Extending duration of letermovir prophylaxis in haploidentical stem cell transplantation.
Haematologica. 2024 July 11. doi: 10.3324/haematol.2024.285766 [Epub ahead of print]

Publisher's Disclaimer.

E-publishing ahead of print is increasingly important for the rapid dissemination of science. Haematologica is, therefore, E-publishing PDF files of an early version of manuscripts that have completed a regular peer review and have been accepted for publication.

E-publishing of this PDF file has been approved by the authors.

After having E-published Ahead of Print, manuscripts will then undergo technical and English editing, typesetting, proof correction and be presented for the authors' final approval; the final version of the manuscript will then appear in a regular issue of the journal.

All legal disclaimers that apply to the journal also pertain to this production process.

Extending duration of letermovir prophylaxis in haploidentical stem cell transplantation

Key words: letermovir, cytomegalovirus, haploidentical donor, stem cell transplantation, infectious disorders

Running title: Extending duration of letermovir in haplo-SCT

Data availability statement: The data that support the findings of this study are available from the corresponding author upon reasonable request.

Funding statement: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Conflict of interest: No potential conflict of interest was reported by all the authors.

Authors' contributions: PV, PK and SC conceptualized and designed the study. PV performed data collection from the electrical medical records. PV, PK and SC analyzed the data and wrote the first draft of

the manuscript. BL, SG, JD, JS, HN, EB, DJ, PK and SC took care of the patients. All authors edited and approved the final version of the manuscript.

LETTERS TO THE EDITOR

Result from pivotal phase 3 studies demonstrated a significant reduction in clinically significant cytomegalovirus (CMV) infections (CS-CMVi)¹ in patients who received prophylactic letermovir for the first 14 weeks and 28 weeks after transplantation^{2, 3}. However, a significant proportion of participants developed late CS-CMVi after letermovir discontinuation and a small subset of patients underwent haploidentical donor stem cell transplantation (haplo-SCT). Moreover, it has been shown that post-transplantation cyclophosphamide (PTCy)-based graft-versus-host disease (GVHD) prophylaxis is associated with higher likelihood of developing CS-CMVi⁴. Consequently, the optimal duration of letermovir prophylaxis in haplo-SCT with PTCy-based GVHD prophylaxis remains unclear.

We retrospectively evaluated forty-three consecutive adult patients undergoing haplo-SCT using fludarabine-based conditioning regimens with PTCy, tacrolimus, mycophenolate mofetil (MMF) and budesonide as GVHD prophylaxis, with CMV seropositive recipients or donors. MMF and budesonide were tapered off starting at day +90, while tacrolimus was continued for at least 6 months post-transplant. The study protocol was approved by the Institutional Review Board of University of California, Irvine (IRB 20206215). The median follow-up time was 480 days (interquartile range [IQR] 288 to 793 days). The median age of donors was 35 years (IQR, 23 to 40 years). Ten patients (23.3%) developed human herpesvirus 6 reactivation, letermovir prophylaxis was interrupted by preemptive treatment with foscarnet in this group, for a median duration of 7 days (IQR, 6 to 10 days)⁵. Patient characteristics are summarized in Table 1.

Letermovir at 480 mg once daily was administered starting on day +7 and was extended up to one-year post-transplant, due to perceived higher incidence of CS-CMVi after discontinuation at day 100 post-transplant and because adaptive immunity recovers approximately at 1-year post-transplant⁶. The plasma CMV DNA level was quantified by PCR method and quantitative

