tanta University, <sup>3</sup>Pediatrics, Ministry of Health, Tanta, Egypt

**Background:** Magnetic resonance imaging (MRI) assessment of liver iron concentration (LIC) is necessary for quantitative staging of iron overload in children with  $\beta$ -Thalassemia. There is no enough evidence about the effect of spirulina therapy on LIC.

**Aims:** To assess LIC by MRI in multitransfused  $\beta$ -Thalassemic children infected with HCV before and after Spirulina Therapy.

**Methods:** Thirty multi-transfused  $\beta$ -thalassemic children infected with HCV, were subjected to clinical evaluation, appropriate laboratory investigations and assessment of LIC by MRI. They were classified according to LIC into mild

(group 1) and moderate to severe group (group 2). In addition to standard packed red cell transfusion, Spirulina therapy was given orally for 3 months, after which re-evaluation of these children was performed by repeating the same investigations.

**Results:** There was significant increase in LIC associated with significant changes in other MRI parameters (significant decrease in T2\* and significant increase in R2\*) in patients with  $\beta$ -Thalassemia of moderate to severe group as compared to those of the mild group before treatment. The mean values of serum ferritin (SF) was statistically insignificantly higher among patients of mild group. There was no significant correlation between different MRI parameters and SF level. There was negative correlations between LIC and T2\* and positive correlation between LIC and R2\*. There was significant decrease in values of LIC accompanied with significant improvements in SF after spirulina therapy as compared to their pretreatment values in patients of the moderate to severe group.

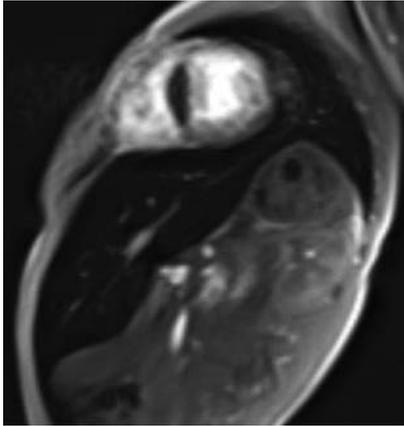

Figure 1.

**Summary/Conclusions:** Spirulina therapy may have favorable effects on lowering the values of LIC in children with  $\beta$ -Thalassemia infected with HCV.

#### PB2195

#### COMBINATION OF DEFERASIROX AND DEFEROXAMINE - A SUCCESSFUL CHELATION THERAPY IN B-THALASSEMIA MAJOR PATIENTS

F. Petropoulou<sup>1,\*</sup>, K. Ventiadi<sup>1</sup>, G. Leveta<sup>1</sup>

<sup>1</sup>Thalassaemia Unit, General Hospital of Athens "G.Gennimatas", Athens, Greece

**Background:** Frequent transfusions required for  $\beta$ -thalassaemia major patients cause iron overload. Without the appropriate chelation therapy, iron toxicity can cause significant heart, liver and endocrine morbidity.

**Aims:** In this case series we estimated the safety and efficacy of iron chelation with the combination of deferasirox (DFX) and deferoxamine (DFO) in transfusion dependent thalassaemia (TDT) patients attending the Thalassaemia Unit in a tertiary hospital in Athens, Greece.

**Methods:** 10 TDT patients were treated with a combination chelation therapy of DFX (30  $\pm$ 10mg/kg/d) and DFO (44 $\pm$ 12mg/kg/d for 2-6 days/wk in 12hr or 24hr infusion rates). Reasons for starting this combination treatment included: 1) treatment with one chelating agent did not succeed in decreasing heart and liver iron, 2) agranulocytosis or severe neutropenia due to deferiprone (DFP) treatment and 3) adverse events recorded with increased doses of one of the chelating agents. The efficacy of the treatment was estimated through MRI measurements of heart and liver iron (T2\*<sub>Heart</sub> and LIC) in combination with serum ferritin levels. Liver enzymes (ALT, AST) and serum creatinine were used to monitor safety of the treatment.

**Results:** Five of the 10 patients had significant liver hemosiderosis (LIC >15 mg Fe/gr d.w.) and 3 had heart iron overload, of which one significant (T2\* 1.9 msec) (Table 1).

Table 1.

	Before starting DFX/DFO combination therapy	12mos into the DFX/DFO combination therapy
Serum Ferritin mean	3,360 ng/mL (range 1,700- 6,200)	2,450 ng/mL (range 800-4,900)
Liver Iron Concentration (LIC) mean	19.0 mg Fe/gr d.w. (range 6.2-46.4)	9 mg Fe/gr d.w. (range 1.6- 28.4)
Cardiac T2* mean	24.1 msec (range 1.9-36)	32.3 msec (range 5.2 -39.5)

The combination treatment was well tolerated without adverse events or effects on liver and kidney function.

**Summary/Conclusions:** The combination chelation with DFX/DFO can decrease iron overload and represents a safe and effective option when monotherapy is not effective or not well tolerated.

#### PB2196

#### EVALUATION OF THREE AUTOMATIC DEVICES FOR HEMOGLOBINOPATHY DIAGNOSTICS IN MULTI-ETHNIC POPULATIONS

C. Hartevelde<sup>1,\*</sup>, Y. Daniel<sup>2</sup>, G. Bakker-Verweij<sup>1</sup>, G. Ivaldi<sup>3</sup>

<sup>1</sup>Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands, <sup>2</sup>Special Haematology, Guy's Hospital, London, United Kingdom, <sup>3</sup>Laboratorio di Genetica Umana, Ospedale Galliera, Genoa, Italy

**Background:** We have tested three different dedicated haemoglobin separation devices for their capacity of performing the diagnostics of hemoglobinopathies. These involve the Variant II<sup>TM</sup> HPLC (BioRad), the Capillarys2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210<sup>TM</sup> High Resolution HPLC of Trinity Biotech (Menarini).

**Aims:** As the latter device is new to the market a multisite precision study was performed testing the reproducibility of the system across three test sites (Leiden, Genoa and London) using the same set of samples for several following days. The results between these three sites were compared and evaluated. Moreover we have tested the capacity to detect the most common structural haemoglobin variants, such as HbS, HbC, HbD, HbE and less common Hb variants important to be diagnosed in multi-ethnic populations found in the U.K., The Netherlands and Northern Italy as well as elevated HbA<sub>2</sub>, as indicator for beta-thalassaemia carriers.

**Methods:** tHb variant separation using the Variant II<sup>TM</sup> HPLC (BioRad), the Capillarys2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210<sup>TM</sup> High Resolution HPLC of Trinity Biotech (Menarini). Molecular analysis to verify the hemoglobin variants found.

**Results:** We present the data of the comparison studies using the replicates of the three different sites for the Premier Hb9210<sup>TM</sup> and of 100 normal samples and 217 patient samples for a variety of beta-thalassaemia trait and haemoglobin (Hb) variants, including the molecular data of the beta-thalassaemia mutations and Hb variants.

**Summary/Conclusions:** All three apparatuses identified the common Hb variants and beta-thalassaemia trait in carriers, homo-, hetero- and compound heterozygotes with the expected sensitivity and specificity. The Premier Hb9210<sup>TM</sup> High Resolution HPLC of Trinity Biotech shows comparable separation and quantitation on the three different sites using the same samples and is suitable for the analysis of samples suspected of having hemoglobinopathy and the diagnosis of beta-thalassaemia trait or Hb variants.

#### PB2197

#### RED BLOOD CELL EXTENDED PARAMETERS IN HAEMOGLOBINOPATHIES

M. Stamou<sup>1</sup>, E. Petridou<sup>1</sup>, A. Kotanidou<sup>1</sup>, A. Agorasti<sup>1,\*</sup>

<sup>1</sup>Laboratory Haematology, General Hospital of Xanthi, Xanthi, Greece

**Background:** Sysmex® XE-5000 analyzer incorporates new research Red Blood Cell (RBC) parameters, derived from flow fluorescence cytometry technology, including%HYPO-He, which indicates the percentage of RBC with haemoglobin (Hb) content <17 pg, and%MicroR which indicates the percentage of RBC with mean cell volume <60 fL.

**Aims:** The aim of this study was to establish the reference range of our Laboratory for the parameters%HYPO-He &%MicroR, to investigate their values in haemoglobinopathies and their correlation, if any, with Hb A<sub>2</sub> levels in heterozygous  $\beta$ -thalassaemia.

**Methods:** Reference ranges were obtained from 175 healthy adult subjects (27 men, median age of 34 years & 148 women, median age of 30 years); control group (group A), 89 haemoglobinopathy heterozygotes (32 men, median age of 29 years & 57 women, median age of 30 years) were included in the study and classified into three groups; group B:  $\beta$ -thalassaemia heterozygotes, N=46, group C:  $\alpha$ -thalassaemia heterozygotes, N=21 and group D: Hb O-Arab heterozygotes, N=22. We retrospectively recorded the results of full blood count analysis on Sysmex® XE-5000 analyzer including%HYPO-He &%MicroR, of Hb pattern analysis (TOSOH®, G7) and ferritin levels (Roche®, cobas e411). All subjects included in the study presented ferritin levels within the normal range for age and gender. Statistical analysis: one-way ANOVA (Tukey post-hoc), Mann-Whitney, Pearson's correlation tests were applied. Reference ranges were calculated as the mean $\pm$ 2SD of the distribution. P value <0.05 was considered to be statistically significant. Data refer as median (percentiles).

**Results:** The reference ranges of our Laboratory for the parameters%HYPO-He &%MicroR are 0.0 – 0.6% & 0.2 – 2.9%, respectively, and they are independent of gender and age (P=0.715, P=0.168 & P=0.073, P=0.843). There was a statistically significant difference between the groups as determined by one-way ANOVA for both parameters (all P <0.0001). Heterozygous  $\beta$ -thalassaemia presents statistically significantly higher%HYPO-He values [11.6 (4.2-27.6)] as compared to groups A [0.3 (0.2-0.3)], C [1.9 (0.6-4.6)], D [0.6 (0.4-0.8)] (all P <0.0001), while there was no statistically significant difference of%HYPO-He values between heterozygous Hb O-Arab and groups A and C (P=0.965 & P=0.134, respectively) based on Tukey post hoc test. Heterozygous  $\beta$ -thalassaemia presents statistically significantly higher%MicroR values [41.5 (22.9-58.7)] as compared to groups A [1.5 (1.1-2.0)], C [10.8 (7.9-20.5)] and D

[6.1 (4.2-9.0)] (all  $P < 0.0001$ ). Both parameters %HYPO-He & %MicroR are correlated positively in a statistically significant degree with Hb A<sub>2</sub> levels in heterozygous  $\beta$ -thalassaemia ( $r=0.567$ ,  $P < 0.0001$ ,  $y=0.050x+5.317$  &  $r=0.680$ ,  $P < 0.0001$ ,  $y=0.042x+4.371$ , respectively).

**Summary/Conclusions:**  $\beta$ -thalassaemia heterozygotes present higher values of %HYPO-He & %MicroR compared to  $\alpha$ -thalassaemia and Hb O-Arab heterozygotes. %HYPO-He & %MicroR are possibly useful parameters for evaluating the relative severity of different genotypes in heterozygous  $\beta$ -thalassaemia because of the statistically significant positive correlation with Hb A<sub>2</sub> levels.

## PB2198

### PERFORMANCE OF THE ALPHA-GLOBIN STRIPASSAY® AND MLPA® FOR THE DIAGNOSIS OF ALPHA-THALASSAEMIA

J. Oosterbos<sup>1</sup>, H. Claerhout<sup>2\*</sup>, C. L. Hartevelde<sup>3</sup>, E. Lierman<sup>4</sup>, D. Kieffer<sup>2,5</sup>

<sup>1</sup>Department of Pharmaceutical and Pharmacological Sciences, KU Leuven,

<sup>2</sup>Department of Laboratory Medicine, University Hospitals Leuven, Leuven,

<sup>3</sup>Department of Clinical Genetics, Leiden University Medical Center, Leiden,

<sup>4</sup>Center for Human genetics, University Hospitals Leuven, <sup>5</sup>Department of

Microbiology and Immunology, KU Leuven, Leuven, Belgium

**Background:** Diagnosing  $\alpha$ -thalassaemia requires second line diagnostics involving DNA analysis. Multiplex ligation probe amplification® (MLPA®) is a molecular technique introduced as a diagnostic tool for  $\alpha$ -thalassaemia. This semi-quantitative technique determines the relative copy number of up to 60 DNA sequences and is able to detect deletions and duplications in a DNA sample. A novel commercial tool, the  $\alpha$ -Globin StripAssay®, aims to detect the most common  $\alpha$ -thalassaemia deletions and point mutations. The test involves three steps: DNA isolation, PCR reaction and a hybridization step to test strip containing allele-specific oligonucleotide probes immobilised as an array of parallel lines.

**Aims:** Our objective was to evaluate the  $\alpha$ -Globin StripAssay® as a useful alternative for MLPA® in second line  $\alpha$ -thalassaemia diagnostics.

**Methods:** Eight samples, including 7 known deletions (SEA, THAI, MED, homozygous and heterozygous -  $\alpha^{3.7}$ , heterozygous -  $\alpha^{4.2}$ , ( $\alpha$ )<sup>20.5</sup>) and 1 mutation (Hb Constant Spring) were analysed using multiplex Gap-PCR (deletions) and Sanger sequencing (point mutation) at the Leiden University Medical Center. These samples were anonymised and analysed in duplicate by MLPA® and  $\alpha$ -Globin StripAssay® at our center. A comparison of diagnostic performance, interpretation, turnaround time (TAT) and costs (reagent and labour) was done.

**Results:** There are no significant differences between the MLPA® and the  $\alpha$ -Globin StripAssay® results and each identification corresponded to the result of the reference lab in Leiden. MLPA® however provided additional information about underlying polymorphisms. Interpretation of the  $\alpha$ -Globin StripAssay® was easier and faster compared to MLPA®. The  $\alpha$ -Globin StripAssay® proved to have a shorter TAT, but on the other hand, the costs for MLPA® were significantly less.

**Summary/Conclusions:** Despite its straightforward interpretation, shorter TAT and the ability of detecting both (known) deletions and point mutations, the significantly higher costs of the  $\alpha$ -Globin StripAssay® may hinder its routine use. Specialised laboratories are usually acquainted with the MLPA technique and in these settings the ability to detect both known and unknown deletions is a plus for research purposes.

## PB2199

### CARDIAC AND HEPATIC IRON ASSESSMENT OF YOUNG ADULTS WITH TRANSFUSION DEPENDENT THALASSEMIA: TIME TO THINK BEYOND FERRITIN

K. Mishra<sup>1\*</sup>, S. Kashyap<sup>1</sup>, A. Khadwal<sup>1</sup>, A. Jandial<sup>2</sup>, D. Lad<sup>1</sup>, G. Prakash<sup>1</sup>, R. Das<sup>3</sup>, N. Varma<sup>3</sup>, P. Malhotra<sup>1</sup>, S. Varma<sup>1</sup>

<sup>1</sup>internal medicine , <sup>2</sup>Pgimer, Chandigarh, Chandigarh, India, <sup>3</sup>haematology, Pgimer, Chandigarh, Chandigarh, India

**Background:** With the improvement in availability of blood transfusion practices and progress in chelation therapy, there is an increasing population of thalassaemic patients surviving into adulthood in developing countries. However, there is scarcity of clinical, biochemical and radiological data showing cardiac and hepatic iron assessment in these chronically transfused individuals.

**Aims:** 1. Cardiac and hepatic iron assessment in young adults with TDT. 2. Compare the ferritin level with T2\* MRI finding.

**Methods:** in this prospective observational study we analysed demographic details, clinical features and cardiac and liver iron assessment of young adults with (TDT) at recently established adult thalassaemia clinic at PGIMER, Chandigarh. For cardiac and liver iron assessment serum ferritin, ECG, 2D Echo, MUGA scan, Liver function test, Fibroscan (if indicated) and T2\* MRI of Liver and heart was done. All patients who were diagnosed in childhood and referred to adult haematology unit at age  $\geq 18$  years and had received more than 20 blood transfusions were included in the study.

**Results:** A total of 53 patients (n=53) were analysed. The mean age was 23 yrs. Majority of patients (56%) were male. The average age at diagnosis and at first transfusion was 7 months & 11months respectively. The average years of PRBC transfusion was 23 yrs. The average number of transfusion in last

two years prior to registration was 24 PRBC units. The mean age at start of chelation was 10.0 yrs. Mean duration of chelation was 14 yrs. Majority (88%) had growth failure with mean height of 159.6 cm & mean weight of 51.5 kg respectively. Splenomegaly was present in 47% and hepatomegaly in 25% patients. Twenty-eight percent have undergone splenectomy at an average age of 12.6 yrs. The mean of highest ferritin levels was 6131 ng/mL and the mean ferritin at the time of registration was 2919 ng/mL. LFT were deranged in 25% of patients. Evidence of cardiac dysfunction (ECG/MUGA) was present in 22% of patients. Iron overload in liver and heart as measured with T2\* MRI was present in 56% & 28% respectively (Figure 1).

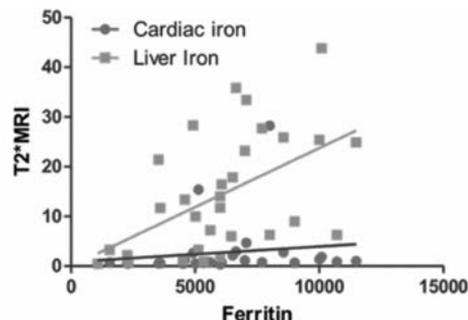

Figure 1.

**Summary/Conclusions:** majority of patients registered in our clinic are living a healthy life. All of them were on iron chelation therapy and the dose was being adjusted as per the serum ferritin level. Amongst asymptomatic individuals with no evidence of cardiac or hepatic dysfunction, evaluation by T2\*MRI picked up evidence of hepatic and cardiac iron overload. Therefore, its prudent to monitor patients with T2\*MRI and accordingly escalate or de-escalate chelation therapy.

## PB2200

### THALASSEMIA IN MADRID: A PICTURE OF THE CURRENT SITUATION

E.J. Bardón-Cancho<sup>1\*</sup>, M. García-Morín<sup>1</sup>, Y. Aguilar-de la Red<sup>1</sup>, B. Ponce-Salas<sup>1</sup>, G. Perez-Rus<sup>2</sup>, C. Pascual<sup>2</sup>, E. Dulín<sup>3</sup>, C. Beléndez<sup>1</sup>, E. Cela<sup>1</sup>

<sup>1</sup>Section of Pediatric Hematology and Oncology, Department of Pediatrics,

<sup>2</sup>Department of Hematology, <sup>3</sup>Newborn Screening Laboratory (Community of

Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina- Universidad Complutense de Madrid, Madrid, Spain

**Background:** Diagnosis of thalassemia (Thal) in a Mediterranean country as Spain, could be thought as endemic, but few data are available so far. Moreover, attention to hemoglobinopathies is focused on sickle cell disease.

**Aims:** The aim of our study was to find out the prevalence of Thal and clinical significant hemoglobinopathies other than sickle cell diseases in a referral center for newborn sickle screening, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

**Methods:** The study is observational, unicentric, descriptive and retrospective, carried out in December 2016 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with Thal and other not sickle-hemoglobinopathies who had attended at least once to the hematology clinic were included. Demographic characteristics (date of birth, gender, country of birth) and clinical ones (genotype or Thal type, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

**Results:** The total number of patients included was 31 (9 Thalassemia Major (TM), 1 Thalassemia Intermedia (TI), 21 other not sickle-hemoglobinopathies). The center follows 209 sickle patients, which leads to a ratio sickle/not sickle of 6.74 (Table 1). Ratio boy/girl is 1.21 for all group. Most of patients were born in Spain (90.32%), although 6.45% were born in Asia and one patient was born in Rumania. Considering the parents, 32% were born in Europe, 29% from Africa, 25% from Asia, and 12% from America. 92% of those patients born in Spain were detected in their first days of life due to universal screening detection implemented in Madrid since 2003. Median age at first diagnosis was 0.70 years (0-16.35). Median age at the end of inclusion was 9.39 years (range 1.90 to 35.44). 35% of them had molecular genotyping for diagnostic confirmation. Two out of 10 patients with Thal had HLA identical siblings. Quelation treatment was added to standard treatment to all the patients with Thal: 7 received deferasirox, 3 were treated with deferoxamine and 2 with deferiprone; 2 of the patients required double quelation. Two out of 10 patients with Thal underwent

splenectomy. None of these patients had sepsis or meningitis. Three Thal patients underwent progenitor stem cell transplantations and they remain on complete chimerism in the present moment. Patients lost to follow-up summed up 14: 3 emigrated to other countries, 2 continue the monitor of their diseases in other centers or in adults units and 7 for unknown reasons. There was one death (3.22%) for a cause unrelated to his illness.