measurement range of CMV DNA assay was 50-156 million IU/mL (1.70 - 8.19 log IU/mL). Preemptive treatment was initiated when detection of CMV DNA in plasma exceeded 50 IU/mL for two consecutive instances. Letermovir was resumed for secondary prophylaxis after completing preemptive treatment, with at least two consecutive undetected plasma CMV DNA. The median duration of letermovir exposure was 255 days (IQR, 179 to 344 days). Twenty-six patients (60.5%) developed at least one episode of CS-CMV_i, with 6 patients (24%) receiving additional immunosuppressive agents (five on corticosteroids and one on eculizumab plus rituximab). The median time to CS-CMV_i post-transplant was 50 days (IQR, 11 to 213 days), with a median plasma level of CMV DNA of 160 IU/mL (IQR, 74 to 276 IU/mL). The median peak plasma level of CMV DNA was 665 IU/mL (IQR, 326 to 1,900 IU/mL) at a median of 79 days post-transplant (IQR, 35 to 215 days). The cumulative incidence of first CS-CMV_i at day 100, 180, 270 and 365 were 34.9% (95% confidence interval [CI] 21.2-48.9%), 39.5% (95% CI 25.1-53.6%), 54.2% (95% CI 38.1-67.7%) and 63.1% (95% CI 46.1-76.1%), respectively (Figure 1). One patient (2.3%) developed CMV pneumonitis at 29 days post-transplant. CMV resistance testing was not performed during the first episode of CS-CMV_i. Twenty-three (88.5%) patients with first CS-CMV_i, including fourteen patients who had an initial plasma level of CMV DNA above 150 IU/mL, responded to first-line preemptive treatment with either foscarnet (*N*=11) or valganciclovir (*N*=12). However, three patients received maribavir as a salvage treatment due to refractory CS-CMV_i. Twenty-four patients received letermovir as secondary prophylaxis after completing preemptive treatment. Eight of these patients (33.3%) subsequently developed a second CS-CMV_i, with a 100-day cumulative incidence of failure from secondary prophylaxis at 29.4% (95% CI 13.1-48.0%) (Figure 1). The median duration of second CS-CMV_i was 37 days after starting secondary letermovir prophylaxis (IQR, 14 to 42 days), with a median level of plasma CMV DNA at 64 IU/mL (IQR, 54 to 86 IU/mL). One patient out of eight developed a third episode of CS-CMV_i on day 118 post-transplant, and subsequently died from COVID pneumonia on day 134 post-transplant. The median post-transplant day for letermovir

discontinuation was 374 (IQR, 351 to 418 days), with 1-year cumulative incidence of letermovir discontinuation at 80.6% (95% CI 63.0%-90.4%) (Supplemental Figure 1). The only factor associated with a lower risk of CS-CMV_i was lower hematopoietic cell transplantation comorbidity index (HCT-CI) (subdistribution hazard ratio [SHR] 0.82, [95% CI 0.68-0.99], P=0.04). No CMV-related mortality occurred.

Focusing on transplant outcomes, all patients achieved neutrophil engraftment at a median of 17 days post-transplant (IQR, 15 to 19 days). Forty-two patients (97.7%) achieved platelet engraftment at a median of 23 days post-transplant (IQR, 19 to 27 days), one patient died from pneumonia prior to platelet engraftment at day 206 post-transplant. There was no significant difference between patients with and without CS-CMV_i with regards to median day post-transplant for neutrophil (17 vs. 16 days; P=0.97) and platelet (24 vs. 23 days; P=0.17) engraftment. Cox proportional hazards and subdistribution hazard model using CS-CMV_i as a time-varying covariate, did not demonstrate differences in transplant outcomes between patients with and without CS-CMV_i. The 1-year non-relapse mortality in subgroups with and without CS-CMV_i were 23.0% (95% CI 8.3%-42.1%) and 31.0% (95% CI 11.2%-53.6%), respectively (SHR 0.13, [95% CI 0.01-1.71], P=0.12). The 1-year cumulative incidence of relapse in subgroups with and without CS-CMV_i were 11.5% (95% CI 2.9%-26.7%) and 5.9% (95% CI 0.4%-23.5%), respectively (SHR 1.86, [95% CI 0.18-19.75], P=0.61). The 1-year progression-free survival (PFS) and overall survival (OS) between the cohort with and without CS-CMV_i were 65.5% (95% CI 42.1%-81.3%) vs. 63.1% (95% CI 35.3%-81.6%), (HR 0.48, [95% CI 0.09-2.69], P=0.40) and 69.4% (95% CI 45.9%-84.3%) vs. 69.1% (95% CI 40.7%-85.9%) (HR 0.28, [95% CI 0.03-2.74], P=0.28), respectively. In addition, there were no differences in cumulative incidence of grade II-IV acute GVHD (7.7% [95% CI 1.3%-21.7%] vs. 5.9% [95% CI 0.04%-23.5%] at 100 days, SHR 0.84 [95% CI 0.05-14.04], P=0.90) and moderate to severe chronic GVHD (6.6% [95% CI 0.4%-25.7%] vs. 9.0% [95% CI 0.6%-32.8%] at 2 years post-transplant,