Table 1.

Hemoglobinopathies	n (%)
Heterozygote $\beta$ -Thal + Another variant of Hb (C, D, Andrew-Minneapolis, J Baltimore)	6 (28.57)
Hb CC	4 (19.04)
Hb EE	2 (9.52)
Heterozygote Hb O-Arab	2 (9.52)
Hb OO	1 (4.76)
Hb DD	1 (4.76)
Hb S + Hb Korle-Bu	1 (4.76)
Hb H	1 (4.76)
Hb DE	1 (4.76)
Hb CE	1 (4.76)
Hb OC	1 (4.76)

Not sickle-hemoglobinopathies

**Summary/Conclusions:** Early diagnosis derived from universal neonatal screening for sickle cell disease allows an effective health education and prompt therapy to other hemoglobinopathies, and a correct and thorough follow-up of these patients.

#### PB2201

##### PREVALENCE AND CAUSES OF CLOTTING TIMES PROLONGATION IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEMIA

I. Tartaglione<sup>1,\*</sup>, M. Caiazza<sup>1</sup>, A. Bonadies<sup>1</sup>, D. Roberti<sup>1</sup>, M. Casale<sup>1</sup>, S. Scianguetta<sup>1</sup>, F. Rossi<sup>1</sup>, S. Perrotta<sup>1</sup>

<sup>1</sup>Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania "Luigi Vanvitelli", Naples, Italy

**Background:** Thalassemia is traditionally known to be a thrombophilic, rather than hemorrhagic, disorder. In spite of this, prolongation of clotting times are often reported. Understanding if there is a real risk of bleeding, and what this risk can be associated to, is crucial, especially in relation to the frequent referral to surgery (e.g. for splenectomy, cholecistectomy). Hepatopathy due to iron overload or HCV infection has been addressed as a main cause of this finding, even though disorders in the clotting profile are often reported also in patients with no alterations of hepatic function. The impairment of factors XI and XII often reported has been hypothesized to be secondary to intravascular haemolysis or multiple transfusions (Caocci *et al*, *Acta Haematol* 1978, Mcfadyen *et al*, *Ann Hematol* 2014), but no data are available to confirm this supposition.

**Aims:** To determine the prevalence of clotting disorders in a group of Transfusion dependent Thalassemia (TDT) patients and to assess the correlation with hepatopathy, degree of the hemolysis, transfusion frequency, erythroblastosis, iron chelation.

**Methods:** TDT patients followed at our center for whom clotting tests were available were included. From chart review data were collected regarding clotting times, demographics, disease history, comorbidities and concomitant medications, iron chelation therapies, iron overload (serum ferritin, LIC, cardiac T2\*), liver function tests, hemolysis parameters, hemocromocitometric values. Patients on anticoagulation therapy were excluded.

**Results:** 56 TDT patients (female 55,35%) were enrolled in our study, mean age 26,02±13,38 years, 17 of them were pediatric. In 20/56 patients (35,71%) prolongation of clotting time was found: this included both prolonged INR (23,21%) and prolonged aPTT ratio (25%); 7 patients (12,5%) had both prolonged INR and aPTT. Subgroup with clotting disorder (group A) was compared to subgroup with clotting times within normal ranges (group B) using T-Test. No differences were found in terms of sex, age, genotype, transfusion interval, hemolysis degree, comorbidities, HCV infection included, iron overload, liver function, erythroblastosis and platelets levels, nor in history of thrombotic complications. No patients had history of hemorrhagic disease. Pretransfusion Hb was lower in patients with prolonged clotting times (p=0,045); none of the patients in Group A was splenectomized (p=0,042).

**Summary/Conclusions:** In our population clotting disorders were not correlated with hepatic disease, nor hemolysis or transfusions. The mild correlation with lower Hb values and with the lacking splenectomy could be consistent with the known effect of low Ht on lab procedures for clotting tests. In relation to this observation in patients with altered coagulation tests the repetition of clotting test after blood transfusion could be advisable to overcome the low Hb effect.

#### PB2202

##### COMPOUND HETEROZYGOSITY FOR HAEMOGLOBIN ADANA AND A-THALASSAEMIA IN GREECE. CLINICAL PHENOTYPE AND GENETIC COUNSELING

S. Theodoridou<sup>1,\*</sup>, A. Teli<sup>2</sup>, E. Yfanti<sup>3</sup>, T.-A. Vyzantiadis<sup>4</sup>, M. Economou<sup>2</sup>

<sup>1</sup>Thalassaemia Unit, Hippokraton General Hospital, <sup>2</sup>First Department of Pediatrics, Aristotle University, Thessaloniki, <sup>3</sup>Thalassaemia Centre, Laikon General Hospital, Athens, <sup>4</sup>First Microbiology Department, Aristotle University, Thessaloniki, Greece

**Background:** Haemoglobin (Hb) Adana (HBA2Q.C.179>A) in interaction with deletional and nondeletional  $\alpha$ -thalassaemia mutations leads to HbH or, less commonly to thalassaemia intermedia with clinical manifestations varying from asymptomatic forms to severe anemia. First line screening tests are unable to detect the highly unstable variant. **Aims:** We report two cases of Hb Adana co-inheritance with the  $\alpha$ -thalassaemia 3.7 kb deletion - the only  $\alpha$ -thal and Hb Adana double heterozygosity cases diagnosed in subjects of Greek origin.

**Methods:** The first case concerns a 3 year old girl, born from parents referred for genetic counseling at the 11<sup>th</sup> week of a second gestation. The mother showed an Hb of 10.7g/dl, RBC 4.04 X 10<sup>9</sup>/L, MCV 80,7 fl, MCH 26.4 pg, Hb A2 2.8% and Hb F 1%, with positive inclusion bodies, and her ethnic (Greek) and regional background was of high risk for thalassaemia. The partner came from the same region, and he showed an Hb of 13.8g/dl, RBC 5.88 X 10<sup>9</sup>/L, MCV 73,1 fl, MCH 23.5 pg, Hb A2 2.4% and Hb F1% and inclusion bodies were found positive. DNA analysis was requested and, routine investigation was performed in their first offspring. The girl had an Hb of 8.2 g/dl, RBC 3.82 X 10<sup>9</sup>/L, MCV 70 fl, MCH 22 pg, Hb A2 1.9% and Hb F 2.3%, while her ferritin levels were 226ng/ml and inclusion bodies were found. On clinical examination she was found to be of normal weight and height for her age, but presented with paleness, icteric sclera and mild splenomegaly. Genetic analysis revealed that the mother carried the  $\alpha$ -thalassaemia 3.7 kb deletion defect. The father carried the rare non deletional Hb Adana. As suspected from the haematological data, their offspring was a compound heterozygote for Hb Adana variant in trans to a 3.7  $\alpha$ + thal deletion. The second case concerns a 17-year-old boy, diagnosed with Hb Adana co-inheritance with the  $\alpha$ -thalassaemia 3.7 kb deletion at the age of 8 years. At diagnosis, findings were compatible with a very mild phenotype and growth was not impaired. The boy retained a mild hypochromic microcytic anemia (Hb~10g/dl, MCV 71 fl, MCH 23 pg, RDW 18.6%, reticulocyte count 5.1%), until adolescence but at the age of 11 transfusion initiation was decided due to marked splenomegaly and limited weight and height gain. For the following years he was transfused approximately once a month, necessitating chelation therapy. Weight, height and pubertal development were normal by the age of 15, but splenomegaly persisted. Splenectomy was decided and transfusions were stopped shortly afterwards. During the following months the boy retained an Hb of 9.5 g/dl, however, he complained of constant fatigue and impaired physical activity and asked to get back on a transfusion program.

**Results:** In both cases diagnosis was incidental highlighting the mild phenotype. However, the co inheritance of Hb Adana with the 3.7 kb  $\alpha$ + thal deletion is rare, with only the presenting cases in Greece, and in a few other families in Turkey, Southeast Asia, Philippines and Albania. The clinical phenotype of the combination seems to be a mild disease with a non-transfusion-dependent thalassaemia intermedia phenotype. Nonetheless, clinical severity prediction is always a difficult issue and phenotypes may change overtime as demonstrated by the second case described above.

**Summary/Conclusions:** Long follow-up of such rare cases is necessary in order to gain as much information as possible, so as to offer the best management to the patients and the most accurate genetic counseling.

## Thrombosis and vascular biology

PB2203

### ANTITHROMBOTIC EFFECTS OF PEPTIDE PGPL IN EXPERIMENTAL THROMBUS FORMATION

M. Grigorjeva<sup>1,\*</sup>, L. Lyapina<sup>1</sup>, T. Obergan<sup>1</sup>

<sup>1</sup>Biology, Lomonosov Moscow State University, Moscow, Russian Federation

**Background:** Previously, it was established that proline- and glycine-containing peptides have fibrinolytic, anticoagulant activity, inhibit platelet aggregation and thrombin activity *in vitro* and *in vivo*. Besides, it is known that short peptides of this family also have antithrombotic effects.

**Aims:** To study the influence of Pro-Gly-Pro-Leu (PGPL) and amino-acid leucine on fibrinolytic and anticoagulant blood activity, platelet aggregation and to estimate their possibility to reduce the formation of experimental blood clots.

**Methods:** Experiments were carried out on white rats (200-250 g) according to the ethical principles of the Helsinki Declaration. Peptide PGPL (1 mg/kg), leucine (0.33 mg/kg - equivalent to its content in PGPL) and saline (control rats) were intranasal entered to rats within 3 days. 1 hour after the last drugs administration we induced the formation of thrombus in v.jugularis (Wessler model). The degree of thrombus formation was estimated on thrombus weight. Fibrinolytic activity and activity of tissue-plasminogen activator (t-PA) of blood plasma were measured by fibrin plate method. Anticoagulant activity (APTT-test) and ADP-induced platelet aggregation were detected by standard methods.

**Results:** Our experiments demonstrated that preliminary intranasal administration of PGPL (before formation of thrombus) leads to increase of APTT, fibrinolytic and t-PA activity on 18%, 62%, 35% accordingly from control rats. Besides, we observed the decrease of platelet aggregation. Also we indicated the reduction of thrombus weigh in PGPL-treated rats on 68.5% comparatively with control rats. The thrombus weigh after leucine treatment decreased on 30% compared with control rats. But administration of leucine did not change of haemostasis system parameters.

**Summary/Conclusions:** Thus administration of PGPL enhanced of anticoagulant, fibrinolytic and antiplatelet activity in rats blood plasma. PGPL pretreatment lead to prevention of experimental venous thrombus formation. Therefore, PGPL may be used as perspective anticoagulant and fibrinolytic agent with direct antithrombotic effect.

PB2204

### TREATMENT AND OUTCOME OF THROMBOTIC MICROANGIOPATHY IN MALAYSIA

Y.Y. Yap<sup>1,\*</sup>, K.B. Law<sup>1</sup>, P.A.B. Zulkarnain<sup>1</sup>, S. Carlo<sup>1</sup>, R. Ramli<sup>1</sup>, J. Sathar<sup>1</sup>, K.M. Chang<sup>1</sup>

<sup>1</sup>Department of Haematology in Ampang Hospital, Ministry of Health, Selangor, Malaysia

**Background:** Thrombotic Thrombocytopenic Purpura (TTP) is a potentially lethal disease that there is still no promising cure in this era. The ADAMTS-13 deficiency or defect in the disease has enabled clinician to recognize another entity which is Thrombotic Microangiopathy (TMA). This entity includes TTP, typical Haemolytic Uraemic Syndrome (HUS), Cancer associated TMA, Atypical HUS, Pregnancy TMA, SLE related TMA and Transplant TMA.

**Aims:** This study is to focus on the treatment among the TMA and the outcome of the disease.

**Methods:** The data was collected from year 2012 to 2016 from Ampang Hospital via the electronic hospital information system (EHIS) and external records traced from Haemostasis laboratory in Ampang Hospital as well as from other hospitals nationwide.

**Results:** There were total of 243 suspected TMA cases, encompassing 97 (39.9%) males and 146 (60.1%) females. The median age for this cohort was 34 years. Only 54 (24.15%) patients were diagnosed as TTP based on ADAMTS-13 activity  $\leq 10\%$ . Treatments were evaluated by using complete case details from Ampang Hospital cohort (69 cases). From this cohort, only 59 cases had ADAMTS-13 activity testing. There were 24% Primary Acquired TTP, 5% typical HUS, 3.4% atypical HUS, 3.4% Pregnancy TMA, 3.4% SLE related TMA, 20.3% Transplant TMA, 1.7% Cancer associated TMA and 37% TMA of other causes. The average plasma exchange was 8.4 cycles, and was higher in patients with ADAMTS-13 activity of  $\leq 10\%$  (11.4 cycles) as compared to those with ADAMTS-13  $> 10\%$  (7.7 cycles). No infectious diseases were transmitted as a result of plasma exchange or plasma infusion. Treatments used in the patients included immunosuppressant therapy like methylprednisolone (85.5%), monoclonal antibody like rituximab (36.2%), bortezomib (11.6%), cyclophosphamide (10.1%), cyclosporine (10.1%), and vincristine (26.1%). The survival outcome seemed to be worse among the transplant TMA in comparison to other groups (log-rank,  $p < 0.0001$ ). Transplantation was also associated with higher odd of death among TMA cases (OR: 14.8571, 95% CL: 1.7385, 126.9707). Those with confirmed TTP was inevitably doing better than the others in terms of overall survival (log-rank,  $p = 0.0299$ ). The odds of death was 4.36 times higher in patients with ADAMTS-13 activity  $> 10\%$  (OR: 4.36, 95% CL: 1.0961, 17.3714), indicating secondary TTP may have inferior treatment and

disease outcomes than primary TTP like congenital or acquired TTP. Besides, the complications of the disease were also evaluated which revealed 26.9% of renal failure and 52.2% of neurological deficit. Furthermore, 8.7% were complicated by Venous Thromboembolism, either provoked or spontaneous. The odds of relapse is 2.9 times higher given the ADAMTS-13 activity  $\leq 10\%$  to ADAMTS-13 activity  $> 10\%$ .

**Summary/Conclusions:** This study illustrated that the standard treatment like plasma exchange and immunosuppressant therapy are only effective in genuine TTP whereas those masquerading TTP (TMA) would be more challenging to be tackled in terms of improving the outcome. The task to investigate other types of TMA prospectively will be highly desirable in the future.

PB2205

### ANTIPHOSPHOLIPID ANTIBODY PROFILE AND ORGAN INVOLVEMENT IN CRITALLY ILL PATIENTS WITH AUTOIMMUNE DISEASES

P. Zambrano<sup>1,2,\*</sup>, J. Aponte<sup>1</sup>, A. Sanchez<sup>2</sup>, M.T. Ospina<sup>2</sup>, Y. Forero<sup>1</sup>, J. Carrizosa<sup>3</sup>, E. Aviles<sup>4</sup>, A. Cartagena<sup>1</sup>, C. Zapata<sup>1</sup>, C. Gamboa<sup>1</sup>

<sup>1</sup>Universidad de La Sabana, <sup>2</sup>Hospital Universitario de la Samaritana, <sup>3</sup>Fundación Santa Fe De Bogotá, Bogotá, <sup>4</sup>Universidad de La Sabana, Bogotá, Colombia

**Background:** Antiphospholipid antibodies (APA) are a group of proteins directed against the phospholipids of cell membranes, such as cardiolipins or phospholipid binding proteins. APA presence provokes microvascular, arterial or venous thrombotic events indicating somehow the relationship between the immune system, the hemostatic system, and the inflammatory response. It has been suggested that their presence in a critically ill patient is related to thrombotic manifestations, organ dysfunction, and death.

**Aims:** The aim of this study was to evaluate the prevalence of antiphospholipid antibodies in critically ill patients with autoimmune diseases and the rate of organ involvement.

**Methods:** Retrospective and descriptive study of patients admitted to the intensive care unit of Hospital Universidad de la Samaritana between 2008 and 2016, in Bogotá, Colombia.

**Results:** A total of 79 patients were found to have systemic lupus erythematosus (SLE), antiphospholipid syndrome and vasculitis. 17 patients (22%) were positive for antiphospholipid antibodies. Of these, 76% were women and mean age was 38 years (18-63 years). APA profiles showed positivity with this distribution: one positive antibody, n=9 patients (53%) (lupus anticoagulant antibody being the most common), two positive antibodies in n=4 patients (23%) and three positive antibodies in n=4 patients. Anemia (100%), monocytosis (64%), thrombocytopenia (40%) and prolonged INR (17%) were found in 88% of patients on admission to the ICU. In descending order, other organ involvement was found to be: pulmonary and renal dysfunction (70%), shock (53%), central nervous system involvement (41%), cardiovascular (23%), and gastrointestinal (22%). 82% of this cohort had positive anti-nuclear antibodies (ANA) and 23% anti-cytoplasmic antibodies (ANCA). 100% of patients had elevated C-reactive protein (CRP), and APACHE II score average was 11 points (Table 1).

Table 1.

n	Gender	Age (years)	Lupus anticoagulant	Anticardiolipin antibodies	Antiphospholipid antibodies	Anti - B2 microglobulin
1	Female	26	Not available	IgG	Not available	Not available
2	Female	25	Positive	IgM	No available	Not available
3	Female	63	Negative	Negative	IgM	Not available
4	Female	19	Positive	Negative	IgG	Not available
5	Male	63	Positive	Negative	Not available	Not available
6	Female	61	Positive	IgG	Not available	Negative
7	Male	62	Positive	Negative	Not available	Negative
8	Female	30	Positive	Negative	Not available	Negative
9	Male	53	Positive	Negative	Not available	Not available
10	Male	53	Positive	IgM/IgG	Not available	Negative
11	Female	18	Positive	IgM	Negative	Negative
12	Female	29	Not available	Not available	Not available	IgG
13	Female	18	Negative	IgM	IgG	IgG
14	Female	20	Positive	IgG	IgG	Not available
15	Female	49	Negative	IgG	IgG	IgG
16	Female	22	Positive	Negative	Negative	Not available
17	Female	35	Positive	Negative	Negative	Negative

Demographic data and antiphospholipid antibody distribution.

**Summary/Conclusions:** Hematologic, renal and pulmonary involvement are the most commonly compromised in patients with antiphospholipid antibodies positivity in patients with autoimmune diseases in the ICU. Based on these results, a prospective study is proposed in order to evaluate the presence of APA and their impact on mortality and multi-organ dysfunction in these patients.

PB2206

### PREVALENCE OF ANTIPHOSPHOLIPID ANTIBODY AND HBA1C IN T2DM WITH DIABETIC VASCULAR COMPLICATIONS

T U. Nwagha<sup>1,\*</sup>, O. Agwu<sup>1</sup>

<sup>1</sup>Haematology & Immunology, University Of Nigeria Teaching Hospital, Enugu, Nigeria

**Background:** Antiphospholipid antibodies (APLS) have been implicated in vascular (arterial, venous or both) thrombosis. Diabetes Mellitus (DM), as a disease entity has been associated with hyper-coagulable and pro-thrombotic states, with studies showing an increased procoagulant state and thrombotic events especially in poorly controlled Type 2 Diabetes Mellitus (T<sub>2</sub>DM).

**Aims:** The aim of the study is to assess the APLS and HbA1c levels and evaluate the correlation between APLS levels and HbA1c in T<sub>2</sub>DM patients with diabetic vascular complications.

**Methods:** This was a cross-sectional study of subjects with T2DM attending the diabetic clinic of University of Nigeria Teaching Hospital. A total of two hundred and ten (210) subjects were recruited for this study. There were grouped into three (complicated T2DM, uncomplicated T2DM and health control. Each had 70 subjects matched for sex and age. Lupus anticoagulant (LA) was assayed using DRVVT (technoclon GmbH Austria) IgG $\beta$ 2GPI-ACA was assayed using ELISA test kit (Genway Bio-tech San Diego USA), HbA1C was assayed using D10<sup>TM</sup> haemoglobin analyzer. Ethical clearance was obtained from ethical committee UNTH.

**Results:** The prevalence of LA was 7.1%, 4.3% and 4.3% for complicated T2DM, uncomplicated and healthy control subjects respectively, while the prevalence of IgG-B2GPI ACA was 4.3% in all groups. The mean HbA1C were 8.2(1.5), 8.0 (1.7), 5.6 (0.38) for complicated, uncomplicated T2DM and control subjects respectively. ANOVA showed a significance difference in mean HbA1C among complicated uncomplicated T2DM and healthy controls. Post hoc analysis showed this difference was between complicated T2DM and healthy controls ( $p < 0.001$ , 95% CI -3.0 to -2.1) and in uncomplicated T2DM and healthy control subjects ( $p < 0.001$ , 95% CI -2.8 to -2.0) there was a significant correlation between HbA1C and IgG $\beta$ 2GPI-ACA for complicated T2DM ( $r = 0.316$ ),  $P = 0.008$  and uncomplicated T2DM ( $r = 0.316$ ),  $P < 0.001$ )

**Summary/Conclusions:** The study did not find any causal or other association between T2DM and the occurrence of APLS positivity, however, APLS may be simply an aggravating factor for vascular complications especially in poor controlled T2DM

## PB2207

### VWF THR789ALA GENETIC VARIANTS CORRELATE WITH DISEASE PHENOTYPE IN EGYPTIAN PATIENTS WITH ACUTE CORONARY SYNDROME

N. Osman<sup>1\*</sup>, M. Younes<sup>1</sup>, R. Yaseen<sup>1</sup>, A. Fathy<sup>1</sup>

<sup>1</sup>Clinical Pathology, Menoufia University, Shebin Elkom, Egypt

**Background:** von Willbrand factor antigen level (vWF: Ag) was shown to contribute to the risk of cardiovascular disease. vWF Thr789Ala single nucleotide polymorphism is thought to affect factor level and function.

**Aims:** This study aimed to investigate the impact of genetic variants at that position on the risk of acute coronary syndrome (ACS).

**Methods:** The study included 112 patients of ACS; 31 with unstable angina (UA) and 81 with myocardial infarction (MI) as well as 118 healthy controls. vWF: Ag level was measured by ELISA. The gene analysis was carried out by polymerase chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles.

**Results:** vWF: Ag levels were significantly higher in MI (111.68 $\pm$ 24.77 IU/dl) and UA (110.27 $\pm$ 23.44 IU/ml) patients compared to healthy controls (71.13 $\pm$ 13.72 IU/dl),  $p < 0.001$  for both groups. The majority of patients with UA (80.6%) were Ala789 homozygous, 6.5% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. Regarding the MI group, Ala789 genotype was present in 34.6%, Thr789Ala genotype was the predominant genotype and was seen in 48.1% of patients and Thr789 homozygous was present in 17.3% of patients. The genotype frequency in the control group was as follow; 47.4% were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789 homozygous. The genotype distribution was significantly different among the 3 groups,  $p < 0.001$ , and between the groups with UA and MI,  $p < 0.001$ . Ala789 homozygous genotype was an independent risk factor for UA while the Thr789Ala genotype was shown as an independent risk factor of MI.

**Summary/Conclusions:** vWF Thr789Ala genotype is independent risk factor for UA and has significant impact on the type of myocardial ischemia. It should be incorporated in a risk assessment model to identify individual patient risk and guide the management plan.

## PB2208

### THE INFLUENCE OF FIBRINOGENASE ISOLATED FROM THE ANTARCTIC SCALLOP ON BLOOD COAGULATION

N. Raksha<sup>1\*</sup>, D. Gladun<sup>1</sup>, T. Ishchuk<sup>1</sup>

<sup>1</sup>Biochemistry, Educational and Scientific Center "Institute of Biology and Medicine" Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

**Background:** At the present time, cardiovascular diseases such as acute myocardial infarction, ischemic heart diseases, and stroke are the most important causes of the human mortality around the world. Thrombosis is probably the most common symptom among cardiovascular diseases. Thrombolytic

agents have been extensively used in the therapeutic treatment of thrombosis. But most of them have some serious shortcomings, including limited efficacy, short plasma half-life, large therapeutic dose or allergic response. Considering the global burden, the search continues for a safe and cheap thrombolytic agent to treat cardiovascular diseases. To date, many investigators have been trying to improve the safety and efficacy of thrombolytic therapy. Fibrinogenolytic enzymes or fibrinogenases because of their role in dissolving of blood clots as well as prevention their formation have attracted special medical and scientific attention. Enzymes that affect hemostasis have been isolated from different sources. In recent years, special attention is paid to the hydrobionts from the Antarctic region which are poorly explored and potentially can be a valuable source of new bioactive compounds, in particular enzymes.

**Aims:** The main goal of current research was to test the effect of fibrinogenase from marine hydrobiont the Antarctic scallop *Adamussium colbecki* on platelet aggregation and blood coagulation.

**Methods:** Fibrinogenase from the crude tissue extract of *A. colbecki* was isolated by three-step procedure (affinity chromatography on SBTI-sepharose following affinity chromatography on Blue-Sepharose and size exclusion chromatography on Superdex 75-PG). Platelet aggregation was determined by AT-02 aggregometer (Medtech, RF). The platelet count was adapted to 2.5x10<sup>5</sup> platelets/ $\mu$ L with platelet-poor plasma. Then, fibrinogenase (12.5  $\mu$ g/mL or 6.25  $\mu$ g/mL) was added 2 min before the addition of the platelet aggregation inducer (5x10<sup>-6</sup> M ADP). The changes in light transmittance were continuously monitored during 8 min, and the percentage of aggregation, in the presence of the samples, was calculated comparing the transmittance against the controls. Activated partial thromboplastin time (APTT) and prothrombin time (PT) were measured in CLOTimer analyzer.

**Results:** According to our result investigated enzyme inhibited ADP-induced platelet aggregation and the inhibition increased with increasing concentration of the enzyme. Data analysis revealed a significant ( $p < 0.05$ ) inhibition of ADP-induced platelet aggregation by 80.5% for 12.5  $\mu$ g/mL of fibrinogenase and by 31.8% for 6.25  $\mu$ g/mL of fibrinogenase. Isolated fibrinogenase may inhibit platelet aggregation by hydrolyzing the A $\alpha$ -chain of fibrinogen to prevent fibrinogen from combining with fibrinogen receptor on platelet membrane. In addition, fibrinogen degradation products may act as competitive inhibitors of platelet-fibrinogen bridging formation. We also investigated the effect of fibrinogenase on blood coagulation by determination of APTT and PT. According to our result APTT increased in 2.25 and 1.25 times at the concentration of fibrinogenase of 12.5  $\mu$ g/mL and 6.25  $\mu$ g/mL, respectively. The fibrinogenase also prolonged PT from 18 s to 68 s when the concentration of enzyme was 6.25  $\mu$ g/mL.

**Summary/Conclusions:** Further investigations of fibrinogenase from *A. colbecki* are interesting and would probably help to develop new therapeutic agents to treat thrombotic disorders.

## PB2209

### IMPORTANCE OF MONITORING PATIENTS WITH DIRECT ORAL ANTICOAGULANTS

L.F. Ávila Idrovo<sup>1\*</sup>, A. Bernardo Gutierrez<sup>1</sup>, A. Caro Gómez<sup>1</sup>, D. Martínez Carballeira<sup>1</sup>, I. Soto Ortega<sup>1</sup>

<sup>1</sup>Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain

**Background:** A major advantage of these agents is the lack of a requirement for monitoring, due to less variability in drug effect for a given dose, however it's recommended monitoring the drug for Rivaroxaban Apixaban and Endoxaban use anti-Xa chromogenic studies and for Dabigatran Hemoclot thrombin inhibitor and Ecarin clotting time (DTI test).

**Aims:** Determine the effectiveness of laboratory tests to monitor patients treated with direct oral anticoagulants.

**Methods:** We conducted a retrospective study with 227 patients who received direct oral anticoagulants (DOACs) between January 2015 and December 2016. One hundred eighteen patients (52%) receive Rivaroxaban, fifty patients (22%) receive Dabigatran and fifty nine patients receive Apixaban (26%). We analyzed the variables that's increases the bleeding risk such as age, weight, prothrombin time (PT) and activated partial thromboplastin time (aPTT), therapeutic range of the drug, and measurement of serum creatinine.

**Results:** We found 10% of toxicity with Dabigatran, a 7% with Rivaroxaban and a 3% with Apixaban. Thirty-five patients (15%) developed bleeding of which 11% patients had a minor bleeding and a 4% of patients had a mayor bleeding, we also found that 6% of patients with Dabigatran, 2.5% with Rixaroxaban and 1.5% with Apixaban developed thrombotic episodes. Twenty percent of patient didn't have therapeutic range of the drug. For each DOACs is shown in Table 1. When we analyzed the patients who had hemorrhage we found that all patients with Dabigatran prolonged aPTT and the PT in 80%, for other DOACs is shown in Table 1. A retrospective case-matched analysis was performed comparing 35 patients who developed bleeding with an equal number of patients who did, case and control groups were matched according to age, weight and measurement of serum creatinine we didn't found significant difference.

**Summary/Conclusions:** In our series, in patients with dabigatran and who suffered bleeding, we found a significant prolongation of aTTP and PT, demonstrating the importance of laboratory tests prior to the administration of these agents and in emergency situations, for these reason should be include PT

and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency and control laboratory tests in patients that receive DOACs.

**Table 1.**

Variable	Apixaban	Rivaroxaban	Dabigatran
percentage	25.9%	51.9%	22%
toxicity	3.3%	6.7%	10%
thrombotic episodes	1.6%	2.5%	6%
percentage out of therapeutic range	8.4%	24.5%	22%
prolonged aPTT	8.4%	2.5%	80%
prolonged PT	16.9%	21%	4%
<b>Bleeding</b>	<b>(35) 15.4%</b>		
percentage	34.2%	20.8%	7.8%
prolonged aPTT	8.3%	22.2%	100%
prolonged PT	25%	33.3%	80%
median therapeutic range	177	142	154
median serum creatinine	1mg/dl		
median age	81		
median weight	71		

**PB2210**

**HEREDITARY RISK FACTORS OF VENOUS THROMBOEMBOLISM IN YOUNG WOMEN TAKING ESTROGEN DRUGS**

A. Chechulova<sup>1,\*</sup>, S. Kapustin<sup>2</sup>, S. Karpich<sup>2</sup>, V. Shmeleva<sup>2</sup>, V. Soldatenkov<sup>2</sup>, L. Papayan<sup>2</sup>, V. Soroka<sup>1</sup>, P. Chechulov<sup>3</sup>

<sup>1</sup>Vascular surgery, Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, <sup>2</sup>Russian Research Institute of Hematology and Transfusiology, <sup>3</sup>Dzhanelidze Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

**Background:** Estrogens are recognized as the most common risk factor of venous thromboembolism (VTE) in young women. The cumulative risk of VTE in patients taking estrogens is significantly increased in carriers of inherited thrombophilia. However, the known hereditary risk factors – mutations FV Leiden and FII G20210A could be detected in only 20-30% of patients with VTE.

**Aims:** To identify the most common hereditary risk factors of VTE in young women taking estrogen drugs.

**Methods:** We examined 133 young women with acute VTE (mean age 37.4 years; 16-45), who were genotyped by PCR-RFLP method for DNA polymorphism in 9 genes: FI-A Thr312Ala, FI-B -455 G/A, FII 20210 G/A, FV 1691 G/A, FXII 46 C/T, FXIII-A Val34Leu, PAI-1 -675 4G/5G, EPCR Ser219Gly, TPA 311bp Ins/Del. We compared the distribution of studied genotypes in three groups of patients with VTE: taking estrogens (n=30, group 1), with idiopathic VTE (n=42, group 2) or having other risk factors (n=61, group 3). Intergroup differences in genotype frequencies were assessed by Fisher's exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated with SPSS software version 17.0 (SPSS Inc, Chicago, IL, USA).

**Results:** The frequencies of prothrombotic genotypes in groups 1, 2 and 3, respectively, were: FV 1691GA – 20.0%, 21.4% and 13.1%; FII 20210GA – 10.0%, 9.8% and 7.1%; FI-B -455AA – 10.0%, 2.4% and 1.6%; FI-A 312Ala/Ala – 13.3%, 14.3% and 13.1%; TPA 311bp Ins/Ins – 16.7%, 28.6% and 31.1%; PAI-1 -675 4G/4G – 36.7%, 42.9% and 27.9%; EPCR 219Ser/Gly – 16.7%, 19.0% and 23.0%; EPCR 219Gly/Gly – 3.3%, 7.1% and 0.0%; FXII 46TT – 13.3%, 0.0% and 9.8%; FXIII-A 34 Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences between the groups have been detected only for the FXIII-A 34Leu/Leu variant, which was more frequently found in patients with idiopathic VTE than in the group with estrogens (OR=6.5; 95% CI: 1.2-63.4; p=0.012) and women having other risk factors (OR=2.2; 95% CI: 0.8-7.6; p=0.05). The frequency of FI-B -455AA genotype in young women with DVT developed after taking estrogen drugs was 4- and 6-fold higher, respectively, when compared to the group with idiopathic VTE and patients having other risk factors (10.0% vs 2.4%; OR=4.1, 95% CI: 0.02-2.2, p=0.16 and 10.0% vs 1.6%; OR=6.6, 95% CI: 0.7-67.0, p=0.067).

**Summary/Conclusions:** FV Leiden and FII 20210G/A mutations as well as the FI-B -455AA genotype are frequently seen in young women with DVT developed after taking estrogen drugs. Further studies are needed to clarify genetic risk factors contributing to VTE development in this group.

**KNOWLEDGE AND ATTITUDE OF MEDICAL DOCTORS ON ANTICOAGULATION THERAPY IN TERTIARY HOSPITALS IN NIGERIA**

T.U. Nwagha<sup>1,\*</sup>, R. Anakwue<sup>2</sup>, O. Ukpabi<sup>3</sup>, E. Onwubuya<sup>4</sup>, N. Obeka<sup>5</sup>, I. Okoye<sup>6</sup>, B. Azubuikwe<sup>6</sup>

<sup>1</sup>Haematology & Immunology, <sup>2</sup>Internal medicine, University Of Nigeria Teaching Hospital, Enugu, <sup>3</sup>Internal medicine, Abia state Teaching Hospital, Umuahia, <sup>4</sup>Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, <sup>5</sup>Internal medicine, Federal Medical center , Abakiliki, <sup>6</sup>Internal medicine, Amaku Specialist hospital, Awka, Nigeria

**Background:** Thromboembolic and hypercoagulable diseases are common life-threatening but treatable problems in hospital practice. The most effective and economical approach to decreasing the burden of VTE is to prevent the development of DVT and PE in patients especially in acutely ill hospitalized medical patients. Health care providers in Nigeria may have significant gaps in their anticoagulation knowledge that could affect their decision to prescribe anticoagulation therapy as there are no national guidelines on the use of anticoagulation in Nigeria.

**Aims:** The purpose of this present study was to examine the knowledge and attitude of medical doctors on anticoagulation in tertiary hospitals in Nigeria.

**Methods:** The present study is a multicentre survey of the use of anticoagulants among clinicians in South East Nigeria. A pretested questionnaire was administered to clinicians in six tertiary hospitals in the south-east of Nigeria. The following institutions participated in the survey: University of Nigeria Teaching Hospital Enugu, Federal Medical Centre, Abakaliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba, Amaku Specialist Hospital, Awka and Nnamdi Azikiwe Teaching Hospital, Nnewi. The Likert scale which is in grades from one to five: 1 strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly disagree was used. To determine the agreement degree three levels were identified (high medium and low).

**Results:** There were 528 respondents. 378 of them were males (71.6%) and 150 were females (28.4%). 31.1% of the respondents, were junior residents and the consultants represented only 20.6% of the respondents. Most of the respondents, 189 (35.8%) had less than 5 years clinical experience while the least of the respondents (8.7%) had between 16-20 years clinical experience. We observed that most respondents irrespective of their job grades didn't know about Fondaparinux and the DOAC (except those in the specialist - registrar job grades) as the overall p=(0.000), <0.05 and were significant. We also observed that responses were divided on malignancy as an indication for anticoagulation. The overall P=0.002, <0.05 and was significant. The p value for other indications for anticoagulation >0.05 and was not significant. The majority knew of prothrombin test and p value was 0.03, less than alpha value of 0.05 and was significant. On the contrary, Majority does not know about anti-Xa assay, p-value=0.02, <0.05, was also significant. Their affirmative response on the mode of action as one of the differences showed a p=0.000, <0.05, was significant. On the contrary, the non-affirmative response to drug and food interaction, p=0.03, was also significant. Based on results of the statement analysis, the variables were ranked according to the value of their mean. All except one variable had p-values of <0.05. The statement "Do you think anticoagulation therapy/prophylaxis is clinically important" had the highest mean of 4.60 and had a high degree of agreement. The statement "Should hospital inpatient with >3 days admission routinely receive anticoagulation?" had the lowest mean of 2.27 with a p-value of 0.015 had a low degree of agreement.

**Summary/Conclusions:** There is a need to upscale knowledge attitude and practice of the use anticoagulation agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some subspecialties that were not reflected in this survey.

**PB2214**

**INTERLEUKIN -10 GENE POLYMORPHISMS AND THE RISK OF UNPROVOKED DVT IN EGYPTIAN PATIENTS**

H. Ellithy<sup>1,\*</sup>, G. Shaheen<sup>2</sup>, S. Elmoamly<sup>1</sup>

<sup>1</sup>Internal medicine- clinical Hematology Unit, <sup>2</sup>Clinical pathology, Kasr Al-ainy school of medicine- Cairo university, Cairo, Egypt

**Background:** Thrombosis is often multifactorial, caused by both genetic and acquired risk factors. The inflammatory process is linked to pathogenesis of venous thrombosis. Venous thrombosis is considered to be mediated by an imbalance in proinflammatory as compared with anti-inflammatory molecules. One of the important anti-inflammatory cytokine is interleukin-10 (IL-10) with important immunoregulatory functions. Primarily, IL-10 counterbalances the potentially harmful effects of tumor necrosis factor α (TNFα) and other pro-inflammatory mediator such as IL-1b, IL-6, and IL-8 from monocytes/macrophages. Three important single nucleotide polymorphisms (SNP) affect IL-10 expression, including: 1082 A/G, 819 C/T, and 592 C/A. Studying the association between genetic polymorphisms of anti-inflammatory cytokines such as IL-10, and venous thrombosis may suggest using of polymorphisms as a predictive genetic marker of future VTE.

**Aims:** The objective of this study was to evaluate a possible association between IL-10 -1082A/G, and -592C/A polymorphisms with DVT.

**Methods:** The study was conducted on 115 patients with symptomatic DVT proved by venous duplex ultrasound; divided into two cohorts: group A included

60 patients with unprovoked DVT, and group B included 55 patients with provoked DVT. Gene mutations for IL-10-1082A/G, and -592C/A were performed using PCR-restriction fragment length polymorphism assay. We studied the association between IL-10 gene polymorphisms and occurrence of either provoked or non-provoked DVT. We also investigated the link between these polymorphisms and the recurrence of DVT and family history of DVT.

**Results:** in our study IL101082AG gene analysis revealed that mutant genotypes distribution is statistically significant different compared to the wild genotype distribution, being higher in group A (with unprovoked DVT) than in group B (with provoked DVT); as GG genotype was detected in 14 patients (63.6%) versus 8 patients (36.4%) in group A and B respectively (P value=0.037); AG genotype was detected in 30 patients (63.8%) compared to 17 patients (36.2%) in group A and B respectively (P value=0.007). However, there is no correlation was found between IL101082 mutant genotypes distribution and VTE recurrence (P value= 0.738 and 1 respectively) or positive family history of VTE (P value= 0.101 and 0.714 respectively), compared to wild genotype. IL10592AC gene analysis showed that mutant genotypes (GG and AG) distribution showed no statistically significant difference (p value= 0.43 and 0.687 for GG and AG genotypes respectively) compared to wild genotypes distribution, also there is no correlation was found between IL10592AC mutant genotypes distributions and VTE recurrence (P value= 1 and 0.284 for GG and AG genotypes respectively) or positive family history of VTE (P value= 0.67 and 1 for GG and AG genotypes respectively), compared to wild genotype (AA).

**Summary/Conclusions:** IL101082AG gene polymorphism is associated with risk of unprovoked DVT, however it is not associated with either risk of recurrence or positive family history.