SHR 0.59 [95% CI 0.04-8.77], P=0.70) between patients with and without CS-CMV_i (Supplemental Figure 2). After adjusting for age, sex, Karnofsky Performance Scale, HCT-CI and disease risk index, there were no differences in PFS (HR 0.94, [95% CI 0.16-5.51], P=0.95) and OS (HR 0.45, [95% CI 0.05-4.26], P=0.48) between the two groups.

Immune reconstitution was evaluated by analyzing peripheral blood absolute lymphocyte subset count including CD3⁺, CD3⁺CD4⁺, CD3⁺CD8⁺, CD19⁺, and CD3⁺CD56⁺ lymphocytes. Using a mixed effects linear model to account for multiple measurements per patient and multiple imputation method to impute missing lymphocyte subsets data, the occurrence of CS-CMV_i was associated with lower CD3⁺ (coefficient -79.65, P=0.03), CD3⁺CD4⁺ (coefficient -35.52, P=0.02), CD3⁺CD8⁺ (coefficient -60.23, P=0.02) and CD19⁺ (coefficient -38.68, P=0.04) lymphocyte subsets at 1-year post-transplant. However, no association was found between CS-CMV_i and CD56⁺ lymphocyte recovery after transplant (coefficient 29.45, P=0.54) (Figure 2).

This reports demonstrated one of the longest durations of letermovir administration for CMV prophylaxis after transplantation. Despite a median duration of letermovir exposure of 255 days, the cumulative incidence of CS-CMV_i was high at 63.1% throughout the first-year post-transplant. Significantly, 39.5% and 54.2% of patients experienced CMV reactivation by day 180 and day 270 post-transplant, respectively, demonstrating the need to further extend the duration of letermovir or to investigate a novel prophylaxis strategy other than letermovir. However, it remains unclear whether the consistent use of PTCy-based GVHD prophylaxis could be the main factor, and if the higher incidence and need to extend letermovir prophylaxis will be observed in HLA-matched donor transplants in the future, as PTCy is being extended to these transplants^{7, 8}. The incidence of CS-CMV_i in our report was higher than in previous studies^{2, 3}. The inclusion of only haploidentical donors with PTCy-based GVHD prophylaxis and early preemptive treatment with a lower cutoff plasma CMV DNA level at 50 IU/mL, compared with

other studies suggesting a cutoff of 137 IU/mL (150 copies/mL)^{2, 9} might be contributing to a higher incidence of CS-CMV_i. We have found a consistent decrease in absolute T-cell subsets and B-cells in CS-CMV_i cohort which significantly associated with a higher HCT-CI, suggesting that either that patients with higher comorbidities have been less likely to develop an immune response or that CMV exerts a negative impact on immunologic reconstitution in these patients. Extending letermovir for CMV prophylaxis might overcome the negative impact of CS-CMV_i, as our study showed no significant differences in transplant outcomes between the two groups of patients with and without CS-CMV_i. Despite the apparent safety and tolerability of extending duration of letermovir prophylaxis, delay in recovery of CMV-specific immunity and letermovir resistance could be a concern associated with extending the duration prophylaxis^{10, 11}. Prospective randomized studies are needed in this group of patients as well as patients receiving PTCy-based GVHD prophylaxis to assess the need for extended duration. Additionally, a cost-effectiveness analysis would be useful to assess resource utilization.

In conclusion, our study reported real-world experience with extended letermovir prophylaxis in a cohort of haplo-SCT patients. CS-CMV_i developed up to one-year post-transplant suggesting that extending letermovir prophylaxis or novel prophylaxis strategy is needed. In addition, secondary prophylaxis with letermovir can be applied after completing preemptive treatment. Larger studies are needed to confirm these findings and assess the need to extend letermovir prophylaxis in HLA matched transplants receiving PTCy-based GVHD prophylaxis.