## PB2215

### CATASTROPHIC ANTI-PHOSPHOLIPID SYNDROME TRIGGERED BY SEPSIS. A PROSPECTIVE CASE STUDY HIGHLIGHTING BIOLOGICAL CONCEPTS AND MANAGEMENT STRATEGIES IN THIS COMPLEX AND LIFE THREATENING DISEASE

M. Hua<sup>1,\*</sup>

<sup>1</sup>Haematology, Liverpool Hospital, Sydney, Australia

**Background:** Catastrophic antiphospholipid syndrome (CAPS) is a rare and life threatening event characterized by widespread intravascular thrombosis and multi-organ failure. Rarely is CAPS associated with bleeding diathesis, but has been reported in cases with severe thrombocytopenia and acquired prothrombin inhibitors. APS auto-antibodies are heterogeneous and may undergo post-translational modification during antigen stimulation altering its pathogenicity and thrombotic risk. Sepsis and associated disseminated intravascular coagulation is a known phenomenon where cytokines influence pro-coagulant and anti-coagulant pathways on multiple levels to induce haemostatic chaos.

**Aims:** Demonstrate the role of sepsis in triggering life threatening CAPS, and highlight the management strategies used in this highly complex and fatal disease.

**Methods:** Prospective case study illustrating two separate atypical CAPS presentations and the management strategies employed. *1<sup>st</sup> episode (2015):* 54F with long standing 27 years of triple positive APS, pro-thrombotic history with recurrent thrombosis despite optimal anticoagulation. Her pro-thrombotic equilibrium was altered after a respiratory tract infection where she presented with severe headaches. Subsequent investigations demonstrated multiple atraumatic intra-cranial haemorrhages followed by concurrent extensive cerebral venous thrombosis. *2<sup>nd</sup> episode (2017):* She presented with subdural haemorrhage, preceded by fevers and respiratory symptoms. She then developed pleuritic chest pain and dyspnoea after temporary cessation of anticoagulation for 24 hours. Imaging confirmed multiple pulmonary emboli with areas of infarction. Respiratory symptoms worsened with progressive interstitial ground glass changes on CT consistent with atypical pulmonary infection. Shortly after low therapeutic anti-coagulation she developed acute abdominal pain and hypotension. CT confirmed significant bilateral adrenal haemorrhages. *Management Strategies:* (A) Rapid reduction in APS pathogenic auto-antibodies via plasma exchange, B cell depletion therapy and immune modulation. (B) Treatment of underlying infectious trigger. (C) Judicious anticoagulation with anti-Xa monitoring and (D) long term hydroxy-chloroquine and statin therapy.

**Results:** The two life threatening presentations of CAPS were triggered by an infectious event, supporting the biological concept that anti-phospholipid antibodies can be immune modulated altering his pathogenic capabilities creating haemostatic havoc. There are similarities and a degree of overlap with sepsis and the pathophysiology behind disseminated intravascular coagulopathy. Rapid reduction in the pathogenic auto-antibodies using combination plasma exchange, immune modulation and B cell depletion therapy is effective in this acute setting. Judicious anticoagulation and treatment of the precipitating infection is important in turning off the immune response driving this life-threatening coagulopathy.

**Summary/Conclusions:** CAPS is rare and life threatening, often triggered by an infectious event, trauma or temporary cessation of anticoagulation. It requires prompt recognition and timely commencement of therapy.

## PB2216

### HAEMATOLOGICAL CORRELATES OF ISCHEMIC STROKE AND TRANSIENT ISCHEMIC ATTACK : LESSONS LEARNED

H. Gunasekara<sup>1,\*</sup>, I. Pathiraja<sup>2</sup>

<sup>1</sup>Health, Teaching Hospital- Kegalle, Kegalle, <sup>2</sup>Health, Provincial Department of Health Services, North Western Province, Sri Lanka

**Background:** Haematological abnormalities are known to cause Ischemic Stroke or Transient Ischemic Attack (TIA). The identification of haematological correlates plays an important role in management and secondary prevention

**Aims:** The objective of this study was to describe haematological correlates of stroke and their association between stroke profile. The haematological correlates screened were Lupus Anticoagulant, Dysfibrinogenemia, Paroxysmal nocturnal haemoglobinuria (PNH), Sickle cell disease, Systemic Lupus Erythematosus (SLE) and Myeloproliferative Neoplasms (MPN).

**Methods:** A cross sectional descriptive study was conducted in a sample of 152 stroke patients referred to haematology department of National Hospital of Sri Lanka for thrombophilia screening. Following tests were performed to assess each hematological correlates (Table 1).

Table 1.

Hematological correlate	Tests performed
Lupus anticoagulant	Diluted Russell's Viper Venom Test and Kaolin clotting time
Sickle cell disease	Full blood count (FBC), blood picture and sickling test and High Performance Liquid Chromatography
Paroxysmal nocturnal haemoglobinuria	FBC, blood picture, Ham test and flowcytometry
Myeloproliferative neoplasms	FBC, blood picture, Janus Kinase 2 (V617F) mutation analysis, erythropoietin level and bone marrow examination
Dysfibrinogenemia	TT, fibrinogen antigen test, clot observation and claus test
Systemic lupus erythematosus	Anti nuclear antibodies

**Results:** Among study sample, 134 patients had strokes and only 18 had TIA. The recurrence of stroke/TIA was observed in 13.2% of patients. The majority of patients (94.7%) have had radiological evidence of thrombotic event. One fourth of patients had past thrombotic events while 12.5% had family history of thrombosis. Out of haematological correlates screened Lupus anticoagulant was the most common haematological correlate (n=16) and dysfibrinogenemia (n=11) had the next high prevalence. One patient was diagnosed with Essential thrombocythaemia and one with SLE. None of the patients were positive for screening tests done for sickle cell disease and PNH.

**Summary/Conclusions:** The Haematological correlates were identified in 19% of our study sample. Among stroke profile only presence of past thrombotic history was statistically significantly associated with haematological disorders (P= 0.04). Therefore hematological disorders appear to be an important factor in etiological work up of stroke patients particularly in patients with past thrombotic events.

## PB2217

### ANTIPLATELET AND FIBRINOLYTIC EFFECTS OF ARGININE-CONTAINING PEPTIDES IN HEALTHY RATS AND RATS WITH METABOLIC SYNDROME

Y. Song<sup>1,\*</sup>, M. Grigorjeva<sup>1</sup>, T. Obergan<sup>1</sup>

<sup>1</sup>M.V.Lomonosow Moscow State University, Moscow, Russian Federation

**Background:** Currently, the number of diabetes, hypercholesterolemia, metabolic syndrome (MS) patients has increased sharply in the world. MS is metabolic disorders with increase of cholesterol and glucose levels, dyslipemia, endothelial dysfunction. This is accompanied by an increase in blood clotting, including platelet aggregation strengthening and reducing the activity of the plasminogen activator. Thus, the MS may predispose to venous thrombosis. It is known that, regulatory oligopeptides involved in the conservation normal functional activity of coagulation, anticoagulation, insular systems of the organism, fat metabolism. It is also known that some amino acids, particularly arginine, improve rheological properties of blood and reduce platelet aggregation.

**Aims:** To study the effect of tripeptides Pro-Arg-Gly and Gly-Arg-Pro, containing arginine in the molecule, on platelet aggregation and tissue plasminogen activator (t-PA) activity in a healthy organism and the development of the experimental MS.

**Methods:** Experiments were carried out on Wistar rats weighing 300-350 g in accordance with the ethical principles of the Helsinki Declaration. Two groups of animals were used: healthy rats and rats with experimental MS. Peptides were intranasal injected in doses of 1 mg / kg once daily for 5 days. 0.85% NaCl solution was injected to control rats in the same time frame. MS in rats was caused by a hyper-cholesterol fat-rich diet (FD) for 6 weeks. Blood samples were taken from the jugular vein 1 hour after the last drug administration. Activity of t-PA (fibrin plate method) and ADP-induced platelet aggregation (standard method) were measured in blood plasma.

**Results:** The intranasal administration of peptides Gly-Arg-Pro, and Pro-Arg-Gly to healthy animals resulted a reduction of platelet aggregation by 23% and 52% compared with the control. Both peptides induced enhancement t-PA activity of 2 or 3.5 times respectively. In rats with experimental MS these effects were preserved, besides, platelet aggregation was decreased by 27% (Pro-Arg-Gly) and 38% (Gly-Arg-Pro) compared with the control.

**Summary/Conclusions:** We concluded that intranasal administration of tripeptides Pro-Arg-Gly and Gly-Arg-Pro to organism of healthy rats and in rats with experimental MS show antiplatelet and fibrinolytic effects of the blood. Thus, arginine-containing peptides could potentially be used as antithrombotic drugs that protect the organism from the blood coagulation and thrombus formation.

**PB2218**

**THE PRINCIPAL COMPONENT ANALYSIS USING CALIBRATED AUTOMATED THROMBOGRAM PARAMETERS AS A POTENTIAL QUALITY CONTROL FOR MEASURING PROCOAGULANT ACTIVITIES OF IMMUNOGLOBULINS**

H. Oh<sup>1,\*</sup>, C. Ahn<sup>1</sup>, S. Han<sup>1</sup>, H. Song<sup>1</sup>, K. Han<sup>1</sup>, G. Min<sup>1</sup>, J. Kim<sup>1</sup>, S. Park<sup>1</sup>, K. Jung<sup>1</sup>

<sup>1</sup>Blood Products Division, National Institute of Food and Drug Safety Evaluation, Cheongju-si, Korea, Republic Of

**Background:** The calibrated automated thrombogram (CAT) is a method to monitor the generation of thrombin. It can be described by four variables; lag time, peak thrombin, time to peak, and velocity index. Currently, due to thromboembolic event related risks of immunoglobulins, the CAT is widely used to quantify the thrombogenic potential associated with immunoglobulin manufacturing processes and products. However, there is currently no officially approved method for such assessments and even this results are highly variable in inter-laboratories comparison. In this study, to obtain a summary score, we applied the principal component analysis (PCA) for these four outcomes measured from CAT method. The PCA is a statistical procedure concerned with elucidating the covariance structure of a set of variables. In particular it allows us to identify the principal directions in which the data varies.

**Aims:** In this study, our interest is to apply PCA method in order to find appropriate dose related with CAT variables and to reduce variation of procoagulant values in Immunoglobulin products.

**Methods:** The CAT are measured in a 96 well plate fluorometer equipped with a 390/460 filter set and a dispenser. Usually experiments are carried out in triplicate. During the measurement, a dedicated software program, Thrombinoscope compares the readings from the trigger wells and the calibrator wells, calculates thrombin concentration and displays the thrombin concentration in time. Outcomes from CAT were analyzed in the principal component analysis (PCA) which is a statistical procedure that allows us to summarize high dimensional data with a smaller number of representative variables that collectively explain most of the variability. Statistical analyses were performed with R 2.5.

**Results:** Four variables measured from CAT have different distribution and too large variations. For example, the mean(sd) of each variable (lag time, peak thrombin, time to peak, and velocity index) are 24.66(8.01), 80.16(94.52), 31.28(9.78), 19.08(28.86), respectively. Therefore, to remedy such high variability among variables and to find a score, PCA method is applied. Then the dose values calculated based on the PCA scores have mean 0.393 and a much smaller variation (sd=0.583) (Table 1).

**Table 1.**

CAT Parameters Range of commercial IVIG products. (show in mean±SD)				The dose levels estimated based on the PCA scores.				
Sample	n	Lag Time(min)	Peak Height(µM)	Time to Peak(min)	VelIndex(M/min)	Sample	n	dose (µg/mL)
A	3	27.76±6.32	25.68±22.04	35.04±6.50	3.53±3.14	A	3	0.73±0.12
B	3	28.07±9.32	24.78±25.32	35.33±10.02	3.51±3.82	B	3	0.63±0.24
C	3	26.30±7.66	35.27±32.92	33.15±8.06	5.22±5.12	C	3	1.17±0.30
D	3	25.07±6.42	40.81±34.90	31.59±6.66	6.31±5.62	D	3	1.43±0.12
E	3	23.82±5.46	33.00±25.68	30.89±5.90	4.72±4.04	E	3	1.20±0.60
F	3	23.45±0.22	44.60±43.34	30.53±1.22	6.48±6.80	F	3	1.53±0.46
G	3	25.86±2.38	26.08±29.90	33.98±4.08	3.37±4.32	G	3	0.50±0.20
H	3	26.22±2.32	27.29±2.38	32.77±2.30	4.20±0.40	H	3	1.03±0.46
I	3	26.11±2.00	25.74±3.30	32.48±1.78	4.07±0.78	I	3	0.97±0.42
J	3	23.45±1.02	47.91±8.00	29.18±0.70	8.39±1.74	J	3	2.43±0.64
K	3	26.44±1.94	24.23±2.38	32.78±1.56	3.84±0.68	K	3	0.87±0.21
L	3	26.11±3.42	24.45±3.38	32.37±3.38	3.91±0.72	L	3	0.90±0.26

**Summary/Conclusions:** The PCA value showed a good agreement with four CAT outcomes and less variation. The PCA method could be used to monitor the process of immunoglobulin manufacturing.

**PRIMARY THROMBOPHILIA IN MÉXICO XII: MISCARRIAGES ARE MORE FREQUENT IN PERSONS WITH THE STICKY PLATELET SYNDROME**

G.J. Ruiz Argüelles<sup>1,\*</sup>, G.J. Ruiz-Delgado<sup>1</sup>, Y. Cantero-Fortiz<sup>2</sup>, M.A. Mendez-Huerta<sup>3</sup>, M. Leon-Gonzalez<sup>4</sup>, A.A. Leon-Peña<sup>4</sup>, A.K. Nuñez Cortes<sup>4</sup>, J.C. Olivares-Gazca<sup>4</sup>, J.A. Arizaga Berber<sup>4</sup>

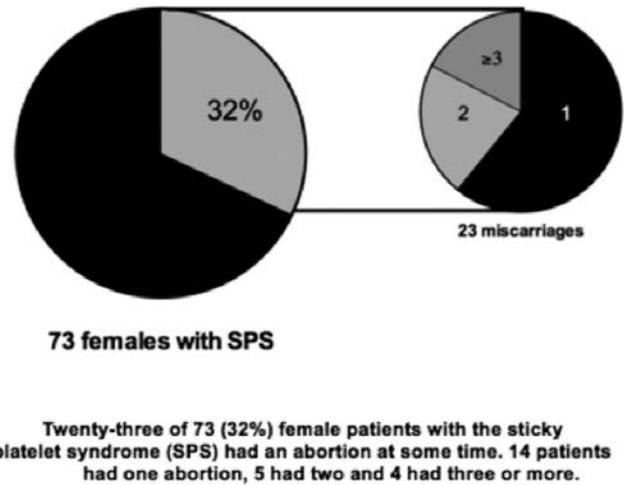

<sup>1</sup>Hematología, Centro de Hematología y Medicina Interna, <sup>2</sup>Universidad de las Americas Puebla, <sup>3</sup>Laboratorios Clínicos de Puebla, <sup>4</sup>Centro de Hematología y Medicina Interna, Puebla, Mexico

**Background:** The sticky platelet syndrome (SPS) is an inherited condition which leads into arterial and venous thrombosis. There is scant information about the association between the SPS and obstetric complications.

**Aims:** To assess the relationship of the SPS and fetal loss in a single institution.

**Methods:** The obstetric history of all the consecutive female patients prospectively studied along a 324 month period, in a single institution with a history of thrombosis and a clinical marker of primary thrombophilia was reviewed.

**Results:** Between 1989 and 2016, 268 consecutive patients with a clinical marker of primary thrombophilia and a history of arterial or venous thrombosis were studied; of these, 108 were female patients. Within this subset of thrombophilic female persons, 77 (71%) had been pregnant at some moment. Twenty eight of these 77 patients (37%) had had a spontaneous abortion and 24 out of these (86%) were found to have the SPS. On the other hand, in a subset of 73 female patients with the SPS who had been pregnant, 32% had miscarriages. These figures are significantly higher than the prevalence of abortions in the Mexican general population of pregnant women, which is 12-13% (*chi square*=7.47; *p*=0.0063). Accordingly, the relative risk of having a miscarriage is 2.66 times higher in female patients with the SPS than in the general population (*p*=0.0014) (Figure 1).

**Figure 1.**

**Summary/Conclusions:** In México, female patients with the SPS experience significantly more spontaneous abortions than the general population. Since the treatment of the SPS is simple and effective and could in turn prevent adverse obstetric outcomes, its investigation in women studied because obstetric complications may be useful and deserves further research.

**PB2220**

**CROSS-SECTIONAL ANALYSIS OF VENOUS THROMBOEMBOLISM IN YOUNG INDIAN MALES; NEW INSIGHTS INTO AN OLD PROBLEM**

S.K. Das<sup>1,\*</sup>, Y. Uday<sup>1</sup>, R. Kapoor<sup>1</sup>, T. Verma<sup>1</sup>, S. Das<sup>1</sup>, V. Nair<sup>1</sup>

<sup>1</sup>Hematology, Army Hospital (Research & Referral), New Delhi, India

**Background:** Venous thromboembolism (VTE) comprising of deep vein thrombosis (DVT) and pulmonary embolism (PE) is one of the major cardiovascular causes of death along with MI and stroke. Though earlier works has suggested that DVT is rarer in Asian population, recent studies have revealed that this might not be so. Most of the studies conducted in Asia in general and India specifically has been on hospitalized patients with minimal representation of young healthy individuals.

**Aims:** We aimed at studying the disease variables of VTE in young healthy males of Indian origin and compare the same with other Indian studies as well as the global statistics.

**Methods:** Hospital records of 176 Color Doppler Flow Index (CDFI) and /or Contrast Enhanced Computed Tomography (CECT) proven VTE patients being followed up in a tertiary care hospital was analyzed retrospectively to document cause (provoked/ unprovoked), venous systems involved, thrombophilia profile, duration of anti-coagulation and recurrence.

**Results:** Among the study population, 49.8% had a provoked VTE. 90.9% subjects had DVT, mostly of the lower limb, 15.3% had PE with DVT, 2.8% had PE alone and 6.2% had splanchnic vein thrombosis including portal vein thrombosis. In the subjects who had undergone thrombophilia profile, 41.9% had Protein C, 58.1% Protein S and 25.9% Antithrombin III deficiency. Lupus anticoagulant screen was positive for 13% of the screened subjects. The average duration of anti-coagulation was 18 months with majority (98.2%) patients on Vitamin K antagonist. The recurrence rate in our study population was found to be 11.4% (Table 1).

**Summary/Conclusions:** Young Indian males have different disease variables

for VTE as compared to western population. The exact pathophysiology of such differences needs to be studied further to formulate strategies for effective screening and prevention.

Table 1.

Investigation	Positive	Negative
Protein C (n=62)	41.3%	58.7%
Protein S (n=62)	54.8%	45.2%
Antithrombin III (n=62)	23.1%	76.9%
Lupus anticoagulant and Activated Protein C Resistance (APCR) with Factor V Leiden		
	Positive	Negative
Lupus anticoagulant (n=62)	11.3%	88.7%
APCR with Factor V (n=62)	17.7%	82.3%

## PB2221

### A PRELIMINARY STUDY ON THE EFFECTS OF AMPHIBIAN CRUDE SKIN SECRETIONS ON SOME PARAMETERS OF HEMOSTATIC SYSTEM

I. Nikolaeva<sup>1,\*</sup>, O. Marushchak<sup>1</sup>, O. Oskyrko<sup>1</sup>, T. Halenova<sup>1</sup>, O. Savchuk<sup>1</sup>

<sup>1</sup>Biochemistry, Educational and Scientific Centre "Institute of Biology and Medicine", Taras Shevchenko Kyiv National University, Ukraine, Kyiv, Ukraine

**Background:** A lot of bio-chemical compounds from secretion of the amphibian skin glands with various biological activities have been isolated and characterized. Several recent studies indicate that amphibian skin secretions can be a source of molecules affecting the platelet activity. We are interested to look for other bioactive components of the amphibian skin which exhibit ability to influence on diverse parameters of hemostatic system.

**Aims:** We performed a preliminary study of the some effects of amphibian crude skin secretions on hemostasis.

**Methods:** Adult specimens (both sexes) of *Bombina bombina*, *Bombina variegata*, *Bufo bufo*, and *Bufo viridis* were collected from outdoors in Kyiv region of Ukraine. The crude skin secretions were collected by washing with ultrapure water and centrifuged to remove debris. The supernatants were lyophilized and kept at -20 °C till use. In the experiments we used fresh prepared water solution of lyophilized skin secretions. Protein concentration was determined by Bradford method with BSA as a standard. Rabbit platelet-rich plasma (PRP, 2x10<sup>5</sup> cells/μL) and platelet-poor plasma were obtained following standard protocols. Platelet fraction (PF) was purified by gel-filtration on Sephadex G 50 column. Platelet aggregation was measured by aggregometer AT-02 (Medtech, Russia). Coagulation parameters (prothrombin time (PT), thrombin time (TT)), as well as activated partial thromboplastin time (APTT)) were measured by coagulometer (Rayto, RT-2201C) using corresponding commercial kits (Renam, Russia).

**Results:** The lyophilized *B. bufo* skin secretions in dose-dependent manner induced platelet aggregation in both PRP and purified PF; its final concentration of 50 mg of total protein/mL caused the same effect as 5x10<sup>-6</sup>M ADP. These results indicated that skin components acted directly on platelets, maybe through their surface receptors. The lyophilized skin secretions of *B. variegata* and *B. viridis* also activated platelet aggregation but their effects were lower than *B. bufo* skin secretions. The skin secretions from all studied amphibian did not influence on PT and TT except *B. viridis* which prolonged TT by 40%. The values of APTT were significantly enhanced in 3.4 and 2.3 times under the influence of crude skin secretions (final concentration of 0.2 mg total protein/mL plasma) of *B. bombina* and *B. variegata*, respectively.

**Summary/Conclusions:** The obtained results indicate the prospects of the search for potential modulators of hemostatic system among the amphibian skin bioactive compounds. To establish their physiological and functional mechanisms of action, the further purification and characterization of components from the skin gland secretions are necessary.

### PLASMINOGEN-DEFICIENT PATIENTS

H. Kızılöçak<sup>1,\*</sup>, G.N. Özdemir<sup>2</sup>, G. Dikme<sup>1</sup>, B. Koç<sup>1</sup>, G. İskeleli<sup>3</sup>, B. Dönmez Demir<sup>4</sup>, N.M. Christiansen<sup>5</sup>, M. Ziegler<sup>5</sup>, H. Özdağ<sup>4</sup>, V. Schuster<sup>5</sup>, T. Celkan<sup>1</sup>

<sup>1</sup>Istanbul University Cerrahpasa Medical Faculty, Pediatric Hematology-Oncology, <sup>2</sup>Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology Oncology Dept., <sup>3</sup>Istanbul University, Cerrahpasa Medical Faculty, Ophthalmology, Istanbul, <sup>4</sup>Ankara University, Biotechnology Institute, Ankara, Turkey, <sup>5</sup>University of Leipzig, Leipzig, Germany

**Background:** Congenital plasminogen (Plg) deficiency is a rare autosomal recessive disorder that leads to the development of ligneous membranes on mucosal surfaces.

**Aims:** Here we report our experience with local and intravenous fresh frozen plasma (FFP).

**Methods:** Our cohort consisted of 14 patients and their 8 first-degree relatives. The patients have been diagnosed between 3 months and 18 years of age, and the median age at the time of first clinical manifestation was 4.5 months (range 3 days to 12 months).

**Results:** Conjunctivitis is the main complaint, hydrocephalus and hearing loss follow. In 10 patients, ligneous membranes were surgically removed but all recurred. Nine patients were treated with intravenous and conjunctival FFP. Two patients had no complaints after treatment. Most patients needed transfusion with FFP every three weeks. Only one patient had severe endophthalmitis and lost vision in one eye before treatment. Two female patients and one male patient had undergone multiple surgeries for ligneous conjunctivitis despite being treated with FFP. The response rate to FFP treatment was 6/9 (66%). Another 8-year-old female with severe bronchial membranes was treated with FFP and t-PA through bronchoscopy. Venous thrombosis did not occur in any of the patients. Nine have consanguineous parents. The genetic evaluation of our patients revealed heterogeneous mutations as well as polymorphisms.

**Summary/Conclusions:** The diagnosis and treatment of Plg deficiency is challenging, and there is no consensus on treatment. Topical and iv FFP may be used with clinical outcome.

### THE TREATMENT OF HEREDITARY TROMBOPHILIA DURING PREGNANCY

M. Theodosiou<sup>1,\*</sup>, I. Ionita<sup>1,2</sup>, E.-C. Budai<sup>1,2</sup>, C. Hategan<sup>1</sup>, D.-N. Oros<sup>1,2</sup>, E.-C. Fenes<sup>1</sup>, R.-S. Buriman<sup>1</sup>, H.-M. Ionita<sup>1,2</sup>

<sup>1</sup>Hematology, Spitalul Clinic Municipal de Urgenta Timisoara/Municipal Emergency Hospital Timisoara, <sup>2</sup>Hematology, Victor Babes University of Medicine and Pharmacy Timirosara, Timisoara, Romania

**Background:** Thrombophilias are genetic conditions that increase the risk of thromboembolic disease. The use of anticoagulant therapy during pregnancy is challenging because of the potential for both fetal and maternal complications. The most common complication is venous thromboembolism.

**Aims:** This study is conducted in order to assess the importance of treatment during pregnancy for women with hereditary thrombophilia, the risks of not treating the disease or treating incorrectly.

**Methods:** This study includes a total of 207 women, from which 83% were treated with low molecular weight heparin and Aspirin during pregnancy regardless if it was their first pregnancy or not and the rest 17% remained untreated during pregnancy. The success of the treatment is based on the completion of the pregnancy and the good health of the fetus.

**Results:** A total of 207 women were included into the study, 172 were treated with low molecular weight heparin and Aspirin while 35 were treated with just Aspirin. Out of 172 patients in the low molecular weight heparin group 155 managed to give birth which accounts for a 90% success rate with a reported case of fetal growth restriction and 2 cases of abruption while the remaining 17 women which represent the 10% of the treated patients were unsuccessful in completing their pregnancy with 14 women presenting pregnancy loss on the first trimester and 2 having late fetal loss, only one case of preeclampsia was recorded. Out of the 35 women who did not receive treatment with low molecular weight heparin and only with Aspirin, 21 managed to complete their pregnancies representing the 60% out of which 2 cases presented with Abruptio and 4 cases with fetal growth restriction, out of the 14 women who represent the 40% who were unsuccessful in completing their pregnancies 7 cases were recorded during the first trimester while 3 more had late fetal loss and 4 cases of preeclampsia.

**Summary/Conclusions:** Women treated for thrombophilia had a lower percentage of fetal loss than their no treatment group counterparts. There is an urgent need for appropriate guidelines for these patients in our medical center.

## PB2224

### LEARNING ABOUT VALIDATIONS OF THE DVT SCREENING TEST IN PATIENTS WITH SUSPECTED UPPER LIMB THROMBOSIS:

#### A PERSPECTIVE FROM THE CLINICAL PRACTICE

H.N. Fernandez - Leyva<sup>1,\*</sup>

<sup>1</sup>Haematology, Croydon University Hospital, London, United Kingdom

**Background:** Deep vein thrombosis (DVT) of the upper limbs represents 1-4% of DVT, most of them related to central venous catheter and / or malignancy. Thrombosis involving the deep veins (ie, subclavian, axillary, brachial) can lead to complications as pulmonary embolism (PE) and long-term sequelae. PE from upper extremity sources accounts for about 6% of cases. Initial treatment in acute context include fibrinolysis and subsequent anticoagulation (Grade 2C). When symptomatology is mild and/or onset of symptoms undetermined (>2 weeks), minimum anticoagulation 3 months is recommended. If there are associated anatomical abnormalities, the possibility of surgical vascular thoracic decompression must be assessed.

**Aims:** To ascertain D-dimer diagnostic accuracy for upper extremity DVT. **Methods:** A retrospective audit was undertaken to determine the aetiology and clinical presentation on patients which UDVT at presentations. Patients with a formal malignancy confirmed before the diagnosis was excluded. A D dimer (DD) with a cut off cut off levels validated for lower limb DVT was performed. **Results:** A total of 18 patients was identified in the period of 2012 to 2016. All the cases investigations included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominant was male in this group the symptomatology were related to physical efforts in a 60% (Paget-Shroetter Syndrome) whereas in female serie the predominant was thrombophilic defects (factor V Leiden). The average age was 33 years (ranging from 21 to 68 years) and 2 elderly patients a new diagnosis of cancer was confirmed (thyroid and lung) (odds ratio, 3.24; 95% CI, 1.13-9.38). The 85% of the patients had an unprovoked event; four patients have a diagnosis of catheter related thrombosis and four cases a thrombophilic defect (factor V Leiden) precipitated by anticonceptive. Two patients had a diagnosis of SLE. We had four cases of positive DD screening (both were marginally elevated,  $P < 0.01$ ). The risk of re-thrombosis was non significant but in the subanalysis of relapsing thrombotic event populations the risk of relapse increased proportionally in relation of thrombophilic defect and high BMI. A trend towards a higher rate of recurrent thrombosis (was observed among patients with BMI > 25 (42.6%) compared to those with a BMI < 25 (33%). This difference reached statistical significance in women with BMI > 25, who had recurrent event in 51.7% of the cases vs those with BMI < 25 (29.7%) ( $p < 0.05$  CI 0.03, 0.41).

**Summary/Conclusions:** In the unprovoked serie the relation of DD was positive in less than 30% of the cases and non statistically significant ( $p < 0.01$ ). In the case of subclavian vein occlusion this is result in limited clot burden (which explain the correspondence with negative DD value). The risk of re-thrombosis is associated with thrombophilic defect and high BMI exclusively. The DD adjusted to age and specific young population need to be addressed (age adjusted DD cut off adapted of the specific population). A prospective studies of DD in suspected UDVT need to be addressed.

#### PB2225

##### THE INFLUENCE OF HEPARINOID FROM THE PEONY ROOTS ON THE THROMBUS DISSOLUTION

M. Lyapina<sup>1,\*</sup>, T. Obergan<sup>1</sup>

<sup>1</sup>M.V.Lomonosov Moscow State University, Moscow, Russian Federation

**Background:** Many plants have an effect on the blood clotting system. It is known that there are heparin-like substances in some types of peony roots (*Paeonia lactiflora*, *Paeonia suffruticosa*). It proved that there is an anticoagulant activity in extracts from such roots.

**Aims:** The intention is to show the inhibitory effect of the extract of *Paeonia lactiflora* roots (EA) on processes fibrin and thrombus formation.

**Methods:** We used the standard coagulologic methods for determining anticoagulant activity by APTT test, antiplatelet, total fibrinolytic activity (TFA), fibrinolytic activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with prothrombotic condition caused by intravenous administration of subthreshold doses of tissue thromboplastin at a dose of 0.6–0.7 ml per 200 g body weight in rats. After 30 min after injection of thromboplastin, we injected intraperitoneally 0.1 mL of 1% of extract of EP and after 30 minutes we determined parameters of hemostasis in the blood plasma.

**Results:** It was shown that after administration of the indicated doses thromboplastin occurs hypercoagulability in blood plasma of animals (APTT decreased by 23% SFA - 15%, FDPA - 12%; increased platelet aggregation by 18% compared to control animals not receiving thromboplastin). Normalization of blood clotting is installed in the experimental rats after application EP (recovery of platelet aggregation to 98%, APTT- to 100%, up to 95% SFA- FDPA and - up to 67% compared with control). The high degree of FDPA indicates the ability of EP to obstruct the process of the formation of fibrins and thrombosis. Heparin components in EP interact with fibrin monomers which do not participate in their conversion to fibrin polymer. As a result, stable fibrin polymer or thrombus is not formed.

**Summary/Conclusions:** Consequently, the extract of *Paeonia lactiflora* roots containing heparinoid contributes to the restoration of coagulation properties in blood of animals in prothrombotic condition and prevents thrombosis. In the initial stages of fibrin formation, it causes the thrombus dissolution.

#### PB2226

##### LOW MOLECULAR WEIGHT HEPARIN AND HIGH MOLECULAR WEIGHT HEPARIN: COMBINATION WITH ADRENORECEPTOR ANTAGONISTS AND PREVENTION OF THROMBUS FORMATION

M. Golubeva<sup>1,\*</sup>, M. Grigorjeva<sup>1</sup>

<sup>1</sup>Biology, Lomonosov Moscow State University, Moscow, Russian Federation

**Background:** Retrombosis and thromboembolia are the most common side

effects of thrombolytic therapy. One of the possible causes of thrombosis is the entering of thromboplastin in the blood stream. Marker of thromboplastin is an intrinsic membrane glycoprotein 5'-nucleotidase (5'NT) that is present as an enzyme in a wide variety of cells. Recently it was shown that compensatory reaction of haemostasis system by using different fibrinolytic drugs was connected with the stimulation of the sympathetic nervous system. Besides, it is known that selective and nonselective  $\alpha$ -adrenoreceptor blocking agents have fibrinolytic and antiplatelet effects. The prevention of thrombosis complication is very important field of pathophysiology and medical practices. Therefore, we studied effects of different  $\alpha$ -adrenoreceptor antagonists and the influence of these substances combinations with various anticoagulant and fibrinolytic agents on blood coagulation during many years.

**Aims:** The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with different  $\alpha$ -adrenoreceptor antagonists (AA) on experimental thrombosis prevention.

**Methods:** Experiments were carry out on 50 white laboratory rats weighing 200-230 g according to the ethical principles of the Helsinki Declaration. Anticoagulant and antithrombotic effects of LMWH or HMWH were studied in two rat models of thrombosis – thrombosis in v. jugularis (Wessler) and thrombosis in arterio-venous shunt (direct registration of blood pressure). The  $\alpha$ -AA digydroergotoxin (DET – 1mg/kg),  $\alpha_1$ -AA prazosin (PZ – 2mg/kg), LMWH or HMWH (40 USP/kg) were injected in v.jugularis. Saline was administrated in control rat groups. The thrombus were formed 15 or 180 min after substances injected. The degree of thrombus formation (TF) was detected in ball (Wessler model) and by time of TF (arterio-venous shunt model). In blood plasma the activity of 5'NT was detected. The results were processed statistically.

**Results:** The increase of anticoagulant and antithrombotic effects of LMWH or HMWH by pretreatment of DET or PZ were shown in both animal models of venous thrombosis. The degree of TF by Wessler model may be estimated as 3.7 (saline), 1.3 (LMWH), 1.8 (HMWH), 0.9-1.1 (DET+ LMWH or PZ+LMWH) and 1-1.3 (DET+ HMWH or PZ+HMWH). Besides, it has been shown that TF was accompanied with significant hypercoagulation of blood: 5'NT activity was increased in 2 time comparatively with normal level. LMWH or HMWH combinations with DET or PZ administration led to normalization of 5'NT level in blood plasma. In arterio-venous shunt model it has been shown that the time of TF was 2 min (saline), that was accompanied with the decrease of blood pressure (on 40-50 mmHg). In this case the time of TF was prolonged in 4 time (LMWH) or 2 time (HMWH) comparatively with saline group 15 min after injection; in 4.5-5 time (DET+ LMWH or PZ+LMWH) or 3-3.5 time (DET+HMWH or PZ+HMWH) comparatively with saline group 180 min after injection.

**Summary/Conclusions:** Thus we confirmed that LMWH (as one, as in combination with  $\alpha$ -adrenoreceptor antagonists) has definite advantages over HMWH. Besides our results show that  $\alpha$ -adrenoreceptor antagonists significantly improvement antithrombotic effect of anticoagulant agents (LMWH and HMWH). Therefore the combination of LMWH with selective and nonselective  $\alpha$ -adrenoreceptor antagonists may be effective used for prevention of venous thrombosis development and thromboembolia.

#### PB2227

##### THE POLICY AND PRACTICE OF ANTICOAGULATION THERAPY AMONG CLINICIANS IN SOUTHEAST NIGERIA.

T. U. Nwagha<sup>1,\*</sup>, R. Anakwue<sup>2</sup>, O. Ukpabi<sup>3</sup>, E. Onwubuya<sup>4</sup>, N. Obeka<sup>5</sup>, I. Okoye<sup>6</sup>, B. Azubuike<sup>6</sup>

<sup>1</sup>Haematology & Immunology, <sup>2</sup>Internal medicine, University Of Nigeria Teaching Hospital, Enugu, <sup>3</sup>Internal medicine, Abia state Teaching Hospital, Umuahia, <sup>4</sup>Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, <sup>5</sup>Internal medicine, Federal Medical center, Abakiliki, <sup>6</sup>Internal medicine, Amaku Specialist hospital, Awka, Nigeria

**Background:** In the absence of anticoagulation therapy, the risk of Venous thromboembolism; deep-vein thrombosis (DVT) and pulmonary embolism (PE) in medically ill patients is comparable to that in moderate-risk surgical patients. Previous studies have revealed grossly inadequate knowledge and a dismal practice of anticoagulation among healthcare workers in some resource poor countries. Prophylactic anticoagulation is under-prescribed in Nigeria, South Africa, as well as in many other countries in Africa.

**Aims:** The aims of the study are to evaluate the practice of anticoagulant therapy. It will also document the frequency of drug-induced complications resulting from the use of anticoagulants and presence of an anticoagulation policy in the hospitals surveyed.

**Methods:** This is a multicentre cohort survey of the practice of anticoagulant therapy among clinicians in South East Nigeria. A pretested validated questionnaire was administered to clinicians in five tertiary hospitals in the southeast of Nigeria. The questionnaire was designed to assess their practices anticoagulation therapy. The questionnaire was administered consecutively on clinicians in the participating centers. The following institutions participated in the survey: University of Nigeria Teaching Hospital Enugu, Federal Medical Centre, Abakiliki, Federal Medical Centre Umuahia, Abia State Teaching Hospital, Aba and Amaku Specialist hospital Awka. Statistical package for Social Science (SPSS) software, version 18 (SPSS Inc., Chicago, IL) was used for analysis.

**Results:** A total of 528 clinicians were involved in the survey. There were more males 378 (71.6%) than females, 150 (28.4%) the clinicians who practiced for less than 5 years are in the majority 189 (35.8%) and those with 15-20 years of practice 46 (8.7%) are in the minority. Only 52 of the respondents (9.8%) claimed their institutions had an anticoagulation policy while 274 (51.9%) of them said there was no such policy and 168 (31.2%) do not know of any policy. Unfractionated heparin was the most frequently used (96.8%) and fondaparinux was the most infrequently used (42%). Most of the prescriptions were done by younger clinicians who are the highest in number. The consultants prescribed heparin and warfarin most, with the newer anticoagulants taking the rear position. Only 193 (36.6%) of the respondents routinely prescribed anticoagulation therapy when indicated. 412 (78%) of respondents believe the risk of anticoagulation outweighs the benefits while 439 (83.1%) identified cost is an important variable in prescribing anticoagulation agent. Anti-coagulation prophylaxis was the most frequently used for patients immobilized or bedridden (94.1%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulation agents (50.6%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents 492 (93.2%), 1 (0.2%) respectively.

**Summary/Conclusions:** This survey has shown the lack of anticoagulation policies among the centers that participated. Our survey has also shown deficiencies in the areas of practice of anticoagulation among the clinicians in the Southeast of Nigeria. These gaps can be remedied by continuous medical education and by the establishment of anticoagulation policies.

#### UMBILICAL CORD BLOOD PLASMA INFUSION PROMOTES BLOOD CELL RECOVERY IN INPATIENTS WITH ACUTE LEUKEMIA UNDERGOING CHEMOTHERAPY

Y. Lu<sup>1,\*</sup>, X. Zhang<sup>1</sup>, X. Li<sup>2</sup>, Y. Zou<sup>1</sup>, Z. Lin<sup>1</sup>

<sup>1</sup>The third Affiliated Hospital of Sun Yat-Sen University, <sup>2</sup>The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Umbilical cord blood plasma (UCBP) is separated from umbilical cord blood. UCBP contains a variety of hematopoietic growth factors which can stimulate hematopoiesis.

**Aims:** The aim of this work is to explore the influence of UCBP infusion on blood cell recovery in patients with acute leukemia undergoing chemotherapy.

**Methods:** Patients with the diagnosis of acute leukemia were included in this study and they were randomly distributed to experimental group and control group. Patients in experimental group received infusion of 100ml UCBP with the same ABO and Rh blood type every day after chemotherapy for five days and patients in control group received placebo for the same time. Blood routine were tested every day until WBC  $>4.0 \times 10^9/L$  and PLT  $>20 \times 10^9/L$ .

**Results:** 25 patients were included in the study of which 23 were brought into statistics. 13 patients were in experimental group and 10 in control group. There were no difference in age, gender and dose intensity of chemotherapy between the two groups ( $P > 0.05$ ). The average recovery time of the blood neutrophil granulocyte  $>0.5 \times 10^9/L$  in experimental group and control group were respectively  $(8.53 \pm 3.26)$  days versus  $(12.92 \pm 4.75)$  days ( $P < 0.05$ ) and that of PLT  $>20 \times 10^9/L$  was respectively  $(9.24 \pm 3.68)$  days versus  $(13.15 \pm 5.76)$  days ( $P < 0.05$ ). No UCBP transfusion-related side effects were found.

**Summary/Conclusions:** UCBP administration is safe as treatment for cytopenia and could promote blood cell recovery in patients with acute leukemia undergoing chemotherapy.

### PB2229

#### TOWARD BETTER BLOOD TRANSFUSION PRACTICE: A SUCCESSFUL RED BLOOD CELL UTILIZATION TOOLS IN A TERTIARY CARE HOSPITAL

A. Aly<sup>1</sup>, G. Mawad<sup>1</sup>, E. Alzaabi<sup>1</sup>, A. Aly<sup>1,\*</sup>

<sup>1</sup>Mafraq Hospital, Abu Dhabi, United Arab Emirates

**Background:** The need for blood in hospitals continues to exceed the volume collected by the transfusion services. The gross over-ordering of blood, in excess of actual and anticipated needs leads to substantial costs and a burden to the transfusion services. In addition, over-ordering leads to non-availability of cross-matched units for other patients who might be in urgent need of transfusion.

**Aims:** We are aiming to reduce the Cross-match-to-transfusion ratio (C:T ratio) & improve blood utilization in Mafraq Hospital.

**Methods:** In 2011 the ordering practice at Mafraq Hospital, a designated Trauma Centre, had been evaluated. Data collected retrospectively over a one year period and a C:T ratio adopted by the American Association of Blood Bank was calculated for all various subspecialties including Surgery, Internal Medicine, Pediatrics and Obstetrics and Gynecology. All procedures related to hospital transfusion practice been retrieved and re-evaluated to address gaps. Policy of maximum surgical blood ordering (MSBO) was implemented based upon both results of audits and by discussion and agreement between medical teams. Focused training and education has been followed to increase the awareness of the health care workers. Plus monitoring of C:T ratio on monthly basis, blood bank team had arranged meetings with the departments that were over-ordering cross-matches to explain that group & save test is a safe, effective and financially beneficial strategy. Communicating with the physicians had been the most challenging aspect of implementing the policy changes. Regular audits had been conducted to measure the compliance and effectiveness of the blood management practice.

**Results:** Compared to the international guidelines, C:T ratios in 2010 was beyond the acceptable target and ranged between 2.5 to 3.2 highlighting the over-ordered cross-matched blood in certain sub-specialties. This practice of ordering was probably because of the fear that blood will not be available, if needed. Following implementation of control and continuous monitoring measures while establishing proper procedures such as transfusion guidelines, administration of blood and blood products and Maximum Surgical Ordering Practice, Mafraq blood bank, supported by the Transfusion and Tissue & Quality & Patient Safety Committees, achieved a great success in reducing C:T ratio  $<2$  all through 2016 Figure 1. The reduction of C:T ratio had improved blood inventory control and reduced the workload of the blood bank staff. Because fewer units of cross-matched PRBC are being ordered, the blood bank has been able to decrease the number of units of blood stocked in house and hence decreasing the number of expired units & reducing money loss Figure 1. The savings in technologist time is particularly significant since the blood bank is most of the time at a minimal staffing level.

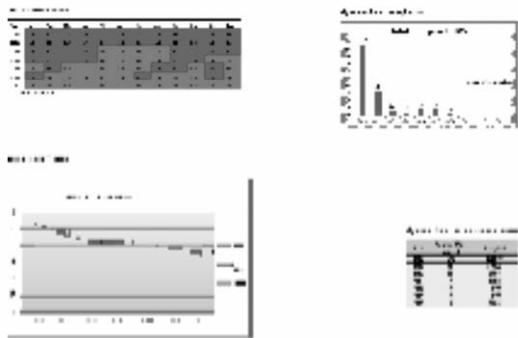

Figure 1.

**Summary/Conclusions:** There is a tendency to order blood in excess, either by asking for an increased number of units or as a standby precautionary measure. Adherence to MSBO & transfusion guidelines, hospital can achieve C:T ratios below 2.0. The introduction of strategies for improved blood utilization has been shown to be cost effective and safe. Future comparison analysis with facilities with well-established blood management program can enhance the current program and ensure continuous proper utilization.

**PB2230**

**SAFETY AND EFFICACY OF A PROTHROMBIN COMPLEX CONCENTRATE IN VKA REVERSAL AND OFF-LABEL INDICATIONS**

M. Marcos Jubilar<sup>1,\*</sup>, J.A. Garcia Erce<sup>2</sup>, N. Martinez Calle<sup>1</sup>, J.A. Paramo<sup>1</sup>, R. Figueroa<sup>1</sup>, S. Villar<sup>1</sup>, M. Quintana<sup>3</sup>

<sup>1</sup>Hematology and Hemotherapy, Clínica Universidad de Navarra, <sup>2</sup>Hematology and Hemotherapy, Complejo Hospitalario de Navarra, Pamplona, <sup>3</sup>Intensive Medicine, Hospital Universitario La Paz, Madrid, Spain

**Background:** Prothrombin complex concentrates (PCC) are highly purified mixtures of plasma coagulation factors that contains vitamin K dependent and anticoagulation factors, they are approved for urgent reversal of vitamin K antagonists (VKA). Massive bleeding-associated coagulopathy guidelines include PCC in their management, although as an off-label indication.

**Aims:** The aim of the present work is to evaluate safety and efficacy of PCC in a case series of VKA reversal and refractory coagulopathy associated with major bleeding.

**Methods:** Retrospective review of cases treated with a four-factor PCC between January 2010 to January 2016 in two tertiary University Hospitals. As safety endpoints we evaluated infusion reactions and incidence of thromboembolic events by self reported registry. The efficacy endpoints were studied in two separate cohorts: 1) INR correction for VKA reversal and 2) coagulopathy correction and early mortality (24 hours) in major bleeding coagulopathy.

**Results:** 328 patients were included (47.25% male), median age 78 years (range 19-102). PCC was used in the following cases: 1) 66.67% in VKA reversal indication (181 patients due to hemorrhage and 33 prior to emergent surgery), mean dose of PCC 1333.51 IU; 2) 30.54% in refractory coagulopathy in major bleeding (30 patients due to massive bleeding protocol activation, 43 patients in hepatopathy coagulopathy and 25 patients in bleeding not related with any of previous reasons) a mean dose of PCC 1681.63 IU was used. Safety endpoint: Two infusion reactions were reported potentially related to PCC use, they were not specified neither as anaphylaxis nor as pulmonary edema, and 8 thrombotic episodes were observed (2.4%): 5 pulmonary embolism, 2 deep venous thrombosis and 1 portal thrombosis, 75% of the events appear in the group of VKA reversal. Efficacy endpoint: VKA reversal in bleeding patients was effective in 97% of them, 76.5% with complete reversal of INR value (INR<1,5), 34.25% of patients required red blood cell (RBC) transfusion, with a mean of 1.32 RBC. Prior to invasive procedure VKA reversal was effective in 83% of patients, all procedures taking place with no bleeding complication, 36,3% of patients needed RBC with a mean of 1.12 units. 24 hours mortality in refractory coagulopathy associated to major bleeding was 31,6%, having a worse outcome (40% rate of death) those who suffer a massive bleeding coagulopathy, all death related with absence of bleeding control. A global INR correction happen in 76.7% of patients, complete correction in 40.7%. 63,26% received previous to PCC fresh frozen plasma.

Invasive hemostatic procedures were required in 20% of the whole series.

**Summary/Conclusions:** A four-factor prothrombin complex was safe and effective as adjuvant treatment in refractory coagulopathy due to major bleeding as well as for the emergent reversal of VKA.

**PB2231**

**TRACEABILITY OF RED BLOOD CELLS IN A HOSPITAL TRANSFUSION LABORATORY**

M. Tserga<sup>1</sup>, A. Argyrou<sup>1,\*</sup>, S. Nikolopoulou<sup>1</sup>, A. Gafou<sup>1</sup>

<sup>1</sup>Blood Bank, General and Oncology Hospital “Agioi Anargyroi”, Athens, Greece

**Background:** According to European legislation (2002/98/EC, 2005/61/EC) as a requirement of hemovigilance system traceability (confirmation of final destination of blood components in hospitals) information should be kept for 30 years, improving the quality and safety of the transfusion process. Various methods are available from simple paper-based procedures to full electronic blood tracking systems. The ideal goal is to trace the final fate of 100% of the red blood cell (RBC) units, from donor to recipient and vice versa.

**Aims:** To check the ability to trace each individual unit from donor to recipient or disposal in our hospital.

**Methods:** To ensure compliance, the minimum traceability data set for retention is a mix of 1) Wards’ paper files (file of transfusions and/or patient records: 14/2 wards respectively). 2) HTL electronic records and paper records. The transfusion practitioner is responsible for the collection and maintenance of traceability data.

**Results:** During the year 2016, the number of RBC units transfused in our hospital was 2128. The traceability status of the transfused units is shown in the Table 1.

Table 1.

Traceability of transfused units			
Traceability	Description	N	N total: 2128
Confirmed	Full match of data	2067/2128 (97.13%)	2067
Presumed	Wrong number of unit in the ward	25/2128 (1.18%)	
Presumed	No number of the unit in the ward	7/2128 (0.33%)	32
Unknown	No data in the ward*	29/2128 (1.36%)	29

\* Patients’ data has been archived for long-term retention.

**Summary/Conclusions:** Although we are satisfied that the results represent a reasonably accurate working model of the current situation, the trail of a unit is less reliable after blood has left the HTL. 1. Patients’ notes to provide traceability are not totally reliable. It is apparent that the ward staff plays a key-role part in the chain and this highlights the need for them to receive training to emphasize the importance of their contribution to hospital compliance. 2. The indications are that the essential requirements on traceability are not fully met by the current laboratory computer system. A configuration is needed to produce a report which lists components which have been assigned for use but do not have an entry for return to stock or final fate. Ongoing problems will be referred to the Hospital Transfusion Committee. 3. For the longer term ultimately only effective IT system in both wards and HTL can ensure total traceability and we recommend the inclusion of electronic tracking system in the National Blood Donor Registry Programme (EMA)

**PB2232**

**NON-HEMOLYTIC FEBRILE POST-PLATELET-TRANSFUSION REACTIONS IN HEMATOLOGICAL PATIENTS**

A. Rakhmani<sup>1,\*</sup>, E. Mikhaylova<sup>2</sup>, I. Dubinkin<sup>3</sup>, V. Troitskaya<sup>2</sup>, O. Kalmikova<sup>3</sup>, M. Danilevskaya<sup>3</sup>, T. Gaponova<sup>1</sup>

<sup>1</sup>Clinical Research Department of processing and cryopreservation of blood cells,

<sup>2</sup>Clinical Research department of chemotherapy and bone marrow depression,

<sup>3</sup>Scientific clinical laboratory quality control and safety of transfusions, Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

**Background:** Platelet concentrate (PC) transfusions are the main method of thrombocytopenia correction in hematological patients, but multiple transfusions could trigger alloimmunity and refractoriness to transfusions.

**Aims:** Comparison of post-transfusion reactions in hematological patients with individual matching and without individual matching receiving PC transfusion support.

**Methods:** In 2015-2016, we observed 948 hospitalized patients, who received 12.344 PC transfusions. Individual matching of PCs was performed by cross-matching on the Galileo-Neo (Immucor) analyzer. Statistical processing was performed using the chi-squared test with Yates’ correction.

**Results:** 107 of 948 patients developed refractoriness to PC transfusions (12% of total patients). Out of them, 21 patients received 389 PC transfusions without individual matching. 86 patients received 1705 PC transfusions with individual matching. During transfusions without individual matching to non-refractory patients, 0.003% of non-hemolytic febrile reactions (NHFR) have been record-

ed, after matching to refractory patients the frequency was 0.002%. Before matching to refractory patients, the frequency of NHFR was (0.03%) (Table 1).

**Table 1.**

Status	Patients	Transfusions	Post-transfusion reactions	% of all transfusions	P
Refractory with matching	86	2027	6	0,002	*P<0,01
Refractory before matching	21	389	15	0,03	
Non-refractory without matching	841	9928	30	0,003	*P<0,01

**Summary/Conclusions:** The frequency of NHFR in groups with refractoriness with individual matching is significantly lower (10 fold) compared to groups with refractoriness before the matching (P<0,01)\*.

## PB2233

### RARE DONORS AND MALARIA

A. Berzuini<sup>1,\*</sup>, B. Foglieni<sup>1</sup>, M. Spreafico<sup>1</sup>, D. Prati<sup>1</sup>

<sup>1</sup>Department of Haematology and Transfusion Medicine, Ospedale A. Manzoni, Lecco, Italy

**Background:** Migratory flows of sub-saharan (SSA) persons throughout the world are expected to continuously increase. A significant proportion of SSA citizens are affected by Sickle Cell Disease (SCD), condition requiring repeated blood transfusions. Many centuries of malaria pressure have induced in SSA natives a homogeneous selection of peculiar haematologic characteristics, such as the absence of high frequency red cell antigens (defining a rare blood) that cannot be found in donors of European descent so that many SCD transfused patients experience the fearful occurrence of red cell alloimmunization. For these reasons haematologists are expecting to access to Rare Blood Banks in order to assure a full match between donor and recipient's blood, that may be obtained from donors sharing the same ethnicity. Unfortunately SSA donor recruitment is counteracted by the widespread diffusion of infections contracted before migration: one of these is malaria. In SSA malaria may occur subclinically and is characterized by a slow antibody clearance. This peculiar condition, the so-called semi-immunity, has been induced by a strong genetic pressure, and is a kind of co-evolutionary process characterized by the co-existence and persistence of small entity of *Plasmodium* genome with relative antibodies. Molecular techniques are unreliable to detect a small number of Plasmodia, which may otherwise be sufficient to induce a transfusion transmitted malaria (TTM). The serologic assessment, despite the low specificity, remains the most sensitive and reliable method to detect the semi-immune status in blood donors (1).

**Aims:** The aim of this study was to assess the prevalence of malaria immunity in a cohort of healthy SSA citizens.

**Methods:** Since 2010 in our Department of Haematology and Transfusion Medicine we recruited 184 SSA citizens, in good health, who agreed to underwent clinical and laboratory investigations to become a blood donor. All of them were born in SSA Africa and lived there for at least the first 5 years of life. 70% of subjects didn't recognize any previous malaria fever. The last travel/stay in Africa was 1-20 years (median 3 yrs), and 48% of returning people had received prophylaxis. Malaria serology was determined by a commercial enzyme immunoassay kit (Malaria EIA Ab, BioRad).

**Results:** Overall 75% of persons were positive for malaria antibodies. Serologic positivity was found in 75% of persons no more exposed in 5 recent years and even in 83% (19/23) persons settled in Italy since 10-20 years. Serologic positivity was present in 100% of people from Benin, 85% from Burkina Faso, 78% from Ivory Coast and Cameroon, 63% from Senegal. We followed antibody concentration in 50 persons (136 assays), and we observed a slightly negative trend that, in most cases, was followed by a prolonged phase of low antibody levels. 4/50 became negative after three years.

**Summary/Conclusions:** The identification of malaria antibodies is essential in SSA native donors and, by far, irreplaceable in order to avoid the risk of TTM. Until pathogen inactivation techniques will become available, we have a very low expectation to introduce SSA blood in Blood Bank inventories. Haematologists have to wait some years for the forthcoming SSA second generation that will allow to fully match the entire SCD patient community.

### EFFICACY AND INFLUENCE OF IRON CHELATION THERAPY ON RED BLOOD CELL TRANSFUSIONS

A. Parvu<sup>1,2,\*</sup>, M. Iancu<sup>3</sup>, A. Vasilache<sup>2</sup>, T. Torok<sup>2</sup>, I.-A. Zsoldos<sup>1</sup>, M. Zdrenghea<sup>1</sup>, L. Petrov<sup>2</sup>, C. Seles<sup>2</sup>, L. Urian<sup>2</sup>, A. Todinca<sup>4</sup>, C. Truica<sup>5</sup>, A. Bojan<sup>1</sup>

<sup>1</sup>Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, <sup>2</sup>Hematology, "Prof. dr. Ion Chiricuta" Oncological Institute, <sup>3</sup>IT, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, <sup>4</sup>Hematology, Baia-Mare County Hospital, <sup>5</sup>Hematology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Baia-Mare, Romania

**Background:** Chelation therapy is recommended for transfused patients that have an elevated serum ferritin level (over 1000 microg/l), evidence of iron overload or received over 20 units of red blood cell transfusions (RBCT). Deferasirox showed efficacy and safety in maintaining or reducing body iron (assessed by liver iron concentration or serum ferritin). Iron chelation therapy was associated with hematopoiesis improvement in transfusion-dependent patients and interruption of Deferasirox treatment of transfusions dependent myelodysplastic patients produced loss of erythroid response.

**Aims:** Aim of the study: to assess the results of Deferasirox efficacy, side effects and to study if the number of RBCT decreased after starting Deferasirox.

**Methods:** We have done a retrospective, transversal study including all the adult politransfused patients treated with Deferasirox in three counties Hematology Departments of Nord-West Romanian hospitals. Criteria of Deferasirox treatment: over 20 RBCT, serum ferritin level over 1000 microg/l.

We created a data collection sheet including: demographics, information on patients' disease, serum ferritin level at start of and during treatment, Deferasirox dose, data about dose modification, adverse effects of Deferasirox and their management, reasons for treatment discontinuing, evaluation of comorbidities that could increase serum ferritin level, number of RBCT before and after starting the treatment.

**Results:** We included 40 politransfused patients treated with Deferasirox, age average 63. The diagnosis included myelodysplastic syndromes (most of patients), thalassemia, other anemias. Myelodysplastic patients were treated with low dose chemotherapy, epigenetic treatment, RBCT and bethalasemic/anemic patients were transfused. The baseline value of ferritin was between 1075 - 6187 microg/l. Deferasirox dose: 20-30 mg/kg. There was a significant reduction in serum ferritin from baseline for all the patients. Ferritin median at start, 3631 microg/l decreases at 1537 microg/l after 6 months of treatment and at 994 microg/l after 12 months of treatment. There were 8 patients that had descendent levels of ferritin, but during infectious episodes the ferritin increases for a short period of time. Digestive adverse events appeared in three cases (two cases of diarrhea and one case of digestive hemorrhagic episode). In all these cases the treatment was temporarily discontinued. In three cases, treatment was stopped because low ferritin level (under 500 microg/l). RBCT were administered before (mean 2.43 units/month) and after starting Deferasirox (mean 1.39 units/month), the difference is statistically significant (Student Test, t(39)=6.98, p<0.001). After starting Deferasirox treatment mean number of RBCT decreased, mean of differences (95% CI) was 1.04. We analyzed the group of 23 patients treated with Deferasirox less than 12 months, and the patients treated more than 12 months, 15 patients. In both groups the difference of RBCT means (before and after the start of the treatment) are statistically significant (for the patients treated less than 12 months: Student Test, t(23)=8.12, p<0.001 and for the patient treated more than 12 months: Student test, t(15)=3.03, p=0.008).

**Summary/Conclusions:** Analyzing our group of 40 patients, Deferasirox proves to be effective and safe. Adverse effects that determined a temporary stop of the treatment were mild/medium short time digestive reactions. The number of red blood cell transfusion significantly decreased after starting Deferasirox treatment.

## PB2235

### LIBERAL VS RESTRICTIVE COMPARATIVE TRANSFUSIONAL STUDY IN ONCOLOGICAL POPULATION

M.I. Touzón Andión<sup>1,\*</sup>, M. Gestal<sup>1</sup>, A. Varela<sup>1</sup>, M. Castro<sup>1</sup>, C. Moineiro<sup>1</sup>, R. García de Villaescusa<sup>1</sup>

<sup>1</sup>Transfusion, Centro Oncológico de Galicia, La Coruña, Spain

**Background:** Allogeneic transfusion therapy is perhaps one of the most widely used treatments without good evidence support, despite many years of application in clinical practice. This, coupled with blood shortages, the impossibility of achieving zero risk, the lack of evidence that transfusion may increase consumption or decrease tissue oxygen debt and the existence of an association with an increase in morbidity and mortality have favoured that we join efforts towards its optimal use.

**Aims:** Optimal use in our adult oncological population and evidence that restrictive transfusion (TR, Hb 7-9 grs / dl) is not greater or lower to the liberal transfusion (TL, Hb 8-10 grs / dl), keeping hemoglobin in safe levels for the patient.

**Methods:** A research was performed from October 1st, 2015 through December 31st, 2016. We analyzed the proportion of patients receiving packed red cells (CH) and the number of units transfused as well as post-transfusion control in order to describe the outcome of the CH versus TL strategies in the cancer population under the study.

**Results:** See Table 1.

**Summary/Conclusions:** The results obtained in our series of 311 cancer

patients indicate that the restrictive strategy has been equally effective and probably superior to the liberal one maintaining Hb at a safe level in each patient, as well as quality of life and comfort in a subgroup with advanced and terminal cancer.

Table 1.

Transfusional Therapy	Patients (N*)	Hb Pre (X)	Hb Post (X)	yield /CH (grs/dl)
RT	192	8,1	9,1	1,0
LT	97	7,4	9,4	1,0
PWC	22	8,0	-	-
TPT	311	7,8	9,2	1,0

X: RBC transfused: 1,3

Hb Pre: Pre-transfusional haemoglobin; Hb Post: Post-transfusional haemoglobin; PWC: Patients without post transfusion Hblevel; TPT: Total Patients Transfused; X-: half haemoglobin.

PB2236

HIGH RISK OF HBV INFECTION IN VACCINATED POLYTRANSFUSED CHILDREN

M. El-Sayed<sup>1</sup>, Z. Said<sup>2</sup>, E. A. E. Abou Elmagd<sup>2</sup>, E. Salama<sup>3</sup>, F. Ebeid<sup>1,\*</sup>  
<sup>1</sup>Pediatric Department, Ain Shams University, Faculty of Medicine, <sup>2</sup>Microbiology Department, Faculty of Medicine (for girls), Al-Azhar University, <sup>3</sup>Community Medicine Department, National Research Center, Cairo, Egypt

**Background:** Children receiving chemotherapy for neoplastic diseases are still susceptible to Hepatitis B virus (HBV) infection despite the national HBV vaccination program coverage for all infants since 1992.

**Aims:** This study aimed to analyze immunity against HBV and occurrence of HBV breakthrough infections in polytransfused children who had been vaccinated during infancy.

**Methods:** The study included 89 children with hematological disorders and malignancies, who were categorized into group (A): 37 receiving chemotherapy (M:F 20:17; mean age:7.7±4.0) and group (B): 52 polytransfused children (M:F 31:21; mean age:7.6±3.2). A matched healthy control group (n=162) was also included. All patients and controls had received their primary vaccination against HBV in infancy. Quantitative anti-HBs were tested for patients and controls. Patients' sera were tested for HBsAg, anti-HBc, and HBV-DNA (nested PCR for surface, core & x-regions).

**Results:** Levels of anti-HBs between 10-100 IU/L and ≥100 IU/L were found among 13.5% and 21.6% [group (A)], 44.2% and 11.5% [group (B)] and 32.1% and 10.5% of controls respectively. There was a significant difference in HBsAb between patients receiving chemotherapy (group A) and both groups B patients (p=0.008) and controls (p=0.032). However, no difference was found between polytransfused children [group (B)] and controls.

HBsAg was positive in 21(67.7%) children under chemotherapy [group (A)] compared to 10 (32.2%) polytransfused children [group (B)] (p<0.0005). Overall, 49 patients (55%) were HBV-DNA positive; 44 c-region positive, 7 s-region positive, 2 positive for both c and s-regions and one positive for c and x-regions. Of those, only 21 patients (42.8%) were also positive for HBsAg; while 28 (47.2%) had occult HBV infection (HBsAg-negative). There was no significant difference between patients receiving chemotherapy [group (A)] and polytransfused children [group (B)] (p 0.157), regarding the rate of HBV DNA. Anti-HBs ≥10 IU/L co-existed in 38.7% (12/31) of HBsAg positive patients and 49% (24/49) of HBV-DNA positive patients.

**Summary/Conclusions:** Children with neoplastic diseases vaccinated during infancy were at a high risk for HBV infection. The effect of immunosuppression on the HBV protective level favored overt HBV infection in children receiving chemotherapy. The co-existence of anti-HBs with HBsAg and/or HBV-DNA demonstrated a possible residual transfusion-transmission risk with mutant HBV strains.

PB2237

THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS: THE EXPERIENCE OF ISTANBUL FACULTY OF MEDICINE

Z. Karakas<sup>1,\*</sup>, D. Soydemir<sup>1</sup>, M. Yanaşık<sup>1</sup>, A. Akcay<sup>2</sup>, G. Ozturk<sup>3</sup>  
<sup>1</sup>Pediatric Hematology-Oncology, Istanbul University Istanbul Medicine Faculty, <sup>2</sup>Pediatric Hematology-Oncology, Acibadem University, <sup>3</sup>Pediatric Hematology-Oncology, Acibadem University, Istanbul, Turkey

**Background:** Isohemagglutinins that develop against ABO blood group antigens are very important in transfusion and transplantation medicine. Today, 30-40% of allogeneic stem cell transplantations are ABO incompatible transplantation, 20-25% of which are major, 20-25% are minor and remaining bi-directionally incompatible transfusion. Our study; based on the knowledge that isohemagglutinins play an important role in blood transfusion policies in patients undergoing ABO incompatible hematopoietic stem cell transplantation(HSCT) has been shaped by the assumption that each healthy blood bank donor may be potential transfusion donors for ABO incompatible HSCT transplant recipients

**Aims:** In this study, we investigated the isohemagglutinin titer values of the individuals with A, B and O blood groups; the distribution of the isohemagglutinin titers according to the decades and gender. Also we examined the possibility of determining the isohemagglutinin cut off value in Turkish society.

**Methods:** One thousand five voluntary blood donors (48 female, 957 male), randomly chosen from the donors, providing the criteria to be a standard blood donor in Blood Center Department, Istanbul Faculty of Medicine were studied. This study was approved by the Ethics Committee of Istanbul Medical Faculty. In the donor population group; blood group A (%40) was the most common and blood group AB was the rarest blood group. According to the Rh D phenotypes; 85% of the population was Rh D positive and 15% of the population was Rh D negative. The frequency of our blood group was determined similar with other European countries. The most common age range of one thousand five voluntary blood donors, including the same rate individuals with blood group A, B and O, was the age range between 26 and 35 years. Forward and reverse blood group determination were performed to these donors and also we identified the Anti-B Ig M and Ig G isohemagglutinin titer values for blood group A; Anti-A Ig M and Ig G titer values for blood group B; eventually both Anti-A Ig M /Ig G and Anti-B Ig M/ Ig G izohemagglutinin titer values for blood group O by using column agglutination methods. Statistical analysis was performed with NCSS (Number Cruncher Statistical System) 2007 (Kaysville, Utah, USA).

**Results:** While the titer value of Anti-A Ig M isohemagglutinin was 1:128 for female individuals with blood group B; the titer values of both Anti-B Ig M (1:128 and 1:256), Anti-B Ig G (1:1024) and Anti-A Ig M (1:256) isohemagglutinins were statistically significance in female individuals rather than male ones. The levels of isohemagglutinin in the blood groups A, B and O are shown in Table 1A,B. There was no statistical difference in anti-B IgG and IgM titers in blood group A, anti-A IgG and IgM titers in blood group B and anti-A IgG and IgM titers in blood group O between males and females(p>0.05). However Anti-B IgG and IgM antibody titers were higher in females than males in donors with blood group O respectively p=0,017 (p<0,05) and p= 0.001 (p<0,01) (Figure 1 A,B).

Table 1.

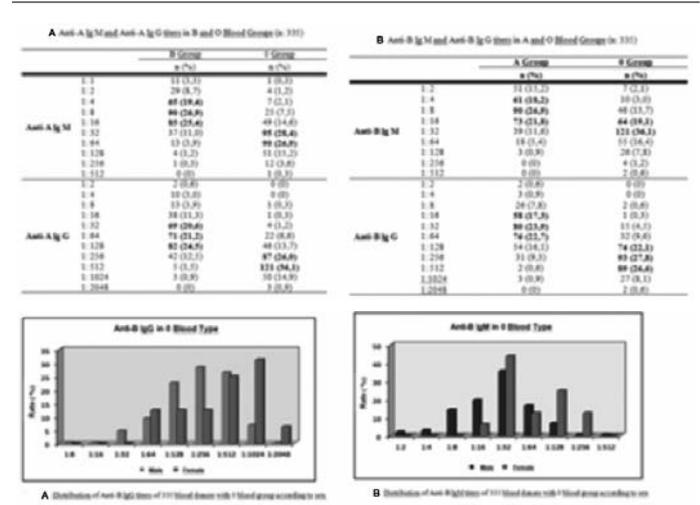

Figure 1.

**Summary/Conclusions:** Female individuals of blood bank donors participated in our study have higher isohemagglutinin titer values rather than male individuals. Recurrent blood group incompatibility in pregnancy, invasive diagnostic and therapeutic approaches for risk analysis in fetal examination during pregnancy, perinatal complications causing fetomaternal hemorrhage after pregnancy or during birth and lastly autoimmune diseases cause the enhancement of isohemagglutinin titer values in female individuals. Regarding the gender differences; nutrition, vaccination and recurrent blood transfusion history of blood bank donors also effect and change the isohemagglutinin titers of individuals. Population specific isohemagglutinin titer values play a key role in blood donation policy of patients undergoing hematopoietic stem cell transplantation. Consequently; we predict that Turkish community-specific isohemagglutinin cut off titer values can be identified and we will hope our knowledge on this issue in the future with the increase of research is going to increase further.

PB2238

THE NEW METHOD OF PURIFICATION FACTOR COAGULATION VIII

N. Shurko<sup>1,\*</sup>, T. Danysh<sup>1</sup>, V. Novak<sup>2</sup>  
<sup>1</sup>laboratory biochemistry of blood, <sup>2</sup>Hematology, State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

**Background:** The human plasma of blood can be transfused directly to patients or pooled and fractionated into plasma protein products. Plasma contains about 60-80 g/L of protein, of which about 95% are used for many therapeutic prod-

ucts. The main proteins that use for treatment many diseases are albumine (45 g/L), immunoglobulin (8-11 g/L), factors coagulations. The Factor VIII (FVIII) is one of the blood coagulation factor and it deficient causing development of bleeding disorders known as Haemophilia A. The purification of FVIII is generally required for the treatment Haemophilia A or von Willebrand's disease and heavy loss of blood, requires relatively high purity for medical use.

**Aims:** optimization of a process purification of FVIII by the method of affinity chromatography on the Diasorb-aminopropyl matrix with triazin active dyes as ligands.

**Methods:** adsorption/precipitation, ion-exchange chromatography on DEAE-Sepharose, affinity chromatography on the Diasorb-aminopropyl matrix with Active Scarlet Damask 4GT as ligands in combination methods of antiviral treatment.

**Results:** The process plasma fractionation is largest industry segment in manufacture of therapeutic concentrate of plasma proteins. We developed technological scheme that involves fractionation plasma of blood in combinations of classical methods of protein precipitation and two chromatographic steps: ion exchange and affinity chromatography.

Of all plasma fractionation methods, chromatography is the best candidate for purification of factor coagulation, especially FVIII. The methods adsorption/precipitation permits the fractionation of large volumes of plasma, but the quality of the product obtained by chromatography is superior.

We offer: fresh frozen plasma – adsorption of proteins on the barium citrate – adsorption of proteins on Al(OH)<sub>3</sub> – adsorption of proteins to PEG-4000 – viral inactivation (solvent-detergent method) – ion exchange chromatography on DEAE-Sepharose – viral inactivation (ammonium thiocyanate) – dye-ligand affinity chromatography (Diasorb-Active Scarlet Damask 4GT). We got the drug of FVIII with specific activity 69.65±2.24 IU/mg protein.

**Summary/Conclusions:** we developed technological scheme of plasma fractionation and reached a high degree of purification of coagulation FVIII.

#### PB2239

##### PRIMARY TROMBOTIC MICROANGIOPATHIES. REVISION IN A CENTER OF THE LAST 8 YEARS

T. Castañó<sup>1,\*</sup>, S. Sanchez<sup>1</sup>, T. Arquero<sup>1</sup>, M. Yuste<sup>1</sup>, E. Askari<sup>1</sup>, P. Llamas<sup>1</sup>  
<sup>1</sup>Fundación Jiménez Díaz, MADRID, Spain

**Background:** Thrombotic microangiopathies are a group of rare diseases characterized by non-immune microangiopathic hemolytic anemia, thrombocytopenia and involvement of organs of varying intensity, mainly renal and CNS damage. TTP and HUS are the most important forms of TMA and without adequate treatment administered early are associated with high morbidity and mortality.

**Aims:** To review our experience in the management of the primary TMA and to raise a series of questions that perhaps could improve the approach of these pathologies

**Methods:** We made a retrospective, descriptive analysis of ten cases diagnosed of primary thrombotic microangiopathy (TTP n=5; typical HUS n=3; atypical HUS n=2) over the last eight years, 70% of which were women with an average age between 40-60 years. Only three cases had previous records of autoimmune diseases (MTCO, RA and HIV), all of which would eventually develop TTP. We requested ADAMTS13 levels on all cases, they were low (<5-10%) only in those patients diagnosed with TTP, and on the other hand confirming the positivity for Shiga toxin in those patients who eventually developed typical HUS.

**Results:** Regardless of the diagnosis, 10-12 plasma exchanges were performed to improve the biological parameters of hemolysis, requiring the placement of a central catheter, most commonly at the right jugular vein (70%) due to the lower risk of thrombotic and infectious complications. Although renal involvement is frequent in HUS, only two of the patients required dialysis without recovery of baseline renal function. Is to be noted the part played by the approval in 2011 of eculizumab and how patients eight years ago suffered a torpid course, requiring a greater number of plasmapheresis and the side effects this carries. However, we still do not know its repercussions out of indication. In our study, it was used in a patient with a diagnosis of HUS associated with an infection with good evolution, although perhaps this result is due only to the natural evolution of the disease. Another controversial point is the use of antibiotics, which are known to worsen the clinical course of these processes, but because of a concomitant infection or new positive determination of the Shiga toxin, as occurred with two of our patients diagnosed of HUS had to be used. Finally, 30% of the patients have relapsed after the first episode with a primary diagnosis of a TTP.

**Summary/Conclusions:** Thrombotic microangiopathies are a group of processes of enormous complexity, in addition to the low frequency with which they are usually present in our usual clinical practice requiring a large deployment of means to reach an early diagnosis and begin treatment as soon as possible given that the unfortunate prognosis of these patients. With this study we have raised a series of questions to improve the management of this type of diseases:

The need to request levels of ADAMTS13 in patients diagnosed with TTP or to repeat the determination of Shiga toxin in patients with typical HUS as part of the disease follow-up and to try to prevent possible relapses.

The use of eculizumab out of indication in typical HUS and whether the

improvement in the picture is due to the drug or by natural evolution of the disease. The real benefit of using plasmapheresis in patients diagnosed with typical HUS. The use of antibiotics and possible harm to the diagnosis made.

#### PB2240

##### HAEMOVIGILANCE REPORTS OF ADVERSE BLOOD DONOR REACTION AMONG VOLUNTARY BLOOD DONORS IN TERTIARY CARE HOSPITAL IN KATHMANDU, NEPAL

B. Nepal<sup>1,\*</sup>

<sup>1</sup>Blood Bank, Grande International Hospital, Kathmandu, Nepal

**Background:** Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure

**Aims:** To identify and understand the complication of adverse donor reactions though the incidence of reactions of blood donation among blood donor in the tertiary care hospital in Nepal

**Methods:** This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outlines of reported and communicated adverse donor reaction were also collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive

**Results:** In the present study 6,955 whole blood donors were included, during the period of 2 years, 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as, sweating; 27(25.72%), Light headedness; 19(18.09%), nausea and vomiting; 15(14.28), allergy and bruises;11(10.47%), sore arm; 9(8.58%) and hematoma; 8(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis;11(10.49%), loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors

**Summary/Conclusions:** The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donors is lower than in other studies. Donor age and donation status were strong possibilities of complications.

**Background:** Whereas p53 is mostly non-mutated in AML, various oncogenic pathways, frequently through enhancing the activity of its major antagonist Mdm2, suppress its activity. We have previously showed that genetic ablation of CK1a robustly activates p53 (doi:10.1038/nature09673). However, with no selective CK1a inhibitors for *in vivo* use, the therapeutic value of CK1a inhibition in hematological malignancies cannot be validated.

**Aims:** To develop small molecule CK1a inhibitors and assess their effect in mouse models of human leukemia.

**Methods:** CK1a inhibitors were identified via cell-based screening based on p53 activation. We focused on a small class of pyrazole-pyrimidine scaffolds, which through extensive medicinal chemistry yielded derivatives with high affinity binding, validated by crystallography studies, potent CK1a inhibitory activity and a good pharmacokinetic profile. Anti-leukemic activity was assessed by oral treatment in mouse models of AML: MLL-AF9 and Bcr-Abl Blast Crisis

**Results:** We first demonstrated the inhibitors' anti-leukemic effect by single oral dose treatment, robustly inducing p53 activation and blast cell cyto-reduction (Figure 1).

Single-dose inhibitor effects treated for 6hrs (BM Western blot and blood smear) and 16hrs (tissue records), in heavily leukemic mice, showing strong cyto-reduction in the spleen and bone marrow and pro-apoptotic signaling of combined inhibition of P-TEFb (CDK9) and CK1a, evident by RNA Pol II phospho-CTD inhibition and activation of DNA damage response (yH2AX) and p53

Figure 1.

These inhibitors distinguished leukemic from normal hematopoietic stem cells: they did not affect normal hematopoietic CFUs, but eliminated leukemic CFUs at an IC50 <9nM. We tested the long-term oral therapeutic effects of the inhibitors in MLL-AF9 leukemic mice. Whereas all vehicle-treated mice succumbed to the disease within a month, 40-50% of inhibitor-treated mice survived with no signs of disease up to 5 months' observation, nor had the surviving mice any sequela of long-term treatment; all had normal blood counts and normal organ morphology and histology. Long-term leukemia control with possible cure, attesting to eradication of LSCs and preservation of normal HPSCs was demonstrated by transplanting leukemia-treated BM into lethally irradiated mice: all transplanted mice recovered and none showed any evidence of residual disease within 6 months. To elucidate the mechanisms by which the inhibitors distinguished leukemia from normal hematopoietic cells, we profiled the kinome affinity of the inhibitors and further studied their signaling effects *in vitro* and *in vivo*. We found that CK1a inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and suppress the RNA Pol II elongation factor P-TEFb (CDK9-CyclinT1 complex). This property, validated by co-crystallography studies, enables the inhibitors to disrupt super-enhancers (SE), demonstrated by suppression of chromatin H3K27 acetylation and Brd4 association. As a result, transcription of SE-dependent major anti-apoptotic leukemia oncogenes including Mdm2, Bcl-2 and Mcl-1 was nearly abolished and inhibitor-treated leukemia cells underwent apoptosis. Strikingly, brief drug exposure (10mins *in vitro*; 2hrs *in vivo*) results in prolonged (24hrs) SE suppression. This unique property, which is at variance with the current occupancy-driven pharmacological paradigm, likely, contributes to

the dramatic therapeutic effect of co-targeting CK1a and P-TEFb in leukemia. **Summary/Conclusions:** We developed a new class of small molecule inhibitors that co-target CK1a and P-TEFb. These inhibitors induce very rapid, robust activation of p53 in synergy with shutdown of leukemic super-enhancers, resulting in a lasting, powerful and specific anti-leukemic therapeutic effects *in vivo*, with cure potential.

**Background:** Mantle cell lymphomas (MCL) are characterized by the primary translocation t(11;14)(q13;q32) involving *CCND1* and *IGH* genes in virtually all cases. Recently, a small subset of cyclin D1-negative (cyclin D1<sup>-</sup>) MCL has been recognized. About half of these cases have *CCND2* gene rearrangements and overexpression of this gene. However, the primary oncogenic events in cyclin D1<sup>-</sup>/cyclin D2<sup>-</sup>MCL still remain elusive.

**Aims:** To identify potential mechanisms driving the pathogenesis of cyclin D1<sup>-</sup>/cyclin D2<sup>-</sup>MCL.

**Methods:** We investigated 66 cyclin D1<sup>-</sup>/SOX11<sup>+</sup>MCL cases by a combination of fluorescence *in situ* hybridization (FISH), gene expression profiling by Affymetrix U133+2.0 and qPCR (n=51), and copy number arrays (n=47) (Agilent CGH 1M, Affymetrix Oncoscan and 500K). Six cases were investigated by genome-wide sequencing including 4 mate-pair whole-genomes, 4 whole exomes, and 1 whole-genome sequencing. The male/female ratio was 2.5:1 and median age at diagnosis 66 years.

**Results:** Most cyclin D1<sup>-</sup>MCL (49/51, 96%) showed overexpression of other G1 cyclins: *CCND2* in 33/50 (66%), *CCND3* in 12/51 (24%), and moderate overexpression of both *CCNE1* and *CCNE2* in 4/35 (11%). *CCND2* rearrangements were detected by FISH in 25/33 cases (76%) with *CCND2* overexpression, but the remaining *CCND2*<sup>+</sup> cases and those with *CCND3* overexpression did not show *CCND2*, *CCND3* and *IG* rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of *IG* light chain regions including the enhancer regulatory elements (2 *IGK* and 1 *IGL*) near *CCND3* gene in the three cases with cyclin D3 overexpression. These rearrangements were confirmed by Sanger sequencing and FISH with specifically designed probes to recognize the cryptically rearranged regions. Furthermore, using these probes we detected 6 additional cases with cryptic *IGK-CCND3*, as well as 3 cases with *IGK-CCND2* juxtaposition in tumors with high levels of *CCND3* and *CCND2*, respectively. Taken together, 74% and 18% cases corresponded to cyclin D2<sup>+</sup> and cyclin D3<sup>+</sup> MCL, respectively, whereas 6% showed overexpression of *CCNE1* and *CCNE2* without gene rearrangements. The whole-genome analysis of one cyclin D1<sup>-</sup> MCL with *CCNE1* and *CCNE2* overexpression identified 29 somatic protein-coding mutations, 42 complex structural variants and 24 copy number alterations (including *CDKN2A* and *RB1* homozygous deletions) but not rearrangements involving any of the *IG* genes or G1 cyclins. The global genomic profile of 47 cyclin D1<sup>-</sup> MCL was highly complex (mean 13 alterations/case) and similar to 102 conventional SOX11<sup>+</sup> MCL, with significantly more gains at 7p and 18q in the cyclin D1<sup>-</sup> MCL. Moreover, 32% cases had chromothripsis at least in one chromosome.

**Summary/Conclusions:** We have identified a novel *IG* light chain locus-associated rearrangement, consisting of cryptic insertion of *IG* enhancer near *CCND3* gene that leads to cyclin D3 overexpression. Similarly, we found cryptic insertions of *IGK* enhancer region into *CCND2* gene. Both aberrations were undetectable by cytogenetics and FISH break-apart approaches. Overall, 65/66 (98%) MCL had G1 cyclin overexpression. The detection of these rearrangements with cus-

tom FISH probes or that of high levels of *CCND2* or *CCND3* by qPCR, together with *SOX11* expression, are helpful diagnostic tools to recognize cyclin D1<sup>+</sup> MCL and provide insights on the pathogenesis of this rare subgroup.

## LB2602

### ARNT/HIF-1BETA LINKS POOR CLINICAL OUTCOME TO MICROENVIRONMENTAL HYPOXIA AND HIGH-RISK 1Q GAIN IN MULTIPLE MYELOMA

F. Jin<sup>1,\*</sup>, X. Liu<sup>1</sup>, C. Wu<sup>1</sup>, P. Yang<sup>1</sup>, X. Yu<sup>1</sup>, X. Wang<sup>2</sup>, L. Ye<sup>3</sup>, Y. Sun<sup>4</sup>, J. Sun<sup>1</sup>, S. Gao<sup>1</sup>, Y. Dai<sup>4</sup>

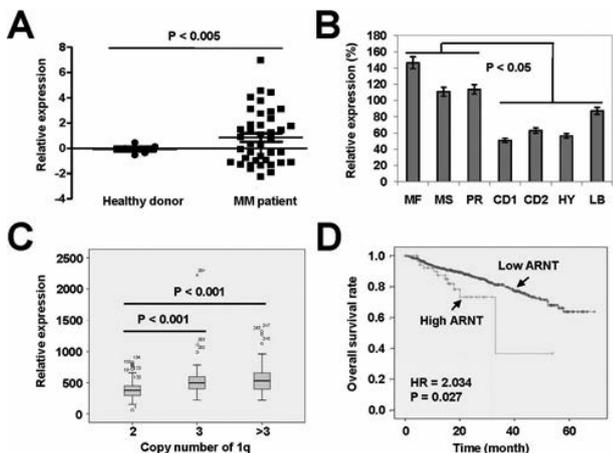

<sup>1</sup>Department of Hematology, <sup>2</sup>Department of Neurology, <sup>3</sup>Department of Spine Surgery, <sup>4</sup>Laboratory of Cancer Precision Medicine, The First Hospital of Jilin University, Changchun, China

**Background:** 1q (1q21 gain) is a common high-risk subtype of multiple myeloma (MM), which drives MM progression, confers drug resistance, and correlates with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression.

**Aims:** To understand the function and clinical significance of hypoxia-induced factor-1 $\beta$  (HIF-1 $\beta$ ), a gene located in the 1q21 region, in 1q MM and hypoxic microenvironment.

**Methods:** The relationship between 1q or HIF-1 $\beta$  and Btz response or overall survival (OS) was analyzed in patients with newly-diagnosed MM (NDMM). Western blot and qPCR analyses were performed to determine expression of HIF-1 $\beta$  and other 1q21 genes in 1q+ vs 1q- or drug-resistant MM cells, or under hypoxia. The function of HIF-1 $\beta$  was evaluated using genetic means and pharmacological inhibitors.

**Results:** In a cohort of 180 NDMM patients, median OS (mOS) was 29 and 43 months for cases with (w) or without (w/o) 1q (P=0.038), among which 24.3, 43.3, and 43.8 months for 1q copy number >3, =3, and =2 (P=0.030), respectively; whereas Btz-based therapy displayed a marked increase in response rate  $\geq$ VGPR, it failed to improve mOS of 1q patients significantly (28.5 and 33.9 months for patients w or w/o Btz treatment, P=0.983); in contrast, Btz treatment dramatically prolonged mOS in patients w/o vs w 1q (53.7 and 28.5 months, P=0.016). To explore the molecular basis for the adverse effect of 1q on prognosis, expression of the 1q21 genes related to drug resistance was examined. Notably, robust expression of HIF-1 $\beta$  at protein level was found in 1q+ MM cells, while no difference observed in CKS1B, a biomarker widely used for 1q MM, or PSMB4 and MCL-1. Further, analysis of additional 40 NDMM patients revealed that HIF-1 $\beta$  mRNA level was significantly higher in MM patients, compared to normal donors (n=5, P<0.005); analysis of the microarray database UAMS "Multiple Myeloma DataBase" (University of Arkansas) also showed that HIF-1 $\beta$  expression was higher with MM progression, in high (e.g., MF, MS, PR) vs low risk (e.g., CD1, CD2, HY, LB; P<0.05) subtypes, or in w 1q vs w/o 1q (P<0.001 for copy number  $\geq$ 3), as well as correlated to shorter OS (P=0.027). In the *in vitro* study, HIF-1 $\beta$  was markedly up-regulated in MM cells acquired drug-resistance against Btz and lenalidomide, while no changes observed in other 1q21 genes (e.g., PSMD4, CKS1B). Ectopic expression of HIF-1 $\beta$  in 1q- cells reduced sensitivity of Btz. Hypoxia (1% O<sub>2</sub>) or its chemical mimetic lactic acid induced HIF-1 $\beta$  expression and Btz resistance, an event reversed by shRNA knockdown of HIF-1 $\beta$ . Furthermore, hypoxia-induced HIF-1 $\beta$  expression was associated with activation of NF- $\kappa$ B, which was prevented by the IKK inhibitor parthenolide, leading to restoration of Btz sensitivity in Btz-resistant cells (Figure 1).

**ARNT/HIF-1 $\beta$  expression correlates high-risk molecular subtypes, 1q gain, and poor outcome in multiple myeloma (MM).** (A-C) ARNT expression was analyzed in newly-diagnosed MM patients vs normal donors (A), in high- (MF, MS, PR) vs low-risk (CD1, CD2, HY, LB) molecular subtypes of MM patients (B), and in patients with (copy number = or > 3) vs without 1q (copy number = 2) MM. (D) The relationship between ARNT expression and overall survival of MM patients was examined by Kaplan-Meier analysis.

Figure 1.

**Summary/Conclusions:** Together, these findings argue that HIF-1 $\beta$  represents a novel biomarker for risk stratification and prognostic prediction of MM patients, especially those with high-risk cytogenetics such as 1q. They also suggest that HIF-1 $\beta$  might play a critical role in drug resistance related to microenvironmental factors (particularly hypoxia) and 1q21 gain, therefore serving as a potential therapeutic target for development of agents or therapy to overcome intrinsic and acquired drug resistance in MM.

## LB2603

### ANTI-CD69 MAB TREATMENT INCREASES THE CAPACITY OF NK CELLS TO ELIMINATE HYPER-REACTIVE ALLOGENIC T CELLS AND PREVENTS ACUTE GRAFT VERSUS HOST DISEASE

K. Tsilingiri<sup>1,\*</sup>, M. Relano<sup>1</sup>, Antonio Balas<sup>2</sup>, Valle Gómez García de Soria<sup>2</sup>, Yaiza Pérez García<sup>2</sup>, C. Muñoz-Calleja<sup>2</sup>, P. Martín<sup>1</sup>

<sup>1</sup>Centro Nacional de Investigaciones Cardiovasculares, <sup>2</sup>Hospital Universitario de la Princesa, Madrid, Spain

**Background:** Hematopoietic stem cell transplantation remains the best therapeutic option for blood malignancies. Acute graft versus host disease (aGVHD) is one of the main potentially fatal complications of this treatment with an incidence as high as 50%. The NK cell population has been extensively studied as a potential target for treatments, as these cells have the capacity to potentiate the graft versus leukemia effect with a minimum risk for graft versus host reactions. Indeed, the abundance of circulating NK cells has been inversely correlated with the probability to develop (aGVHD). CD69 is a C-type lectin expressed on the surface of certain immune cell progenitors as well as activated mature leukocytes. CD69<sup>-/-</sup> NK cells were previously shown to eliminate tumour cells more effectively than WT NK cells.

**Aims:** We wished to examine whether CD69<sup>-/-</sup> NK cells would have a higher cytolytic capacity against activated allogenic T cells and whether this would lead to successful aGVHD prevention.

**Methods:** We took advantage of a fully allogenic aGVHD mouse model in which wild type (WT) or CD69<sup>-/-</sup> BALBc mice were lethally irradiated and reconstituted with C57/BL6 HSCs and naive T cells. Results were confirmed by *in vitro* killing assays as well as by use of CD69 neutralizing antibodies. Mouse strains deficient in T cells, B cells and NK cells were used to establish the NK cells as the population responsible for the observed phenotype. Mass cytometry was employed for extensive phenotyping of WT and CD69<sup>-/-</sup> NK cells and RNAseq analyses were used to elucidate the molecular mechanisms implicated.

**Results:** CD69<sup>-/-</sup> mice were highly resistant to aGVHD and significantly more efficient at eliminating hyper-reactive allogenic T cells *in vivo*. This phenotype was reproduced in WT mice treated with a CD69 neutralizing monoclonal antibody during disease induction. Mass cytometry analyses showed that NK cells lacking CD69 expression upregulate the Ly49D and Ly49G2 receptors, responsible for self/non-self discrimination. Further, expression of inhibitory receptors such as CD94/NKG2A was downregulated in CD69<sup>-/-</sup> NK cells. Finally, *in vivo* data and RNAseq analyses indicated that CD69<sup>-/-</sup> NK cells are resistant to apoptosis. Preliminary data on NK cell chimerism from HSCT patients indicate that host NK cells can persist shortly after conditioning and transplant, and could be targeted with anti-CD69 mAb to avoid clonal expansion of highly reactive donor T cells.

**Summary/Conclusions:** NK cells treated with anti-CD69 mAb show a higher capacity to eliminate hyper-reactive allogenic T cells and confer resistance to aGVHD. This data could pave the way for novel therapeutic strategies to optimize allogenic HSCT.

**Background:** CTL019 is an investigational chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses (CRs) and a manageable safety profile in a previously reported single-center trial in adult patients (pts) with R/R DLBCL.

**Aims:** Results of a planned interim analysis of a single-arm, open-label, multicenter, global phase 2 trial of CTL019 in pts  $\geq 18$  y with R/R DLBCL (JULIET; NCT02445248) are reported.

**Methods:** Industry-manufactured CAR T cells were provided to pts at 27 centers on 4 continents using a global supply chain. Pts had received  $\geq 2$  lines of chemotherapy and had disease progression after or were ineligible for autologous stem cell transplant (autoSCT). Autologous T cells were transduced with a lentiviral vector encoding an anti-CD19 CAR, expanded, cryopreserved, shipped, and infused at study sites. The primary endpoint (centrally reviewed by an independent review committee) was best overall response rate (ORR: CR + partial response [PR]).

**Results:** 141 pts were enrolled. Following restaging, bridging therapy, and lymphodepleting chemotherapy (fludarabine 25 mg/m<sup>2</sup>/cyclophosphamide 250 mg/m<sup>2</sup>/day  $\times$  3 days or bendamustine 90 mg/m<sup>2</sup>/day  $\times$  2 days), 85 pts received a single dose of CTL019 transduced cells (median,  $3.1 \times 10^8$  [range,  $0.1\text{--}6.0 \times 10^8$ ] cells). Median time from infusion to data cutoff (20 December 2016) was 3.7 mo. Median age was 56 y (range, 24–75) and median prior lines of antineoplastic therapy, 3 (range, 2–7). 51% of pts had prior autoSCT. Among 51 pts with  $\geq 3$  mo follow-up or earlier discontinuation, best ORR was 59% (95% CI, 44% to 72%) with 43% CR and 16% PR; the primary endpoint was met. CR and PR rates at 3 mo were 37% and 8%, respectively. All pts in CR at 3 mo remained in CR at data cutoff. Efficacy was observed across prognostic subgroups. Median duration of response was not reached. CTL019 was detectable in peripheral blood by quantitative PCR for up to 355 days in responders. Cytokine release syndrome (CRS) was graded using the Penn scale and managed by a protocol-specific algorithm. CRS occurred in 57% of infused pts (17% grade 3; 9% grade 4); no CRS-associated deaths occurred. 16% of pts received tocilizumab for CRS management. 13% of pts had grade 3/4 neurologic adverse events (AEs), managed with supportive care; no cerebral edema was reported. Grade 3/4 cytopenias lasting  $>28$  days and grade 3/4 febrile neutropenia occurred in 21% and 14% of pts, respectively. 3 pts died from disease progression within 30 days of infusion. No deaths were attributed to CTL019.

**Summary/Conclusions:** This planned interim analysis of a global study of CTL019 in adults with R/R DLBCL confirms the high response rates and durable CRs observed in the previous single-center experience in a cohort of highly pretreated patients. Centralized manufacturing was feasible. CTL019 was generally tolerated without instance of treatment-related mortality. CRS and other AEs could be effectively and reproducibly managed by appropriately trained investigators.

**Background:** Hematopoietic stem cells (HSCs) are multipotent stem cells capable of sustaining all mature blood cells throughout life. During development,

HSCs arise directly from specialized endothelial cells called hemogenic endothelial (HE) cells within the developing aorta-gonad-mesonephros (AGM) region, in a process termed endothelial-to-hematopoietic transition (EHT). However, despite extensive studies in various animal models, the genetic program driving human HSC emergence remains largely unknown. We have previously reported the generation of hemogenic precursor cells from mouse fibroblasts with the expression of the transcription factors (TFs) Gata2, cFos, Gfi1b and ETV6. These TFs induce a dynamic, multi-stage hemogenic process that progresses through an endothelial-like intermediate, recapitulating developmental hematopoiesis *in vitro*.

**Aims:** Here, to better understand the molecular events underlying human HE cell specification we expressed hemogenic TFs in human fibroblasts and mapped the TF binding sites at initial stages of reprogramming.

**Methods:** To determine the transcription factors binding sites we used Chromatin Immunoprecipitation coupled with sequencing (ChIP-seq).

**Results:** We demonstrate that human fibroblasts can be reprogrammed into hemogenic cells by the expression of GATA2, GF11B and FOS. Induced cells express CD34 and CD49f and display dynamic endothelial to hematopoietic transcription programs. In addition, reprogrammed fibroblasts repopulate immunodeficient NSG mice and generate hematopoietic progeny of multiple lineages, including T-cells and myeloid cells. Mechanistically, GATA2 display dominant and independent targeting activity during the early phases of reprogramming while GF11B depends on GATA2 to bind most of its targets. Interestingly, GATA2 and GF11B interact and co-occupy a cohort of target sites engaging sites preferentially with AP-1 motifs, including the RUNX1 locus. This cooperative binding is reflected by the engagement of open enhancers and promoters marked by H3K4me3, H3K4me1 and H3K27ac in the fibroblast genome that initiates the silencing of fibroblast genes while activating the hemogenic program.

**Summary/Conclusions:** Together, these findings uncover a collaborative TF interaction that specify a human hemogenic program and EHT. These findings shed light on the processes controlling human HSC specification and provide means to generate human reprogrammed HSCs at high efficiency for transplantation.

## LB2606

### BONE MARROW SITES DIFFERENTLY IMPRINT DORMANCY AND CHEMORESISTANCE TO T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Pflumio<sup>1,\*</sup>, J. Calvo<sup>1</sup>, X. Cahu<sup>1</sup>, S. Poglio<sup>1</sup>, M.-L. Arcangeli<sup>1</sup>, T. Leblanc<sup>1</sup>, F. Ballerini<sup>2</sup>, A. Baruchel<sup>3</sup>, J. Landman-Parker<sup>2</sup>, E. Delabesse<sup>4</sup>, B. Uzan<sup>1</sup>

<sup>1</sup>INSERM, Fontenay-aux-roses, <sup>2</sup>AP-HP Hôpital Trousseau, <sup>3</sup>AP-HP Hôpital R Debré, Paris, <sup>4</sup>CHU Toulouse, Toulouse, France

**Background:** T-cell acute lymphoblastic leukemia (T-ALL) is a disease of T-cell progenitors, which mainly affects children and young adults. Numerous genomic alterations such as *NOTCH1/FBXW7* mutations, *TLX1/3* overexpression or *SIL-TAL1* deletion are known to induce survival, proliferation and differentiation block in T-ALL cells. Interactions between leukemic cells and their microenvironment also contribute to T-ALL pathogenesis. Cell-cell contacts - Delta-Like/Jagged-Notch1, integrin LFA1/ICAM1 - and secreted factors - such as interleukin 7 and 18 or CXCL12 - are key players in T-ALL development. In the course of the disease, T-ALL cells settle in various environments such as thymus, blood, bone marrow (BM), pleura or lymph nodes, which differ in terms of cell content, extracellular matrix and secreted factors. To which extent these distinct niches imprint niche-specific features on T-ALL cells is not well understood.

**Aims:** Compare the growth of leukemic cells from human and mouse T-ALL in various BM sites. Uncover novel mechanisms of chemoresistance, in relation with the BM microenvironment.

**Methods:** We used grafts of human and mouse T-ALL in immune-deficient and normal mice, respectively. We explored the behavior of leukemic cells *ex-vivo* and *in vivo* after they had engrafted different BM sites of the mouse body (femurs, Thorax and Tail vertebrae). We tested their respective chemoresistance to conventional drugs (dexamethasone, vincristine, cytarabine).

**Results:** We observed that mouse and human T-ALL develop slowly in tail vertebrae BM compared to thorax vertebrae and femur BM. T-ALL recovered from tail BM display lower cell surface marker expression and decreased metabolism and cell cycle progression, demonstrating a dormancy phenotype. Functionally tail-derived T-ALL exhibit a deficient short-term *ex vivo* growth and a delayed *in vivo* propagation. These features are non-cell autonomous as T-ALL from tail and thorax share identical genomic abnormalities and functional disparities disappear *in vivo* and in prolonged *in vitro* assays. Importantly tail-derived T-ALL display higher intrinsic resistance to cell cycle-related drugs, *i.e.* vincristine sulfate and cytarabine, but not to dexamethasone. T-ALL recovered from gonadal adipose tissues or from co-cultures with adipocytes share metabolic, cell cycle and phenotypic or chemoresistance features with Tail-derived T-ALL.

**Summary/Conclusions:** These results demonstrate that BM sites differentially orchestrate T-ALL propagation. T-ALL derived from adipocyte-rich BM are associated with quiescence and decreased response to cell cycle dependent chemotherapy indicating that adipocyte-rich aged BM or pathologies enhancing BM adipocyte content may help leukemia escaping drug treatment.
